UNITED STATES OF AMERICA
BEFORE THE
FEDERAL ENERGY REGULATORY COMMISSION

North American Electric Reliability Corporation	**)** **)**	**Docket No. _______**

PETITION OF THE
NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION
FOR APPROVAL OF
PROPOSED RELIABILITY STANDARD(S) PRC-029-1 AND PRC-024-4

Pursuant to Section 215(d)(1) of the Federal Power Act ("FPA")[1] and Section 39.5 of the regulations of the Federal Energy Regulatory Commission ("FERC" or "Commission"),[2] the North American Electric Reliability Corporation ("NERC")[3] hereby submits for Commission approval proposed Reliability Standard PRC-029-1 Frequency and Voltage Ride-through Requirements for Inverter-based Generating Resources, proposed Reliability Standard PRC-024-4 Frequency and Voltage Protection Settings for Synchronous Generators, Type 1 and 2 Wind Plants, and Synchronous Condensers, and the proposed definition of the term Ride-through for inclusion in the *Glossary of Terms used in NERC Reliability Standards*.[4] As discussed herein, the proposed Reliability Standards would advance the reliability of the Bulk-Power System ("BPS") by establishing voltage and frequency ride-through criteria for Generator Owners of Inverter-Based Resources ("IBR") to continue to inject current and perform voltage support during a BPS disturbance and prohibit momentary cessation in the no-trip zone during disturbances.

---

1 16 U.S.C. § 824o.

2 18 C.F.R. § 39.5 (2024).

3 The Commission certified NERC as the electric reliability organization ("ERO") in accordance with Section 215 of the FPA. *N. Am. Elec. Reliability Corp.*, 116 FERC ¶ 61,062 (2006) [hereinafter ERO Certification Order].

4 The *Glossary of Terms used in NERC Reliability Standards* ("NERC Glossary" or "Glossary") is available on the NERC website at https://www.nerc.com/pa/Stand/Glossary%20of%20Terms/Glossary_of_Terms.pdf. Unless otherwise indicated, all capitalized terms used in this petition shall have the meaning set forth in the NERC Glossary.

The proposed Reliability Standards are an integral part of NERC's proposed framework to address IBR performance issues in a comprehensive and holistic manner. The proposed Reliability Standards addressed in this filing are responsive to the Commission's directives in Order No. 901 directing NERC to submit new or revised standards addressing IBR ride-through performance requirements by November 4, 2024.[5] As discussed in detail below, the proposed Reliability Standards are part of a set of standards that collectively respond to the Commission's directives for requirements addressing IBR ride-through settings, ride-through performance, data recording, and analysis and mitigation of unexpected IBR performance. This proposed framework consists of the following standards and definitions:

- Proposed definition of the term Inverter-Based Resource, for inclusion in the *Glossary of Terms used in NERC Reliability Standards* (*separately filed, concurrently with this petition*);[6]
- Proposed Reliability Standard PRC-028-1 – Disturbance Monitoring and Reporting Requirements for IBR, with comprehensive disturbance monitoring and reporting requirements to IBR (*separately filed, concurrently with this petition*);
- Proposed Reliability Standard PRC-029-1 – Frequency and Voltage Ride-through Requirements for IBR, with capability and performance-based requirements for IBR Ride-through performance; and
- Proposed Reliability Standard PRC-030-1 – Unexpected Inverter-Based Resource Event Mitigation, requiring analysis and mitigation of IBR performance issues (*separately filed, concurrently with this petition*).

---

5 Order No. 901, *Reliability Standards to Address Inverter-Based Resources*, 185 FERC ¶ 61,042 (2023) [hereinafter Order No. 901].

6 The proposed definition for this term, which is used throughout the proposed Reliability Standards addressed in the filing, as follows:

> **Inverter-Based Resource (IBR)**: A plant/facility consisting of individual devices that are capable of exporting Real Power through a power electronic interface(s) such as inverter or converter, and that are operated together as a single resource at a common point of interconnection to the electric system. IBRs include, but are not limited to, plants/facilities with solar photovoltaic (PV), Type 3 and Type 4 wind, battery energy storage system (BESS), and fuel cell devices.

NERC requests that the Commission approve the proposed Reliability Standards, provided in Exhibit A hereto, as just, reasonable, not unduly discriminatory or preferential, and in the public interest. NERC also requests approval of: (1) the associated Implementation Plan (Exhibit B); the associated Violation Risk Factors ("VRFs") and Violation Severity Levels ("VSLs") (Exhibit F); and the retirement of currently effective Reliability Standard PRC-024-3.

As required by Section 39.5(a) of the Commission's regulations,[7] this petition presents the technical basis and purpose of the proposed Reliability Standards, a summary of the development history (Exhibit G), and a demonstration that the proposed Reliability Standards meet the criteria identified by the Commission in Order No. 672[8] (Exhibit C). The NERC Board of Trustees adopted the proposed Reliability Standards on October 8, 2024.

I. SUMMARY

Multiple NERC disturbance reports,[9] including those analyzing the Blue Cut Fire[10] and Canyon 2 Fire,[11] have demonstrated a risk to the reliability of the BPS when IBRs have failed to ride-through system disturbances. Across multiple system events, a widespread loss of generating resources – solar photovoltaic ("solar PV"), wind, synchronous generation, and battery energy

storage systems ("BESS") – have abnormally tripped, ceased current injection, or reduced power output with control interactions. BPS-connected generating resources remaining connected during normal and contingency conditions is a critical component of BPS reliability; the unexpected loss of widespread generating assets poses a significant risk to BPS reliability. Generator ride-through is a foundational essential reliability service. Ensuring fault ride-through capability enables dynamic reactive power support, frequency response, and other services.

For this reason, NERC identified the need for a comprehensive Ride-through Reliability Standard for IBRs.[12] This need was further reinforced when the Commission issued Order No. 901, directing the development of new or modified Reliability Standards to address risks associated with IBRs, including new requirements for disturbance monitoring data sharing, IBR performance requirements, and post-event performance validation.

Proposed Reliability Standard PRC-029-1 would address the important reliability issue of IBR Ride-through performance through capability and performance-based requirements for IBRs. Consistent with the relevant Commission directives in Order No. 901, proposed PRC-029-1 would advance reliability by: (1) establishing a clear understanding of what it means for a generator to Ride-through a disturbance; (2) establishing voltage and frequency Ride-through criteria for IBRs to prevent the unnecessary tripping and momentary cessation of current due to phase lock loop loss of synchronism; and (3) ensuring that post-disturbance ramp rates return to pre-disturbance levels.

With the development of proposed Reliability Standard PRC-029-1 addressing IBRs, it became necessary to revise the applicability of currently effective Reliability Standard PRC-024-3, which addresses frequency and voltage settings for generating resources. Proposed Reliability

12 *See* Exhibit G, Complete Record of Development at item 17.

Standard PRC-024-4 would revise the applicable facility types to exclude IBRs and to include type 1 and type 2 wind resources and synchronous condensers. NERC determined there is no reliability need to impose actual disturbance Ride-through requirements on these resources, and that restrictions for frequency and voltage protection setting ranges would continue to be appropriate. Together the proposed Reliability Standards would help ensure that applicable BPS connected resources would Ride-through system disturbances and avoid the negative reliability impacts associated with unnecessary tripping and momentary cessation.

For these reasons, which are summarized here and stated more fully below, NERC requests that the Commission approve the proposed Reliability Standards and Ride-through definition, provided in Exhibit A hereto, as just, reasonable, not unduly discriminatory or preferential, and in the public interest.

III. REGULATORY BACKGROUND

A. Regulatory Framework

By enacting the Energy Policy Act of 2005,[14] Congress entrusted the Commission with the duties of approving and enforcing rules to ensure the reliability of the BPS, and with the duty of certifying an ERO that would be charged with developing and enforcing mandatory Reliability Standards, subject to Commission approval. Section 215(b)(1) of the FPA states that all users, owners, and operators of the BPS in the United States will be subject to Commission-approved Reliability Standards.[15] Section 215(d)(5) of the FPA authorizes the Commission to order the ERO to submit a new or modified Reliability Standard.[16] Section 39.5(a) of the Commission's regulations requires the ERO to file for Commission approval each Reliability Standard that the ERO proposes should become mandatory and enforceable in the United States, and each modification to a Reliability Standard that the ERO proposes to make effective.[17]

The Commission has the regulatory responsibility to approve Reliability Standards that protect the reliability of the BPS and to ensure that such Reliability Standards are just, reasonable, not unduly discriminatory or preferential, and in the public interest. Pursuant to Section 215(d)(2) of the FPA and Section 39.5(c) of the Commission's regulations, the Commission will give due weight to the technical expertise of the ERO with respect to the content of a Reliability Standard.[18]

B. NERC Reliability Standards Development Procedure

The proposed Reliability Standards were developed in an open and fair manner and in accordance with the Commission-approved Reliability Standard development process.[19] NERC develops Reliability Standards in accordance with Section 300 (Reliability Standards Development) of its Rules of Procedure and the NERC Standard Processes Manual.[20] In its ERO Certification Order, the Commission found that NERC's proposed rules provide for reasonable notice and opportunity for public comment, due process, openness, and a balance of interests in developing Reliability Standards and thus satisfies certain criteria for approving Reliability Standards.[21] The development process is open to any person or entity with a legitimate interest in the reliability of the BPS. NERC considers the comments of all stakeholders. Further, a vote of stakeholders and adoption by the NERC Board of Trustees is required before NERC submits the Reliability Standard to the Commission for approval.

IV. THE NEED FOR RIDE-THROUGH STANDARDS ADDRESSING INVERTER-BASED RESOURCES

A. Disturbances on the BPS Indicate that IBRs are Failing to Ride-through as they Should to Maintain Reliability.

In 2017, following a series of grid disturbances involving IBRs, NERC developed the Inverter-Based Resources Performance Task Force, or IRPTF. This group undertook a comprehensive review of all NERC Reliability Standards to determine if there were opportunities to address gaps or otherwise improve the standards to assure reliability considering the unprecedented growth of IBRs on the BPS.

[19] Order No. 672 at P 334.

[20] The NERC Rules of Procedure, including Appendix 3A, NERC Standard Processes Manual, are available at http://www.nerc.com/AboutNERC/Pages/Rules-of-Procedure.aspx.

[21] ERO Certification Order at P 250.

In 2019, the IRPTF published a white paper summarizing its work. Among other things, the IRPTF highlighted issues with the then effective PRC-024 Reliability Standard, PRC-024-2 - Generator Frequency and Voltage Protective Relay Settings.[22] In this white paper, the IRPTF found that misinterpretation of the requirements of Reliability Standard PRC-024-2 led to the intentional and unnecessary tripping of solar PV resources during the Blue Cut Fire[23] and Canyon 2 Fire[24] disturbances because some entities misinterpreted the area outside of the "No Trip" curve as a "Must-Trip" requirement instead of as a "May-Trip" zone. The intent of the PRC-024-2 voltage ride-through requirement was to define the minimum and maximum voltage conditions where generating resources may trip from protective relaying for voltage excursions. The IRPTF recommended that clarifications to the standard be made so entities would know that being outside a "No-Trip" zone does not mean the unit must trip, but rather it may trip to protect its equipment.

To address this misinterpretation, NERC initiated Project 2018-04 Modifications to PRC-024-2 to address the IRPTF recommendations. Project 2018-04 Modifications to PRC-024-2 developed the currently effective version of the PRC-024 Reliability Standard, PRC-024-3 - Frequency and Voltage Protection Settings for Generating Resources in 2019 that the Commission approved in 2020.[25]

B. NERC Efforts to Address Reliability Risks with IBRs failing to Ride-Through System Disturbances.

While Reliability Standard PRC-024-3 addressed the misinterpretation identified in the IRPTF report, events were still occurring following its development where IBRs were failing to

23 Blue Cut Fire Disturbance Report *supra* note 10.

24 Canyon 2 Fire Disturbance Report, *supra* note 11.

25 *N. Am. Elec. Reliability Corp.,* Docket No. RD20-7-000 (July 9, 2020). Reliability Standard PRC-024-3 became effective in the United States on October 1, 2022.

Ride-through a disturbance.[26] These events made it clear that additional Reliability Standard requirements were needed to comprehensively address the issue of IBRs failing to Ride-through system disturbances. Reliability Standard PRC-024-3 is an equipment settings standard focused solely on voltage and frequency protection, and, in turn, does not address risks associated with IBR Ride-through capabilities.

In 2022, following its analysis of over 10 disturbances involving widespread loss of IBRs, NERC revised and repurposed an existing project to modify the PRC-024 standard, Project 2020-02 Transmission Connected Resources, to address IBR Ride-through performance. The purpose of Project 2020-02 Modifications to PRC-024 (Generator Ride-Through) was to retire Reliability Standard PRC-024-3 and replace it with a performance-based Ride-through standard that ensures generators remain connected to the BPS during system disturbances. The Standard Authorization Request for the project provided:

> Across all events, a widespread loss of generating resources – solar PV, wind, synchronous generation, and battery energy storage systems (BESS) – have abnormally tripped, ceased current injection, or reduced power output with control interactions. Generator ride-through is a foundational essential reliability service. BPS-connected generating resources remaining connected during normal and contingency conditions is a critical component of BPS reliability. Ensuring fault ride-through capability enables dynamic reactive power support, frequency response, and other services. The unexpected loss of widespread generating assets poses a significant risk to BPS reliability.[27]

The Project 2020-02 drafting team determined that Ride-through performance requirements for IBRs should be addressed by a separate standard from synchronous resources because of the different natures of synchronous resources and IBRs, including their risks, performance, and equipment capabilities. During the drafting team's development of a performance-based standard for IBRs in proposed Reliability Standard PRC-029-1, the

[26] Event Reports, supra note 9.
[27] *See* Exhibit G, Complete Record of Development at item 17.

Commission issued Order No. 901, directing the development of Reliability Standards for IBRs, including Reliability Standards to address IBR ride through performance. Accordingly, development of proposed Reliability Standard PRC-029-1 was aligned with the Commission's directives in Order No. 901 related to performance requirements for registered IBRs, which are described further below.

C. Order No. 901 Directs NERC to Develop Reliability Standards to Address Concerns Related to IBRs at "All Stages of Interconnection, Planning, and Operations"

On October 19, 2023, the Commission issued Order No. 901,[28] directing the development of Reliability Standards to address IBRs. In Order 901, and preceding Notice of Proposed Rulemaking, the Commission cites multiple ERO resources on IBR issues, including reliability guidelines, white papers, reliability assessments, technical reports, event reports, NERC alerts, and other resources, as underscoring the need for mandatory Reliability Standards to address reliability concerns related to IBRs at "all stages of interconnection, planning, and operations."[29] While the Commission acknowledged that NERC and industry groups had efforts underway to address the reliability risks associated with IBRs, the Commission directed NERC to address specific reliability gaps because the existing Reliability Standards do not adequately address the reliability risks posed by the increasing numbers of IBRs connecting to the BPS.[30] The Commission directed NERC to develop new and revised Reliability Standards to address the following four topic areas

[28] *See* Order No. 901.

[29] *Id.* at P 25.

[30] *Id.* at Section III.

of IBR issues: (1) data sharing;[31] (2) data and model validation;[32] (3) planning and operational studies;[33] and (4) performance requirements.[34]

Within these four topic areas, the Commission identified the specific reliability issues that must be addressed. In so doing, the Commission distinguished between IBRs currently registered with NERC for compliance purposes, or will be in the future based on the approved revisions in the IBR Registration Approval Order ("registered IBRs");[35] IBRs that are not registered with NERC ("unregistered IBRs") but which need to be modeled for reliability; and IBRs that are connected to the distribution system, but, in the aggregate, can impact BES reliability ("IBR-DERs").[36] NERC was directed to develop responsive standards and submit them to the Commission on a three-year, staggered timeframe.

With respect to the implementation of the directed standards modifications, the Commission stated, "we believe that there is a need to have all of the directed Reliability Standards effective and enforceable well in advance of 2030 and direct NERC to ensure that the associated implementation plans sequentially stagger the effective and enforceable dates to ensure an orderly industry transition for complying with the IBR directives in this final rule prior to that date."[37]

---

31 *See* Order No. 901 at PP 66-109 (discussion of directives related to data sharing requirements).

32 *See id.* at PP 110-161 (discussion of directives related to data and model validation requirements).

33 *See id.* at PP 162-177 (discussion of directives related to planning and operational studies requirements).

34 *See id.* at PP 178-211 (discussion of directives related to performance requirements).

35 On November 22, 2022, the Commission issued an order directing NERC to undertake actions to expand the class of IBRs that are required to register with NERC and comply with NERC Reliability Standards. *Registration of Inverter-Based Resources*, 181 FERC ¶ 61,124 (2022) [hereinafter IBR Registration Order]. Specifically, the Commission directed NERC to explain how it will identify and register owners and operators of IBRs that are connected to the Bulk-Power System, but are not required to register with NERC under the Bulk Electric System definition, that have an aggregate material impact on the reliable operation of the Bulk-Power System." *Id.* at P 1.

The Commission approved NERC's proposed expansion of the Generator Owner and Generator Operator registry criteria to encompass additional IBRs in an order issued June 27, 2024. *Order Approving Revisions to North American Electric Reliability Corporation Rules of Procedure and Requiring Compliance Filing*, 187 FERC ¶ 61,196 (2024) [hereinafter IBR Registration Approval Order].

36 Order No. 901 at P 4 n.14.

37 Order No. 901 at P 226.

Additionally, the Commission directed NERC to submit an informational filing, within 90 days of the date of the order, detailing a comprehensive standards development plan and explanation of how NERC would prioritize the development of new or modified Reliability Standards.[38] This work plan is described in Section V *infra*.

1. Order No. 901 Ride-through Directives

Citing the NERC disturbance reports and white papers, the Commission directed NERC to develop new or revised Reliability Standards to require Generator Owners of registered IBRs to meet ride-through performance requirements. The Commission stated:

> Pursuant to section 215(d)(5) of the FPA, we adopt the NOPR proposal and direct NERC to develop new or modified Reliability Standards that require registered IBR generator owners and operators to use appropriate settings (i.e., inverter, plant controller, and protection) to ride through frequency and voltage system disturbances and that permit IBR tripping only to protect the IBR equipment in scenarios similar to when synchronous generation resources use tripping as protection from internal faults. The new or modified Reliability Standards must require registered IBRs to continue to inject current and perform frequency support during a Bulk-Power System disturbance. Any new or modified Reliability Standard must also require registered IBR generator owners and operators to prohibit momentary cessation in the no-trip zone during disturbances. NERC must submit new or modified Reliability Standards that establish IBR performance requirements, including requirements addressing frequency and voltage ride through, post-disturbance ramp rates, phase lock loop synchronization, and other known causes of IBR tripping or momentary cessation.[39]

The Commission recognized that there may be instances where an exemption to the ride-through requirements may be necessary and directed NERC to consider if such an exemption would be appropriate in its standard development process as follows:

> Therefore, we direct NERC through its standard development process to determine whether the new or modified Reliability Standards should provide for a limited and documented exemption

[38] Order No. 901 at P 222.

[39] *Id.* at P 190.

> for certain registered IBRs from voltage ride-through performance requirements. Any such exemption should be only for voltage ride-through performance for those existing IBRs that are unable to modify their coordinated protection and control settings to meet the requirements without physical modification of the IBRs' equipment.[40]

The Commission also directed that if NERC determined that an exemption was necessary from Ride-through requirements, to develop standards to mitigate the reliability impacts of said exemption as follows:

> Pursuant to section 215(d)(5) of the FPA, we modify the NOPR proposal. To the extent NERC determines that a limited and documented exemption for those registered IBRs currently in operation and unable to meet voltage Ride-through requirements is appropriate due to their inability to modify their coordinated protection and control settings, we direct NERC to develop new or modified Reliability Standards to mitigate the reliability impacts to the Bulk-Power System of such an exemption.[41]

The Commission directed NERC to develop post-disturbance ramp rate requirements as follows:

> Pursuant to section 215(d)(5) of the FPA, we adopt the NOPR proposal and direct NERC to develop and submit to the Commission for approval new or modified Reliability Standards that require post-disturbance ramp rates for registered IBRs to be unrestricted and not programmed to artificially interfere with the resource returning to a pre-disturbance output level in a quick and stable manner after a Bulk-Power System.[42]

The Commission directed NERC to address in its IBR Ride-through standards the different types of loss synchronism as follows:

> We direct NERC to submit to the Commission for approval new or modified Reliability Standards that would require registered IBRs to ride through any conditions not addressed by the proposed new or modified Reliability Standards that address frequency or voltage ride through, including phase lock loop loss of synchronism. The

[40] *Id.* at P 193.

[41] *Id.* at P 199.

[42] *Id.* at P 208.

> proposed new or modified Reliability Standards must require registered IBRs to ride through momentary loss of synchronism during Bulk-Power System disturbances and require registered IBRs to continue to inject current into the Bulk-Power System at pre-disturbance levels during a disturbance, consistent with the IBR Interconnection Requirements Guideline and Canyon 2 Fire Event Report recommendations. Related to ACP/SEIA's comment recommending to revise the directive to require generators to maintain synchronism where possible and continue to inject current to support system stability, we direct NERC, through its standard development process, to consider whether there are conditions that may limit generators to maintain synchronism.[43]

V. NERC'S ORDER NO. 901 WORK PLAN

On January 17, 2024, NERC submitted its Informational Filing that included its Order No. 901 Work Plan.[44] NERC detailed how it will leverage the multiple standards development projects planned or already underway to address IBR-related risks and add new projects as necessary, to ensure that the reliability issues identified by the Commission in Order No. 901 are addressed appropriately through the standards development process. The Order No. 901 Work Plan consists of four key milestones with associated dates for completion, which are consistent with the Commission's direction in Order No. 901, to help ensure that the process proceeds in an orderly and timely manner. These milestones are summarized below:

- **Milestone 1:** Submission of Order No. 901 Work Plan (completed: January 17, 2024)

- **Milestone 2**: Development and Filing of Reliability Standards to Address Performance Requirements and Post-Event Performance Validation for Registered IBRs (completion: November 4, 2024)

- **Milestone 3**: Development and Filing of Reliability Standards to Address Data Sharing and Model Validation for all IBRs (completion: November 4, 2025)

---

[43] *Id.* at P 209.

[44] *Informational Filing of the North American Electric Reliability Corporation Regarding the Development of Reliability Standards Responsive to Order No. 901*, Docket No. RM22-12-000 (Jan. 17, 2024) [hereinafter Order No. 901 Work Plan].

- **Milestone 4:** Development and Filing of Reliability Standards to Address Planning and Operational Studies Requirements for all IBRs (completion: November 4, 2026).

Relevant to this filing, NERC initiated the following standards project to meet the goals set in Milestone 2 of the Order 901 Work Plan:

- Project No. 2020-06, Verifications of Models and Data for Generators,
- Project No. 2021-04, Modifications to PRC-002-2 Disturbance Monitoring,
- Project No. 2020-02 Modifications to PRC-024 (Generator Ride-through), and
- Project No. 2023-02 Analysis and Mitigation of BES Inverter-Based Resource Performance Issues

The standards projects associated with Milestone 2 address IBR performance during disturbances commonly referred to as "Ride-through". These standards will focus on how to adequately monitor, analyze, report, and mitigate IBR performance during a disturbance that occurs in "ride-through" periods.

As relevant to the instant petition and discussed in detail in Section VI(H), proposed Reliability Standard PRC-029-1 addresses the Commission's Order No. 901 directives relating to IBR Ride-through performance, described in the previous section, by requiring that Generator Owners of IBRs ride through voltage and frequency excursions within the zones defined in the standard. Proposed Reliability Standard PRC-024-4 proposes to remove IBR from Reliability Standard PRC-024 to maintain capability-based requirements for synchronous generators, synchronous condensers, and asynchronous type 1 and type 2 wind generation. A summary of the Reliability Standards developed to address the Milestone 2 directives is provided below.

A. Project 2020-06 Verifications of Models and Data for Generators

Addressed in a separate filing filed concurrently with this petition, Project 2020-06 Verifications of Models and Data for Generators proposes to establish a new defined term, Inverter-Based Resource ("IBR"), for inclusion in the NERC Glossary, as follows:

> **Inverter-Based Resource (IBR)**: A plant/facility consisting of individual devices that are capable of exporting Real Power through a power electronic interface(s) such as an inverter or converter, and that are operated together as a single resource at a common point of interconnection to the electric system. Examples include, but are not limited to, plants/facilities with solar photovoltaic (PV), Type 3 and Type 4 wind, battery energy storage system (BESS), and fuel cell devices.

The proposed definition of Inverter-Based Resource ("IBR") would establish a consistent understanding of the meaning of the term across all NERC Reliability Standards going forward. This term is used throughout the Order No. 901 Work Plan Milestone 2 Reliability Standards discussed below.

B. Project 2021-04 Modifications to PRC-002-2 Disturbance Monitoring

Addressed in a separate filing filed concurrently with this petition, Project 2021-04 Modifications to PRC-002-2 Disturbance Monitoring[45] proposes to establish a new Reliability Standard PRC-028-1, Disturbance Monitoring and Reporting Requirements for IBRs, to create new capability-based requirements disturbance monitoring and reporting for IBRs. The purpose of proposed Reliability Standard PRC-028-1 would be "[t]o have adequate data available from Inverter-Based Resources to evaluate Inverter-Based Resource ride-through performance during system disturbances and to provide data for Inverter-Based Resource model validation." The data collected under proposed Reliability Standard PRC-028-1 would be used to inform other Reliability Standards for Milestone 2, 3, and 4 as actual IBR performance is a core component of Order No. 901.

---

[45] Project 2021-4 Modifications to PRC-002 – Phase II, https://www.nerc.com/pa/Stand/Pages/Project-2021-04-Modifications-to-PRC-002-2.aspx Project 2021-04 Modifications to PRC-002 – Phase II, https://www.nerc.com/pa/Stand/Pages/Project-2021-04-Modifications-to-PRC-002-2.aspxhttps://www.nerc.com/pa/Stand/Pages/Project-2021-04-Modifications-to-PRC-002-2.aspx.

Proposed Reliability Standard PRC-028-1, Requirement R4, provides that Generator Owners would have continuous dynamic disturbance recording data and storage to determine the electrical quantities for each main power transformer(s) it owns. This data collected under PRC-028-1 would be used to inform the analysis conducted under PRC-030-1 following an IBR performance issue. The data collected under PRC-028-1 will be essential for assessing ongoing ride-through performance for the purposes of modeling under Milestone 3. In addition, Project 2021-04 Modifications to PRC-002-2 Disturbance Monitoring proposes to remove IBR as applicable facilities from PRC-002, as the framework of that standard remains sufficient for synchronous resources.

C. Project 2020-02 Modifications to PRC-024 (Generator Ride-through)

Project 2020-02, Modifications to PRC-024,[46] proposes to establish a new Reliability Standard PRC-029-1, Frequency and Voltage Ride-through Requirements for Inverter-based Resources, to create capability-based and performance-based requirements for IBR ride-through performance. As discussed in detail herein, Proposed Reliability Standard PRC-029-1 would "ensure that IBRs Ride-through to support the BPS during and after defined frequency and voltage excursions."

Proposed Reliability Standard PRC-029-1 would establish ride-through performance criteria and focus on the evaluation and documentation of ride-through capability. The proposed PRC-029-1 is generally an event-based standard though it is also required to provide evidence of

[46] Project 2020-02 Modifications to PRC-024 (Generator Ride-through), https://www.nerc.com/pa/Stand/Pages/Project_2020-02_Transmission-connected_Resources.aspx Project 2020-02 Modifications to PRC-024 (Generator Ride-through), https://www.nerc.com/pa/Stand/Pages/Project_2020-02_Transmission-connected_Resources.aspxhttps://www.nerc.com/pa/Stand/Pages/Project_2020-02_Transmission-connected_Resources.aspx.

the capability to ride-through future grid disturbances by means such as dynamic models and simulation results.

In addition, Project 2020-02, Modifications to PRC-024, proposes to remove IBR from Reliability Standard PRC-024 to maintain capability-based requirements for synchronous generators, synchronous condensers, and asynchronous type 1 and type 2 wind generation.

D. Project 2023-02 Analysis and Mitigation of BES Inverter-Based Resource Performance Issues

Addressed in a separate filing filed concurrently with this petition, Project 2023-03, Analysis and Mitigation of BES Inverter-Based Resource Performance Issues,[47] proposes to establish new Reliability Standard PRC-030-1 to create new risk-based requirements for IBR Generator Owners related to IBR Performance. Proposed Reliability Standard PRC-030-1 would require Generator Owners to identify any complete facility loss of output, or changes in Real Power output that are at least 20 MW and at least 10% of the plant's gross nameplate rating, occurring within a four second period.[48] Generator Owners would then be required to analyze their IBR facility performance during the event, for the purpose of determining the root cause(s) of change(s) in Real Power output; documenting the facility's ride-through performance including Reactive Power response during the event; assessing any performance issues identified and if corrective actions are needed; and determining the applicability of the root cause(s) to the Generator Owner's other IBR facilities. As discussed below, the data from proposed Reliability Standard PRC-028-1

[47] Project 2023-02 Analysis and Mitigation of BES Inverter-Based Resource Performance Issues, https://www.nerc.com/pa/Stand/Pages/Project-2023-02-Performance-of-IBRs.aspx.

[48] Changes in Real Power for the following are excluded: changes associated with intermittent primary energy source availability, created by changes such as variation in wind speed and solar irradiance; resource dispatch, resource ramping, planned outages, or planned resource testing; a Transmission or collection system loss that, by configuration, disconnects the Inverter-Based Resource generator; or Real Power reduction due solely to a Protection System Misoperations being analyzed and corrected under PRC-004 Reliability Standard.

and the ride-through criteria established in proposed Reliability Standard PRC-029-1 would inform the analysis of ride-through performance in PRC-030-1.

Upon request, the analysis results would be provided to the requesting associated Reliability Coordinator, Balancing Authority, or Transmission Operator. If performance issues and a need for corrective actions are identified in the analysis, the Generator Owner would develop and communicate to the associated Reliability Coordinator, Balancing Authority, and Transmission Operator either a Corrective Action Plan for the identified IBR, including other applicable facilities owned by the Generator Owner, or a technical justification that addresses why corrective actions would not be taken. The Corrective Action Plan would then be implemented with any changes communicated to the associated Reliability Coordinator.

Collectively, the proposed Reliability Standards would enhance the reliability of the BPS by addressing critical IBR reliability issues in accordance with Milestone 2 of NERC's Order No. 901 Work Plan.

VI. JUSTIFICATION FOR APPROVAL: PROPOSED RELIABILITY STANDARD PRC-029-1

Proposed Reliability Standard PRC-029-1 addresses a gap in the currently effective Reliability Standards related to IBR ride-through performance during system disturbances. BPS connected generating resources remaining connected during normal and contingency conditions is a critical component of BPS reliability. Ensuring fault ride-through capability enables dynamic Reactive Power support, frequency response, and other services. Multiple NERC disturbance reports involving IBRs have shown that the unexpected and widespread loss of generating assets poses a significant risk to BPS reliability. Proposed Reliability Standard PRC-029-1 would address this issue and advance the reliability of the BPS by establishing frequency and voltage Ride-through performance criteria for IBRs to prevent unnecessary tripping or momentary cessation of current injection.

The currently effective Reliability Standards related to disturbance monitoring and generator performance during system disturbances were developed with a focus on synchronous generation resources. This focus was appropriate as it reflected the generation mix that comprised the BPS at the time they were originally developed.[49] As the resource mix is transforming to include an increasing amount of IBRs,[50] a different approach that takes into consideration the technical and operational characteristics of IBRs is needed to ensure reliability going forward.

While IBRs can produce Real and Reactive Power like synchronous generators, IBRs do not react to disturbances on the BPS in the same way. Traditional synchronous resources that are not connected to a fault will automatically ride through[51] a disturbance because they are synchronized (i.e., connected at identical speeds) to the electric power system and physically linked to support the system voltage or frequency during voltage or frequency fluctuations by continuing to produce Real and Reactive Power due to their inherent inertia.

In contrast, IBRs are not directly synchronized to the electric power system and must be programmed to support the electric power system and to ride-through a disturbance. The operational characteristics of IBRs coupled with their equipment settings may cause them to reduce

---

49 PRC-024-3 and PRC-002 are the standards for ride-through and disturbance monitoring, respectively.

50 *See e.g., 2020 Long Term Reliability Assessment Report* at 9 (Dec. 2020), https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2020.pdf (2020 LTRA Report); *2021 Long Term Reliability Assessment Report* at 29 (Dec. 2021). https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2021.pdf. (NERC projects IBR nameplate capacity additions of approximately 504 GW of solar and 360 GW of wind (i.e., a total nameplate capacity of 864 GW) and cumulative retirements of approximately 60 GW of nuclear, coal, natural gas, and biomass to the Bulk-Power System over the next decade.)

51 *See Standardization of Generator Interconnection Agreements & Procs.*, Order No. 2003, 104 FERC ¶ 61,103, at P 562 n.88, (2003). (defining ride through as "a Generating Facility staying connected to and synchronized with the Transmission System during system disturbances within a range of over- and under-frequency[/voltage] conditions, in accordance with Good Utility Practice.").

power output, whether by tripping offline[52] or ceasing to inject current without tripping offline (known as momentary cessation),[53] individually or in the aggregate in response to a single fault on a transmission or sub-transmission system. Thus, the impact of IBRs is not restricted by the size of a single facility or an individual balancing authority area, but by the number of IBRs or percent of generation made up by IBRs within an interconnection. This is of particular concern because currently many simulations inaccurately predict that IBRs will maintain Real Power output and provide voltage and frequency support consistent with the purpose of Reliability Standard PRC-024-3.

Unless IBRs are configured and programmed to ride-through normally cleared transmission faults, the potential impact of losing IBRs individually or in the aggregate will continue to increase as IBRs are added to the BPS and make up an increasing proportion of the resource mix. As evaluated in past NERC reports and white papers, a controller and protection setting standard has been insufficient at ensuring actual IBR performance during voltage and frequency disturbances, contributing to a growing reliability issue.

For these reasons, the Project 2020-02 drafting team determined that Ride-through performance requirements for IBRs should be addressed by a separate standard from synchronous resources that account for the characteristics of IBRs, including their risks, performance, and equipment capabilities, as demonstrated in several recent events exhibiting significant IBR ride-

---

[52] Tripping offline is a mode of operation during which part of or the entire IBR disconnects from the Bulk-Power System and therefore cannot supply Real and Reactive Power.

[53] NERC, *Reliability Guideline BPS-Connected Inverter-Based Resource Performance* at p. 11 (Sept. 2018) (IBR Performance Guideline) (Momentary cessation is a mode of operation during which the inverter remains electrically connected to the Bulk-Power System, but the inverter does not inject current during low or high voltage conditions outside the continuous operating range. As a result, there is no current injection from the inverter and therefore no active or reactive current (and no active or reactive power)) https://www.nerc.com/comm/RSTC_Reliability_Guidelines/Inverter-Based_Resource_Performance_Guideline.pdf.

through deficiencies.[54] As result, the drafting team developed a new standard, PRC-029-1, to address the Ride-through performance of IBRs, and that PRC-024-4 would be revised to only be applicable to synchronous generators, type 1 and 2 wind plants, and synchronous condensers.

Proposed Reliability Standard PRC-029-1 addresses the reliability issues identified in multiple NERC events reports and Order No. 901 by preventing unnecessary tripping or momentary cessation of current due to phase lock loop loss of synchronism or other causes and ensuring post-disturbance ramp rates return to pre-disturbance levels. Where the need for an exemption exists, due to hardware limitations on legacy equipment, proposed Reliability Standard PRC-029-1 ensures that it is documented, communicated to all relevant entities, accepted by the Compliance Enforcement Authority, and that the entity operates to whatever its capability is to mitigate potential reliability impacts. In so doing, proposed Reliability Standard PRC-029-1 addresses the Commission's directives to address IBR ride-through issues in Order No. 901.

NERC developed the proposed Reliability Standard using NERC's standards development process. This process included multiple public comment and ballot periods. Notably, the NERC Board of Trustees initiated the use of Section 321 of the NERC Rules of Procedure at its August 15, 2024 meeting for this project in order to meet the Commission's timeline set forth in Order No. 901 directives. Section 321 allows the NERC Board of Trustees to take special actions when a ballot pool has failed to approve a proposed Reliability Standard that contains a provision to adequately address a specific matter identified in a directive. Under this special authority, the NERC Board of Trustees directed the NERC Standards Committee to work with NERC Staff to convene a technical conference to gather input from industry to address the outstanding issues and revise PRC-029-1. The technical conference took place on September 4-5, 2024, and it focused on

---

[54] Event Reports *supra* note 9.

unresolved issues raised by stakeholders during the PRC-029-1 comment periods. Proposed Reliability Standard PRC-029-1 was revised based on the input from the technical conference and received the required weighted segment approval of the ballot body during its last ballot period from September 24 through October 4, 2024. The NERC Board of Trustees adopted the proposed Reliability Standards on October 8, 2024. A full summary of development is included in Exhibit G.

In this section, NERC provides an overview of the proposed Reliability Standard, with a summary of the supporting rationale, and demonstrates how proposed Reliability Standard PRC-029-1 is consistent with and addresses the directives in paragraphs 190, 193, 199, 208 and 209 of Order No. 901, listed above in Section IV(C)(1).

Additional information may be found in the Consideration of Directives included as Exhibit D, Summary of Issues and Alternatives Considered Memo included as Exhibit H, Technical Rationale for Proposed Reliability Standard PRC-029-1, included as Exhibit E-2 to this petition, as well as the Complete Record of Development, included as Exhibit G.

A. Proposed Definition of Ride-Through

Proposed Reliability Standard PRC-029-1 uses the term "Ride-through", which NERC proposes to include in the NERC Glossary. The proposed definition is:

> **Ride-through:** The plant/facility remains connected and continues to operate through voltage or frequency system disturbances.

Under the NERC *Standard Processes Manual*, definitions themselves may not include statements of performance requirements. The addition of the term Ride-through within the NERC Glossary would establish a consistent understanding of the meaning of the term across all NERC Reliability Standards going forward and clarify what is expected for a plant or facility to Ride-through a disturbance. The specific performance requirements and measures to demonstrate Ride-through are to be found within the Requirements and Attachments of proposed Reliability Standard PRC-029-1. This term is used in proposed Reliability Standard PRC-030-1 as well. References to "Ride-through criteria" in proposed Reliability Standard PRC-030-1 allow for those additional analytics to include further evaluations with PRC-029-1 Ride-through performance requirements as appropriate, while preventing duplication of those performance requirements in different Reliability Standards.

B. Title and Purpose

The title of proposed Reliability Standard PRC-029-1 is Frequency and Voltage Ride-through Requirements for Inverter-based Resources. The purpose of proposed Reliability Standard PRC-029-1 is: "To ensure that IBRs Ride-through to support the Bulk Power System (BPS) during and after defined frequency and voltage excursions."

C. Applicability

Proposed Reliability Standard PRC-029-1 is applicable to Generator Owners that own: (1) BES IBRs; and (2) non-BES IBRs that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

The proposed standard includes as applicable entities those Generator Owners that own IBRs meeting the Bulk Electric System definition criteria, which have traditionally been subject to registration for compliance with NERC Reliability Standards. It also includes those Generator Owners that own the non-BES IBRs that NERC will register in accordance with revisions to its

Rules of Procedure approved by the Commission in 2024.[55] As such, the applicability of proposed Reliability Standard PRC-029-1 is consistent with paragraph 190 of Order No. 901, in which the Commission directed NERC to develop Reliability Standards that require registered IBRs to ride-through frequency and voltage system disturbances, continue to inject current and perform frequency support during a BPS disturbance, and prohibit momentary cessation in the no-trip zone during disturbances, and establish IBR performance requirements, including requirements addressing frequency and voltage Ride through, post-disturbance ramp rates, phase lock loop synchronization, and other known causes of IBR tripping or momentary cessation.

D. Requirement R1

Proposed Reliability Standard PRC-029-1 Requirement R1 establishes requirements that all applicable IBRs will Ride-through grid voltage disturbances consistent with the "must Ride-through zone" and operation regions specified in Attachment 1. Proposed Requirement R1 would provide as follows:

> R1. Each Generator Owner shall ensure the design and operation is such that each IBR meets or exceeds Ride-through requirements, in accordance with the "must Ride-through[1] zone" as specified in Attachment 1, except in the following conditions: *[Violation Risk Factor: High] [Time Horizon: Operations Assessment]*
>
> - The IBR needed to electrically disconnect in order to clear a fault;
> - The voltage at the high-side of the main power transformer[2] went outside an accepted hardware limitation, in accordance with Requirement R4;

55 *See* IBR Registration Approval Order, *supra* note 38 Presently, the NERC *Glossary* defines the Generator Owner as the "Entity that owns and maintains generating Facility(ies)", with the term "Facility" defined as "A set of electrical equipment that operates as a single Bulk Electric System Element (e.g., a line, a generator, a shunt compensator, transformer, etc.)." NERC has initiated a separate, high priority project, Project 2024-01 Rules of Procedure Definitions Alignment (Generator Owner and Generator Operator), to align the definitions of Generator Owner and Generator Operator in the *Glossary* with the recently approved versions of those terms as used in the NERC Rules of Procedure. The first phase of this project is scheduled for completion in early 2025. Additional information on this project is available at https://www.nerc.com/pa/Stand/Pages/Project-2024-01-Rules-of-Procedure-Definitions-Alignment_GO-and-GOP.aspx.

- The instantaneous positive sequence voltage phase angle change is more than 25 electrical degrees at the high-side of the main power transformer and is initiated by a non-fault switching event on the transmission system[3]; or
- The Volts per Hz (V/Hz) at the high-side of the main power transformer exceed 1.1 per unit for longer than 45 seconds or exceed 1.18 per unit for longer than 2 seconds.

[1] Includes no tripping associated with phase lock loop loss of synchronism.

[2] For the purpose of this standard, the main power transformer is the power transformer that steps up voltage from the collection system voltage to the nominal transmission/interconnecting system voltage for IBRs. In case of IBR connecting via a dedicated Voltage Source Converter High Voltage Direct Current (VSC-HVDC), the main power transformer is the main power transformer on the receiving end.

[3] Current blocking mode may be used for non-fault initiated phase jumps greater than 25 degrees in order to prevent tripping.

Under Requirement R1, Generator Owners of IBRs must be able to demonstrate Ride-through performance by not tripping or entering momentary cessation and must continue to exchange current and remain electrically connected, consistent with the magnitude and duration performance criteria in Attachment 1 of proposed PRC-029-1. Momentary cessation is when an inverter is temporarily current blocking while still remaining connected. Requirement R1 restricts momentary cessation to only two system conditions: 1) non-fault line switching caused voltage phase angle jumps in excess of 25 degrees that could result in tripping unless the inverter goes into current blocking, and 2) while voltage at the plant-system interface is less than 0.10 per unit during which time it may be difficult or impractical to maintain current exchange.

The drafting team determined that the terminology for "must Ride-through zones" and "operation regions" should be consistent with those terms as used within IEEE 2800-2022.[56] The "must Ride-through zones" are defined in terms of voltage and frequency magnitude and time duration. Usage of the term "must Ride-through zone," compared to the term "No trip zone," was

[56] IEEE, *Standard for Interconnection and Interoperability of Inverter-Based Resources (IBR) Interconnecting with Associated Transmission Electric Power Systems*(Apr. 22, 2022), https://standards.ieee.org/ieee/2800/10453/ (IEEE 2800-2022) (establishing uniform technical minimum requirements for the interconnection, capability, and performance of IBRs for reliable integration onto the Bulk-Power System).

also determined to prevent industry from inaccurately interpreting everything outside to be a "must trip zone". While tripping of IBR plants is permitted outside of the defined "must Ride-through zones," protection and controllers should be set in accordance with the actual capability of the IBR. Additionally, the drafting team determined that the voltage thresholds of each operation region should be based on measurements taken on the high-side of the main power transformer, which is also consistent with IEEE 2800-2022. BESS units also must comply with Requirement R1 in all operating modes including charging, discharging, and idle (energized, but not charging or discharging). A BESS in idle mode must be capable of responding to system voltage and frequency excursions as it does in charging or discharging modes.

These Ride-through zones were established based on the drafting team's experience with voltage and frequency excursions in planning and operating criteria disturbances, underfrequency load shedding stages, reasonable and practical limits of IBR voltage and frequency tolerances, and Reliability Standard PRC-024-3 voltage and frequency relay setting graphs. These include adequate margins against worst-case conditions that could be brought about during system disturbances. During the development of proposed Reliability Standard PRC-029-1, the drafting team proposed more stringent (i.e., more broad) criteria than those used in IEEE 2800-2022 due to the anticipated decrease in System inertia caused by the continual changing resource mix. Considering comments from industry received throughout the standard development process and discussion during the technical conference convened under Section 321 of the NERC Rules of Procedure, the frequency must Ride-through zones were changed to be more similar to IEEE 2800-2022 Ride-through zones. The frequency Ride-through zones are more robust than the currently effective in PRC-024-3 and require demonstration of performance. The proposed frequency Ride-through criteria is sufficient to address the recommendations identified in current NERC event reports and assessments.

Phase lock loop loss of synchronism poses a significant risk to reliability by causing IBRs to unexpectedly trip offline. When a grid disturbance occurs, such as a close-in fault or a relatively large switching event, the grid voltage may experience a rapid phase angle shift. In such cases, the phase angle displacement can be large enough to pose challenges for the phase lock loop to track the terminal voltage, cause control instability within the inverter, such as the inner current control loop or the DC link control loop, and even lead to tripping of the inverter due to the malfunction of the controls. Since phase angle jumps are common occurrences on the BPS, the proposed standard requires the IBR to be designed and operated to Ride-through a minimum phase angle jump of 25 electrical degrees. This is a typical value and aligns with the requirement in IEEE 2800-2022. Some IBR equipment has phase lock loop loss of synchronism protection, referring to a protective function that operates when the phase angle displacement exceeds a threshold for a predetermined period of time (on the order of a couple of milliseconds). Historically, this protection has been used by some inverter manufacturers, especially for inverters in distribution systems. For the IBR connected to the BPS, this protection function should be disabled. If it is enabled, the phase angle jump protection setting should be configured such that the IBR shall only trip to prevent equipment damage. Tripping due to phase lock loop loss of synchronism is specifically not permitted within voltage and frequency must Ride-through zones.

The proposed Reliability Standard provides for the following exceptions to Attachment 1 performance criteria: 1) an IBR needs to trip to clear a fault; 2) voltage at the high-side of the main power transformer goes outside an accepted and a documented hardware equipment limitation established in accordance with Requirement R4; 3) instantaneous positive sequence voltage phase angle jumps more than 25 electrical degrees at the high-side of the main power transformer initiated by a non-fault switching events occur on the transmission system; or 4) volts per Hz (V/Hz) at the high-side of the main power transformer exceed 1.1 per unit for longer than 45 seconds or exceed 1.18 per unit for longer than 2 seconds. These exemptions are considered reasonable limits to ensure system stability during a voltage phase angle while protecting the hardware from incurring damage.

E. Requirement R2

Proposed Reliability Standard PRC-029-1 Requirement R2 establishes voltage Ride-through performance criteria during system disturbances for all applicable IBRs. Acceptable performance criteria depend on the operation region that an IBR is presently in or when in transition from one operation region to another operation region. Proposed Requirement R2 would provide as follows:

> R2. Each Generator Owner shall ensure the design and operation is such that the voltage performance for each IBR adheres to the following during a voltage excursion, unless a documented hardware limitation exists in accordance with Requirement R4. [Violation Risk Factor: High] [Time Horizon: Operations Assessment]
>
> 2.1. While the voltage at the high-side of the main power transformer remains within the continuous operation region as specified in Attachment 1, each IBR shall:
>
> 2.1.1. Continue to deliver the pre-disturbance level of Real Power or available Real Power[4], whichever is less.[5]
>
> 2.1.2. Continue to deliver Reactive Power up to its Reactive Power limit and according to its controller settings.
>
> 2.1.3. Prioritize Real Power or Reactive Power when the voltage is less than 0.95 per unit, the voltage is within the continuous operating region, and the IBR cannot deliver both Real Power and Reactive Power due to a current limit or Reactive Power limit, unless otherwise specified through other mechanisms by an associated Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.
>
> 2.2. While voltage at the high-side of the main power transformer is within the mandatory operation region as specified in Attachment 1, each IBR shall exchange current, up to the maximum capability to provide voltage support, on

the affected phases during both symmetrical and asymmetrical voltage disturbances, either under[6]:

- Reactive Power priority by default; or
- Real Power priority if required through other mechanisms by an associated Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

2.3. While voltage at the high-side of the main power transformer is within the permissive operation region, as specified in Attachment 1, each IBR may operate in current blocking mode if necessary to avoid tripping. Otherwise, each IBR shall follow the requirements for the mandatory operation region in Requirement R2.2.

2.3.1. If an IBR enters current blocking mode, it shall restart current exchange in less than or equal to five cycles of positive sequence voltage returning to a continuous operation region or mandatory operation region.

2.4. Each IBR shall not itself cause voltage at the high-side of the main power transformer to exceed the applicable high voltage thresholds and time durations in its response as voltage recovers from the mandatory or permissive operation regions to the continuous operation region.

2.5. Each IBR shall restore Real Power output to the pre-disturbance or available level[7] (whichever is lesser) within 1.0 second when the voltage at the high-side of the main power transformer returns from the mandatory operation region or permissive operation region (including operating in current blocking mode) to the continuous operation region, as specified in Attachment 1, unless an associated Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator requires a lower post-disturbance Real Power level requirement or requires a different post-disturbance Real Power restoration time through other mechanisms.[8]

[4] “Available Real Power" refers to changes of facility Real Power output attributed to factors such as weather patterns, change of wind, and change in irradiance, but not changes of facility Real Power attributed to IBR tripping in whole or part.

[5] Except if this would occur during a frequency excursion. The Real Power response should recover in accordance with the primary frequency controller.

[6] In either case and if required, the magnitude of Real Power and reactive current shall be as specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

[7] “Available Real Power" refers to changes of facility Real Power output attributed to factors such as weather patterns, change of wind, and change in irradiance, but not changes of facility Real Power attributed to IBR tripping in whole or part.

[8] Except if this would occur during a frequency excursion. The Real Power response should recover in accordance with the primary frequency controller.

Under Requirement R2, a Generator Owner must adhere to the specific performance criteria that is needed to assure consistent IBR performance within each operation region in

Attachment 1 and when in transition between regions. A default post-disturbance ramp rate of 1.0 second is specified unless a faster or slower rate is specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator to accommodate specific system post-disturbance recovery needs. Any Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator specified ramp rate becomes the standard requirement.

Requirement R2 Part 2.1 would ensure that when the voltage at the high-side of the main power transformer ("MPT") recovers to the continuous operation region from either the mandatory operation region or the permissive operation region, an IBR delivers the pre-disturbance level of Real Power or available Real Power, whichever is less. "Available Real Power" allows for changes of facility Real Power output attributed to factors such as weather patterns, change of wind, and change in irradiance, but not changes attributed to IBR tripping in whole or part. This requires an IBR to exit the "High Voltage Ride Through ("HVRT")" or "Low Voltage Ridge Through ("LVRT")" modes properly such that it does not cause reduction in the Real Power when the high-side of MPT voltage recovers to within the continuous operation region. When the voltage at the high-side of the MPT is greater than 0.90 per-unit and less than 0.95 per-unit, IBRs are expected to exit the LVRT mode and come back to "normal operating mode". If an IBR has a default total current limit of 1.0 per-unit, the apparent power production of an IBR will be limited below 1.0 per-unit (e.g., the per-unit value of IBR terminal voltage). In such case, the IBR needs to configure a preference setting, either to maintain pre-disturbance Real Power or maximize the Reactive Power to further help with voltage recovery, or according to requirements specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

Requirement R2 Part 2.2 would ensure that when the voltage at the high-side of the MPT is within the mandatory operation region, IBRs inject or absorb reactive current proportional to the level of terminal voltage deviations they measure. For each IBR, the Generator Owner shall follow Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator specified certain magnitude of Reactive Power response to voltage changes, if available. By default, reactive current prioritization shall be configured unless Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator requires Real Power priority.

Requirement R2 Part 2.3 would ensure that when the voltage at the high-side of the MPT is within the permissive operation region, IBRs continue to Ride-through, though they are briefly allowed to enter the current block mode if necessary to avoid tripping off from the grid. In developing this provision, the drafting team took into consideration the physical operational capability of the power electronics devices under such low voltage conditions. The IBR shall restart current exchange in less than or equal to five cycles of positive sequence voltage returning to the continuous operation region or mandatory operation region. If the interconnecting entity has performance requirements that are more stringent than the standard, the Generator Owner should follow the requirements set by the interconnecting entity.

Requirement R2 Part 2.4 would ensure that, when a fault is cleared on the transmission system, the voltage regulators of connected IBRs must adjust the reactive current injection to restore the transmission system voltage to the pre-disturbance voltage as defined by the automatic voltage regulator ("AVR") setpoint. It was considered that tuning of the AVR requires a balance between multiple competing physical factors, e.g., rise time, overshoot, and transient stability. However, it is anticipated that IBR controls will be tuned to allow for a stable post-disturbance voltage recovery without causing excessive overshoot or undershoot of the setpoint. When such overshoots do occur, they must not exceed the magnitudes and durations specified in the applicable table given in Attachment 1. Furthermore, the proposed standard anticipates that control system tuning to prevent such over/under voltages will focus on the speed at which the controller responds to setpoint changes rather than on the magnitude of the reactive current response. For example, reductions in k-factor to prevent over/under voltages should only be considered as a last resort.

Requirement R2 Part 2.5 would ensure that the IBR returns to effective pre-disturbance operation unless otherwise specified or needed by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator. The voltage recovery within 1 second from a disturbance is consistent with IEEE-2800 and there was no technical basis to deviate from that time duration. Ensuring that IBRs can return to pre-disturbance operation is vital to reliability. Post-disturbance injection should be coordinated by Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator because injecting current at pre-disturbance levels during the recovery from a disturbance may overcorrect in some localized areas that is not always practical or desirable for reliability.

F. Requirement R3

Proposed Reliability Standard PRC-029-1 Requirement R3 establishes Ride-through requirements for all applicable IBRs during frequency excursion events. Proposed Requirement R3 would provide as follows:

> R3. Each Generator Owner shall ensure the design and operation is such that each IBR meets or exceeds Ride-through requirements during a frequency excursion event whereby the System frequency remains within the "must Ride-through zone" according to Attachment 2 and the absolute rate of change of frequency (RoCoF)[9] magnitude is less than or equal to 5 Hz/second, unless a documented hardware limitation exists in accordance with Requirement R4. *[Violation Risk Factor: High] [Time Horizon: Operations Assessment]*
>
> [9] Rate of change of frequency (RoCoF) is calculated as the average rate of change for multiple calculated system frequencies for a time period of greater than or equal to 0.1 second. RoCoF is not calculated during the fault occurrence and clearance.

Under proposed Requirement R3, IBRs would be required to remain electrically connected and continue to exchange current during a frequency excursion event in which the frequency remains within the must Ride-through zone according to Attachment 2 and while the absolute rate of change of frequency ("RoCoF") magnitude is less than or equal to 5 Hz/second. Some IBR controllers are sensitive to RoCoF, particularly auxiliary equipment that are essential for IBR performance, during a frequency excursion event.

Under Requirement R3, IBRs would be allowed to trip for an absolute RoCoF exceeding 5Hz/sec within the must Ride-through zone of Attachment 2 to maintain the stability of the IBR or prevent equipment damage. Failure to Ride-through due to RoCoF exceeding 5Hz/sec shall only be allowed during a generator/load imbalance event that causes the frequency to deviate from nominal. Additionally, IBR frequency protection settings should only be set to protect the IBR from damage caused by operation at off-nominal frequency. The IBR Generator Owner must ensure that the IBR frequency protection does not prevent an IBR from being able to Ride-through in accordance with Requirement R3.

Analysis of the Blue Cut Fire event[57] found that a significant amount of solar PV resources incorrectly determined a frequency deviation that triggered protection systems, causing those IBR to trip. These IBR controllers were not set to calculate frequency over a window of time and averaged to verify controller measurements. Under Requirement R3, frequency must be calculated as the average rate of change over multiple calculated system frequencies for some time greater than or equal to 0.1 seconds to minimize this kind of misoperation tripping of IBRs on the RoCoF setting. The RoCoF calculation is not applicable during the occurrence and clearance of a fault (i.e., protection should not trip due to any perceived RoCoF during the entire disturbance and

57 *Supra* note 10.

recovery period), and the IBR should not trip at the onset of a fault, during a fault, or at fault clearance due to the ROCOF calculation, i.e., this controller setting should be disabled during faults. The RoCoF calculation should begin after fault clearance and is only applicable for generation/load imbalance disturbances such as a system separation, an island condition, or the loss of a large load or generator.

Requirement R3 additionally requires IBR Ride-through when the calculated RoCoF is equal to or less than 5 Hz/s. This magnitude and threshold criteria is consistent with IEEE 2800-2022 and determined to be necessary to address anticipated increases of deviations from nominal grid frequency. Nominal grid frequency reflects a balance of system generation and load. A system event that causes a generation/load imbalance will cause system frequency to deviate from nominal. The system may experience an over-frequency event (in the case of more generation than load) or an under-frequency event (in the case of less generation than load). System inertia resists deviation from nominal frequency, giving system operators additional time to rebalance generation and load. System inertia is dependent on the amount of rotating mass connected to the system (i.e., synchronous generators or motors). The larger the system inertia, the slower the system frequency will deviate from the nominal value and the lower the grid RoCoF, giving more time to try to rebalance generation and load. As the grid continues to experience a shift towards generation that does not have rotating mass, planners and operators must account for increasing system frequency deviations from nominal values.

A reduction in system inertia is an inevitable consequence of a power system transitioning toward more IBR and less synchronous generators; however, the utilization of IBR-specific control features (i.e., advanced control modes and grid forming technologies) can provide additional stability benefits to help mitigate the loss of inertia. As discussed in the previous paragraph, less system inertia means the frequency will deviate from the nominal value more quickly during a generation/load imbalance event and will expose the system to a higher RoCoF.

To avoid the risk of widespread tripping, proposed Reliability Standard PRC-029-1 Attachment 2 provides a wider frequency Ride-through band than presently exists in Reliability Standard PRC-024-3 Attachment 2. This is consistent with IEEE 2800-2022, which contains frequency Ride-through times and thresholds are more stringent (i.e. wider) than those presently in Reliability Standard PRC-024-3 and contain continuous operation ranges that exceed the frequency excursions observed during major BPS disturbances. Additionally, detailed feedback from original equipment manufacturers ("OEM") provides insight that they are already designing IBR equipment that conforms with the criteria in IEEE 2800-2022. Aligning the frequency Ride-through criteria in proposed Reliability Standard PRC-029-1 with those in IEEE 2800-2022 provides a meaningful benefit to reliability while also minimizing cost and timeline implications as OEM are already designing conforming equipment.

G. Requirement R4

Proposed Reliability Standard PRC-029-1 Requirement R4 allows for IBRs that are already existing and in operation at the time proposed PRC-029-1 goes into effect ("legacy IBRs") to obtain an exemption to the voltage and frequency Ride-through requirements if hardware replacements would be necessary to comply with Requirements R1 through Requirement R3. Proposed Requirement R4 would provide as follows:

> R4. Each Generator Owner identifying an IBR that is in-service by the effective date of PRC-029-1, has known hardware limitations that prevent the IBR from meeting Ride-through criteria as detailed in Requirements R1-R3, and requires an exemption from specific Ride-through criteria shall:[10] *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

4.1. Document information supporting the identified hardware limitation no later than 12 months following the effective date of PRC-029-1. This documentation shall include:

4.1.1. Identifying information of the IBR (name and facility number);

4.1.2. Which aspects of Ride-through requirements that the IBR would be unable to meet and the capability of the hardware due to the limitation;

4.1.3. Identification of the specific piece(s) of hardware causing the limitation;

4.1.4. Technical documentation verifying the limitation is due to hardware that would need to be physically replaced to meet all Ride-through criteria, and that the limitation cannot be remedied by software updates or setting changes; and

4.1.5. Information regarding any plans to remedy the hardware limitation (such as an estimated date).

4.2. Provide a copy of the information detailed in Requirement R4.1, except for any material considered by the original equipment manufacturer to be proprietary information, to the associated Planning Coordinator(s), Transmission Planner(s), Transmission Operator(s), Reliability Coordinator(s), and the Compliance Enforcement Authority (CEA) no later than 12 months following the effective date of PRC-029-1.[11]

4.2.1. Provide any response for additional information requested by the associated Planning Coordinator(s), Transmission Planner(s), Transmission Operator(s), Reliability Coordinator(s), and the CEA to the requestor within 90 days of the request.

4.2.2. Provide a copy of the acceptance of a hardware limitation by the CEA to the associated Planning Coordinator(s), Transmission Planner(s), Transmission Operator(s), and Reliability Coordinator(s) within 90 days of receiving the acceptance. [11]

4.3. Each Generator Owner with a previously accepted limitation that replaces the hardware causing the limitation shall document and communicate such a hardware change to the associated Planning Coordinator(s), Transmission Planner(s), Transmission Operator(s), and Reliability Coordinator(s) within 90 days of the hardware change.

4.3.1. When existing hardware causing the limitation is replaced, the exemption for that Ride-through criteria no longer applies.

Under Requirement R4, Generator Owners owning legacy IBRs would be allowed exemptions from the voltage or frequency Ride-through performance criteria in Requirements R1-R3 if such limitations are documented and communicated to the Planning Coordinator, Transmission Planner, Reliability Coordinator, and Transmission Operator of the respective footprints in which the IBR is located. The Planning Coordinator, Transmission Planner, Reliability Coordinator, and Transmission Operator would then need to take the voltage or frequency Ride-through limitations into account in planning and operations.

The drafting team determined that an exemption to the Ride-through performance criteria was necessary for legacy IBRs because of the hardware limitations associated with those facilities. Specifically, it was determined that the anticipated difficulty of Generator Owners having to wholesale retrofit and redesign legacy facilities currently in operation would be unreasonable and unduly burdensome, and it could lead to undesirable impacts on reliability. Entities would be required to take units offline to retrofit or risk noncompliance and could choose to retire the units instead of retrofit based on economic considerations. A proposed IBR Ride-through standard having no exemptions could result in a resource capacity deficiency due to these retired units and thus lead to a substantial negative impact to reliability of the BPS.

A Generator Owner may seek an exemption from both the voltage and frequency Ride-through criteria. In Order No. 901 the Commission only directed NERC to consider if an exemption from the voltage Ride-through criteria was necessary. After reviewing stakeholder feedback on the draft standard, the drafting team concluded that an exemption to the frequency Ride-through criteria would also be necessary and appropriate. During the technical conference convened under Section 321, the Standards Committee and NERC Staff included a panel discussion on frequency exemptions. Panelists discussed various challenges related to legacy IBR, such as difficulties obtaining more detailed information on equipment capabilities; specifically for manufacturers who are no longer in business and for IBR that are no longer supported by the manufacturer. Other concerns raised included the possibility that manufacturers would not be willing to provide design or hardware limitation documentation should they identify the information to be proprietary information.[58]

Following the technical conference, NERC staff and the Standards Committee determined that a frequency exemption to the Ride-through criteria was necessary, in addition to the voltage exemption contemplated in Order No. 901, because of hardware-based capability limitations due to manufacture design for a significant amount of installed IBRs. Without a frequency exemption, these legacy IBRs may be required to go offline to refit to comply with proposed Reliability Standard PRC-029-1. It was determined that a potential disconnection of a large amount of installed IBR capacity overwhelmingly indicated a reliability need to allow for a documented and limited set of exemptions for IBR from voltage and frequency ride-through criteria. In light of this reliability concern, Requirement R4 of proposed Reliability Standard PRC-029-1 allows for a documented, and limited, set of exemptions for IBR from frequency Ride-through criteria. This exemption process is discussed below.

Under Requirement R4 Part 4.1, the IBR Generator Owner must document the need for an exemption. The documentation must identify the hardware that prevents the IBR from meeting Ride-through criteria, describe the aspect(s) of the Ride-through criteria that cannot be met, and provide information regarding what the IBR is capable of despite the limitation. Any exemptions due to hardware limitations must not be construed as complete exemptions from the applicable Ride-through criteria in Attachment 1. Exemptions must be specific and limited to the voltage or frequency band(s) and associated duration(s) that cannot be satisfied or as to the number of cumulative voltage deviations within a ten-second time period that the equipment can Ride-

58 *See* Exhibit G Complete Record of Development at item 14, Day 2 Recording and Transcript of the Standards Committee & NERC Ride-through Technical Conference; Project 2020-02 Modifications to PRC-024 (Generator Ride-through) Related Files; posted September 18, 2024.

through if its less than four deviations within any ten-second time period. For this reason, when describing the hardware limitations, the Generator Owner must identify the specific equipment and explain the characteristic(s) of that equipment that prevent Ride-through.

Under Requirement R4 Part 4.2, this Generator Owner must submit such information to the Transmission Planner, Planning Coordinator, Reliability Coordinator, Transmission Operator, and Compliance Enforcement Authority. Further, the IBR must perform in accordance with the capability of the plant, accounting for the limitation, for those criteria identified in the documentation for exemption.

Under Requirement R4 Part 4.2.1, the Generator Owner is required to supply further information on the need for and the nature of the exemption if requested by the Transmission Planner, Planning Coordinator, Reliability Coordinator, Transmission Operator, or Compliance Enforcement Authority.

Under Requirement R4 Part 4.2.2, the Compliance Enforcement Authority must accept that all aspects of the documentation specified in proposed Requirement R4 have been provided by the Generator Owner before an exemption can granted. This would ensure that NERC has visibility into each hardware exemption that is granted and that they have been accurately limited to the particular limitation of the hardware. NERC would work with the Regional Entities to develop a framework for evaluating any exemption submissions in a fair and consistent manner across the ERO Enterprise. NERC would also monitor the use of this process and the disposition of requests as the proposed standard is implemented. To the extent NERC determines any further action would be prudent, it would be dependent on the volume and nature of the hardware limitations being submitted for Compliance Enforcement Authority acceptance. NERC will consult with Commission staff as it performs this oversight activity.

Under Requirement R4 Part 4.3, if the hardware causing the limitation is replaced and the limitation is removed, then the exemption no longer applies. The IBR Generator Owner must communicate to the Planning Coordinator, Transmission Planner, Reliability Coordinator, and Transmission Operator of the hardware and change to anticipated performance within 90 days of the hardware replacement. This is to ensure that all IBRs capable of fully complying with the Ride-through criteria in Requirements R1-R3 do so as soon as possible.

H. Consideration of FERC Order No. 901 Directives

Proposed Reliability Standard PRC-029-1 is responsive to the Commission's performance directives in paragraphs 190, 193, 199, 208 and 209 of Order No. 901, described above in Section IV(C)1. The Commission directed NERC to develop performance-based Reliability Standards that require IBRs to Ride-through system disturbances and require post-disturbance ramp rates to return to pre-disturbance levels. The Commission further directed NERC to determine if an exemption from Ride-through criteria is necessary and, if so, that it is only for a limited and documented set of existing IBRs, and that NERC develop new or modified Reliability Standards to mitigate the reliability impact of any such exemptions. The following discussion summarizes how proposed Reliability Standard PRC-029-1 addresses these directives, as further discussed in the Consideration of Directives included as Exhibit D hereto.

1. <u>Paragraph 190 Directing Reliability Standards Addressing IBR Ride-through Performance</u>

In paragraph 190 of Order No. 901, the Commission issued several directives for NERC related to Reliability Standards for IBRs to Ride-though system disturbances. Each of these are addressed in turn below.

First, the Commission directed NERC to require that registered IBRs "ride through frequency and voltage system disturbances and that permit IBR tripping only to protect the IBR equipment in scenarios similar to when synchronous generation resources use tripping as protection from internal faults."[59] To address the reliability concerns for the voltage component of this directive, proposed Reliability Standard PRC-029-1 Requirement R1 would require registered Generator Owners of IBRs to both design and operate their IBR plants to Ride-through voltage excursions within "must Ride-through zones" according to how these zones are defined in the standard. Proposed Reliability Standard PRC-029-1 Requirement R3 would require the same design and operation Ride-through requirements for Ride-through frequency excursions. The must Ride-through zones used within the requirements and Attachments are defined in terms of voltage and frequency magnitudes and time durations. Tripping of IBR plants is permitted only outside of the defined must Ride-through zones.

Second, in paragraph 190, the Commission directed NERC to require that registered IBRs "continue to inject current and perform frequency support during a Bulk-Power System disturbance."[60] NERC addresses this directive in proposed Reliability Standard PRC-029-1 Requirements R1-R3. These requirements would require IBRs to Ride-through system disturbances. The proposed Ride-through definition states that IBR facilities must remain connected and continue to fulfill their established control and regulation functions (which generally involve exchange of current) to qualify as riding through system disturbances. Support of frequency is predicated on, and to a large degree achieved by being able to Ride-through system disturbances.

Third, in paragraph 190, the Commission directed NERC to develop requirements that "prohibit momentary cessation in the no-trip zone during disturbances."[61] Proposed Reliability

---

59 Order No. 901 P 190.

60 *Id.*

61 *Id.*

Standard PRC-029-1 addresses this directive in Requirement R1, which would require IBRs to meet or exceed Ride-through requirements in Attachment 1. As discussed above, these Ride-through requirements would restrict the use of momentary cessation to the following two system conditions: 1) non-fault line switching caused voltage phase angle jumps in excess of 25 degrees that could result in tripping unless the inverter goes into current blocking; and 2) voltage at the plant-system interface that is less than 0.10 per unit during which time it may be difficult or impractical to maintain current exchange.

Lastly, in paragraph 190, the Commission directed NERC to require that registered IBRs have "performance requirements, including requirements addressing frequency and voltage Ride-through, post-disturbance ramp rates, phase lock loop synchronization, and other known causes of IBR tripping or momentary cessation."[62] Proposed Reliability Standard PRC-029-1 addresses this directive in Requirement R1. As noted above, Requirement R1 establishes IBR frequency and voltage Ride-through requirements. The proposed requirement also specifies a default post-disturbance ramp rate of 1.0 second unless a faster or slower rate is specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator to accommodate specific system post-disturbance recovery needs. Additionally, tripping due to phase lock loop loss of synchronism is specifically not permitted within voltage and frequency must Ride-through zones.

2. Paragraph 193: Consideration of Voltage Ride-Through Performance Exemptions

In paragraphs 193 and 199 of Order No. 901, the Commission directed NERC to consider whether the proposed new or revised Reliability Standard should contain exemptions to the Ride-

---

[62] *Id.*

through performance requirements for those legacy IBRs that are currently in operation and unable to meet the requirements.

First, in paragraph 193 of Order No. 901, the Commission directed NERC to "determine whether the new or modified Reliability Standards should provide for a limited and documented exemption for certain registered IBRs from voltage Ride-through performance requirements."[63] As discussed more fully above, NERC has determined that a limited and documented exemption for certain registered IBRs from voltage or frequency Ride-through performance requirements would be appropriate. Thus, proposed Reliability Standard PRC-029-1 Requirement R4 establishes a process by which entities may obtain an exemption from the voltage or frequency Ride-through criteria of PRC-029-1 Requirement R1 or Requirement R3 for IBR plants/facilities that are in service at the effective date of the standard. Although Order No. 901 was silent regarding the need for NERC to consider frequency Ride-through exemptions, NERC determined that frequency exemptions were needed to address significant OEM design capability limits regarding frequency thresholds. More information on why a frequency exemption was determined to be necessary can be found in the discussion of Requirement R4, above, and in the Summary of Issues and Alternatives Considered Memo included as Exhibit H.

In all cases, the IBR Generator Owner must document the need for an exemption, and the documentation must explain what hardware prevents the IBR from meeting Ride-through criteria, which aspect(s) of the Ride-through criteria that cannot be met, and information regarding what the IBR is capable of despite the limitation. The Generator Owner must then submit this information to the Transmission Planner, Planning Coordinator, Reliability Coordinator, Transmission Operator, and Compliance Enforcement Authority. Further, the IBR must perform

63 *Id.* at P 193.

in accordance with the capability of the plant, accounting for the limitation, for those criteria identified in the documentation for exemption. The Compliance Enforcement Authority checks that all aspects of the documentation specified in Requirement R4 have been provided by the Generator Owner, and the Generator Owner is required to supply further information on the need for and the nature of the exemption if requested by the Transmission Planner, Planning Coordinator, Reliability Coordinator, Transmission Operator, or Compliance Enforcement Authority. The implementation plan provides a 12-month time window for exemption requests to be submitted following the enforcement date. Following the 12-month window, further exemption requests will not be accepted or could be considered an admission of non-compliance.

Second, in paragraph 193 the Commission directs NERC "to ensure that any such exemption would be applicable for only existing equipment that is unable to meet voltage Ride-through performance. When such existing equipment is replaced, the exemption would no longer apply, and the new equipment must comply with the appropriate IBR performance requirements…"[64] The exemption provision in Requirement R4 addresses this directive by providing that exemptions are available only for IBR plants/facilities that are in service at the effective date as noted above. The exemption provision also stipulates that once the plant/facility hardware causing the limitation is replaced, the exemption no longer applies.

Lastly, in paragraph 193 the Commission directed NERC "to require the limited and documented exemption list (i.e., IBR generator owner and operator exemptions) to be communicated with their respective Bulk-Power System planners and operators."[65] The exemption provision in Requirement R4 addresses this directive as it requires an IBR Generator Owner to

---

64 *Id.*

65 *Id.*

supply its exemption request documentation to its Transmission Planner, Planning Coordinator, Reliability Coordinator, and Transmission Operator within the 12-month window following the effective date as noted above.

3. Paragraph 199: Mitigation of Reliability Impacts from Ride-through Exemptions

In paragraph 199 of Order No. 901, the Commission directed NERC to mitigate the reliability impacts to the Bulk-Power System of any exemptions from Ride-through requirements.[66] The reliability impacts of voltage or frequency must Ride-through exemptions are mitigated by existing NERC Reliability Standards addressing the responsibilities of Transmission Planners, Planning Coordinators, Reliability Coordinators, and Transmission Operators.[67] These entities routinely conduct evaluations of potential impacts to the grid for a variety of different operating conditions, scenarios, and time windows. These entities have the obligation to require Corrective Action Plans be developed in accordance with the requirements of those other standards when such adverse system conditions exceeding acceptable thresholds are identified in the studies required by those other standards. Additionally, under Milestone 4 of the Order No. 901 Work Plan, NERC will develop Reliability Standards that will specifically require evaluations that include accurately-modeled performance capabilities of IBR, inclusive of any documented Ride-through criteria exemption accepted through the process detailed in proposed Reliability PRC-029-1 Requirement R4, and that evaluate for reliability impacts on the BPS.

4. Paragraph 208: Post-Disturbance Ramp Rates Return to Pre-Disturbance Output

In paragraph 208 of Order No. 901, the Commission directed NERC to "develop and submit to the Commission for approval new or modified Reliability Standards that require post-disturbance ramp rates for registered IBRs to be unrestricted and not programmed to artificially interfere with the resource returning to a pre-disturbance output level in a quick and stable manner after a Bulk-Power System disturbance event."[68] Proposed Reliability Standard PRC-029-1 addresses this directive in Requirement R2. As noted above, Requirement R2 is responsive to this directive because it has a default post-disturbance ramp rate of 1.0 second specified unless a faster or slower rate is specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator to accommodate specific system post-disturbance recovery needs. Any Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator specified ramp rate criteria becomes the standard required criteria for this aspect of Ride-through performance.

5. Paragraph 209: Ride-Through Standards Must Address Different Types of Loss of Synchronism

Paragraph 209 of Order No. 901 contains several directives for NERC regarding IBRs ability to Ride-Through different types of loss of synchronism. Each of these are addressed in turn.

First, the Commission directed NERC to require that registered IBRs "ride through any conditions not addressed by the proposed new or modified Reliability Standards that address frequency or voltage ride through, including phase lock loop loss of synchronism."[69] Proposed Reliability Standard PRC-029-1 addresses this directive in Requirement R1. As noted above, under Requirement R1, phase lock loop loss of synchronism is not allowed as a cause of tripping while

[68] Order No. 901 at P 208.

[69] *Id*. at P 209.

voltage remains within the must Ride-through zone unless there are phase jumps more than 25 degrees caused by non-fault switching events. A footnote under Requirement R1 also specifically states that phase lock loop loss of synchronism as not a permissible condition for tripping while voltage remains within the must Ride-through zone.

Second, the Commission directed NERC to require that registered IBRs "ride through momentary loss of synchronism during Bulk-Power System disturbances and require registered IBRs to continue to inject current into the Bulk Power System at pre-disturbance levels during a disturbance, consistent with the IBR Interconnection Requirements Guideline and Canyon 2 Fire Event Report recommendations."[70] Proposed Reliability Standard PRC-029-1 addresses this directive in Requirements R1 and R2. As noted above, Requirement R1 specifically does not permit tripping due to phase lock loop loss of synchronism within voltage and frequency must Ride-through zones. Requirement R2 specifies that IBRs are required to have Real and Reactive Power performance during voltage disturbances. Additionally, Requirement R2 requires IBRs to return to pre-disturbance power injection. Requirement R2 Part R2.1.1 includes a provision to return to "Available Active Power" to allow for "changes of facility Real Power output attributed to factors such as weather patterns, change of wind, and change in irradiance." However, "changes of facility Real Power attributed to IBR tripping in whole or part" are not permitted under Requirement R2 Part R2.1.1. The reason for this is to ensure clarity regarding allowable changes due to changes in the IBR fuel source rather than due to any tripping of the IBR, in whole or in part.

[70] *Id.*

Lastly, the Commission directed NERC "to consider whether there are conditions that may limit generators to maintain synchronism."[71] NERC determined that IBRs are non-synchronous but can exhibit forms of instability other than loss of synchronism. System stability is a shared responsibility of Transmission Planners, Planning Coordinators, Reliability Coordinators, and Transmission Operators. IBR generation levels may need to be restricted by these entities to maintain System stability or to mitigate known System constraints to a localized area.

VII. JUSTIFICATION FOR APPROVAL: PROPOSED RELIABILITY STANDARD PRC-024-4

Proposed Reliability Standard PRC-024-4 contains revisions that would enable the standard to be retained as a protection-based standard with applicability to only synchronous generators, synchronous condensers, and type 1 and type 2 wind units. Proposed Reliability Standard PRC-024-4 would continue to address frequency and voltage protection setting ranges for synchronous units as they do not require performance-based requirements to Ride-through disturbances. Additionally, consistent with the proposed definition of IBR developed under Project 2020-06, type 1 and 2 wind units are not considered IBRs. These wind turbine types operate as asynchronous generating resources and do not have modern controllers capable of riding through system events.

The revised standard applicability of proposed Reliability Standard PRC-024-4 is supported by the different natures of synchronous and IBR generation resources, including their risks, performance, and equipment capabilities. As described above, NERC's Project 2020-02, Modifications to PRC-024, was initiated by NERC in response to several event reports where widespread loss of IBRs abnormally tripped, ceased current injection, or reduced power output

---

71 *Id.*

with control interactions. For the reasons described below, there is no need to impose actual disturbance Ride-through requirements on synchronous units but only to include restrictions for frequency and voltage protection setting ranges as maintained in PRC-024-4.

The behavior of rotating synchronous generators during faults and other disturbances on the transmission system is well established and understood in comparison to IBR generation. The disturbance Ride-through vulnerabilities of synchronous generators are pole slipping instability and undervoltage dropout of critical plant auxiliary equipment, leading to tripping of a generator. NERC determined that these issues did not need to be addressed in Project 2020-02, as pole slipping (or loss of synchronism) can be managed by Real Power dispatch constraints or stability System Operating Limits. Auxiliary equipment has not posed a Ride-through risk.

Over-frequency protection, under-frequency protection, over-voltage protection, and under-voltage protection may or may not be applied to synchronous generating units. If applied, settings should be coordinated between the needs of generating unit protection and the no-trip zones within PRC-024-4 attachments. Coordination of generating unit capabilities, voltage regulating controls, and protection is addressed within Reliability Standard PRC-019-2. Excitation and governing controls affect synchronous generator Ride-through behavior to some degree but because of progressive improvement, standardization, and level of maturity of these controls, they are rarely a cause of unnecessary tripping during disturbances. In addition, there are other existing NERC standards to prevent unnecessary tripping of the generators during a system disturbance such as PRC-025-2 - Generator Relay Loadability and PRC-026-2 - Relay Performance During Stable Power Swings.

NERC developed the proposed Reliability Standard using NERC's standards development process. This process included multiple public comment and ballot periods. The NERC Board of Trustees adopted proposed Reliability Standard PRC-024-4 on October 8, 2024.

In this section, NERC provides an overview of the proposed Reliability Standard, with a summary of the supporting rationale. Additional information may be found in the Technical Rationale for Proposed Reliability Standard PRC-024-4, included as Exhibit E-1 to this petition, as well as the Complete Record of Development, included as Exhibit G.

A. Title and Purpose

The title of proposed Reliability Standard PRC-024-4 is – Frequency and Voltage Protection Settings for Synchronous Generators, Type 1 and 2 Wind Plants, and Synchronous Condensers. The purpose is to ensure that protection of synchronous generators, type 1 and type 2 wind resources, and synchronous condensers do not cause tripping during defined frequency and voltage excursions in support of the BPS.

B. Applicability

Proposed Reliability Standard PRC-024-4 is still applicable to Generator Owners and Transmission Owners, as well as Planning Coordinators which are applicable entities only in the Quebec Interconnection. The functional entity responsible for setting frequency, voltage, and volts per hertz protection for synchronous generators, type 1 and 2 wind plants, and synchronous condensers is either the Generator Owner or Transmission Owner. Modifications are proposed in PRC-024-4 to expand functional entity applicability to include "Transmission Owners that apply protection" because of the inclusion of synchronous condenser applicability in section 4.2.2.

The Applicable Facilities in subparts in Section 4.1.1 were modified to restrict PRC-024-4 to synchronous generators and type 1 and 2 wind plants. Section 4.2.2 was added to include synchronous condensers and associated equipment.

C. Requirements

Proposed Reliability Standard PRC-024-4 modifies Requirements R1, R2, R3, and R4 to include the Transmission Owner as a functional entity applicable to each requirement due to the addition of synchronous condensers in the applicable facilities. Additionally, modifications were made to Requirements R1, R2, R3, and R4 to include language that relates to type 1 and 2 wind plants and synchronous condensers and to remove language that relates to IBR functionality since IBRs are addressed in proposed Reliability Standard PRC-029-1.

VIII. ENFORCEABILITY OF PROPOSED RELIABILITY STANDARDS

The proposed Reliability Standards include measures that support each requirement by clearly identifying what is required and how the ERO will enforce the requirement. These measures help ensure that the requirements will be enforced in a clear, consistent, and non-preferential manner and without prejudice to any party.[72] Additionally, the proposed Reliability Standards include VRFs and VSLs. The VRFs and VSLs provide guidance on the way that NERC will enforce the requirements of the proposed Reliability Standards. The VRFs and VSLs for the proposed Reliability Standards comport with NERC and Commission guidelines related to their assignment. Exhibit F provides a detailed review of the VRFs and VSLs, and the analysis of how the VRFs and VSLs were determined using these guidelines.

IX. EFFECTIVE DATE OF THE PROPOSED RELIABILITY STANDARDS

NERC respectfully requests that the Commission approve the proposed Reliability Standards to become effective as set forth in the proposed Implementation Plan, provided in Exhibit B hereto. The proposed Implementation Plan provides that the proposed Reliability Standards PRC-024-4 and PRC-029-1 shall become effective on the first day of the first calendar

[72] Order No. 672 at P 327.

quarter that is twelve calendar months after the effective date of the Commission's order approving the proposed Reliability Standard. Currently effective Reliability Standard PRC-024-3 would be retired immediately prior to the effective date of proposed Reliability Standard PRC-024-4. The Implementation Plan for proposed PRC-029-1 provides phased-in compliance dates for both capability and performance-based elements of Requirements R1, R2, and R3 for BES IBRs and non-BES IBRs.

For BES IBRs, the implementation timeframe for capability-based elements is as follows. Generator Owners shall comply with the portion of Requirements R1, R2, and R3 relating to the design of their BES IBRs to meet the requirements by the effective date of the standard. Additionally, the implementation timeframe for the exemption process in Requirement R4 is the effective date of the standard.

For non-BES IBRs, the implementation timeframe for capability-based elements is as follows. Generator Owners shall comply with the portion of Requirements R1, R2, and R3 relating to the design of their applicable non-BES IBRs until the later of: (1) January 1, 2027; or (2) the effective date of the standard. Additionally, the implementation timeframe for the exemption process in Requirement R4 is the later of: (1) January 1, 2027; or (2) the effective date of the standard.

For all IBRs, the implementation timeframe performance-based elements is as follows. Generator Owners shall not be required to comply with the portion of Requirements R1, R2, and R3 relating to the operation of IBRs to meet the requirements until the entity has established the required disturbance monitoring equipment capabilities for those IBRs in accordance with the implementation plan for proposed Reliability Standard PRC-028-1.[73] Under that plan, Generator Owners will follow a phased-in compliance timeline with requirements to establish disturbance monitoring capabilities fully implemented by January 1, 2030.

This Implementation Plan recognizes the need for this phased in compliance timeline so entities can establish disturbance monitoring capabilities before having to comply with the performance-based elements of proposed Reliability Standard PRC-029-1. Further, Generator Owners and Generator Operators owning or operating BPS connected IBRs that do not meet NERC's current definition of BES will be registered no later than May 2026 in accordance with the IBR Registration proceeding in FERC Docket No. RR24-2. To ensure an orderly registration and compliance process for these entities, as well as fairness and consistency in the standard's application among similar asset types, the proposed Implementation Plan provides additional time for both new and existing registered entities to come into compliance with new IBR Ride-through requirements for their applicable IBRs not meeting the BES definition. In so doing, this Implementation Plan advances an orderly process for new registrants while allowing existing

---

[73] The proposed implementation plan for proposed Reliability Standards PRC-028-1 and PRC-002-5 provides that the proposed standards would become effective the first calendar quarter following regulatory approval. Implementation of PRC-028-1 would then follow a phased-in compliance timeline, ending by 2030. The relevant dates under that plan are as follows:

BES IBRs: Generator Owners shall comply with requirements to establish disturbance monitoring data recording capabilities for 50% of their existing BES IBRs (i.e. in commercial operation on or before the effective date) within three calendar years of the effective date of PRC-029-1, and 100% of their BES IBRs by January 1, 2030. If a Generator Owner has only one such BES IBR, it shall comply within three calendar years. For new BES IBRs, Generator Owners shall comply within 15 calendar months following the effective date of the standard or by the commercial operation date, whichever is later.

Non-BES IBRs: Generator Owners shall comply with requirements to establish disturbance monitoring data recording capabilities for 100% of those non-BES IBRs in commercial operation prior to May 15, 2026 by no later than January 1, 2030. Generator Owners shall comply with for their new non-BES IBRs within 15 calendar months following the effective date of the standard or by the commercial operation date, whichever is later.

Additional information is available in Section VIII and Exhibit B to NERC's Petition for Approval of Proposed Disturbance Monitoring Reliability Standards PRC-028-1 and PRC-002-5 (Nov. 4, 2024).

entities to focus their immediate efforts on their assets posing the highest risk to the reliable operation of the BPS.

Consistent with Order No. 672, the proposed implementation plan balances the urgency in the need to implement new requirements for IBR Ride-through performance, a need which is demonstrated in multiple NERC event reports and highlighted in Order No. 901, while providing a reasonable amount of time for those who must comply to develop the necessary procedures, software, facilities, staffing, or other relevant capability.[74] The proposed implementation plan is also consistent with the Commission's directive in Order No. 901 that "there is a need to have all of the directed Reliability Standards effective and enforceable well in advance of 2030 and direct NERC to ensure that the associated implementation plans sequentially stagger the effective and enforceable dates to ensure an orderly industry transition for complying with the IBR directives in this final rule prior to that date."[75]

---

74 Order No. 672 at P 333.

75 Order No. 901 at P 226.

X. CONCLUSION

For the reasons set forth above, NERC respectfully requests that the Commission approve:

- proposed Reliability Standards PRC-024-4 and PRC-029-1, and associated elements included in Exhibit A, effective as proposed herein;
- the proposed Implementation Plan included in Exhibit B; and
- the retirement of Reliability Standard PRC-024-3 effective as proposed herein.

Respectfully submitted,

/s/ Alain Rigaud

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

Draft 3 of PRC-024-4 is posted for final ballot. Non-substantive corrections were identified during the last additional ballot. This draft includes those corrections.

Completed Actions	Date
Standards Committee accepted revised Standard Authorization Request (SAR) for posting	April 19, 2023
Standards Committee approved waivers to the Standards Process Manual	December 13, 2023
25-day formal comment period with initial ballot	March 27 - April 22, 2024
15-day formal comment period and additional ballot	June 18 – July 8, 2024

Anticipated Actions	Date
Final ballot	September 25 – September 30, 2024
Board Adoption	October 8, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

None

A. Introduction

1. **Title:** **Frequency and Voltage Protection Settings for Synchronous Generators, Type 1 and Type 2 Wind Resources, and Synchronous Condensers**

2. **Number:** **PRC-024-4**

3. **Purpose:** To assure that protection of synchronous generators, type 1 and type 2 wind resources, and synchronous condensers do not cause tripping during defined frequency and voltage excursions in support of the Bulk Power System (BPS).

4. **Applicability:**

4.1. Functional Entities:

4.1.1. Generator Owners that apply protection listed in Sections 4.2.1 or 4.2.2.

4.1.2. Transmission Owners that apply protection listed in Section 4.2.2.

4.1.3. Transmission Owners (in the Quebec Interconnection only) that own a BES generator step-up (GSU) transformer or main power transformer (MPT)[1] and apply protection listed in Section 4.2.1.

4.1.4. Planning Coordinators (in the Quebec Interconnection only)

4.2. Facilities[2]:

4.2.1 Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip the generating resource(s); or (ii) provide signals to the generating resource(s) to trip; and are applied to the following:

4.2.1.1 Bulk Electric System (BES) synchronous generators.

4.2.1.2 BES GSU transformer(s) for synchronous generators.

4.2.1.3 High-side of the synchronous generator-connected unit auxiliary transformer[3] (UAT) installed on BES generating resource(s).

4.2.1.4 Individual dispersed power producing type 1 or type 2 wind resource(s) identified in the BES Definition, Inclusion I4.

---

[1] For the purpose of this standard, the MPT is the power transformer that steps up voltage from multiple small synchronous generators (e.g. multiple small hydro generators connecting to a common bus) or from a type 1 or type 2 wind resource collector station to transmission voltage .

[2] It is not required to install or activate the protections described in Facilities Section 4.2.

[3] These transformers are variously referred to as station power UAT, or station service transformer(s) used to provide overall auxiliary power to the synchronous generators. This UAT is the transformer connected on the generator bus between the low side of the GSU and the generator terminal.

4.2.1.5 Elements that are designed primarily for the delivery of capacity from multiple synchronous generators connecting to a common bus or individual dispersed power producing type 1 or type 2 wind resources identified in the BES Definition, Inclusion I4, to the point where those resources aggregate to greater than 75 MVA.

4.2.1.6 MPT of multiple synchronous generators connecting to a common bus or MPT of individual dispersed power producing type 1 or type 2 wind resources as identified in the BES Definition, Inclusion I4.

4.2.2 Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip transmission connected synchronous condensers; or (ii) provide signals to trip transmission connected synchronous condenser and are applied to the following:

4.2.2.1 BES synchronous condensers

4.2.2.2 BES step-up transformer(s) for synchronous condensers.

4.2.2.3 High-side of the synchronous condenser-connected unit auxiliary transformer (UAT).

4.2.3 **Exemptions:** Protection on all auxiliary equipment within the synchronous generator, type 1 or type 2 wind resource, or synchronous condenser Facility.

5. **Effective Date:** See Implementation Plan for PRC-024-4

B. Requirements and Measures

R1. Each Generator Owner and Transmission Owner shall set applicable frequency protection[4] in accordance with PRC-024-4 Attachment 1 such that the applicable protection does not cause the Facility to which it is applied to trip within the "no trip zone" during a frequency excursion with the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- Applicable frequency protection may be set to trip within a portion of the "no trip zone" for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.

M1. Each Generator Owner and Transmission Owner shall have evidence that the applicable frequency protection has been set in accordance with Requirement R1, such as dated setting sheets, calibration sheets, calculations, or other documentation.

R2. Each Generator Owner and Transmission Owner shall set applicable voltage protection[5] in accordance with PRC-024-4 Attachment 2, such that the applicable protection does not cause the Facility to which it is applied to trip within the "no trip zone" during a voltage excursion at the high-side of the GSU or MPT, subject to the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- If the Transmission Planner allows less stringent voltage protection settings than those required to meet PRC-024-4 Attachment 2, then the Generator Owner or Transmission Owner may set its protection within the voltage recovery characteristics of a location-specific Transmission Planner's study.
- Applicable voltage protection may be set to trip during a voltage excursion within a portion of the "no trip zone" for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.

M2. Each Generator Owner and Transmission Owner shall have evidence that applicable voltage protection has been set in accordance with Requirement R2, such as dated setting sheets, voltage-time boundaries, calibration sheets, coordination plots, dynamic simulation studies, calculations, or other documentation.

R3. Each Generator Owner and Transmission Owner shall document each known regulatory or equipment limitation[6] that prevents its Facility, with applicable frequency or voltage protection from meeting the protection setting criteria in Requirements R1 or R2, including (but not limited to) study results, experience from an actual event, or manufacturer's advice. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

---

[4] Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip the synchronous generator(s), type 1 or type 2 wind resource(s), or synchronous condenser(s); or (ii) provide signals to trip the same Facilities.
[5] Ibid.
[6] Excludes limitations caused by the setting capability of the frequency, voltage, and volts per hertz protective relays applied to the synchronous generator(s), type 1 and type 2 wind resource(s), and synchronous condenser(s). This does not exclude limitations originating in the equipment protected by the relay(s).

3.1. The Generator Owner and Transmission Owner shall communicate the documented regulatory or equipment limitation, or the removal of a previously documented regulatory or equipment limitation, to its Planning Coordinator and Transmission Planner within 30 calendar days of any of the following:

- Identification of a regulatory or equipment limitation.
- Repair of the equipment causing the limitation that removes the limitation.
- Replacement of the equipment causing the limitation with equipment that removes the limitation.
- Creation or adjustment of an equipment limitation caused by consumption of the cumulative turbine life-time frequency excursion allowance.

M3. Each Generator Owner and Transmission Owner shall have evidence that it has documented and communicated any known regulatory or equipment limitations that resulted in an exception to Requirements R1 or R2 in accordance with Requirement R3, such as a dated email or letter that contains such documentation as study results, experience from an actual event, or manufacturer's advice.

R4. Each Generator Owner and Transmission Owner shall provide its applicable protection settings associated with Requirements R1 and R2 to the Planning Coordinator or Transmission Planner that models the associated Facility within 60 calendar days of receipt of a written request for the data and within 60 calendar days of any change to those previously requested settings unless directed by the requesting Planning Coordinator or Transmission Planner that the reporting of protection setting changes is not required. *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

M4. Each Generator Owner and Transmission Owner shall have evidence that it communicated applicable protection settings in accordance with Requirement R4, such as dated emails, correspondence or other evidence and copies of any requests it has received for that information.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- The Generator Owner and Transmission Owner shall keep data or evidence of Requirements R1 through R4 for five years or until the next audit, whichever is longer.
- If a Generator Owner or Transmission Owner is found non-compliant, the Generator Owner or Transmission Owner shall keep information related to the non-compliance until mitigation is complete and approved for the time period specified above, whichever is longer.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable frequency protection so that it does not trip according to Requirement R1.
R2.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable voltage protection so that it does not trip according to Requirement R2.
R3.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 30 calendar days but less than or equal to 60 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 60 calendar days but less than or equal to 90 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 90 calendar days but less than or equal to 120 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner failed to document any known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2. OR The Generator Owner or Transmission Owner failed to communicate the documented limitation to its Planning Coordinator and Transmission Planner within 120 calendar

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
				days of identifying the limitation.
R4.	The Generator Owner or Transmission Owner provided its protection settings more than 60 calendar days but less than or equal to 90 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner provided protection settings more than 60 calendar days but less than or equal to 90 calendar days of a written request.	The Generator Owner or Transmission Owner provided its protection settings more than 90 calendar days but less than or equal to 120 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner provided protection settings more than 90 calendar days but less than or equal to 120 calendar days of a written request.	The Generator Owner or Transmission Owner provided its protection settings more than 120 calendar days but less than or equal to 150 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner or provided protection settings more than 120 calendar days but less than or equal to 150 calendar days of a written request.	The Generator Owner or Transmission Owner failed to provide its protection settings within 150 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner failed to provide protection settings within 150 calendar days of a written request.

D. Regional Variances

D.A. Variance for the Quebec Interconnection

This Variance replaces Requirement R2 of the continent-wide standard in its entirety and adds a new requirement, Requirement D.A.5., applicable to Planning Coordinators in the Quebec Interconnection.

This Variance replaces continent-wide Requirement R2 in its entirety with the following:

D.A.2. Each Generator Owner and Transmission Owner shall set applicable voltage protection[7] in accordance with PRC-024 Attachment 2A, such that the applicable protection does not cause the Facility to which it is applied to trip within the "no trip zone" during a voltage excursion at the high-side of the GSU or MPT, subject to the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- For newly designated strategic power plants, applicable protections must comply with the high voltage durations for such plants within 48 calendar months of the notification made pursuant to Requirement D.A.5. During this transition period, voltage protections must at least comply with the high voltage durations for "all power plants".
- Applicable voltage protection may be set to trip during a voltage excursion within a portion of the "no trip zone" of PRC-024 Attachment 2A for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.
- If the Transmission Planner allows less stringent voltage protection settings than those required to meet PRC-024 Attachment 2A, then the Generator Owner or Transmission Owner may set its protection within the voltage recovery characteristics of a location-specific Transmission Planner's study.

M.D.A.2. Each Generator Owner and Transmission Owner shall have evidence that applicable voltage protection has been set in accordance with Requirement R2, such as dated setting sheets, voltage-time boundaries, calibration sheets, coordination plots, dynamic simulation studies, calculations, or other documentation.

This Variance adds the following Requirement:

D.A.5 Each Planning Coordinator shall designate, at least once every five calendar years, the strategic power plants that must comply with Attachment 2A and notify, within 30 calendar days of its designation,

[7] Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip the synchronous generator(s), type 1 or type 2 wind resource(s), or synchronous condenser(s); or (ii) provide signals to trip the same Facilities.

each Generator Owner or Transmission Owner that owns facilities[8] in the strategic power plants. *[Violation Risk Factor: Medium] [Time Horizon: Long-term planning]*

M.D.A.5 Each Planning Coordinator shall have evidence that it designated, at least once every five calendar years, strategic power plants in accordance with Requirement D.A.5, Part 5 and shall have dated evidence that each Generator Owner or Transmission Owner has been notified in accordance with Requirement D.A.5, part 5.2. Evidence may include, but is not limited to letters, emails, electronic files, or hard copy records demonstrating transmittal of information.

[8] Facilities in the strategic power plants include facilities with synchronous generator(s) from the generator up to and including the MPT or GSU.

Violation Severity Levels

This Variance adds a VSL for D.A.5 and modifies the VSL for R2 as follows:

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
D.A.2.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable voltage protection so that it does not trip in accordance with Requirement D.A.2. OR The Generator Owner or Transmission Owner set its applicable voltage protection in accordance with Requirement D.A.2 but, for strategic power plants, failed to do so within 48 months of notification.
D.A.5.	N/A	The Planning Coordinator designated strategic power plants at least once every five calendar years but notified each Generator Owner or Transmission Owner that owns facilities in the strategic power plants between 31 days and 45 days after its designation.	The Planning Coordinator designated strategic power plants at least once every five calendar years but notified each Generator Owner or Transmission Owner that owns facilities in the strategic power plants between 46 days and 60 days after its designation.	The Planning Coordinator failed to designate, at least once every five years, the strategic power plants that must comply with Attachment 2A. OR The Planning Coordinator failed to notify, each Generator Owner or Transmission Owner that owns facilities in the strategic power plants or notified them more than 60 days after its designation.

Attachment 1
(Frequency No Trip Boundaries by Interconnection[9])

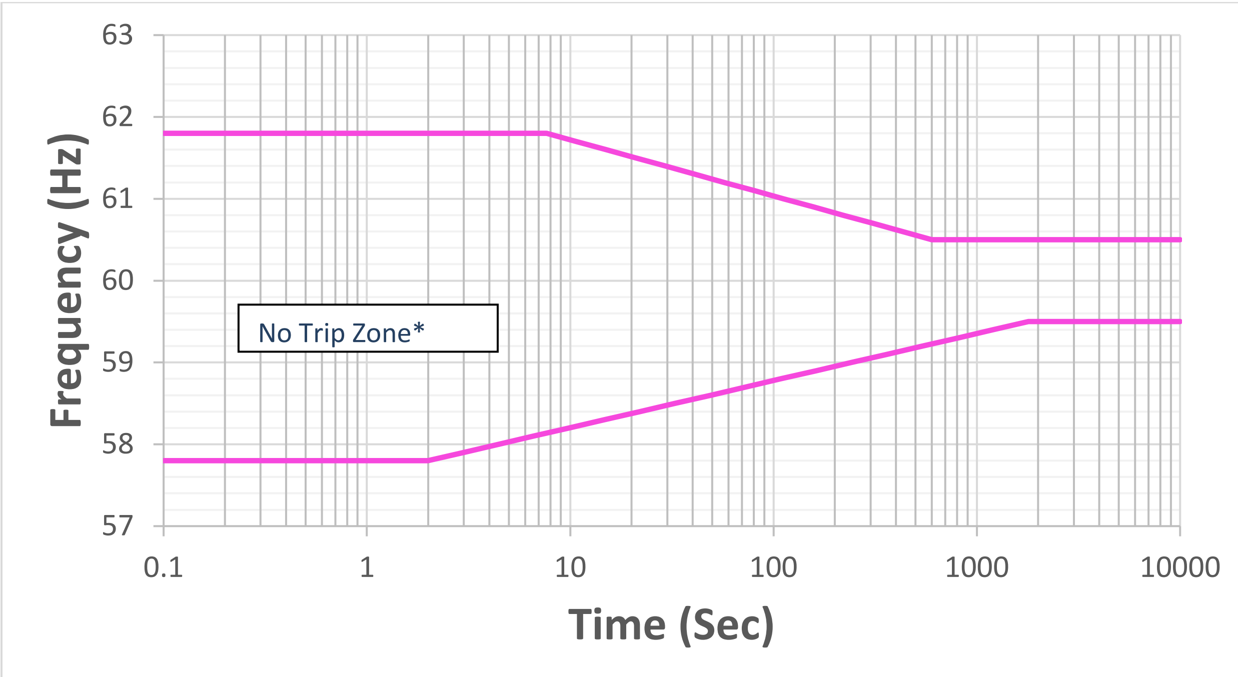

Figure 1: Eastern Interconnection Boundaries

***** *The area outside the "No Trip Zone" is not a "Must Trip Zone."***

Table 1: Frequency Boundary Data Points - Eastern Interconnection

High Frequency Duration		Low Frequency Duration	
Frequency (Hz)	Minimum Time (Sec)	Frequency (Hz)	Minimum Time (sec)
≥61.8	Instantaneous[10]	≤57.8	Instantaneous[11]
≥60.5	$10^{(90.935-1.45713*f)}$	≤59.5	$10^{(1.7373*f-100.116)}$
<60.5	Continuous operation	> 59.5	Continuous operation

[9] The figures do not visually represent the "no trip zone" boundaries before 0.1 seconds and after 10,000 seconds. The Frequency Boundary Data Points Table defines the entirety of the "no trip zone" boundaries.
[10] Frequency is calculated over a window of time. While the frequency boundaries include the option to trip instantaneously for frequencies outside the specified range, this calculation should occur over a time window. Typical window/filtering lengths are three to six cycles (50 – 100 milliseconds). Instantaneous trip settings based on instantaneously calculated frequency measurement is not permissible.

≥1.200	0.00	<0.45	0.15
≥1.175	0.20	<0.65	0.30
≥1.15	0.50	<0.75	2.00
≥1.10	1.00	<0.90	3.00
<1.10	4.00	≥ 0.90	4.00

Attachment 2: Voltage Boundary Clarifications – Eastern, Western, and ERCOT Interconnections

Boundary Details:

1. Unless otherwise specified by the Transmission Planner, the per unit voltage base for these boundaries is the nominal transmission system voltage (e.g., 100 kV, 115 kV, 138 kV, 161 kV, 230 kV, 345 kV, 400 kV, 500 kV, 765 kV, etc.).
2. The values in the table represent the minimum time durations allowed for specified voltage excursion thresholds.
3. When evaluating volts per hertz protection, either assume a system frequency of 60 Hertz or the magnitude of the high voltage boundary can be adjusted in proportion to deviations of frequency below 60 Hertz.
4. Voltages in the boundaries assume RMS fundamental frequency phase-to-ground or phase-to-phase per unit voltage.
5. For applicability to PRC-024, the "no trip zone" ends at 4 seconds.

Evaluating Protection Settings:

The voltage values in the Attachment 2 voltage boundaries are voltages at the high-side of the GSU/MPT. For resources with multiple stages of step up to reach interconnecting voltage, this is the high-side of the transformer with a low side below 100kV and a high-side 100kV or above**.** When evaluating protection settings, consider the voltage differences between where the protection is measuring voltage and the high-side of the GSU/MPT. A steady state calculation or dynamic simulation may be used.

If using a steady state calculation or dynamic simulation, use the following conditions when evaluating protection settings:

a. The most probable real and reactive loading conditions for the synchronous generator, type 1 or 2 wind resources, or synchronous condenser under study.
b. All installed wind resource reactive support (e.g., static VAR compensators, synchronous condensers, capacitors) equipment is available and operating normally.
c. Account for the actual tap settings of transformers between the generator terminals or the collector station and the high-side of the GSU/MPT.
d. For dynamic simulations, the synchronous generator or condenser automatic voltage regulator is in automatic voltage control mode with associated limiters in service.

Attachment 2A: Voltage Boundary Clarifications – Quebec Interconnection

Boundary Details:

1. The per unit voltage base for these boundaries is the nominal operating voltage (e.g., 120 kV, 161 kV, 230 kV, 315 kV, 735 kV, etc.).
2. The values in the table represent the minimum time durations allowed for specified voltage excursion thresholds.
3. When evaluating volts per hertz protection, either assume a system frequency of 60 Hertz or the magnitude of the high voltage boundary can be adjusted in proportion to deviations of frequency below 60 Hertz.
4. Voltages in the Quebec Interconnection boundaries assume positive-sequence values.

Evaluating Protection Settings:

The voltage values in the Attachment 2A voltage boundaries are voltages at the high-side of the GSU/MPT. For resources with multiple stages of step up to reach interconnecting voltage, this is the high-side of the transformer that connects to the interconnecting voltage. When evaluating protection settings, consider the voltage differences between where the protection is measuring voltage and the high-side of the GSU/MPT. A steady state calculation or dynamic simulation may be used.

If using a steady state calculation or dynamic simulation, use the following conditions when evaluating protection settings:

a. The most probable real and reactive loading conditions for the unit under study.
b. All installed generating plant reactive support (e.g., static VAR compensators, synchronous condensers, capacitors) equipment is available and operating normally.
c. Account for the actual tap settings of transformers between the generator terminals and the high-side of the GSU/MPT.
d. For dynamic simulations, the automatic voltage regulator is in automatic voltage control mode with associated limiters in service.

Exhibit A-2

PRC-024-4 Redline

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

Draft 3 of PRC-024-4 is posted for final ballot. Non-substantive corrections were identified during the last additional ballot. This draft includes those corrections.

Completed Actions	Date
Standards Committee accepted revised Standard Authorization Request (SAR) for posting	April 19, 2023
Standards Committee approved waivers to the Standards Process Manual	December 13, 2023
25-day formal comment period with initial ballot	March 27 - April 22, 2024
15-day formal comment period and additional ballot	June 18 – July 8, 2024

Anticipated Actions	Date
Final ballot	September 25 – September 30, 2024
Board Adoption	October 8, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

None

A. Introduction

1. **Title:** **Frequency and Voltage Protection Settings for Synchronous Generators~~ing~~, Type 1 and Type 2 Wind Resources, and Synchronous Condensers**

2. **Number:** **PRC-024-4~~3~~**

3. **Purpose:** To assure~~set~~ that protection of~~ such that~~ synchronous generators~~ing~~, type 1 and type 2 wind resource~~(s)~~, and synchronous condensers do not cause tripping ~~remain connected~~ during defined frequency and voltage excursions in support of the Bulk ~~Electric~~ Power System (BP~~E~~S).

4. **Applicability:**

   4.1. Functional Entities:

   4.1.1 Generator Owners that apply protection listed in Section 4.2.1 or 4.2.2.

   4.1.2 Transmission Owners that apply protection listed in Section 4.2.2.

   ~~4.1.2~~4.1.3 Transmission Owners (in the Quebec Interconnection only) that own a BES generator step-up (GSU) transformer or main power transformer (MPT)[1] and apply protection listed in Section 4.2.1.

   ~~4.1.3~~4.1.4 Planning Coordinators (in the Quebec Interconnection only)

   4.2. Facilities[2]:

   4.2.1 Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip the generating resource(s); or (ii) provide signals to the generating resource(s) to ~~either~~ trip~~ or cease injecting current~~; and are applied to the following:

   4.2.1.1 Bulk Electric (BES) synchronous generators~~ing resource(s)~~.

   4.2.1.2 BES GSU transformer(s) for synchronous generators.

   4.2.1.3 High-side of the synchronous generator-connected unit auxiliary transformer[3] (UAT) installed on BES generating resource(s).

   4.2.1.4 Individual dispersed power producing type 1 or type 2 wind resource(s) identified in the BES Definition, Inclusion I4.

---

[1] For the purpose of this standard, the MPT is the power transformer that steps up voltage from the collection system voltage to the nominal transmission/interconnecting system voltage for dispersed power producing resources.

[2] It is not required to install or activate the protections described in Facilities Section 4.2.

[3] These transformers are variably referred to as station power UAT, or station service transformer(s) used to provide overall auxiliary power to the generating resource(s). This UAT is the transformer connected on the generator bus between the low side of the GSU and the generator terminal.

4.2.1.5 Elements that are designed primarily for the delivery of capacity from multiple synchronous generators connecting to a common bus or~~the~~ individual dispersed power producing type 1 or type 2 wind resources identified in the BES Definition, Inclusion I4, to the point where those resources aggregate to greater than 75 MVA.

4.2.1.6 MPT[4] of multiple synchronous generators connecting to a common bus or MPT of individual dispersed power producting type 1 or type 2 wind resource~~(~~s~~)~~ as identified in the BES Definition, Inclusion I4.

4.2.2 Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip transmission connected synchronous condensers; or (ii) provide signals to trip transmission connected synchronous condenser and are applied to the following:

4.2.2.1 BES synchronous condensers

4.2.2.2 BES step-up transformer(s) for synchronous condensers.

4.2.2.3 High-side of the synchronous condenser-connected unit auxiliary transformer (UAT).

~~4.2.2~~**4.2.3** **Exemptions:** Protection on all auxiliary equipment within the synchronous generator~~ing~~, type 1 or type 2 wind resource, or synchronous condenser Facility.

5. Effective Date: See the Implementation Plan for PRC-024-4~~3~~.

~~[4] For the purpose of this standard, the MPT is the power transformer that steps up voltage from the collection system voltage to the nominal transmission/interconnecting system voltage for dispersed power producing resources~~

B. Requirements and Measures

R1. Each Generator Owner and Transmission Owner shall set ~~its~~ applicable frequency protection[5] in accordance with PRC-024-4 Attachment 1 such that the applicable protection does not cause the ~~generating resource~~Facility to which it is applied to trip ~~or cease injecting current~~ within the "no trip zone" during a frequency excursion with the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- Applicable frequency protection may be set to trip ~~or cease injecting current~~ within a portion of the "no trip zone" for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.

M1. Each Generator Owner and Transmission Owner shall have evidence that the -applicable frequency protection has been set in accordance with Requirement R1, such as dated setting sheets, calibration sheets, calculations, or other documentation.

R2. Each Generator Owner and Transmission Owner shall set its applicable voltage protection[6~~5~~] in accordance with PRC-024-4 Attachment 2, such that the applicable protection does not cause the ~~generating resource~~Facility to which it is applied to trip ~~or cease injecting current~~ within the "no trip zone" during a voltage excursion at the high- side of the GSU or MPT,- subject to the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- If the Transmission Planner allows less stringent voltage protection settings than those required to meet PRC-024-4 Attachment 2, then the Generator Owner may set its protection within the voltage recovery characteristics of a location-specific Transmission Planner's study.
- Applicable voltage protection may be set to trip ~~or cease injecting current~~ during a voltage excursion within a portion of the "no trip zone" for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.

M2. Each Generator Owner and Transmission Owner shall have evidence that applicable voltage protection has been set in accordance with Requirement R2, such as dated setting sheets, voltage-time boundaries, calibration sheets, coordination plots, dynamic simulation studies, calculations, -or other documentation.

[5] Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip the synchronous generat~~ors~~ing, type 1 or type 2 wind resource(s), or synchronous condenser(s); or (ii) provide signals to ~~the generating resource(s) to either~~ trip ~~or cease injecting current~~the same Facilties.

[6] Ibid

R3. Each Generator Owner and Transmission Owner shall document each known regulatory or equipment limitation[7] that prevents ~~an applicable generating resource(s)~~its Facility, with applicable frequency or voltage protection from meeting the protection setting criteria in Requirements R1 or R2, including (but not limited to) study results, experience from an actual event, or manufacturer's advice. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

3.1. The Generator Owner and Transmission Owner shall communicate the documented regulatory or equipment limitation, or the removal of a previously documented regulatory or equipment limitation, to its Planning Coordinator and Transmission Planner within 30 calendar days of any of the following:

- Identification of a regulatory or equipment limitation.
- Repair of the equipment causing the limitation that removes the limitation.
- Replacement of the equipment causing the limitation with equipment that removes the limitation.
- Creation or adjustment of an equipment limitation caused by consumption of the cumulative turbine life-time frequency excursion allowance.

M3. Each Generator Owner and Transmission Owner shall have evidence that it has documented and communicated any known regulatory or equipment limitations that resulted in an exception to Requirements R1 or R2 in accordance with Requirement R3, such as a dated email or letter that contains such documentation as study results, experience from an actual event, or manufacturer's advice.

R4. Each Generator Owner and Transmission Owner shall provide its applicable protection settings associated with Requirements R1 and R2 to the Planning Coordinator or Transmission Planner that models the associated Facility ~~generating resource(s)~~ within 60 calendar days of receipt of a written request for the data and within 60 calendar days of any change to those previously requested settings unless directed by the requesting Planning Coordinator or Transmission Planner that the reporting of protection setting changes is not required. *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

M4. Each Generator Owner and Transmission Owner shall have evidence that it communicated applicable protection settings in accordance with Requirement R4, such as dated e-mails, correspondence or other evidence and copies of any requests it has received for that information.

[7] Excludes limitations caused by the setting capability of the frequency, voltage, and volts per hertz protective relays applied to the synchronous ~~for the~~ generat~~ing~~ors, type 1 or type 2 wind resource(s), and synchronous condenser(s). This does not exclude limitations originating in the equipment protected by the relay. ~~This also does not exclude limitations of frequency, voltage, and volts per hertz protection embedded in control systems~~.

C. Compliance

1. **Compliance Monitoring Process**

   1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

   1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

   The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

   - The Generator Owner and Transmission Owner shall keep data or evidence Requirement R1 through R4; for five~~3~~ years or until the next audit, whichever is longer.
   - If a Generator Owner or Transmission Owner is found non-compliant, the Generator Owner or Transmission Owner shall keep information related to the non-compliance until mitigation is complete and approved for the time period specified above, whichever is longer.

   1.3. Compliance Monitoring and Assessment Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable frequency protection so that it does not trip ~~or cease injecting current~~ according to Requirement R1.
R2.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable voltage protection so that it does not trip ~~or cease injecting current~~ according to Requirement R2.
R3. D. Regional Variances

D.A. Variance for the Quebec Interconnection

~~This Variance extends the applicability of Requirements R1, R3, and R4 to Transmission Owners in the Quebec Interconnection that own a BES GSU or MPT and apply protection listed in Section 4.2.1, Facilities.~~ This Variance ~~also~~ replaces Requirement R2 of the continent-wide standard in its entirety and adds a new requirement, Requirement D.A.5., applicable to Planning Coordinators in the Quebec Interconnection.

~~In Requirements R1, R3, and R4, all references to "Generator Owner" are replaced with "Generator Owner and Transmission Owner."~~

This Variance replaces continent-wide Requirement R2 in its entirety with the following:

D.A.2. Each Generator Owner and Transmission Owner shall set its applicable voltage protection[8~~5~~] in accordance with PRC-024 Attachment 2A~~a~~, such that the applicable protection does not cause the ~~generating resource~~Facility to which it is applied to trip within the "no trip zone" ~~or cease injecting current~~ during a voltage excursion ~~within the "no trip zone"~~ at the high-~~-~~side of the GSU or MPT, subject to the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- For newly designated strategic power plants, applicable protections must comply with the high voltage durations for such plants within 48 calendar months of the notification made pursuant to Requirement D.A.5. During this transition period, voltage protections must at least comply with the high voltage durations for "all power plants".
- Applicable voltage protection may ~~The generating resource(s) are permitted to~~ be set to trip ~~or to cease injecting current~~ during a voltage excursion within a portion of ~~bounded by~~ the "no trip zone" of PRC-024 Attachment 2A~~a~~ for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.
- If the Transmission Planner allows less stringent voltage protection settings than those required to meet PRC-024 Attachment 2A~~a~~, then the Generator Owner or Transmission Owner may set its protection

[8] Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip the synchronous generator(s), type 1 or type 2 wind resource(s), or synchronous condenser(s); or (ii) provide signals to trip the same Facilities.

within the voltage recovery characteristics of a location-specific Transmission Planner's study.

- ~~Inverter-based resources voltage protection settings may be set to cease injecting current momentarily during a voltage excursion at the high side of the MPT, bounded by the "no trip zone" of PRC-024 Attachment 2a, under the following conditions:~~
    - ~~After a minimum delay of 0.022 s, when the positive-sequence voltage exceeds 1.25 per unit (p.u.) Normal operation must resume once the voltage drops back below 1.25 p.u at the high side of the MPT.~~
    - ~~After a minimum delay of 0.022 s, when the phase-to-ground root mean square (RMS) voltages exceeds 1.4 p.u., as measured at generator terminals, on one or multiple phases. Normal operation must resume once the positive-sequence voltage drops back below the 1.25 p.u. at the high side of the MPT.~~

M.D.A.2. Each Generator Owner and Transmission Owner shall have evidence that applicable voltage protection has been set in accordance with Requirement R2, such as dated setting sheets, voltage-time boundaries, calibration sheets, coordination plots, dynamic simulation studies, calculations, or other documentation.

This Variance adds the following Requirement:

D.A.5 Each Planning Coordinator shall designate, at least once every five calendar years, the strategic power plants that must comply with Attachment 2A~~a~~ and notify, within 30 calendar days of its designation, each Generator Owner or Transmission Owner that owns facilities[9] in the strategic power plants. *[Violation Risk Factor: Medium] [Time Horizon: Long-term planning]*

M.D.A.5 Each Planning Coordinator shall have evidence that it designated, at least once every five calendar years, strategic power plants in accordance with Requirement D.A.5, Part 5 and shall have dated evidence that each Generator Owner or Transmission Owner has been notified in accordance with Requirement D.A.5, part 5.2. Evidence may include, but is not limited to: letters, emails, electronic files, or hard copy records demonstrating transmittal of information.

[9] Facilities in the strategic power plants include facilities with synchronous generator(s) from the generator up to and including the MPT or GSU.

Violation Severity Levels

This Variance adds a VSL for D.A.5 and modifies the VSL for R2 as follows:

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
D.A.2.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable voltage protection so that it does not trip ~~or cease injecting current~~ in accordance with Requirement D.A.2. OR The Generator Owner or Transmission Owner set its applicable voltage protection in accordance with Requirement D.A.2 but, for strategic power plants, failed to do so within 48 months of notification.
D.A.5.	N/A	The Planning Coordinator designated strategic power plants at least once every five calendar years but notified each Generator Owner or Transmission Owner that owns	The Planning Coordinator designated strategic power plants at least once every five calendar years but notified each Generator Owner or Transmission Owner that owns	The Planning Coordinator failed to designate, at least once every five years, the strategic power plants that must comply with Attachment 2A~~a~~.

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
		facilities in the strategic power plants between 31 days and 45 days after its designation.	facilities in the strategic power plants between 46 days and 60 days after its designation.	OR The Planning Coordinator failed to notify, each Generator Owner or Transmission Owner that owns facilities in the strategic power plants or notified them more than 60 days after the its designation.

4	August 2, 2024	Revisions made by the 2020-02 Drafting Team	Revision accounts for changes with PRC-029-1 as part of Milestone 2 of NERC's work plan to address FERC Order No. 901.

Attachment 1

(Frequency No Trip Boundaries by Interconnection[10])

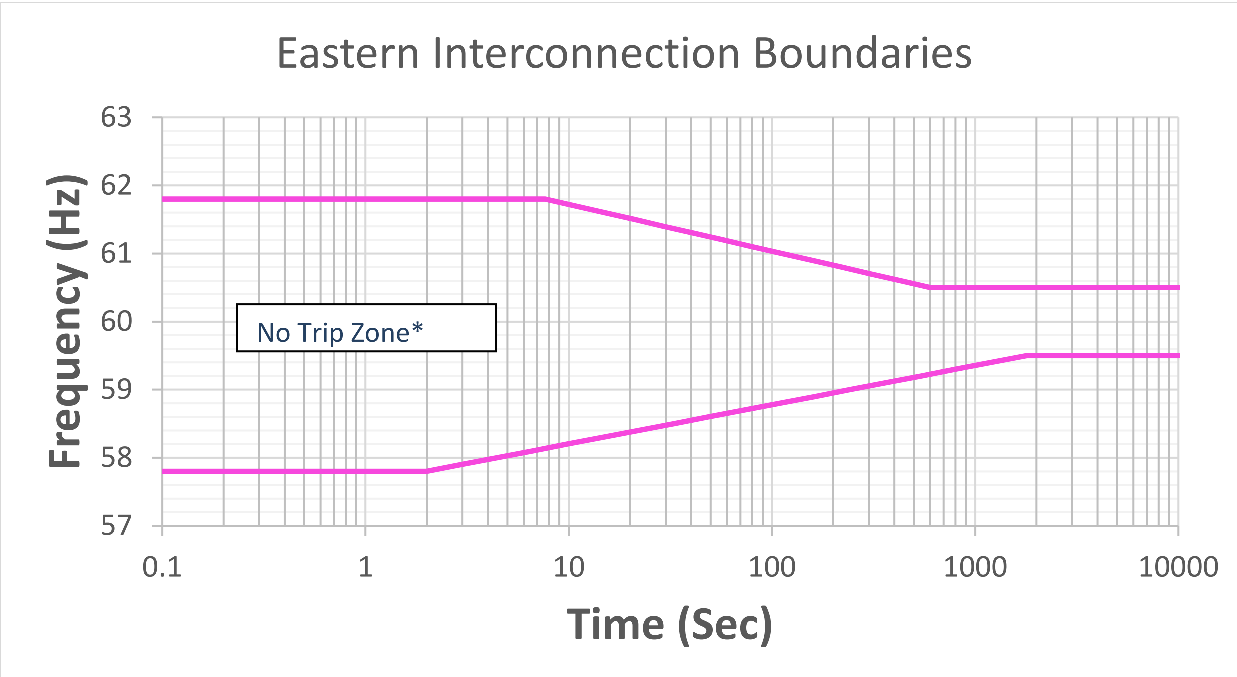

Figure 1: Eastern Interconnection Boundaries

~~Figure 1~~

**** The area outside the "No Trip Zone" is not a "Must Trip Zone."***

Table 1: Frequency Boundary Data Points - Eastern Interconnection

High Frequency Duration		Low Frequency Duration	
Frequency (Hz)	**Minimum Time (Sec)**	**Frequency (Hz)**	**Minimum Time (sec)**
≥61.8	Instantaneous[11]	≤57.8	Instantaneous[11]
≥60.5	$10^{(90.935-1.45713*f)}$	≤59.5	$10^{(1.7373*f-100.116)}$

[10] The figures do not visually represent the "no trip zone" boundaries before 0.1 seconds and after 10,000 seconds. The Frequency Boundary Data Points Table defines the entirety of the "no trip zone" boundaries.

[11] Frequency is calculated over a window of time. While the frequency boundaries include the option to trip instantaneously for frequencies outside the specified range, this calculation should occur over a time window. Typical window/filtering lengths are three to six cycles (50 – 100 milliseconds). Instantaneous trip settings based on instantaneously calculated frequency measurement is not permissible.

~~[10]Voltage at the high side of the GSU or MPT.~~

~~Table 1~~

Attachment 2: Voltage Boundary Clarifications – Eastern, Western, and ERCOT Interconnections

Boundary Details:

1. Unless otherwise specified by the Transmission Planner, the per unit voltage base for these boundaries is the nominal transmission system voltage (e.g., 100 kV, 115 kV, 138 kV, 161 kV, 230 kV, 345 kV, 400 kV, 500 kV, 765 kV, etc.).
2. The values in the table represent the minimum time durations allowed for specified voltage excursion thresholds.
3. When evaluating volts per hertz protection, either assume a system frequency of 60 Hertz or the magnitude of the high voltage boundary can be adjusted in proportion to deviations of frequency below 60 Hertz.
4. Voltages in the boundaries assume RMS fundamental frequency phase-to-ground or phase-to-phase per unit voltage.
5. For applicability to PRC-024, the “no trip zone” ends at 4 seconds.

Evaluating Protection Settings:

The voltage values in the Attachment 2 voltage boundaries are voltages at the high side of the GSU/MPT. For generating resources with multiple stages of step up to reach interconnecting voltage, this is the high side of the transformer with a low side below 100kV and a high side 100kV or above**.** When evaluating protection settings, consider the voltage differences between where the protection is measuring voltage and the high side of the GSU/MPT. A steady state calculation or dynamic simulation may be used.

If using a steady state calculation or dynamic simulation, use the following conditions when evaluating protection settings:

a. The most probable real and reactive loading conditions for the synchronous generator, type 1 or 2 wind resources, or synchronous condenser ~~unit~~ under study.
b. All installed wind resource ~~generating plant~~ reactive support (e.g., static VAR compensators, synchronous condensers, capacitors) equipment is available and operating normally.
c. Account for the actual tap settings of transformers between the generator terminals or the collector station and the high side of the GSU/MPT.
d. For dynamic simulations, the synchronous generator or condenser automatic voltage regulator is in automatic voltage control mode with associated limiters in service.

≥0.90	continuous	≥0.90	continuous

~~*Table 2*~~

Attachment 2A~~a~~: Voltage Boundary Clarifications – Quebec Interconnection

Boundary Details:

1. The per unit voltage base for these boundaries is the nominal operating voltage (e.g., 120 kV, 161 kV, 230 kV, 315 kV, 735 kV, etc.).
2. The values in the table represent the minimum time durations allowed for specified voltage excursion thresholds.
3. When evaluating volts per hertz protection, either assume a system frequency of 60 Hertz or the magnitude of the high voltage boundary can be adjusted in proportion to deviations of frequency below 60 Hertz.
4. Voltages in the Quebec Interconnection boundaries assume positive-sequence values.

Evaluating Protection Settings:

The voltage values in the Attachment 2a voltage boundaries are voltages at the high side of the GSU/MPT. For generating resources with multiple stages of step up to reach interconnecting voltage, this is the high side of the transformer that connects to the interconnecting voltage. When evaluating protection settings, consider the voltage differences between where the protection is measuring voltage and the high side of the GSU/MPT. A steady state calculation or dynamic simulation may be used.

If using a steady state calculation or dynamic simulation, use the following conditions when evaluating protection settings:

a. The most probable real and reactive loading conditions for the unit under study.
b. All installed generating plant reactive support (e.g., static VAR compensators, synchronous condensers, capacitors) equipment is available and operating normally.
c. Account for the actual tap settings of transformers between the generator terminals and the high side of the GSU/MPT.
d. For dynamic simulations, the automatic voltage regulator is in automatic voltage control mode with associated limiters in service.

PRC-029-1

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

Final Draft of PRC-029-1 is posted for a formal comment and additional ballot.

Completed Actions	Date
Standards Committee accepted revised Standard Authorization Request (SAR) for posting	April 19, 2023
Standards Committee approved waivers to the Standards Process Manual	December 13, 2023
25-day formal comment period and initial ballot	March 27 – April 22, 2024
15-day formal comment period and additional ballot	June 18 – July 8, 2024
15-day formal comment period and additional ballot	July 22 – August 12, 2024
14-day formal comment period and additional ballot	September 17 – September 30, 2024
Final Ballot	None Required
Board adoption	October 8, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

Ride-through: The plant/facility remains connected and continues to operate through voltage or frequency system disturbances.

A. Introduction

1. **Title:** **Frequency and Voltage Ride-through Requirements for Inverter-based Resources**
2. **Number:** **PRC-029-1**
3. **Purpose:** To ensure that IBRs Ride-through to support the Bulk Power System (BPS) during and after defined frequency and voltage excursions.
4. **Applicability:**

4.1 Functional Entities:

4.1.1. Generator Owner

4.2 Facilities:

4.2.1. Bulk Electric System (BES) IBRs

4.2.2. Non-BES IBRs that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

Effective Date: See Implementation Plan for Project 2020-02 – PRC-029-1

Standard-only Definition: None

B. Requirements and Measures

R1. Each Generator Owner shall ensure the design and operation is such that each IBR meets or exceeds Ride-through requirements, in accordance with the "must Ride-through[1] zone" as specified in Attachment 1, except in the following conditions: *[Violation Risk Factor: High] [Time Horizon: Operations Assessment]*

- The IBR needed to electrically disconnect in order to clear a fault;
- The voltage at the high-side of the main power transformer[2] went outside an accepted hardware limitation, in accordance with Requirement R4;
- The instantaneous positive sequence voltage phase angle change is more than 25 electrical degrees at the high-side of the main power transformer and is initiated by a non-fault switching event on the transmission system[3]; or
- The Volts per Hz (V/Hz) at the high-side of the main power transformer exceed 1.1 per unit for longer than 45 seconds or exceed 1.18 per unit for longer than 2 seconds.

M1. Each Generator Owner shall have evidence to demonstrate the design of each IBR will adhere to Ride-through requirements, as specified in Requirement R1. Examples of evidence may include, but are not limited to dynamic simulations, studies, plant protection settings, and control settings design evaluation. Each Generator Owner shall retain evidence of actual disturbance monitoring (i.e., sequence of event recorder, dynamic disturbance recorder, and fault recorder) to demonstrate that the operation of each IBR did adhere to Ride-through requirements, as specified in Requirement R1. If the Generator Owner choose to utilize Ride-through exemptions that occur within the "must Ride-through zone" and are caused by non-fault initiated phase jumps of greater than 25 electrical degrees, then each Generator Owner shall also retain evidence of actual disturbance monitoring (i.e., sequence of event recorder, dynamic disturbance recorder, and fault recorder) data to demonstrate that the IBR failed to Ride-through during a phase jump of greater than or equal to 25 electrical degrees, and documentation from their Transmission Planner, Reliability Coordinator, Planning Coordinator, or Transmission Operator that a non-fault initiated switching event occurred.

R2. Each Generator Owner shall ensure the design and operation is such that the voltage performance for each IBR adheres to the following during a voltage excursion, unless a documented hardware limitation exists in accordance with Requirement R4. *[Violation Risk Factor: High] [Time Horizon: Operations Assessment]*

2.1. While the voltage at the high-side of the main power transformer remains within the continuous operation region as specified in Attachment 1, each IBR shall:

[1] Includes no tripping associated with phase lock loop loss of synchronism.

[2] For the purpose of this standard, the main power transformer is the power transformer that steps up voltage from the collection system voltage to the nominal transmission/interconnecting system voltage for IBRs. In case of IBR connecting via a dedicated Voltage Source Converter High Voltage Direct Current (VSC-HVDC), the main power transformer is the main power transformer on the receiving end.

[3] Current blocking mode may be used for non-fault initiated phase jumps greater than 25 degrees in order to prevent tripping.

2.1.1 Continue to deliver the pre-disturbance level of Real Power or available Real Power[4], whichever is less.[5]

2.1.2 Continue to deliver Reactive Rower up to its Reactive Power limit and according to its controller settings.

2.1.3 Prioritize Real Power or Reactive Power when the voltage is less than 0.95 per unit, the voltage is within the continuous operating region, and the IBR cannot deliver both Real Power and Reactive Power due to a current limit or Reactive Power limit, unless otherwise specified through other mechanisms by an associated Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

2.2. While voltage at the high-side of the main power transformer is within the mandatory operation region as specified in Attachment 1, each IBR shall exchange current, up to the maximum capability to provide voltage support, on the affected phases during both symmetrical and asymmetrical voltage disturbances, either under[6]:

- Reactive Power priority by default; or
- Real Power priority if required through other mechanisms by an associated Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

2.3. While voltage at the high-side of the main power transformer is within the permissive operation region, as specified in Attachment 1, each IBR may operate in current blocking mode if necessary to avoid tripping. Otherwise, each IBR shall follow the requirements for the mandatory operation region in Requirement R2.2.

2.3.1 If an IBR enters current blocking mode, it shall restart current exchange in less than or equal to five cycles of positive sequence voltage returning to a continuous operation region or mandatory operation region.

2.4. Each IBR shall not itself cause voltage at the high-side of the main power transformer to exceed the applicable high voltage thresholds and time durations in its response as voltage recovers from the mandatory or permissive operation regions to the continuous operation region.

2.5. Each IBR shall restore Real Power output to the pre-disturbance or available level[7] (whichever is lesser) within 1.0 second when the voltage at the high-side of the main power transformer returns from the mandatory operation region or

[4] "Available Real Power" refers to changes of facility Real Power output attributed to factors such as weather patterns, change of wind, and change in irradiance, but not changes of facility Real Power attributed to IBR tripping in whole or part.
[5] Except if this would occur during a frequency excursion. The Real Power response should recover in accordance with the primary frequency controller.
[6] In either case and if required, the magnitude of Real Power and reactive current shall be as specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.
[7] "Available Real Power" refers to changes of facility Real Power output attributed to factors such as weather patterns, change of wind, and change in irradiance, but not changes of facility Real Power attributed to IBR tripping in whole or part.

permissive operation region (including operating in current blocking mode) to the continuous operation region, as specified in Attachment 1, unless an associated Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator requires a lower post-disturbance Real Power level requirement or requires a different post-disturbance Real Power restoration time through other mechanisms.[8]

M2. Each Generator Owner shall have evidence to demonstrate the design of each IBR will adhere to requirements, as specified in Requirement R2. Examples of evidence may include, but are not limited to dynamic simulations, studies, plant protection settings, and control settings design evaluation. Each Generator Owner shall also retain evidence of actual disturbance monitoring (i.e., sequence of event recorder, dynamic disturbance recorder, and fault recorder) data to demonstrate that the operation of each IBR did adhere to performance requirements, as specified in Requirement R2, during each voltage excursion measured at the high-side of the main power transformer. Regarding R2.1.3, R2.2, and R2.5, the Generator Owner shall retain evidence of receiving such performance requirements, (e.g., email exchange, contract information) if the Transmission Planner, Transmission Operator, Reliability Coordinator, or Planning Coordinator has required the Generator Owner through other mechanisms to follow performance requirements other than those in Requirement R2 (e.g., ramp rates, Reactive Power prioritization).

R3. Each Generator Owner shall ensure the design and operation is such that each IBR meets or exceeds Ride-through requirements during a frequency excursion event whereby the System frequency remains within the "must Ride-through zone" according to Attachment 2 and the absolute rate of change of frequency (RoCoF)[9] magnitude is less than or equal to 5 Hz/second, unless a documented hardware limitation exists in accordance with Requirement R4. *[Violation Risk Factor: High] [Time Horizon: Operations Assessment]*

M3. Each Generator Owner shall have evidence to demonstrate the design of each IBR will adhere to Ride-through requirements, as specified in Requirement R3. Examples of evidence may include, but are not limited to dynamic simulations, studies, plant protection settings, and control settings design evaluation. Each Generator Owner shall also retain evidence of actual disturbance monitoring (i.e., sequence of event recorder, dynamic disturbance recorder, and fault recorder) data to demonstrate the operation of each IBR did adhere to Ride-through requirements, as specified in Requirement R3, during each frequency excursion event measured at the high-side of the main power transformer.

R4. Each Generator Owner identifying an IBR that is in-service by the effective date of PRC-029-1, has known hardware limitations that prevent the IBR from meeting Ride-through criteria as detailed in Requirements R1-R3, and requires an exemption from specific

[8] Except if this would occur during a frequency excursion. The Real Power response should recover in accordance with the primary frequency controller.

[9] Rate of change of frequency (RoCoF) is calculated as the average rate of change for multiple calculated system frequencies for a time period of greater than or equal to 0.1 second. RoCoF is not calculated during the fault occurrence and clearance.

Ride-through criteria shall:[10] *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

4.1. Document information supporting the identified hardware limitation no later than 12 months following the effective date of PRC-029-1. This documentation shall include:

4.1.1 Identifying information of the IBR (name and facility number);

4.1.2 Which aspects of Ride-through requirements that the IBR would be unable to meet and the capability of the hardware due to the limitation;

4.1.3 Identification of the specific piece(s) of hardware causing the limitation;

4.1.4 Technical documentation verifying the limitation is due to hardware that would need to be physically replaced to meet all Ride-through criteria, and that the limitation cannot be remedied by software updates or setting changes; and

4.1.5 Information regarding any plans to remedy the hardware limitation (such as an estimated date).

4.2. Provide a copy of the information detailed in Requirement R4.1, except for any material considered by the original equipment manufacturer to be proprietary information, to the associated Planning Coordinator(s), Transmission Planner(s), Transmission Operator(s), Reliability Coordinator(s), and the Compliance Enforcement Authority (CEA) no later than 12 months following the effective date of PRC-029-1.[11]

4.2.1 Provide any response for additional information requested by the associated Planning Coordinator(s), Transmission Planner(s), Transmission Operator(s), Reliability Coordinator(s), and the CEA to the requestor within 90 days of the request.

4.2.2 Provide a copy of the acceptance of a hardware limitation by the CEA to the associated Planning Coordinator(s), Transmission Planner(s), Transmission Operator(s), and Reliability Coordinator(s) within 90 days of receiving the acceptance.[12]

4.3. Each Generator Owner with a previously accepted limitation that replaces the hardware causing the limitation shall document and communicate such a hardware change to the associated Planning Coordinator(s), Transmission Planner(s), Transmission Operator(s), and Reliability Coordinator(s) within 90 days of the hardware change.

---

[10] The exemption requests for a non-US Registered Entity should be implemented in a manner that is consistent with, or under the direction of, the applicable governmental authority or its agency in the non-US jurisdiction.

[11] To the extent the original equipment manufacturer considers any material to be proprietary, the Generator Owner is required to share this proprietary material only with the CEA.

[12] Acceptance by the CEA is verification that the information provided includes all information listed in Requirement R4.1.

4.3.1 When existing hardware causing the limitation is replaced, the exemption for that Ride-through criteria no longer applies.

M4. Each Generator Owner submitting for an exemption for an IBR that is in-service by the effective date of PRC-029-1, shall have evidence of submission to the CEA consistent with the information listed in Requirement R4.1. Each Generator Owner shall have evidence of communicated copies of each submission in accordance with Requirement R4.2 and to the associated entities described in Requirement R4.2. Acceptable types of evidence for submittals include, but are not limited to, meeting minutes, agreements, copies of procedures or protocols in effect, or email correspondence. Acceptable types of evidence for a hardware limitation may include, but is not limited to damage curves provided by the original equipment manufacturer. Each Generator Owner that receives a request for additional information under Requirement R4.2.1 shall have evidence of providing that information within 90 days. Each Generator Owner that replaces hardware at an IBR that is directly associated with an accepted exemption and that hardware is the cause for the limitation, shall have evidence of communicating the hardware change to the associated entities described in Requirement R4.3 within 90 days of the hardware replacement.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- Each Generator Owner shall retain evidence with Requirements R1, R2, and R3 in this standard for 36 calendar months or the date of the last audit, whichever is greater.
- Each Generator Owner shall retain evidence with Requirement R4 in this standard for five calendar years or the date of the last audit, whichever is greater.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	**Moderate VSL**	**High VSL**	**Severe VSL**
R1.	The Generator Owner failed to ensure the design capability of each applicable IBR to Ride-through in accordance with Attachment 1, except for those conditions identified in Requirement R1.	N/A	N/A	The Generator Owner failed to ensure each applicable IBR adhered to Ride-through requirements in accordance with Attachment 1, except for those conditions identified in Requirement R1.
R2.	The Generator Owner failed to ensure the design capability of each applicable IBR to adhere to performance requirements during voltage excursions, as specified in Requirement R2, unless a documented hardware limitation exists in accordance with Requirement R4. Attachment 1: Voltage Ride-Through Criteria

Table 1: Voltage Ride-through Requirements for AC-Connected Wind IBR [13]

Voltage (per unit)[14]	Operation Region	Minimum Ride-Through Time (sec)
> 1.20	N/A[15]	N/A
≥ 1.10	Mandatory Operation Region	1.0
> 1.05	Continuous Operation Region	1800
≤ 1.05 and ≥ 0.90	Continuous Operation Region	Continuous
< 0.90	Mandatory Operation Region	3.00
< 0.70	Mandatory Operation Region	2.50
< 0.50	Mandatory Operation Region	1.20
< 0.25	Mandatory Operation Region	0.16
< 0.10	Permissive Operation Region	0.16

Table 2: Voltage Ride-through Requirements for All Other IBR

Voltage (per unit)[16]	Operation Region	Minimum Ride-Through Time (sec)
> 1.20	N/A[17]	N/A
> 1.10	Mandatory Operation Region	1.0
> 1.05	Continuous Operation Region	1800
≤ 1.05 and ≥ 0.90	Continuous Operation Region	Continuous
< 0.90	Mandatory Operation Region	6.00
< 0.70	Mandatory Operation Region	3.00
< 0.50	Mandatory Operation Region	1.20
< 0.25	Mandatory Operation Region	0.32
< 0.10	Permissive Operation Region	0.32

[13] Type 3 and type 4 wind resources directly connected to the AC Transmission System.
[14] Refer to bullet #4 below.
[15] These conditions are referred to as the "may Ride-through zone".
[16] Refer to bullet #4 below.
[17] These conditions are referred to as the "may Ride-through zone".

1. Table 1 applies to type 3 and type 4 wind IBR or hybrid IBR that include wind, unless connected via a dedicated Voltage Source Converter - High Voltage Direct Current (VSC-HVDC) transmission facility.
2. Table 2 applies to all other IBR types not covered in Table 1; including, but not limited to, the following facilities:
   a. IBR, regardless of their energy resource, interconnecting via a dedicated VSC-HVDC transmission facility.
   b. Other IBR or hybrid IBR consisting of photovoltaic (PV) and BESS.
3. The applicable voltage for VSC-HVDC system with a dedicated connection to an IBR is on the AC side of the transformer(s) that is (are) used to connect the VSC-HVDC system to the interconnected transmission system.
4. The voltage base for per unit calculation is the nominal phase-to-ground or phase-to-phase transmission system voltage unless otherwise defined by the Planning Coordinator, Transmission Planner, or Transmission Owner.
5. The applicable voltage for Tables 1 and 2 is identified as the voltage max/min of phase-to-neutral or phase-to-phase fundamental root mean square (RMS) voltage at the high-side of the main power transformer.
6. Tables 1 and 2 are only applicable when the frequency is within the “must Ride-through zone” as specified in Figure 1 of Attachment 2.
7. At any given voltage value, each IBR shall Ride-through unless the time duration at that voltage has exceeded the specified minimum Ride-through time duration. If the voltage is continuously varying over time, it is necessary to add the duration within each band of Tables 1 and 2 over any 10 second time period.
8. The specified duration of the mandatory operation regions and the permissive operation regions in Tables 1 and 2 is cumulative over one or more disturbances within any 10 second time period.
9. The IBR may trip for more than four deviations of the applicable voltage at the high-side of the main power transformer outside of the continuous operation region within any 10 second time period.
10. Instantaneous trip settings based on instantaneously calculated voltage measurements with less than filtering lengths of one cycle (16.6 millisecond) are not permissible.
11. The “must Ride-through zone” is the combined area of the mandatory operating regions, the continuous operating regions, and the permissive operating region. All area outside of these operating regions is referred to as the “may Ride-through zone”.

Attachment 2: Frequency Ride-Through Criteria

Table 3: Frequency Ride-through Capability Requirements

System Frequency (Hz)	Minimum Ride-Through Time (sec)
> 61.8	May trip
> 61.2	299
≤ 61.2 and ≥ 58.8	Continuous
< 58.8	299
< 57.0	May trip

1. Frequency measurements are taken at the high-side of the main power transformer.
2. Frequency is measured over a period of time (typically 3-6 cycles) to calculate system frequency at the high-side of the main power transformer.
3. Instantaneous or single points of measurement may not be used in the determination of control settings.
4. At any given frequency value, each IBR shall Ride-through unless the time duration at that frequency has exceeded the specified minimum ride-through time duration.
5. The specified durations of Table 3 are cumulative over one or more disturbances within a 10-minute time period.

New Terms in the NERC Glossary of Terms

This section includes all newly defined, revised, or retired terms used or eliminated in the NERC Reliability Standard. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Proposed New Definition(s):
Ride-through: The plant/facility remains connected and continues to operate through voltage or frequency system disturbances.

Background

The purpose of Project 2020-02 is to modify Reliability Standard PRC-024-3 or replace it with a performance-based Ride-through standard that ensures generators remain connected to the Bulk Power System (BPS) during system disturbances. Specifically, the project focuses on using disturbance monitoring data to substantiate inverter-based resource (IBR) ride-through performance during grid disturbances. The project also ensures associated generators that fail to Ride-through system events are addressed with a corrective action plan (if possible) and reported to necessary entities for situational awareness.

The purpose for this project is based on the culmination of multiple analyses conducted by the ERO Enterprise regarding widespread IBR tripping events. Furthermore, the NERC Inverter-Based Resource Performance Subcommittee[1] has developed comprehensive recommendations for improved performance of IBRs, including the recommendation to develop comprehensive ride-through requirements.

In October 2023, FERC issued Order No. 901[2] which directs the development of new or modified Reliability Standards that include new requirements for disturbance monitoring, data sharing, post-event performance validation, and correction of IBR performance. In January 2024, NERC submitted a filing to FERC outlining a comprehensive work plan to address the directives within Order No. 901.[3] Within the work plan, NERC identified three active Standards Development projects that would need to be filed for regulatory approval with FERC by November 4, 2024. These projects include **2020-02 Modifications to PRC-024 (Generator Ride-through)**[4], **2021-04 Modifications to PRC-002-2**[5], and **2023-02 Analysis and Mitigation of BES Inverter-based Resource Performance Issues**[6].

Project 2020-02

Proposed Reliability Standard PRC-029-1 is a new Reliability Standard that includes Ride-through requirements and performance requirements for IBRs. The scope of this project was adjusted to align with associated regulatory directives from FERC Order No. 901 and the scope of the other projects related to "Milestone 2" of the NERC work plan. The components of this project's Standard Authorization Request (SAR) that related to the inclusions of new data recording requirements are covered in Project 2021-04 and the proposed new PRC-028-1 Reliability Standard. Components of this project's SAR that relate to analytics and corrective actions plans are covered in Project 2023-02 and the proposed new PRC-030-1 Reliability Standard.

PRC-029-1 includes requirements for Generator Owner IBR to continue to inject current and perform voltage support during a BPS disturbance. The standard also specifically requires Generator Owner IBR to prohibit momentary cessation in the no-trip zone during disturbances.

PRC-024-4 includes modifications to revise applicable facility types to remove IBR, retain type 1 and type 2 wind, and to include synchronous condensers.

General Considerations

This implementation plan recognizes the urgent need for Reliability Standards to address IBR ride through performance, as demonstrated by multiple event reports of the last decade, while providing a reasonable period of time for entities to develop the necessary procedures and change their protection and control settings to meet the new requirements. The ERO Enterprise acknowledges that there are IBRs currently in operation and unable to meet voltage Ride-through requirements due to their inability to modify their coordinated protection and control settings. Consistent with FERC Order No. 901, a limited and documented exemption process for those IBR is appropriate and included within this Implementation Plan. Other NERC Standards Development projects will be pursued to address ongoing identification and mitigation of any potential reliability impacts to the BPS for such exemptions.

This implementation plan also recognizes that certain requirements (Requirements R1, R2, and R3) call for entities to "ensure the design and operation" of their IBR units meets certain criteria. Design elements may be implemented more expeditiously than operation requirements; the latter of which will require entities to show compliance through use of actual disturbance monitoring data. Therefore, this implementation plan provides staggered timeframes by which entities shall first ensure the design of their IBR units meets the criteria (12 months following regulatory approval). Subsequent compliance with the "operation" elements of these requirements shall become due as entities install disturbance monitoring equipment on each applicable IBR in accordance with the implementation plan for proposed Reliability Standard PRC-028-1 Disturbance Monitoring and Reporting Requirements for Inverter-based Resources.

The ERO Enterprise acknowledges that Generator Owners and Generator Operators owning or operating Bulk Power System connected IBRs that do not meet NERC's current definition of Bulk Electric System ("BES") will be registered no later than May 2026 in accordance with the IBR Registration proceeding in FERC Docket No. RR24-2. To ensure an orderly registration and compliance process for these entities, as well as fairness and consistency in the standard's application among similar asset types, this implementation plan provides additional time for both new and existing registered entities to come into compliance with Reliability Standard PRC-029-1's requirements for their applicable IBRs not meeting the BES definition. In so doing, this implementation plan advances an orderly process for new registrants while allowing existing entities to focus their immediate efforts on their assets posing the highest risk to the reliable operation of the Bulk Power System.

Effective Date and Phased-in Compliance Dates

The effective dates for the proposed Reliability Standards are provided below. Where the standard drafting team identified the need for a longer implementation period for compliance with a particular section of a proposed Reliability Standard (i.e., an entire Requirement or a portion thereof), the additional time for compliance with that section is specified below. The phased-in compliance dates for those particular sections represent the date that entities must begin to comply with that particular section of the Reliability Standard, even where the Reliability Standard goes into effect at an earlier date.

PRC-024-4

Where approval by an applicable governmental authority is required, Reliability Standard PRC-024-4 shall become effective on the first day of the first calendar quarter that is twelve months after the effective date of the applicable governmental authority's order approving the standard, or as otherwise provided for by the applicable governmental authority.

Where approval by an applicable governmental authority is not required, the Reliability Standard PRC-024-4 shall become effective on the first day of the first calendar quarter that is twelve months after the date the standard is adopted by the NERC Board of Trustees, or as otherwise provided for in that jurisdiction.

PRC-029-1 and definition of Ride-through
Where approval by an applicable governmental authority is required, Reliability Standard PRC-029-1 and the definition of Ride-through shall become effective on the first day of the first calendar quarter that is twelve months after the effective date of the applicable governmental authority's order approving the standard, or as otherwise provided for by the applicable governmental authority.

Where approval by an applicable governmental authority is not required, the Reliability Standard PRC-029-1 and the definition of Ride-through shall become effective on the first day of the first calendar quarter that is twelve months after the date the standard is adopted by the NERC Board of Trustees, or as otherwise provided for in that jurisdiction.

PRC-029-1 Phased-in Compliance Dates

Requirements R1, R2, and R3

Capability-Based Elements

Bulk Electric System IBRs
Entities shall comply with the portion of Requirements R1, R2, and R3 relating to the **design** of their BES IBRs to meet the requirements by the effective date of the standard.

Applicable Non-BES IBRs[7]
Entities shall not be required to comply with Requirements R1, R2, and R3 relating to the **design** of their applicable non-BES IBRs until the later of: (1) January 1, 2027; or (2) the effective date of the standard.

Performance-Based Elements (all applicable IBRs)
Entities shall not be required to comply with the portion of Requirements R1, R2, and R3 relating to the **operation** of IBRs to meet the requirements until the entity has established the required

[7] The standard defines such as IBRs as "Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV."

disturbance monitoring equipment capabilities for those IBRs in accordance with the implementation plan for Reliability Standard PRC-028-1.

Requirement R4

Bulk Electric System IBRs
Entities shall comply with Requirement R4 for their BES IBRs by the effective date of the standard.

Applicable Non-BES IBRs
Entities shall not be required to comply with Requirement R4 or their non-BES IBRs until the later of: (1) January 1, 2027; or (2) the effective date of the standard.

Retirement Date

PRC-024-3

Reliability Standard PRC-024-3 shall be retired immediately prior to the effective date of Reliability Standards PRC-024-4 and PRC-029-1 in the particular jurisdiction in which the revised standard is becoming effective.

Equipment Limitations and Process for Requirement R4

Consistent with FERC Order No. 901, a limited and documented exemption for some legacy IBR with certain documented equipment limitations are acceptable. Per the Order, these IBRs are

> "…typically older IBR technology with hardware that needs to be physically replaced and whose settings and configurations cannot be modified using software updates – may be unable to implement the voltage ride though performance requirements."[8]

To ensure compliance with Requirement R4 and alignment with FERC Order No. 901, only those IBR that are in operation as of the effective date of PRC-029-1 may be considered for potential exemption. Further, only those IBR that are unable to meet ride-through requirements due to their inability to modify their coordinated protection and control settings may be considered for potential exemption.

[8] Order No. 901 at p. 193.

Exhibit C

Order No. 672 Criteria

EXHIBIT C

Order No. 672 Criteria

In Order No. 672,[1] the Commission identified a number of criteria it will use to analyze Reliability Standards proposed for approval to ensure they are just, reasonable, not unduly discriminatory or preferential, and in the public interest. The discussion below identifies these factors and explains how the proposed Reliability Standard has met or exceeded the criteria.

1. Proposed Reliability Standards must be designed to achieve a specified reliability goal and must contain a technically sound means to achieve that goal.[2]

The Proposed Reliability Standards PRC-029-1 - Frequency and Voltage Ride-through Requirements for Inverter-based Resources and Proposed Reliability Standard PRC-024-4 – Frequency and Voltage Protection Settings for Synchronous Generators, Type 1 and 2 Wind Plants, and Synchronous Condensers would advance the reliability of the Bulk-Power System ("BPS") by ensuring applicable BPS connected resources would Ride-through system disturbances and avoid the negative reliability impacts associated with unnecessary tripping and momentary cessation.

---

[1] *Rules Concerning Certification of the Electric Reliability Organization; and Procedures for the Establishment, Approval, and Enforcement of Electric Reliability Standards*, Order No. 672, 114 FERC ¶ 61,104, *order on reh'g*, Order No. 672-A, 114 FERC ¶ 61,328 (2006) [hereinafter Order No. 672].

[2] *See* Order No. 672, *supra* note 1, at P 321 ("The proposed Reliability Standard must address a reliability concern that falls within the requirements of section 215 of the FPA. That is, it must provide for the reliable operation of Bulk-Power System facilities. It may not extend beyond reliable operation of such facilities or apply to other facilities. Such facilities include all those necessary for operating an interconnected electric energy transmission network, or any portion of that network, including control systems. The proposed Reliability Standard may apply to any design of planned additions or modifications of such facilities that is necessary to provide for reliable operation. It may also apply to Cybersecurity protection.").

See Order No. 672, *supra* note 1, at P 324 ("The proposed Reliability Standard must be designed to achieve a specified reliability goal and must contain a technically sound means to achieve this goal. Although any person may propose a topic for a Reliability Standard to the ERO, in the ERO's process, the specific proposed Reliability Standard should be developed initially by persons within the electric power industry and community with a high level of technical expertise and be based on sound technical and engineering criteria. It should be based on actual data and lessons learned from past operating incidents, where appropriate. The process for ERO approval of a proposed Reliability Standard should be fair and open to all interested persons.").

Proposed Reliability Standards PRC-029-1 would require Generator Owners of Inverter-Based Resources ("IBR") to Ride-through voltage and frequency system disturbances with capability and performance-based requirements. Specifically, Reliability Standard PRC-029-1 would include requirements for Generator Owners to: (1) be able to properly Ride-through system disturbances; (2) comply with applicable voltage and frequency Ride-through criteria to prevent the unnecessary tripping and momentary cessation of current due to phase lock loop loss of synchronism; and (3) ensure that post-disturbance ramp rates return to pre-disturbance levels.

Proposed Reliability Standard PRC-024-4 contains revisions to apply only to synchronous generators, synchronous condensers, and type 1 and type 2 wind units. Proposed Reliability Standard PRC-024-4 would continue to address frequency and voltage protection setting ranges, but for synchronous units, type 1 and type 2 wind, and synchronous condensers only as IBRs are now being addressed in proposed PRC-029-1. The revised standard applicability is supported by the different natures of synchronous and IBR generation resources, including their risks, performance, and equipment capabilities. Synchronous units do not require performance-based requirements to Ride-through disturbances and type 1 and 2 wind units operate as asynchronous generating resources and do not have modern controllers capable of riding through system events.

Ensuring fault ride-through capability enables dynamic reactive power support, frequency response, and other services. The unexpected loss of widespread IBRs failing to Ride-through poses a significant risk to BPS reliability and is well documented in multiple disturbance reports and highlighted in Order No. 901.

2. Proposed Reliability Standards must be applicable only to users, owners, and operators of the bulk power system, and must be clear and unambiguous as to what

is required and who is required to comply.[3]

The proposed Reliability Standards are clear and unambiguous as to what is required and who is required to comply, in accordance with Order No. 672. Proposed Reliability Standard PRC-029-1 would apply to Generator Owners owning IBRs that either meet the NERC Bulk Electric System definition or Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

Proposed Reliability Standard PRC-024-4 would apply to synchronous generators, synchronous condensers, and type 1 and type 2 wind units.

The proposed Reliability Standards clearly articulate the actions that applicable entities must take to comply with the standards.

3. A proposed Reliability Standard must include clear and understandable consequences and a range of penalties (monetary and/or non-monetary) for a violation.[4]

The Violation Risk Factors ("VRFs") and Violation Severity Levels ("VSLs") for the proposed Reliability Standard comport with NERC and Commission guidelines related to their assignment, as discussed further in **Exhibit F**. The assignment of the severity level for each VSL is consistent with the corresponding requirement, and the VSLs should ensure uniformity and consistency in the determination of penalties. The VSLs do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar

---

[3] *See* Order No. 672, *supra* note 1, at P 322 ("The proposed Reliability Standard may impose a requirement on any user, owner, or operator of such facilities, but not on others.").

See Order No. 672, *supra* note 1, at P 325 ("The proposed Reliability Standard should be clear and unambiguous regarding what is required and who is required to comply. Users, owners, and operators of the Bulk-Power System must know what they are required to do to maintain reliability.").

[4] *See* Order No. 672, *supra* note 1, at P 326 ("The possible consequences, including range of possible penalties, for violating a proposed Reliability Standard should be clear and understandable by those who must comply.").

violations. For these reasons, the proposed Reliability Standards include clear and understandable consequences in accordance with Order No. 672.

4. A proposed Reliability Standard must identify clear and objective criteria or measures for compliance, so that it can be enforced in a consistent and non-preferential manner.[5]

The proposed Reliability Standards contain measures that support each requirement by clearly identifying what is required and how the requirement will be enforced. These measures help provide clarity regarding how the requirements would be enforced and help ensure that the requirements would be enforced in a clear, consistent, and non-preferential manner and without prejudice to any party.

5. Proposed Reliability Standards should achieve a reliability goal effectively and efficiently, but do not necessarily have to reflect "best practices" without regard to implementation cost or historical regional infrastructure design.[6]

The proposed Reliability Standards achieve their reliability goals effectively and efficiently in accordance with Order No. 672. Proposed Reliability Standard PRC-029-1 would provide robust and technically justified requirements for Generator Owners of IBRs to Ride-through system disturbances and return post-disturbance ramp rates to pre-disturbance levels. Proposed Reliability Standard PRC-029-1 focuses on addressing the important reliability issue of IBR ride-through performance through capability and performance-based requirements for IBRs.

In drafting proposed Reliability Standard PRC-029-1, the drafting team determined that it was necessary to include provisions allowing an exemptions from the Ride-through performance criteria for legacy IBRs because of the hardware limitations associated with those facilities.

---

5 *See* Order No. 672, *supra* note 1, at P 327 ("There should be a clear criterion or measure of whether an entity is in compliance with a proposed Reliability Standard. It should contain or be accompanied by an objective measure of compliance so that it can be enforced and so that enforcement can be applied in a consistent and non-preferential manner.").

6 *See* Order No. 672, *supra* note 1, at P 328 ("The proposed Reliability Standard does not necessarily have to reflect the optimal method, or 'best practice,' for achieving its reliability goal without regard to implementation cost or historical regional infrastructure design. It should however achieve its reliability goal effectively and efficiently.").

Specifically, it was determined that the anticipated difficulty of Generator Owners having to wholesale retrofit and redesign legacy facilities currently in operation to meet the requirements of the proposed standard would be unreasonable and unduly burdensome, and it could lead to undesirable impacts on reliability. This exemption is limited to legacy units and only for those criteria for which the hardware limitation exists.

Proposed Reliability Standard PRC-024-4, which is only minimally revised for applicability, would continue to achieve its reliability goals effectively and efficiently for the facilities to which it applies.

6. Proposed Reliability Standards cannot be "lowest common denominator," i.e., cannot reflect a compromise that does not adequately protect Bulk-Power System reliability. Proposed Reliability Standards can consider costs to implement for smaller entities, but not at consequences of less than excellence in operating system reliability.[7]

The proposed Reliability Standard does not reflect a "lowest common denominator" approach. In accordance with the Commission's direction in Order No. 901, proposed Reliability Standard PRC-029-1 reflects a measured and reasoned consideration of the need for IBRs to Ride-through system disturbances, balanced against the implementation burden on entities. Proposed Reliability Standard PRC-029-1 would advance the reliability of the BPS by establishing frequency and voltage Ride-through performance criteria for IBRs to prevent unnecessary tripping or momentary cessation of current injection. Proposed Reliability Standard PRC-024-4 is only minimally revised to limit its applicability for frequency and voltage protection setting ranges to synchronous units, type 1 and type 2 wind units, and synchronous condensers.

---

[7] *See* Order No. 672, *supra* note 1, at P 329 ("The proposed Reliability Standard must not simply reflect a compromise in the ERO's Reliability Standard development process based on the least effective North American practice—the so-called 'lowest common denominator'—if such practice does not adequately protect Bulk-Power System reliability. Although the Commission will give due weight to the technical expertise of the ERO, we will not hesitate to remand a proposed Reliability Standard if we are convinced it is not adequate to protect reliability.").

See Order No. 672, *supra* note 1, at P 330 ("A proposed Reliability Standard may take into account the size of the entity that must comply with the Reliability Standard and the cost to those entities of implementing the proposed

7. Proposed Reliability Standards must be designed to apply throughout North America to the maximum extent achievable with a single Reliability Standard while not favoring one geographic area or regional model. It should take into account regional variations in the organization and corporate structures of transmission owners and operators, variations in generation fuel type and ownership patterns, and regional variations in market design if these affect the proposed Reliability Standard.[8]

The proposed Reliability Standards would apply consistently throughout North America and would not favor one geographic area or regional model. While the penetration of IBRs may vary by region, proposed Reliability Standard PRC-029-1 would apply to all IBRs due to the reliability risk associated with IBRs failing to Ride-through system disturbances when they are expected to perform. Proposed Reliability Standard PRC-024-4 would continue to apply across North America without favoring any one geographic area or regional model.

Reliability Standard. However, the ERO should not propose a 'lowest common denominator' Reliability Standard that would achieve less than excellence in operating system reliability solely to protect against reasonable expenses for supporting this vital national infrastructure. For example, a small owner or operator of the Bulk-Power System must bear the cost of complying with each Reliability Standard that applies to it.").

[8] *See* Order No. 672, *supra* note 1, at P 331 ("A proposed Reliability Standard should be designed to apply throughout the interconnected North American Bulk-Power System, to the maximum extent this is achievable with a single Reliability Standard. The proposed Reliability Standard should not be based on a single geographic or regional model but should take into account geographic variations in grid characteristics, terrain, weather, and other such factors; it should also take into account regional variations in the organizational and corporate structures of transmission owners and operators, variations in generation fuel type and ownership patterns, and regional variations in market design if these affect the proposed Reliability Standard.").

8. Proposed Reliability Standards should cause no undue negative effect on competition or restriction of the grid beyond any restriction necessary for reliability.[9]

The proposed Reliability Standards would have no undue negative effect on competition and would not unreasonably restrict the available transmission capacity or limit the use of the BPS in a preferential manner. The reliability need for performance-based requirements for IBRs to Ride-through system disturbances (proposed PRC-029-1) is well documented in multiple disturbance reports and highlighted in Order No. 901. The revised applicability reflected in proposed Reliability Standard PRC-024-4 is supported by the different natures of synchronous and IBR generation resources, including their risks, performance, and equipment capabilities.

9. The implementation time for the proposed Reliability Standards is reasonable.[10]

The implementation plan for the proposed Reliability Standards is just and reasonable and appropriately balances the urgency in the need to implement the standards against the reasonableness of the time allowed for those who must comply to develop necessary procedures or other relevant capability. The proposed implementation plan provides that the proposed Reliability Standards PRC-024-4 and PRC-029-1 shall become effective on the first day of the first calendar quarter that is twelve (12) calendar months after the effective date of the Commission's order approving the proposed Reliability Standards. Currently effective Reliability

---

[9] *See* Order No. 672, *supra* note 1, at P 332 ("As directed by section 215 of the FPA, the Commission itself will give special attention to the effect of a proposed Reliability Standard on competition. The ERO should attempt to develop a proposed Reliability Standard that has no undue negative effect on competition. Among other possible considerations, a proposed Reliability Standard should not unreasonably restrict available transmission capability on the Bulk-Power System beyond any restriction necessary for reliability and should not limit use of the Bulk-Power System in an unduly preferential manner. It should not create an undue advantage for one competitor over another.").

[10] *See* Order No. 672, *supra* note 1, at P 333 ("In considering whether a proposed Reliability Standard is just and reasonable, the Commission will consider also the timetable for implementation of the new requirements, including how the proposal balances any urgency in the need to implement it against the reasonableness of the time allowed for those who must comply to develop the necessary procedures, software, facilities, staffing or other relevant capability.").

Standard PRC-024-3 would be retired immediately prior to the effective date of proposed Reliability Standard PRC-024-4.

The Implementation Plan for proposed PRC-029-1 provides phased-in compliance dates for both capability and performance-based elements of Requirements R1, R2, and R3 for BES IBRs and non-BES IBRs.

For BES IBRs, the implementation timeframe for capability-based elements is as follows. Generator Owners shall comply with the portion of Requirements R1, R2, and R3 relating to the design of their BES IBRs to meet the requirements by the effective date of the standard. Additionally, the implementation timeframe for the exemption process in Requirement R4 is the effective date of the standard.

For non-BES IBRs, the implementation timeframe for capability-based elements is as follows. Generator Owners shall comply with the portion of Requirements R1, R2, and R3 relating to the design of their applicable non-BES IBRs until the later of: (1) January 1, 2027; or (2) the effective date of the standard. Additionally, the implementation timeframe for the exemption process in Requirement R4 is the later of: (1) January 1, 2027; or (2) the effective date of the standard.

For all IBRs, the implementation timeframe for performance-based elements is as follows. Generator Owners shall not be required to comply with the portion of Requirements R1, R2, and R3 relating to the operation of IBRs to meet the requirements until the entity has established the required disturbance monitoring equipment capabilities for those IBRs in accordance with the implementation plan for proposed Reliability Standard PRC-028-1.[11] Under that plan, Generator

[11] The proposed implementation plan for proposed Reliability Standards PRC-028-1 and PRC-002-5 provides that the proposed standards would become effective the first calendar quarter following regulatory approval.

Owners will follow a phased-in compliance timeline with requirements to establish disturbance monitoring capabilities fully implemented by January 1, 2030.

This Implementation Plan recognizes the need for this phased in compliance timeline so entities can establish disturbance monitoring capabilities before having to comply with the performance-based elements of proposed Reliability Standard PRC-029-1. Further, Generator Owners and Generator Operators owning or operating BPS connected IBRs that do not meet NERC's current definition of BES will be registered no later than May 2026 in accordance with the IBR Registration proceeding in FERC Docket No. RR24-2. To ensure an orderly registration and compliance process for these entities, as well as fairness and consistency in the standard's application among similar asset types, the proposed Implementation Plan provides additional time for both new and existing registered entities to come into compliance with new IBR Ride-through requirements for their applicable IBRs not meeting the BES definition. In so doing, this Implementation Plan advances an orderly process for new registrants while allowing existing entities to focus their immediate efforts on their assets posing the highest risk to the reliable operation of the BPS.

Implementation of PRC-028-1 would then follow a phased-in compliance timeline, ending by 2030. The relevant dates under that plan are as follows:

BES IBRs: Generator Owners shall comply with requirements to establish disturbance monitoring data recording capabilities for 50% of their existing BES IBRs (i.e. in commercial operation on or before the effective date) within three calendar years of the effective date of PRC-029-1, and 100% of their BES IBRs by January 1, 2030. If a Generator Owner has only one such BES IBR, it shall comply within three calendar years. For new BES IBRs, Generator Owners shall comply within 15 calendar months following the effective date of the standard or by the commercial operation date, whichever is later.

Non-BES IBRs: Generator Owners shall comply with requirements to establish disturbance monitoring data recording capabilities for 100% of those non-BES IBRs in commercial operation prior to May 15, 2026 by no later than January 1, 2030. Generator Owners shall comply with for their new non-BES IBRs within 15 calendar months following the effective date of the standard or by the commercial operation date, whichever is later.

Additional information is available in Section VIII and Exhibit B to NERC's Petition for Approval of Proposed Disturbance Monitoring Reliability Standards PRC-028-1 and PRC-002-5 (Nov. 4, 2024).

This phased in implementation plan is consistent with Order No. 672 and complies with FERC's directive in Order No. 901 that NERC "ensure that the associated implementation plans sequentially stagger the effective and enforceable dates to ensure an orderly industry transition for complying with the IBR directives in this final rule prior to [2030]."[12]

10. The Reliability Standard was developed in an open and fair manner and in accordance with the Commission-approved Reliability Standard development process.[13]

The proposed Reliability Standards were developed in accordance with NERC's Commission-approved processes for developing and approving Reliability Standards. **Exhibit G** includes a summary of the Reliability Standards development proceedings, and details the processes followed to develop the proposed Reliability Standards. These processes included, among other things, comment periods, pre-ballot review periods, and balloting periods. Additionally, all meetings of the standard drafting team were properly noticed and open to the public.

11. NERC must explain any balancing of vital public interests in the development of proposed Reliability Standards.[14]

NERC has identified no competing public interests regarding the request for approval of this proposed Reliability Standards. No comments were received that indicated that the proposed Reliability Standards conflict with other vital public interests.

---

[12] Reliability Standards to Address Inverter-Based Resources, Order No 901, 185 FERC ¶ 61,042 (2023) at P 226.

[13] *See* Order No. 672, *supra* note 1, at P 334 ("Further, in considering whether a proposed Reliability Standard meets the legal standard of review, we will entertain comments about whether the ERO implemented its Commission-approved Reliability Standard development process for the development of the particular proposed Reliability Standard in a proper manner, especially whether the process was open and fair. However, we caution that we will not be sympathetic to arguments by interested parties that choose, for whatever reason, not to participate in the ERO's Reliability Standard development process if it is conducted in good faith in accordance with the procedures approved by the Commission.").

[14] *See* Order No. 672, *supra* note 1, at P 335 ("Finally, we understand that at times development of a proposed Reliability Standard may require that a particular reliability goal must be balanced against other vital public interests, such as environmental, social and other goals. We expect the ERO to explain any such balancing in its application for approval of a proposed Reliability Standard.").

12. Proposed Reliability Standards must consider any other appropriate factors.[15]

No other negative factors relevant to whether the proposed Reliability Standards are just and reasonable were identified.

[15] *See* Order No. 672, *supra* note 1, at P 323 ("In considering whether a proposed Reliability Standard is just and reasonable, we will consider the following general factors, as well as other factors that are appropriate for the particular Reliability Standard proposed.").

NORTH AMERICAN ELECTRIC
RELIABILITY CORPORATION

Exhibit D

Consideration of Directives

Standards Development Consideration of Directives from FERC Order 901

Background

The Federal Energy Regulatory Commission (FERC) issued Order No. 901 on October 19, 2023, which includes directives on new or modified NERC Reliability Standard projects. Order No. 901 addresses a wide spectrum of reliability risks to the grid from the application of inverter-based resources (IBR); including both utility scale and behind the-meter or distributed energy resources. Within the Order, are four milestones that include sets of directives to NERC. The first milestone was achieved on January 17, 2024 as NERC filed its initial work plan to address all aspects of Order No. 901 throughout the next three years.[1] The filed work plan includes extensive detail on Standards Development approach and next steps to accomplish the suite of directives addressing IBR. The work plan was intended to be an initial roadmap to guide development for each of the Reliability Standards Projects identified as a 901-related project.

This document includes specifics for how each directive assigned to Project 2020-02 Modifications to PRC-024 (Generator Ride-through) drafting team have been addressed.

[1] INFORMATIONAL FILING OF THE NORTH AMERICAN RELIABILITY CORPORATION REGARDING THE DEVELOPMENT OF RELIABILITY STANDARDS RESPONSIVE TO ORDER NO. 901; 01/17/2024; https://www.nerc.com/FilingsOrders/us/NERC%20Filings%20to%20FERC%20DL/NERC%20Compliance%20Filing%20Order%20No%20901%20Work%20Plan_packaged%20-%20public%20label.pdf

Index	Paragraph of Order	Milestone	Directive Subpart Summary	Active Project # Draft SAR # or Pending SAR name	Description of How This Directive has Been Addressed
49	190	2	"Pursuant to section 215(d)(5) of the FPA, we adopt the NOPR proposal and direct NERC to develop new or modified Reliability Standards that require registered IBR generator owners and operators to use appropriate settings (i.e., inverter, plant controller, and protection) to ride through frequency and voltage system disturbances and that permit IBR tripping only to protect the IBR equipment in scenarios similar to when synchronous generation resources use tripping as protection from internal faults."	Project 2020-02 Modifications to PRC-024 (Generator Ride-through)	The new standard PRC-029-1 will require registered generator owners of IBRs to both design and operate their IBR plants to ride through voltage and frequency excursions within "must ride-through zones" according to how these zones are defined in the standard. The must ride-through zones are defined in terms of voltage and frequency magnitude and time duration. Tripping of IBR plants is permitted only outside of the defined must ride-through zones. The voltage and frequency must ride-through zones are based on IEEE 2800-2022 no-trip zones and are established in view of experience with voltage and frequency excursions in planning and operating criteria disturbances, under-frequency load shedding stages, reasonable and practical limits of IBR voltage and frequency tolerances, PRC-024-3 voltage and frequency relay setting graphs, and include adequate margins against worst-case conditions that could be brought about during system disturbances.
50	190	2	"The new or modified Reliability Standards must require registered IBRs to continue to inject current and perform frequency support during a Bulk-Power System disturbance."	Project 2020-02 Modifications to PRC-024 (Generator Ride-through)	In association with the new PRC-029 standard, a definition of the term *ride-through* is proposed for addition to the NERC Glossary of Terms that essentially states that IBR facilities must remain connected and continue to fulfill their established control and regulation functions (which generally involve exchange of current) in order to qualify as riding through system disturbances. Support of frequency is predicated on, and to a large degree achieved by the riding through of system disturbances. Frequency regulation (or governing) is presently not a continent-wide necessity and not a requirement on individual generating

					plants/facilities in NERC standards. RTO/ISO requirements may apply.
51	190	2	"Any new or modified Reliability Standard must also require registered IBR generator owners and operators to prohibit momentary cessation in the no-trip zone during disturbances."	Project 2020-02 Modifications to PRC-024 (Generator Ride-through)	Momentary cessation, understood as inverter temporary current blocking while still remaining connected, is restricted to only two system conditions: 1) non-fault line switching caused voltage phase angle jumps in excess of 25 degrees that could result in tripping unless the inverter goes into current blocking, and 2) while voltage at the plant-system interface is less than 0.10 per unit during which time it may be difficult or impractical to maintain current exchange.
52	190	2	"NERC must submit new or modified Reliability Standards that establish IBR performance requirements, including requirements addressing frequency and voltage ride through, post-disturbance ramp rates, phase lock loop synchronization, and other known causes of IBR tripping or momentary cessation."	Project 2020-02 Modifications to PRC-024 (Generator Ride-through)	IBR frequency and voltage ride through requirements are established in the new PRC-029 standard as noted above. A default post-disturbance ramp rate of 1.0 second is specified unless a faster or slower rate is specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator to accommodate specific system post-disturbance recovery needs. Any Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator specified ramp rate becomes the standard requirement. Tripping due to phase lock loop loss of synchronism is specifically not permitted within voltage and frequency must ride through zones.
53	193	2	"Therefore, we direct NERC through its standard development process to determine whether the new or modified Reliability	Project 2020-02 Modifications to PRC-024 (Generator Ride-through)	Exemption from the voltage must ride-through zone requirement of PRC-029-1 is permitted for IBR plants/facilities that are in service at the enforcement date of the standard. The IBR Generator Owner must document the need for an exemption and the documentation must explain what hardware prevents the IBR

Index	Paragraph of Order	Milestone	Directive Subpart Summary	Active Project # Draft SAR # or Pending SAR name	Description of How This Directive has Been Addressed
			Standards should provide for a limited and documented exemption for certain registered IBRs from voltage ride through performance requirements.”		from meeting the requirement and must be specific as to what aspect of the voltage must ride-through zone cannot be met. The Compliance Enforcement Authority checks that all aspects of the documentation specified in the standard have been provided by the GO and the GO is required to supply further information on the need for and the nature of the exemption if requested by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator. The implementation plan provides a 12-month time window for exemption requests to be submitted following the enforcement date. Following the 12-month window, further exemption requests will either not be accepted or could be considered an admission of non-compliance.
54	193	2	“Further, we direct NERC to ensure that any such exemption would be applicable for only existing equipment that is unable to meet voltage ride-through performance. When such existing equipment is replaced, the exemption would no longer apply, and the new equipment must comply with the appropriate IBR performance requirements specified in the Reliability Standards (e.g., voltage and frequency ride	Project 2020-02 Modifications to PRC-024 (Generator Ride-through)	The exemption provision of PRC-029-1 is available only for IBR plants/facilities that are in service at the enforcement date as noted above. The exemption provision also stipulates that once the plant/facility hardware causing the inability to comply with the voltage must ride-through requirement is replaced, the exemption is withdrawn (“no longer applies”).

Project 2020-02 Modifications to PRC-024 (Generator Ride-through)

PRC-024-4 – Frequency and Voltage Protection Settings for Synchronous Generators, Type 1 and 2 Wind Plants, and Synchronous Condensers

General Rationale

The drafting team proposes to modify PRC-024-3 to retain the Reliability Standard as a protection-based standard with applicability to only synchronous generators, synchronous condensers, and type 1 and 2 wind plants. This proposal is a consequence of both the different natures of synchronous and inverter-based generation resources and several recent events exhibiting significant IBR ride-through deficiencies. The behavior of rotating synchronous generators during faults and other disturbances on the transmission system is well established and understood in comparison to IBR generation. The disturbance ride-through vulnerabilities of synchronous generators are pole slipping instability and undervoltage dropout of critical plant auxiliary equipment, leading to tripping of a generator. Pole slipping (or loss of synchronism) can be managed by active power dispatch constraints or stability System Operating Limits, and is outside the scope of Project 2020-02. Undervoltage dropout of critical auxiliary equipment is also outside the scope of Project 2020-02 because of complexities associated with auxiliary systems and how such equipment behaves under low voltage conditions. The Project 2020-02 Standard Authorization Request (SAR) notes that auxiliary equipment has not posed a ride-through risk and the SAR specifically excludes modifications in PRC-024-3 for auxiliary equipment.

Over-frequency protection, under-frequency protection, over-voltage protection, and under-voltage protection may or may not be applied to synchronous generating units. If applied, settings should be coordinated between the needs of generating unit protection and the no-trip zones within PRC-024-4 attachments. Coordination of generating unit capabilities, voltage regulating controls, and protection is addressed within PRC-019-2. Excitation and governing controls affect synchronous generator ride-through behavior to some degree but because of progressive improvement, standardization, and level of maturity of these controls, they are rarely a cause of unnecessary tripping during disturbances. In addition, there are other existing NERC standards to prevent unnecessary tripping of the generators during a system disturbance such as PRC-025-2 “Generator Relay Loadability” and PRC-026-2 “Relay Performance During Stable Power Swings”. For these reasons, there is no need to impose actual disturbance ride-through requirements on synchronous units but only to include restrictions for frequency and voltage protection setting ranges as maintained in PRC-024-4.

Rationale for Applicability Section (4.0)

Functional Entities (4.1)

The functional entity responsible for setting frequency, voltage, and volts per hertz protection for synchronous generators, type 1 and 2 wind plants, and synchronous condensers is either the Generator Owner ~~(GO)~~ or Transmission Owner ~~(TO)~~. Planning Coordinators ~~(PC)~~ are retained as applicable entities only in the Quebec Interconnection. Modifications are proposed in PRC-024-4 to expand functional entity applicability to include “Transmission Owners that apply protection” because of the inclusion of synchronous condenser applicability in section 4.2.2.

Facilities (4.2)

Applicability Facilities subparts in Section 4.1.1 were modified to restrict PRC-024-4 to synchronous generators and type 1 and 2 wind plants. Section 4.2.2 was added to cover synchronous condensers and associated equipment.

Rationale for Requirements R1 through R4

Modifications were made to Requirements R1, R2, R3, and R4 to include the Transmission Owner as a functional entity applicable to each requirement because of the addition of synchronous condensers.

Modifications were made to Requirements R1, R2, R3, and R4 to include language for type 1 and 2 wind plants and synchronous condensers and to remove language that relates to inverter-based resource (IBR) functionality since IBRs will be addressed in a new standard PRC-029-1.

Technical Rationale
PRC-029-1

Technical Rationale

Project 2020-02 Modifications to PRC-024 (Generator Ride-through)

PRC-029-1 – Frequency and Voltage Ride-through Requirements for Inverter-based Generating Resources

General Rationale

The drafting team has created a new Reliability Standard (PRC-029-1) to address inverter-based resource (IBR) disturbance Ride-through performance criteria. This proposal is a consequence of both the different natures of synchronous and inverter-based generation resources and several recent events exhibiting significant IBR Ride-through deficiencies[1]. The proposed PRC-029-1 aligns with certain Ride-through requirements of IEEE Std 2800™, IEEE Standard for Interconnection and Interoperability of Inverter-Based Resources (IBRs) Interconnecting with Associated Transmission Electric Power Systems, primarily for frequency Ride-through, and is structured to follow language from FERC Order No. 901, which states that "NERC has the discretion to consider during its standards development process whether and how to reference IEEE standards in the new or modified Reliability Standards."[2]

The lack of standardization of IBR performance and the software-based nature of the technologies has created reliability challenges associated with the interconnection of IBR facilities to the power grid. The nature of the fast switching of power electronics of IBR generation, IBR's software-based nature, and the electronic interface to the transmission system is such that disturbance Ride-through behavior is largely determined by manufacturer-specific equipment and controls system designs. These controls may be programmed, but also have more restrictive limits on current, both in magnitude and duration. IBR responses to grid disturbances are highly controlled and managed by using fast switching of power electronics devices dependent upon manufacturer specific control system design software that can be programmed in many ways and with various and concurrent Ride-through performance objectives. Rather than attempting to restrict the myriad of control approaches, protections, and settings, it is more straightforward to require Ride-through during defined frequency and voltage excursions.

In contrast to synchronous generation, the need for IBR Ride-through requirements has been heightened by recent events during which IBRs have not met PRC-024-3 frequency and voltage Ride-through expectations, often due to controls and protection only indirectly associated with the system voltage and frequency excursions. In addition to Ride-through, there is the question of what IBRs should be doing as they Ride-through. IBR responses to system disturbances can be beneficial or detrimental to both their own Ride-through and system reliability, often depending on adjustable control settings. Thus, it is essential to set expectations on performance during Ride-through as well as Ride-through capability.

---

[1] Event Reports (nerc.com)
[2] P 195, FERC Order No. 901; https://elibrary.ferc.gov/eLibrary/filelist?accession_number=20231019-3157&optimized=false; October 17, 2023

A further reason for proposing a separate IBR standard is that the inertial and short circuit contributions from IBR are significantly different than synchronous machines. The drafting team thinks that IBRs should Ride through voltage and frequency excursions up to their maximum capability, while using expanded voltage and frequency Ride-through criteria to drive those enhancements. These differences between synchronous machines and IBR contribute to the differences in the frequency and voltage tables and graphs between the PRC-024-4 and PRC-029-1 standards.

The proposed PRC-029-1 must be understood generally as an event-based standard though it is also required to provide evidence of the ability to Ride-through disturbance events by means of dynamic models and simulation results. Compliance with PRC-029-1 is determined chiefly, though not exclusively, from IBR Ride-through performance during transmission system events in the field. An IBR becomes noncompliant with PRC-029-1 when an event in the field occurs that shows that one or more requirements were not satisfied. This intent is clarified by *Operations Assessment* as the Time Horizon designation of requirements R1-R3.

FERC Order No. 901 Directives

PRC-029-1 is proposed in consideration of directives from FERC Order No. 901 that were assigned to the Project 2020-02 drafting team. The following directives were assigned to this drafting team for inclusion in this standards project (paragraph numbers of the FERC Order are included for reference):

- Paragraph 190: “Pursuant to section 215(d)(5) of the FPA, we adopt the NOPR proposal and direct NERC to develop new or modified Reliability Standards that require registered IBR generator owners and operators to use appropriate settings (i.e., inverter, plant controller, and protection) to ride through frequency and voltage system disturbances and that permit IBR tripping only to protect the IBR equipment in scenarios similar to when synchronous generation resources use tripping as protection from internal faults.”
- Paragraph 190: “The new or modified Reliability Standards must require registered IBRs to continue to inject current and perform frequency support during a Bulk-Power System disturbance.”
- Paragraph 190: “Any new or modified Reliability Standard must also require registered IBR generator owners and operators to prohibit momentary cessation in the must Ride-through zone during disturbances.”
- Paragraph 190: “NERC must submit new or modified Reliability Standards that establish IBR performance requirements, including requirements addressing frequency and voltage ride through, post-disturbance ramp rates, phase lock loop synchronization, and other known causes of IBR tripping or momentary cessation.”
- Paragraph 193: “Therefore, we direct NERC through its standard development process to determine whether the new or modified Reliability Standards should provide for a limited and documented exemption for certain registered IBRs from voltage ride through performance requirements.”

- Paragraph 193: "Further, we direct NERC to ensure that any such exemption would be applicable for only existing equipment that is unable to meet voltage Ride-through performance. When such existing equipment is replaced, the exemption would no longer apply, and the new equipment must comply with the appropriate IBR performance requirements specified in the Reliability Standards (e.g., voltage and frequency ride through, phase lock loop, ramp rates, etc.)."
- Paragraph 193: "Finally, we direct NERC, through its standard development process, to require the limited and documented exemption list (i.e., IBR generator owner and operator exemptions) to be communicated with their respective Bulk-Power System planners and operators (e.g., the IBR generator owner's or operator's planning coordinator, transmission planner, reliability coordinator, transmission operator, and balancing authority)."
- Paragraph 199: "Pursuant to section 215(d)(5) of the FPA, we modify the NOPR proposal. To the extent NERC determines that a limited and documented exemption for those registered IBRs currently in operation and unable to meet voltage Ride-through requirements is appropriate due to their inability to modify their coordinated protection and control settings, we direct NERC to develop new or modified Reliability Standards to mitigate the reliability impacts to the Bulk-Power System of such an exemption."
- Paragraph 208: "Pursuant to section 215(d)(5) of the FPA, we adopt the NOPR proposal and direct NERC to develop and submit to the Commission for approval new or modified Reliability Standards that require post-disturbance ramp rates for registered IBRs to be unrestricted and not programmed to artificially interfere with the resource returning to a pre-disturbance output level in a quick and stable manner after a Bulk-Power System."
- Paragraph 209: "The proposed new or modified Reliability Standards must require registered IBRs to ride through momentary loss of synchronism during Bulk-Power System disturbances and require registered IBRs to continue to inject current into the Bulk-Power System at pre-disturbance levels during a disturbance, consistent with the IBR Interconnection Requirements Guideline and Canyon 2 Fire Event Report recommendations."
- Paragraph 209: "Related to ACP/SEIA's comment recommending to revise the directive to require generators to maintain synchronism where possible and continue to inject current to support system stability, we direct NERC, through its standard development process, to consider whether there are conditions that may limit generators to maintain synchronism."
- Paragraph 209: "We direct NERC to submit to the Commission for approval new or modified Reliability Standards that would require registered IBRs to ride through any conditions not addressed by the proposed new or modified Reliability Standards that address frequency or voltage ride through, including phase lock loop loss of synchronism."
- Paragraph 226: "Further, we believe that there is a need to have all of the directed Reliability Standards effective and enforceable well in advance of 2030 and direct NERC to ensure that the associated implementation plans sequentially stagger the effective and enforceable dates to ensure an orderly industry transition for complying with the IBR directives in this final rule prior to that date." (*pertains to multiple projects*)

Rationale for Applicability Section (4.0)

Functional Entities (4.1)

The functional entity responsible for assuring acceptable Ride-through performance of IBR is the Generator Owner.

Facilities (4.2)

Applicability Facilities include only IBR that also meet NERC registration criteria. Language used within PRC-029-1 applicability only refers to IBR as a whole plant/facility. Consistent with FERC Order No. 901, IBR performance is based on the overall IBR plant and disturbance monitoring equipment requirements established under the proposed PRC-028-1. Requirements within PRC-029-1 do not apply to individual inverter units or measurements taken at individual inverter unit terminals.

Rationale for Requirement R1

The objective of Requirement R1 is to ensure that all applicable IBRs will Ride-through grid voltage disturbances consistent with the must Ride-through zone and operation regions specified in **Attachment 1**. IBRs must be able to demonstrate Ride-through performance, that they remain electrically connected, i.e., shall not trip, and continue to exchange current, i.e., shall not enter momentary cessation.

The drafting team determined that the definition of “must Ride-through zones” and “operation regions” should be consistent with those terms as used within IEEE 2800-2022. Additionally, the team determined that the voltage thresholds of each operation region should be based on measurements taken on the high-side of the main power transformer in PRC-029-1, also consistent with IEEE 2800-2022.

Battery Energy Storage Systems (BESS) units also must comply with Requirement R1 in all operating modes including charging, discharging, and idle (energized, but not charging or discharging). A BESS in idle mode must be capable of responding to system voltage and frequency excursions as it does in charging or discharging modes.

Exceptions to **Attachment 1** performance criteria are allowable when 1) an IBR needs to trip to clear a fault, 2) voltage at the high-side of the main power transformer goes outside an accepted and a documented hardware equipment limitation established in accordance with Requirement R4, 3) instantaneous positive sequence voltage phase angle jumps more than 25 electrical degrees at the high-side of the main power transformer initiated by a non-fault switching events occur on the transmission system, or 4) volts per Hz (V/Hz) at the high-side of the main power transformer exceed 1.1 per unit for longer than 45 seconds or exceed 1.18 per unit for longer than 2 seconds.

When a grid disturbance occurs, such as a close-in fault or a relatively large switching event, the grid voltage may experience a rapid phase angle shift. In such cases, the phase displacement $\Delta\theta$ can be large enough to pose challenges for the phase lock loop (PLL) to track the terminal voltage, cause control instability within the inverter, such as the inner current control loop or the DC link control loop, and even lead to tripping of the inverter due to the malfunction of the controls.

Since phase angle jumps are common occurrences on the BPS, this standard requires the IBR to be designed and operated to Ride-through a minimum phase angle jump of 25 electrical degrees. This is a typical value and aligns with the requirement in IEEE 2800-2022.

Some IBR equipment has PLL loss of synchronism protection, referring to a protective function that operates when the angle displacement $\Delta\theta$ exceeds a threshold for a predetermined period of time (on the order of a couple of milliseconds). Historically, this protection has been used by some inverter manufacturers, especially for inverters in distribution systems. For the IBR connected to the BPS, this protection function should be disabled. If it is enabled, the phase angle jump protection setting should be configured such that the IBR shall only trip to prevent equipment damage.

Rationale for Requirement R2

In addition to having minimum voltage Ride-through capability specified in Requirement R1, all applicable IBRs are also required to adhere to certain voltage Ride-through performance criteria during system disturbances. Acceptable performance criteria depend on the operation region that an IBR is presently in or when in transition from one operation region to another operation region. Requirement R2 includes specific performance criteria and is needed to assure consistent IBR performance within and each operation region in **Attachment 1** and when in transition between regions.

Rationale for Requirement R2.1

This subpart of Requirement R2 ensures that when the voltage at the high-side of the main power transformer (MPT) recovers to the continuous operation region from either the mandatory operation region or the permissive operation region, an IBR delivers the pre-disturbance level of Real Power or available Real Power, whichever is less. Available Real Power allows for changes of facility Real Power output attributed to factors such as weather patterns, change of wind, and change in irradiance, but not changes attributed to IBR tripping in whole or part. This requires an IBR to exit the “High Voltage Ride Through (HVRT)” or “Low Voltage Ridge Through (LVRT)” modes properly such that it does not cause reduction in the Real Power when the high-side of MPT voltage recovers to within the continuous operation region.

When the voltage at the high-side of the MPT is greater than 0.90 per-unit and less than 0.95 per-unit, IBRs are expected to exit the LVRT mode and come back to “normal operating mode”. If an IBR has a default total current limit of 1.0 per-unit, the apparent power production of an IBR will be limited below 1.0 per-unit (e.g., the per-unit value of IBR terminal voltage). In such case, the IBR needs to configure a preference setting, either to maintain pre-disturbance Real Power or maximize the Reactive Power in order to further help with voltage recovery, or according to requirements specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

Rationale for Requirement R2.2

This subpart of Requirement R2 ensures that when the voltage at the high-side of the MPT is within the mandatory operation region, IBRs inject or absorb reactive current proportional to the level of terminal voltage deviations they measure. IBRs shall follow Transmission Planner, Planning Coordinator, Reliability

Coordinator, or Transmission Operator specified certain magnitude of Reactive Power response to voltage changes, if available.

By default, reactive current prioritization shall be configured unless Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator requires Real Power priority.

Rationale for Requirement R2.3

This subpart of Requirement R2 ensures that when the voltage at the high-side of the MPT is within the permissive operation region, IBRs continue to Ride-through, though they are briefly allowed to enter the current block mode if necessary to avoid tripping off from the grid. The drafting team takes into consideration the physical operational capability of the power electronics devices under such low voltage conditions. However, the IBR facility shall restart current exchange in less than or equal to five cycles of positive sequence voltage returning to the continuous operation region or mandatory operation region. If the interconnecting entity has performance requirements that are more stringent than the standard, the Generator Owner should follow the requirements set by the interconnecting entity.

Rationale for Requirement R2.4

This subpart of Requirement R2 ensures when a fault is cleared on the transmission system, the voltage regulators of connected IBRs must adjust the reactive current injection to restore the transmission system voltage to the pre-disturbance voltage as defined by the automatic voltage regulator (AVR) setpoint. The drafting team acknowledges that tuning of the AVR requires a balance between multiple competing physical factors, e.g., rise time, overshoot, and transient stability. However, it is anticipated that IBR controls will be tuned to allow for a stable post-disturbance voltage recovery without causing excessive overshoot or undershoot of the setpoint. When such overshoots do occur, they must not exceed the magnitude and duration of the applicable table given in **Attachment 1**. Furthermore, this standard anticipates that control system tuning to prevent such over/under voltages will focus on the speed at which the controller responds to setpoint changes rather than on the magnitude of the reactive current response. For example, reductions in k-factor to prevent over/under voltages should only be considered as a last resort.

Rationale for Requirement R2.5

This subpart of Requirement R2 ensures that the IBR returns to effective pre-disturbance operation unless otherwise specified or needed by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

Rationale for Requirement R3

The objective of Requirement R3 is to ensure that IBRs Ride-through frequency excursion events with magnitude and time durations as defined in Attachment 2.

Grid frequency reflects the balance of system generation and load. A system event that causes a generation/load imbalance will cause system frequency to deviate from nominal. The system may experience an over-frequency event (in the case of more generation than load) or an under-frequency event (in the case of less generation than load). Inertia resists the deviation from nominal frequency, giving the operators additional time to rebalance generation and load. With the current resource mix, system inertia is dependent on the amount of rotating mass connected to the system (i.e., synchronous generators or motors). The larger the system inertia, the slower the system frequency will deviate from the nominal value and the lower the grid Rate Of Change Of Frequency (ROCOF), giving more time to try to rebalance generation and load.

A reduction in system inertia is an inevitable consequence of a power system transiting toward more IBR and less synchronous generators, however the utilization of IBR-specific control features (i.e., advanced control modes and Grid Forming technologies) can provide additional stability benefits to help mitigate the loss of inertia. As discussed in the previous paragraph, less system inertia means the frequency will deviate from the nominal value more quickly during a generation/load imbalance event and will expose the system to a higher ROCOF. A wider frequency Ride-through capability for IBR may be required to avoid the risk of widespread tripping.

When considering an expansion of Ride-through capability, it is important to balance the expansion with the feasibility of producing and installing equipment that can meet the newly proposed criteria. Failure to adequately consider this could result in resource adequacy deficiencies if expanded criteria lead to widespread non-compliance of legacy IBR due to hardware limitations. Further, for newly interconnecting IBR, expanded Ride-through criteria often result in significant design changes that have production time and cost implications. If proposed Ride-through criteria are too stringent and result in costly design changes, those costs could result in a slowing of IBR penetration on the BPS.

For the reasons above, it is imperative that newly created Ride-through criteria are reasonable for both BPS reliability and for the IBR equipment. To date, NERC has analyzed numerous major events including both winter storms Uri and Elliot. No IBR tripped offline for frequency threshold criteria (because the system frequency caused a trip due to exceeding equipment frequency limits) and all frequency-related tripping observed were due to mis-parameterization or the use of instantaneous measurements in protection schemes. Additionally, the deviations in frequency observed during the events listed above did not exceed the PRC-024 criteria. It should be noted that winter storm Uri did produce a frequency excursion extremely close to, and even touching, the criteria in PRC-024.

With no “benchmark events” to inform criteria expansions, studies could be used to assess future BPS needs. These studies would need a detailed list of scenarios, including different IBR penetrations and load levels, and are dependent on the ability to accurately model current and future IBR technologies, including GFM functions. NERC has issued two level 2 alerts related to IBR, one on IBR performance and the second on modeling. These alerts seek to obtain data from IBR while also giving recommendations to mitigate the observed systemic modeling and performance deficiencies of IBR. Given these observed deficiencies and the lack of recently conducted detailed system-wide studies, there is insufficient study-based evidence to inform widely expanded Ride-through criteria.

It is clear however that the performance of the BPS during disturbance will change as the IBR penetration increases. How this performance will change can be predicted with detailed studies, but an incremental approach to expanding Ride-through criteria adds additional stability margin while modeling deficiencies are addressed and detailed studies are conducted.

The frequency Ride-through times and thresholds in IEEE 2800-2022 are more stringent (wider) than those presently in PRC-024-3 and contain continuous operation ranges that exceed the frequency excursions observed during major BPS disturbances. Detailed feedback from original equipment manufacturers (OEM) provides insight that they are already designing IBR equipment that conforms with the criteria in IEEE 2800-2022. For this reason, the frequency Ride-through criteria in the PRC-029 standard are in alignment with those criteria in IEEE 2800-2022, which provides an expansion of Ride-through criteria compared to PRC-024 while also minimizing cost and timeline implications as OEM are already designing conforming equipment.

Requirement R3 does not prescribe specific frequency protection settings for IBR equipment. IBR frequency protection settings should only be set to protect the IBR from damage caused by operation at off-nominal frequency. An IBR owner must ensure that the IBR frequency protection does not prevent an IBR from meeting the R3 Ride-through requirement.

This standard requires that IBRs remain electrically connected and continue to exchange current during a frequency excursion event in which the frequency remains within the must Ride-through zone according to **Attachment 3** and while the absolute ROCOF magnitude is less than or equal to 5 Hz/second. Some IBR controllers and their ability to remain electrically connected and continue to exchange current with the grid are sensitive to ROCOF, particularly auxiliary equipment that are essential for IBR performance, during a frequency excursion event. If needed to maintain the stability of the IBR or prevent equipment damage, the R3 requirement allows the IBR to trip for an absolute ROCOF exceeding 5Hz/sec within the must Ride-through zone of **Attachment 2**. Failure to Ride-through due to ROCOF exceeding 5Hz/sec shall only be allowed during a generator/load imbalance event that causes the frequency to deviate from nominal.

To minimize the misoperation tripping of the IBR on the ROCOF setting, the rate of change of frequency (ROCOF) must be calculated as the average rate of change over multiple calculated system frequencies for some time greater than or equal to 0.1 seconds. The ROCOF calculation is not applicable during the fault occurrence and clearance (i.e., protection should not trip due to any perceived ROCOF during the entire disturbance and recovery period) and should not operate at the onset of a fault, during a fault, or at fault clearance, i.e., it should be disabled during faults. The IBR shall Ride-through any system disturbance while the voltage at the high-side of the main power transformer remains within the must Ride-through zones as specified in **Attachment 1**. The ROCOF measurement should begin after fault clearance and is only applicable for generation/load imbalance disturbances such as a system separation, an island condition, or the loss of a large load or generator.

Rationale for Requirement R4

The objective of Requirement R4 is to ensure legacy IBR (IBR existing as of the enforcement date of PRC-029-1) are able to obtain an exemption to the voltage and frequency Ride-through requirements if hardware replacements or other costly upgrades would be necessary to comply with Requirements R1 through Requirement R3. This provision allows such exemptions as long as such limitations are documented and communicated to the Planning Coordinator, Transmission Planner, Reliability Coordinator, and Transmission Operator of the respective footprints in which the IBR project is located. The Planning Coordinator, Transmission Planner, Reliability Coordinator, and Transmission Operator will then need to take the voltage Ride-through limitations into account in planning and operations.

Limitations must not be construed as complete exemptions from the applicable tables, but must be specific as to which voltage or frequency band(s) and associated duration(s) cannot be satisfied or specific as to the number of cumulative voltage deviations within a ten-second time period that the equipment can Ride-through if less than four. Limitation descriptions should identify the specific equipment and explain the characteristic(s) of that equipment that prevent Ride-through. If any equipment limitation is removed or otherwise corrected, it is likewise necessary to communicate to the Planning Coordinator, Transmission Planner, Reliability Coordinator, and Transmission Operator of this.

Analysis of Violation Risk Factors and Violation Severity Levels PRC-024-4

Violation Risk Factor and Violation Severity Level Justifications

Project 2020-02 Modifications to PRC-024 (Generator Ride-through)
PRC-024-4

This document provides the standard drafting team's (SDT's) justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-024-4. Each requirement is assigned a VRF and a VSL. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the Electric Reliability Organizations (ERO) Sanction Guidelines. The SDT applied the following NERC criteria and FERC Guidelines when developing the VRFs and VSLs for the requirements.

NERC Criteria for Violation Risk Factors

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to BulkPower System instability, separation, or a cascading sequence of failures, or could place the Bulk-Power System at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to BulkPower System instability, separation, or a cascading sequence of failures, or could place the Bulk-Power System at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the Bulk-Power System, or the ability to effectively monitor and control the Bulk-Power System. However, violation of a medium risk requirement is unlikely to lead to Bulk- Power System instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the BulkPower System, or the ability to effectively monitor, control, or restore the BulkPower System. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to Bulk Power System instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk-Power System, or the ability to effectively monitor and control the Bulk-Power System; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk-Power System, or the ability to effectively monitor, control, or restore the Bulk-Power System.

FERC Guidelines for Violation Risk Factors

Guideline (1) – Consistency with the Conclusions of the Final Blackout Report

FERC seeks to ensure that VRFs assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System. In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief.

Guideline (2) – Consistency within a Reliability Standard
FERC expects a rational connection between the sub-Requirement VRF assignments and the main Requirement VRF assignment.

Guideline (3) – Consistency among Reliability Standards
FERC expects the assignment of VRFs corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) – Consistency with NERC's Definition of the Violation Risk Factor Level
Guideline (4) was developed to evaluate whether the assignment of a particular VRF level conforms to NERC's definition of that risk level.

Guideline (5) – Treatment of Requirements that Co-mingle More Than One Obligation
Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

NERC Criteria for Violation Severity Levels

VSLs define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple “degrees” of noncompliant performance and may have only one, two, or three VSLs.

VSLs should be based on NERC’s overarching criteria shown in the table below:

Lower VSL	Moderate VSL	High VSL	Severe VSL
The performance or product measured almost meets the full intent of the requirement.	The performance or product measured meets the majority of the intent of the requirement.	The performance or product measured does not meet the majority of the intent of the requirement, but does meet some of the intent.	The performance or product measured does not substantively meet the intent of the requirement.

FERC Order of Violation Severity Levels

The FERC VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in the standard meet the FERC Guidelines for assessing VSLs:

Guideline (1) – Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline (2) – Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a “binary” type requirement must be a “Severe” VSL.
Do not use ambiguous terms such as “minor” and “significant” to describe noncompliant performance.

Guideline (3) – Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline (4) – Violation Severity Level Assignment Should Be Based on a Single Violation, Not on a Cumulative Number of Violations

Unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

The VRF did not change from the previously FERC approved PRC-024-3 Reliability Standard.

VSLs for PRC-024-4, Requirement R1			
Lower	**Moderate**	**High**	**Severe**
N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable frequency protection so that it does not trip according to Requirement R1.

VSL Justifications for PRC-024-4, Requirement R1	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement adds a functional entity. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties <u>Guideline 2a</u>: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent <u>Guideline 2b</u>: Violation Severity Level Assignments that Contain Ambiguous Language	The proposed VSLs are binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VSL Justifications for PRC-024-4, Requirement R1	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

The VRF did not change from the previously FERC approved PRC-024-3 Reliability Standard.

VSLs for PRC-024-4, Requirement R2			
Lower	**Moderate**	**High**	**Severe**
N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable voltage protection so that it does not trip according to Requirement R2.

VSL Justifications for PRC-024-4, Requirement R2	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement adds a functional entity. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	The proposed VSLs are binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VSL Justifications for PRC-024-4, Requirement R2	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

The VRF did not change from the previously FERC approved PRC-024-3 Reliability Standard.

VSLs for PRC-024-4, Requirement R3			
Lower	**Moderate**	**High**	**Severe**
The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 30 calendar days but less than or equal to 60 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 60 calendar days but less than or equal to 90 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 90 calendar days but less than or equal to 120 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner failed to document any known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2. OR The Generator Owner or Transmission Owner failed to communicate the documented limitation to its Planning Coordinator and Transmission Planner within 120 calendar days of identifying the limitation.

VSL Justifications for PRC-024-4, Requirement R3	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement adds a functional entity. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.

VSL Justifications for PRC-024-4, Requirement R3	
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	The proposed VSLs are binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

The VRF did not change from the previously FERC approved PRC-024-3 Reliability Standard.

VSLs for PRC-024-4, Requirement R4			
Lower	**Moderate**	**High**	**Severe**
The Generator Owner or Transmission Owner provided its protection settings more than 60 calendar days but less than or equal to 90 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner provided protection settings more than 60 calendar days but less than or equal to 90 calendar days of a written request.	The Generator Owner or Transmission Owner provided its protection settings more than 90 calendar days but less than or equal to 120 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner provided protection settings more than 90 calendar days but less than or equal to 120 calendar days of a written request.	The Generator Owner or Transmission Owner provided its protection settings more than 120 calendar days but less than or equal to 150 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner or provided protection settings more than 120 calendar days but less than or equal to 150 calendar days of a written request.	The Generator Owner or Transmission Owner failed to provide its protection settings within 150 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner failed to provide protection settings within 150 calendar days of a written request.

VSL Justifications for PRC-024-4, Requirement R4	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement adds a functional entity. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of	The proposed VSLs are binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VSL Justifications for PRC-024-4, Requirement R4	
Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.

Exhibit F-2

Analysis of Violation Risk Factors and Violation Severity Levels PRC-029-1

Violation Risk Factor and Violation Severity Level Justifications

Project 2020-02 Modifications to PRC-024 (Generator Ride-through)
PRC-029-1

This document provides the drafting team's (DT's) justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-029-1. Each requirement is assigned a VRF and a VSL. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the Electric Reliability Organizations (ERO) Sanction Guidelines. The DT applied the following NERC criteria and FERC Guidelines when developing the VRFs and VSLs for the requirements.

NERC Criteria for Violation Risk Factors

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to Bulk Power System (BPS) instability, separation, or a cascading sequence of failures, or could place the BPS at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to BPS instability, separation, or a cascading sequence of failures, or could place the BPS at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the BPS, or the ability to effectively monitor and control the BPS. However, violation of a medium risk requirement is unlikely to lead to BPS instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the BPS, or the ability to effectively monitor, control, or restore the BPS. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to BPS instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement
A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the BPS, or the ability to effectively monitor and control the BPS; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the BPS, or the ability to effectively monitor, control, or restore the BPS.

FERC Guidelines for Violation Risk Factors

Guideline (1) – Consistency with the Conclusions of the Final Blackout Report
FERC seeks to ensure that VRFs assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the BPS. In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the BPS:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief.

Guideline (2) – Consistency within a Reliability Standard
FERC expects a rational connection between the sub-Requirement VRF assignments and the main Requirement VRF assignment.

Guideline (3) – Consistency among Reliability Standards
FERC expects the assignment of VRFs corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) – Consistency with NERC's Definition of the Violation Risk Factor Level
Guideline (4) was developed to evaluate whether the assignment of a particular VRF level conforms to NERC's definition of that risk level.

Guideline (5) – Treatment of Requirements that Co-mingle More Than One Obligation
Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

NERC Criteria for Violation Severity Levels

VSLs define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple "degrees" of noncompliant performance and may have only one, two, or three VSLs.

VSLs should be based on NERC's overarching criteria shown in the table below:

Lower VSL	Moderate VSL	High VSL	Severe VSL
The performance or product measured almost meets the full intent of the requirement.	The performance or product measured meets the majority of the intent of the requirement.	The performance or product measured does not meet the majority of the intent of the requirement, but does meet some of the intent.	The performance or product measured does not substantively meet the intent of the requirement.

FERC Order of Violation Severity Levels

The FERC VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in the standard meet the FERC Guidelines for assessing VSLs:

Guideline (1) – Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline (2) – Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a "binary" type requirement must be a "Severe" VSL.
Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline (3) – Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline (4) – Violation Severity Level Assignment Should Be Based on a Single Violation, Not on a Cumulative Number of Violations

Unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the “default” for penalty calculations.

VRF Justifications for PRC-029-1, Requirement R1	
Proposed VRF	**High**
NERC VRF Discussion	A VRF of High is appropriate as applicable generating resources must be able to ride-through system disturbances. Failure to ride-through has been documented in multiple NERC reports leading to exacerbated system conditions, resulting in the electrical disconnecting of additional generation and widespread outages.
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is in line with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The assignment of High VRF is consistent with the VRF assignments for other requirements in the proposed Reliability Standard. This requirement has only a main VRF and no different sub-requirement VRFs.
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	Similar requirements in PRC-024-3 are identified as Medium but are based on equipment protection setting documentation rather than actual, recorded performance during a grid disturbance. Therefore, this VRF is in line with other VRFs that address similar reliability goals in different Reliability Standards.
FERC VRF G4 Discussion Guideline 4- Consistency with NERC Definitions of VRFs	This VRF is in line with the definition of a High VRF requirement per the criteria filed with FERC as part of the ERO’s Sanctions Guidelines.
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not co-mingle a higher risk reliability objective and a lesser risk reliability objective.

VSLs for PRC-029-1, Requirement R1			
Lower	**Moderate**	**High**	**Severe**
The Generator Owner failed to ensure the design capability of each applicable IBR to Ride-through in accordance with Attachment 1, except for those conditions identified in Requirement R1.	N/A	N/A	The Generator Owner failed to ensure each applicable IBR adhered to Ride-through requirements in accordance with Attachment 1, except for those conditions identified in Requirement R1.

VSL Justifications for PRC-029-1, Requirement R1	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement is new. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties <u>Guideline 2a</u>: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent <u>Guideline 2b</u>: Violation Severity Level Assignments that Contain Ambiguous Language	The proposed VSLs are binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VSL Justifications for PRC-029-1, Requirement R1	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

VRF Justifications for PRC-029-1, Requirement R2	
Proposed VRF	**High**
NERC VRF Discussion	A VRF of High is appropriate as applicable generating resources must be able to ride-through system disturbances. Failure to ride-through has been documented in multiple NERC reports leading to exacerbated system conditions, resulting in the electrical disconnecting of additional generation and widespread outages.
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is in line with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The assignment of High VRF is consistent with the VRF assignments for other requirements in the proposed Reliability Standard. This requirement has only a main VRF and no different sub-requirement VRFs.
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	Similar requirements in PRC-024-3 are identified as Medium but are based on equipment protection setting documentation rather than actual, recorded performance during a grid disturbance. Therefore, this VRF is in line with other VRFs that address similar reliability goals in different Reliability Standards.
FERC VRF G4 Discussion Guideline 4- Consistency with NERC	This VRF is in line with the definition of a High VRF requirement per the criteria filed with FERC as part of the ERO's Sanctions Guidelines.

VRF Justifications for PRC-029-1, Requirement R2	
Proposed VRF	**High**
Definitions of VRFs	
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not co-mingle a higher risk reliability objective and a lesser risk reliability objective.

VSLs for PRC-029-1, Requirement R2			
Lower	**Moderate**	**High**	**Severe**
The Generator Owner failed to ensure the design capability of each applicable IBR to adhere to performance requirements during voltage excursions, as specified in Requirement R2, unless a documented hardware limitation exists in accordance with Requirement R4.	N/A	N/A	The Generator Owner failed to ensure each applicable IBR adhered to performance requirements during voltage excursions, as specified in Requirement R2, unless a documented hardware limitation exists in accordance with Requirement R4.

VSL Justifications for PRC-029-1, Requirement R2	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement is new. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.

VSL Justifications for PRC-029-1, Requirement R2	
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	The proposed VSLs are binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

VRF Justifications for PRC-029-1, Requirement R3	
Proposed VRF	**Lower**
NERC VRF Discussion	A VRF of High is appropriate that if violated, it would be expected to adversely affect the electrical state or capability of the BPS.
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is in line with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The assignment of High VRF is consistent with the VRF assignments for other requirements in the proposed Reliability Standard. This requirement has only a main VRF and no different sub-requirement VRFs.
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	This VRF is in line with other VRFs that address similar reliability goals in different Reliability Standards.
FERC VRF G4 Discussion Guideline 4- Consistency with NERC Definitions of VRFs	This VRF is in line with the definition of a High VRF requirement per the criteria filed with FERC as part of the ERO’s Sanctions Guidelines.
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not co-mingle a higher risk reliability objective and a lesser risk reliability objective.

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Exhibit G

Summary of Development and Complete Record of Development

Summary of Development History

The following is a summary of the development record for proposed Reliability Standards PRC-024-4 and PRC-029-1. Project 2020-02 was originally initiated in 2020 to revise the PRC-024 standard, as well as several other standards, to include all types of dynamic reactive sources and DC transmission systems used to provide Essential Reliability Services to the Bulk Electric System. The scope of Project 2020-02 was adjusted in 2022 to address ride-through performance for generating resources.

I. Overview of the Standard Drafting Team

When evaluating a proposed Reliability Standard, the Commission is expected to give "due weight" to the technical expertise of the ERO.[1] The technical expertise of the ERO is derived from the standard drafting team ("SDT") selected to lead each project in accordance with Section 4.3 of the NERC Standard Processes Manual.[2] For this project, the SDT consisted of industry experts, all with a diverse set of experiences. A roster of the Project 2020-02 SDT members is included in **Exhibit H**.

II. Standard Development History

A. Project Initiation

In 2020, NERC initiated Project 2020-02 Transmission Connected Resources to address a Standards Authorization Request ("SAR") submitted by the NERC System Analysis and Modeling Subcommittee ("SAMS") proposing to modify Reliability Standards MOD-025-2, MOD-026-1, MOD-027-1, PRC-019-2 and PRC-024-3. The SAMS developed a white paper to support this

project, addressing deficiencies of reactive power support from nonsynchronous generating resources and transmission-connected dynamic reactive sources.[3]

B. Standard Authorization Request Development

On March 18, 2020, the Standards Committee accepted the SAMS SAR and authorized posting the SAR for a 30-day informal comment period and the solicitation of SAR drafting team members.[4] The informal comment period and the nomination period for a SAR drafting team was extended and was open from March 30, 2020 through May 13, 2020.

C. Supplemental Drafting Team Nominations

Supplemental drafting team nominations were held from April 28, 2021 through May 17, 2021 and from November 19, 2021 – December 20, 2021.[5] The Standards Committee appointed the SAR drafting team on September 23, 2021.[6] Additional SAR drafting team members were appointed on February 16, 2022.[7] Since the original SAR had overlapping Reliability Standards with other projects, the Standards Committee determined that the Project 2020-02 drafting team would focus on revisions to PRC-024 and definitions in the *Glossary of Terms used in NERC Reliability Standards*.

D. Acceptance of Revised SAMS SAR

On April 20, 2022, the Standards Committee accepted the revised SAMS SAR, authorized drafting revisions to the Reliability Standards identified in the SAR, and appointed the Project 2020-02 SAR drafting team as the standard drafting team.

E. Standard Authorization Request Development (Generator Ride-Through)

On April 28, 2022, NERC Staff submitted a Standard Authorization Request seeking to retire Reliability Standard PRC-024-3 and replace it with a performance-based ride-through standard that ensures generators remain connected to the Bulk-Power System during system disturbances. The project name for Project 2020-02 was then was changed to Project 2020-02 Modifications to PRC-024 (Generator Ride-Through). On May 18, 2022, the Standards Committee accepted the Modifications to PRC-024 Ride-through SAR and authorized posting of the SAR for a 45-day formal comment period from May 31, 2022 – July 14, 2022. The Standards Committee also authorized the solicitation of supplemental SDT members.[8]

F. Standard Authorization Request Development (Revised)

On April 19, 2023, the Standards Committee accepted the Modifications to PRC-024 Ride-through SAR as revised by the drafting team, authorized drafting revisions to the Reliability Standards identified in the SAR, and appointed the Project 2020-02 SAR drafting team as the Project 2020-02 standards drafting team.[9]

G. Issuance of Federal Energy Regulatory Commission Order No. 901

On October 19, 2023, the Commission issued Order No. 901[10] directing NERC to develop new or modified Reliability Standards addressing reliability concerns related to IBRs. Accordingly, proposed Reliability Standards PRC-029-1 and PRC-024-4, related to performance requirements for registered IBRs, were aligned with associated regulatory directives from Order No. 901.

H. Standards Committee Authorizes Procedural Waiver

On December 13, 2023, the Standards Committee authorized a waiver of Sections 4.7, 4.9 and 4.12 of the Standard Processes Manual to reduce the initial formal comment and ballot period for Project 2020-02 from 45 days to as little as 25 days, with ballot pools formed in the first 10 days and initial ballot and non-binding poll of VRFs and VSLs conducted during the last 10 days of the comment period, additional formal comment and ballot period(s) reduced from 45 days to as little as 15 days, with ballot(s) conducted during the last days of the comment period, and final ballot reduced from 10 days to 5 calendar days.[11]

I. First Posting – Comment Period, Initial Ballot, and Non-binding Poll

On March 20, 2024, The Standards Committee authorized initial posting of proposed Reliability Standards PRC-024-4 and PRC-029-1, the associated Implementation Plan and other associated documents for a 25-day formal comment period from March 27, 2024 through April 22, 2024, with a parallel initial ballot and non-binding poll on the Violation Risk Factors ("VSFs") and Violation Severity Levels ("VSLs") held during the last 10 days of the comment period from

10 *Reliability Standards to Address Inverter-Based Resources*, Order No. 901, 185 FERC ¶ 61,042 (2023).

11 Exhibit G, Complete Record of Development at item 24.

April 12, 2024 through April 22, 2024.[12] The initial ballot and non-binding poll results for the proposed Reliability Standards are as follows:

- Proposed Reliability Standard PRC-024-4 received 61.73 percent approval, reaching quorum at 91.51 percent of the ballot pool. The non-binding poll for the associated VRFs and VSLs received 76.51 percent supportive opinions, reaching quorum at 83.07 percent of the ballot pool.[13]
- Proposed Reliability Standard PRC-029-1 received 25.37 percent approval, reaching quorum at 91.01 percent of the ballot pool. The non-binding poll for the associated VRFs and VSLs received 25.15 percent supportive opinions, reaching quorum at 88.45 percent of the ballot pool.[14]
- The Implementation Plan received 37.5 percent approval, reaching quorum at 91.14 percent of the ballot pool.[15]

There were 79 sets of responses, including comments from approximately 180 different individuals and approximately 111 companies, representing all 10 industry segments.[16]

J. Second Posting - Comment Period, Initial Ballot, and Non-binding Poll

Proposed Reliability Standards PRC-024-4 and PRC-029-1, the associated Implementation Plan and other associated documents were posted for a 20-day formal comment period from June 18, 2024 through July 8, 2024, with a parallel additional ballot and non-binding poll held during

the last 10 days of the comment period from June 28, 2024 through July 8, 2024.[17] The additional ballot and non-binding poll results for the proposed Reliability Standards are as follows:

- Proposed Reliability Standard PRC-024-4 received 82.7 percent approval, reaching quorum at 85.98 percent of the ballot pool. The non-binding poll for the associated VRFs and VSLs received 76.51 percent supportive opinions, reaching quorum at 83.07 percent of the ballot pool.[18]
- Proposed Reliability Standard PRC-029-1 received 35.45 percent approval, reaching quorum at 85.39 percent of the ballot pool. The non-binding poll for the associated VRFs and VSLs received 29.03 percent supportive opinions, reaching quorum at 82.47 percent of the ballot pool.[19]
- The Implementation Plan received 48.59 percent approval, reaching quorum at 85.98 percent of the ballot pool.[20]

There were 63 sets of responses, including comments from approximately 138 different individuals and approximately 91 companies, representing 7 industry segments.[21]

K. Third Posting - Comment Period, Initial Ballot, and Non-binding Poll

Proposed Reliability Standard PRC-029-1, the associated Implementation Plan and other associated documents were posted for a 20-day formal comment period from July 22, 2024 through August 12, 2024, with a parallel additional ballot and non-binding poll held during the last 10 days

of the comment period from August 2, 2024 through August 12, 2024.[22] The additional ballot and non-binding poll results for the proposed Reliability Standards are as follows:

- Proposed Reliability Standard PRC-029-1 received 52.89 percent approval, reaching quorum at 89.51 percent of the ballot pool. The non-binding poll for the associated VRFs and VSLs received 42.58 percent supportive opinions, reaching quorum at 88.05 percent of the ballot pool.[23]
- The Implementation Plan received 60.04 percent approval, reaching quorum at 89.3 percent of the ballot pool.[24]

There were 70 sets of responses, including comments from approximately 159 different individuals and approximately 112 companies representing all 10 industry segments.[25]

L. Proceedings under Section 321 of NERC Rules of Procedure

Following the failure of the third ballot for proposed Reliability Standard PRC-029-1, the NERC Board of Trustees took action at its August 15, 2024 meeting to invoke its special authority under Section 321 of the NERC Rules of Procedure.[26] Finding that the ballot body for draft Reliability Standard PRC-024-1 has not approved a proposed Reliability Standard that contains provisions to adequately address specific matters identified in directives issued by the Commission in Order No. 901, the Board directed the Standards Committee to work with NERC Staff to carry out the following instructions, in accordance with NERC Rules of Procedure Section 321.2:

- Convene a public technical conference to discuss the issues surrounding the FERC directives, including whether or not the proposed Reliability Standard PRC-029-1 (and, to the extent necessary, any conforming changes in proposed Reliability

22 *Id*. at items 76, 80.

23 *Id.* at items 81, 83.

24 *Id.* at item 82.

25 *Id.* at item 78.

26 NERC, *Board of Trustees Meeting Minutes* (Aug. 15, 2024), https://www.nerc.com/gov/bot/Agenda%20highlights%20and%20Mintues%202013/Minutes%20-%20BOT%20Open%20-August%2015%202024.pdf.

Standard PRC-024-4) being developed through Project 2020-02 Modifications to PRC-024 (Generator Ride-through) is just, reasonable, not unduly discriminatory or preferential, in the public interest, helpful to reliability, practical, technically sound, technically feasible, and cost-justified;

- Prepare a memorandum discussing the issues, an analysis of the alternatives considered, and other appropriate matters;
- Use the input from the technical conference to revise the proposed Reliability Standard(s), as appropriate; and
- Re-ballot the proposed Reliability Standard(s) one additional time, with such adjustments are necessary to meet the 45-day deadline provided in NERC Rules of Procedure Rule 321.2.1.

The Standards Committee, working with NERC Staff, convened a technical conference which took place from September 4-5, 2024. This technical conference focused on unresolved issues raised by stakeholders during the comment periods for earlier drafts of proposed Reliability Standard PRC-029-1.[27] Following the technical conference, representatives from the Standards Committee worked with NERC Staff to revise proposed Reliability Standard PRC-029-1 using input from the technical conference and prepare a memorandum discussing the issues, an analysis of the alternatives considered, and other appropriate matters.

M. Fourth Posting - Comment Period, Initial Ballot, and Non-binding Poll for PRC-029-1

Proposed Reliability Standard PRC-029-1, the associated Implementation Plan and other associated documents were posted for a 13-day formal comment period originally scheduled to run from September 13, 2024 through September 30, 2024, with a parallel additional ballot and non-binding poll to be held from September 24, 2024 through September 30, 2024. To allow stakeholders additional time to review the Standards Committee/NERC Staff memorandum, the

27 *Id.* at items 112, 113, 114.

ballot period was extended through October 4, 2024.[28] The additional ballot and non-binding poll results for the proposed Reliability Standard are as follows:

- Proposed Reliability Standard PRC-029-1 received 77.88 percent approval, reaching quorum at 89.51 percent of the ballot pool. The non-binding poll for the associated VRFs and VSLs received 73.6 percent supportive opinions, reaching quorum at 86.85 percent of the ballot pool.[29]
- The Implementation Plan received 77.89 percent approval, reaching quorum at 88.56 percent of the ballot pool.[30]

N. Final Ballot for PRC-024-4

Proposed Reliability Standard PRC-024-4 was posted for a 5-day final ballot period from September 25, 2024 through September 30, 2024. The final ballot for proposed Reliability Standard PRC-024-4 reached quorum at 90.77 percent of the ballot pool, receiving support from 86.41 percent of the voters. The ballot for the Implementation Plan, conducted during the fourth posting for PRC-029-1, reached quorum at 88.56 percent of the ballot pool, receiving support from 77.89 percent of the voters.[31]

O. Board of Trustees Adoption

The NERC Board of Trustees adopted proposed Reliability Standards PRC-024-4 and PRC-029-1 on October 8, 2024.[32]

---

28 *Id.* at item 97.

31 *Id.* at item 107.

32 NERC, *Board of Trustees Agenda Package Feb., 2024*, Agenda Item 2b. (Project 2020-2 Modifications to PRC-24 (Generator Ride-through)), https://www.nerc.com/gov/bot/Agenda%20highlights%20and%20Mintues%202013/Board%20of%20Trustees%20Open%20Meeting%20Agenda%20Package%20October%208%202024%20Attendees.pdf. In approving proposed Reliability Standard PRC-029-1, the NERC Board of Trustees determined that good cause existed to extend the ballot period past the 45 days prescribed in Section 321.2.1, from September 30, 2024 to October 4, 2024.

P. October 16, 2024 Errata

On October 16, 2024, the Standards Committee approved correcting three errata in proposed Reliability Standard PRC-029-1: one non-substantive error in PRC-029-1 and two non-substantive errors in the implementation plan.[33]

Status

The final ballot for **PRC-024-4 - Frequency and Voltage Protection Settings for Synchronous Generators, Type 1 and Type 2 Wind Resources, and Synchronous Condensers,** concluded at **8 p.m. Eastern, Monday, September 30, 2024.**

The re-ballot ballot for **PRC-029-1-4 - Frequency and Voltage Ride-through Requirements for Inverter-Based Resources,** concluded at **8 p.m. Eastern, Friday, October 4, 2024. Per Rule 321 of the Rules of Procedure, there will be no final ballot.**

Background

The Standards Committee accepted the revised SAR and authorized drafting revisions to the Reliability Standards identified in the SAR on April 19, 2023. The objective of the SAR is to modify PRC-024-3 or replace the standard with a performance-based ride-through standard that ensures generators remain connected to the BPS during system disturbances. Specifically, the SAR focuses on using disturbance monitoring data to substantiate IBR ride-through performance during grid disturbances. The SAR also ensures associated generators that fail to ride-through system events are addressed with a corrective action plan (if possible).

FERC Order 901 requires that IBR-related performance requirements for ride-through are completed and filed with FERC by November 4, 2024. This drafting team will address the IBR-related PRC-029 first and modify PRC-024 to only apply towards synchronous machines. Following the approval of PRC-029, the drafting team will consider additional modifications to PRC-024 to assure performance-based requirements for synchronous machines are adequately addressed per the SAR.

Standard(s) Affected – PRC-024

Purpose/Industry Need

From a risk-based perspective, the goal of the standard is to mitigate the ongoing and systemic performance issues identified across multiple Interconnections and across many disturbances analyzed by NERC and the Regions. Ongoing NERC reports and findings from NERC alerts have continued to substantiate that IBR are failing to ride-through in accordance with expectations and multiple NERC guidelines. These issues have been identified in IBRs as well as synchronous generators, with many causes of tripping entirely unrelated to voltage and frequency protection settings as dictated by the currently effective version of PRC-024.

Unofficial Nomination Form

Project 2020-02 Transmission-connected Resources Standard Authorization Request Drafting Team

Do not use this form for submitting nominations. Use the electronic form to submit nominations for **Project 2020-02 Transmission-connected Resources** Standard Authorization Request (SAR) drafting team members by **8 p.m. Eastern, Wednesday, May 13, 2020.** This unofficial version is provided to assist nominees in compiling the information necessary to submit the electronic form.

Additional information is available on the project page. If you have questions, contact Senior Standards Developer, Chris Larson (via email), or at 404-446-9708.

By submitting a nomination form, you are indicating your willingness and agreement to actively participate in face-to-face meetings and conference calls.

Previous drafting or review team experience is beneficial, but not required. A brief description of the desired qualifications, expected commitment, and other pertinent information is included below.

Background

The problem of increasing amounts of reactive power being supplied by nonsynchronous sources was identified in NERC's 2017 Long-term Reliability Assessment. In response to the concern, the Planning Committee (PC) assigned the System Analysis and Modeling Subcommittee (SAMS) to study the issue. The SAMS developed the *Applicability of Transmission-Connected Reactive Devices* white paper, which was approved by the PC at its December 10-11, 2019 meeting. The PC Executive Committee reviewed the draft SAR from SAMS at its January meeting and subsequently approved the SAR by email vote ending on February 11, 2020. The SAR concerning Transmission-Connected Resources (TCR) aims to modify NERC Reliability Standards MOD-025, MOD-026, MOD-027, PRC-019 and PRC-024 to comprehensively include all types of dynamic reactive resources (including static var systems and FACTS) and DC transmission systems used to provide Essential Reliability Services (ERS) in the Bulk Electric System (BES).

Dynamic reactive resources used to provide ERS in the BES include generation resources (rotating machine and inverter-based) as well as transmission connected dynamic reactive resources (power-electronics based). Existing Reliability Standards for verifying the capability, modeling and performance of dynamic reactive resources are only applicable to Facilities comprising generation resources. Augmenting the applicability of these standards to include (nongeneration) transmission-connected reactive resources, both rotating machine (i.e. synchronous condenser) and power-electronics based, will enhance the BES reliability by ensuring that the capability, models and performance are verified and validated for all varieties of dynamic reactive resources utilized in providing ERS in the BES.

Standard(s) affected: MOD-025, MOD-026, MOD-027, PRC-019 and PRC-024
Drafting Team activities include participation in technical conferences, stakeholder communications and outreach events, periodic drafting team meetings and conference calls. Approximately one face-to-face meeting per quarter can be expected (on average three full working days each meeting) with conference calls scheduled as needed to meet the agreed-upon timeline the drafting team sets forth. NERC is seeking individuals who possess experience in the following areas:

- Developing and verifying dynamic models used in long-term planning assessments, specifically for transmission-connected reactive resources*
- Modeling and studying transmission-connected reactive devices during interconnection studies or long-term planning assessments
- Performing equipment capability testing for transmission-connected reactive devices and rotating machines
- Understanding the large disturbance behavior of transmission-connected reactive devices, particularly the power electronic controls that govern the performance of these devices during abnormal grid conditions

* Transmission-connected reactive resources generally refers to FACTS (Flexible AC Transmission System) devices such as Static Var Compensators (SVCs) and Static Synchronous Compensator (STATCOMs) as well as other power-electronic devices that fall in this category such as HVDC circuits and synchronous condensers.

Please briefly describe your experience and qualifications to serve on the requested SAR Drafting Team (Bio):	
If you are currently a member of any NERC drafting team, please list each team here: ☐ Not currently on any active SAR or standard drafting team. ☐ Currently a member of the following SAR or standard drafting team(s):	

If you previously worked on any NERC drafting team please identify the team(s): ☐ No prior NERC SAR or standard drafting team. ☐ Prior experience on the following team(s):
Acknowledgement that the nominee has read and understands both the *NERC Participant Conduct Policy* and the *Standard Drafting Team Scope* documents, available on NERC Standards Resources. ☐ Yes, the nominee has read and understands these documents.

Select each NERC Region in which you have experience relevant to the Project for which you are volunteering:		
☐ MRO ☐ NPCC ☐ RF	☐ SERC ☐ Texas RE ☐ WECC	☐ NA – Not Applicable

Select each Industry Segment that you represent:	
☐	1 — Transmission Owners
☐	2 — RTOs, ISOs
☐	3 — Load-serving Entities
☐	4 — Transmission-dependent Utilities
☐	5 — Electric Generators
☐	6 — Electricity Brokers, Aggregators, and Marketers
☐	7 — Large Electricity End Users
☐	8 — Small Electricity End Users
☐	9 — Federal, State, and Provincial Regulatory or other Government Entities
☐	10 — Regional Reliability Organizations and Regional Entities
☐	NA – Not Applicable

Select each Function[1] in which you have current or prior expertise:	
☐ Balancing Authority	☐ Transmission Operator
☐ Compliance Enforcement Authority	☐ Transmission Owner
☐ Distribution Provider	☐ Transmission Planner
☐ Generator Operator	☐ Transmission Service Provider
☐ Generator Owner	☐ Purchasing-selling Entity
☐ Interchange Authority	☐ Reliability Coordinator
☐ Load-serving Entity	☐ Reliability Assurer
☐ Market Operator	☐ Resource Planner
☐ Planning Coordinator	

Provide the names and contact information for two references who could attest to your technical qualifications and your ability to work well in a group:			
Name:		Telephone:	
Organization:		Email:	
Name:		Telephone:	
Organization:		Email:	

Provide the name and contact information of your immediate supervisor or a member of your management who can confirm your organization's willingness to support your active participation.

Standards Announcement

Project 2020-02 Transmission-connected Dynamic Reactive Resources

Nomination Period Now Open through May 13, 2020

Now Available

Nominations are being sought for **Project 2020-02 Transmission-connected Dynamic Reactive Resources** drafting team members. The due date has been extended, and is now open through **8 p.m. Eastern, Wednesday, May 13, 2020**.

Use the electronic form to submit a nomination. Contact Wendy Muller regarding issues using the electronic form. An unofficial Word version of the nomination form is posted on the Standard Drafting Team Vacancies page and the project page.

By submitting a nomination form, you are indicating your willingness and agreement to actively participate in face-to-face meetings and conference calls. Previous drafting team experience is beneficial but not required.

See the project page (linked above) and nomination form for additional information.

Next Steps

The Standards Committee is expected to appoint members to the drafting team in May 2020. Nominees will be notified shortly after they have been appointed.

For information on the Standards Development Process, refer to the Standard Processes Manual.

Subscribe to this project's observer mailing list by selecting "NERC Email Distribution Lists" from the "Service" drop-down menu and specify “Project 2020-02 Transmission-connected Resources observer list” in the Description Box. For more information or assistance, contact Senior Standards Developer, Chris Larson (via email) or at 404-446-9708.

SAR Type (Check as many as apply)			
☐ New Standard ☒ Revision to Existing Standard ☒ Add, Modify or Retire a Glossary Term ☐ Withdraw/retire an Existing Standard		☐ Imminent Action/ Confidential Issue (SPM Section 10) ☐ Variance development or revision ☐ Other (Please specify)	
Justification for this proposed standard development project (Check all that apply to help NERC prioritize development)			
☐ Regulatory Initiation ☐ Emerging Risk (Reliability Issues Steering Committee) Identified ☐ Reliability Standard Development Plan		☒ NERC Standing Committee Identified ☐ Enhanced Periodic Review Initiated ☐ Industry Stakeholder Identified	
Industry Need (What Bulk Electric System (BES) reliability benefit does the proposed project provide?):			
Dynamic reactive resources used to provide Essential Reliability Services (ERS) in the BES include generation resources (rotating machine and inverter-based) as well as transmission connected dynamic reactive resources (power-electronics based). Existing reliability standards for verifying the capability, modeling and performance of dynamic reactive resources are only applicable to Facilities comprising generation resources. Augmenting the applicability of these standards to include (non-generation) transmission-connected reactive resources – both rotating machine (i.e. synchronous condenser) and power-electronics based – will enhance the BES reliability by ensuring that the capability, models and performance is verified and validated for all varieties of dynamic reactive resources utilized in providing ERS in the BES.			

Requested information
Purpose or Goal (How does this proposed project provide the reliability-related benefit described above?):
Augment the "Applicability – Facilities" and "Applicability-Functional Entities" sections in MOD-025, MOD-026, MOD-027, PRC-019 and PRC-024 reliability standards to address (non-generation) transmission-connected dynamic reactive resources – both rotating machine (i.e. synchronous condenser) and power-electronics based. Also modify Requirements (including applicable attachments) as needed to ensure they continue to address the additional Facilities. As needed, also define new Glossary Terms for all or some of the transmission-connected dynamic reactive devices noted in the SAMS white-paper "*Transmission Connected Dynamic Reactive Resources – Assessment of Applicability in Reliability Standards*".
Project Scope (Define the parameters of the proposed project):
Revise the "Applicability – Facilities" section, "Applicability – Functional Entities" section, and Requirements (including applicable attachments) as needed in MOD-025, MOD-026, MOD-027, PRC-019 and PRC-024 reliability standards to comprehensively address all varieties of transmission-connected dynamic reactive resources that are utilized in providing ERS in the BES.
Detailed Description (Describe the proposed deliverable(s) with sufficient detail for a drafting team to execute the project. If you propose a new or substantially revised Reliability Standard or definition, provide: (1) a technical justification[1]which includes a discussion of the reliability-related benefits of developing a new or revised Reliability Standard or definition, and (2) a technical foundation document (*e.g.* research paper) to guide development of the Standard or definition):
The "Applicability – Facilities" and "Applicability-Functional Entities" sections in MOD-025, MOD-026, MOD-027, PRC-019 and PRC-024 reliability standards will be revised to address (non-generation) transmission-connected dynamic reactive resources based on the recommendations summarized in Table 1 of the SAMS white-paper "*Transmission Connected Dynamic Reactive Resources – Assessment of Applicability in Reliability Standards*". The white-paper also provides the technical justifications for the recommended revisions and the associated reliability benefits. Also modify Requirements (including applicable attachments) as needed to ensure they continue to address the additional Facilities. As needed, also define new Glossary Terms for all or some of the transmission-connected dynamic reactive devices noted as items 1.a – 1.j in the Additional Considerations section of the SAMS white-paper.
Cost Impact Assessment, if known (Provide a paragraph describing the potential cost impacts associated with the proposed project):
Unknown
Please describe any unique characteristics of the BES facilities that may be impacted by this proposed standard development project (*e.g*. Dispersed Generation Resources):
Power-electronics based transmission-connected reactive resources – also known as FACTS (Flexible AC Transmission System) devices – such as: Static Var Compensator (SVC), Static Synchronous Compensator (STATCOM), HVDC Links (LCC or VSC).
To assist the NERC Standards Committee in appointing a drafting team with the appropriate members, please indicate to which Functional Entities the proposed standard(s) should apply (*e.g*. Transmission

[1] The NERC Rules of Procedure require a technical justification for new or substantially revised Reliability Standards. Please attach pertinent information to this form before submittal to NERC.

Requested information
Operator, Reliability Coordinator, etc. See the most recent version of the NERC Functional Model for definitions):
Transmission Owners in addition to the existing Functional Entities
Do you know of any consensus building activities[2] in connection with this SAR? If so, please provide any recommendations or findings resulting from the consensus building activity.
"*Transmission Connected Dynamic Reactive Resources – Assessment of Applicability in Reliability Standards*" white-paper approved by SAMS members.
Are there any related standards or SARs that should be assessed for impact as a result of this proposed project? If so which standard(s) or project number(s)?
PRC-019 SAR requested by SPCS and PRC-024 SAR requested by IRPTF
Are there alternatives (e.g. guidelines, white paper, alerts, etc.) that have been considered or could meet the objectives? If so, please list the alternatives.
No viable alternatives were found by SAMS.

Reliability Principles	
Does this proposed standard development project support at least one of the following Reliability Principles (Reliability Interface Principles)? Please check all those that apply.	
☒	1. Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk power systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☒	3. Information necessary for the planning and operation of interconnected bulk power systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk power systems shall be developed, coordinated, maintained and implemented.
☒	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk power systems.
☐	6. Personnel responsible for planning and operating interconnected bulk power systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk power systems shall be assessed, monitored and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

[2] Consensus building activities are occasionally conducted by NERC and/or project review teams. They typically are conducted to obtain industry inputs prior to proposing any standard development project to revise, or develop a standard or definition.

Market Interface Principles	
Does the proposed standard development project comply with all of the following Market Interface Principles?	Enter (yes/no)
1. A reliability standard shall not give any market participant an unfair competitive advantage.	Yes
2. A reliability standard shall neither mandate nor prohibit any specific market structure.	Yes
3. A reliability standard shall not preclude market solutions to achieving compliance with that standard.	Yes
4. A reliability standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards.	Yes

Transmission Connected Dynamic Reactive Resources and HVDC Equipment – Assessment of Applicability in Reliability Standards

NERC SAMS White Paper
February 2019

Background

The bulk power system (BPS) in North America continues to experience a change in generating resources, technologies, and transmission system devices used to provide essential reliability services (ERS) such as voltage control, frequency control, and ramping/balancing capability. In particular, the BPS is experiencing a rapid change in generation resource mix, with an increasing installation base of inverter-based generation resources and accompanying retirements of synchronous generation resources. Additionally, generation is increasingly being located farther from load centers than it was in the past. These factors are contributing to an increased reliance on non-generation transmission-connected dynamic reactive resources – both rotating machine (i.e. synchronous condenser) and power-electronics based – to provide ERS in the BPS. Synchronous condensers are being used to provide dynamic reactive power and transient voltage support, as well as synchronous inertia and fault current contribution in weak grid conditions. Static var compensators (SVCs) and static compensators (STATCOMs) are increasingly being used to provide dynamic reactive power and transient voltage support.

Many relevant NERC Reliability Standards are not applicable to these types of transmission-connected dynamic reactive resources. It is now clear that an increasing number of these reactive resources are being used to provide the same ERS as generation resources to ensure reliability of the BPS. In many cases, these types of dynamic reactive resources are critical to BPS reliability because they are used to increase power transfer capability, mitigate system instability, provide grid resilience for physical and cyber attacks, and provide safety nets for severe contingencies. In this respect, ensuring their electrical capability, verification of performance, and ability to ride through grid events is no less important than for traditional generators.

The NERC Planning Committee and the NERC System Analysis and Modeling Subcommittee (SAMS) expressed concerns that the existing NERC Reliability Standards may not clearly address non-generation transmission-connected dynamic reactive resources. In response to these concerns, SAMS has developed this white paper that comprises an assessment of the applicability of relevant NERC Reliability Standards to such dynamic reactive resources and provides recommendations to address any identified reliability gap. In particular, SAMS focused on the following NERC Reliability Standards:

- **MOD-025-2:** Verification and Data Reporting of Generator Real and Reactive Power Capability and Synchronous Condenser Reactive Power Capability
- **MOD-026-1:** Verification of Models and Data for Generator Excitation Control System or Plant Volt/Var Control Functions

- **MOD-027-1:** Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions
- **MOD-032-1:** Data for Power System Modeling and Analysis
- **PRC-019-2:** Coordination of Generating Unit or Plant Capabilities, Voltage Regulating Controls, and Protection
- **PRC-024-2:** Generator Frequency and Voltage Protective Relay Settings

Results from this assessment and recommendations for moving forward are provided in this white paper.

Applicability Assessment

SAMS reviewed relevant NERC Reliability Standards related to the model verification, capability testing, disturbance ride through, and protection coordination aspects of generation resources to evaluate if the transmission-connected dynamic reactive resources are included within the applicability sections of these standards. The goal was to determine the reliability need/justification for including transmission-connected dynamic reactive resources as applicable Facilities within the Applicability section of these standards.

Recommended Applicability

Table 1 shows the applicability of relevant NERC Reliability Standards to dynamic reactive resources – including both generation resources and non-generation transmission connected reactive resources. The cells with green bold font show the existing applicability and the cells with red bold italicized font show the recommended applicability based on this SAMS assessment .

For the assessed non-generation reactive resources (refer to Appendix A for their descriptions), each cell includes either a Yes or N/A as the recommendation for its inclusion as Facilities in the Applicability section of the relevant Reliability Standard. The technical basis and justification for the recommended applicability is provided in the following sub-sections.

Table 1: Applicability of Relevant NERC Reliability Standards to Dynamic Reactive Resources

	MOD-025	MOD-026	MOD-027	MOD-032	PRC-019	PRC-024
Synchronous Generator	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**

Existing applicability
SAMS recommendation

[1] Nonsynchronous generating resource

Technical Basis for Applicability

The sub-sections below describe the technical basis and justification for applicability of the relevant NERC Reliability Standard to each type of transmission-connected dynamic reactive resource listed in Table 1.

MOD-025

The purpose of MOD-025 is to ensure that accurate information on generator gross and net Real and Reactive Power capability and synchronous condenser Reactive Power capability is available for planning models used to assess Bulk Electric System (BES) reliability. The technical justification for applicability of MOD-025 recommended in Table 1 is described below:

- **SVC:** A SVC serves many of the same purposes as a synchronous condenser, particularly the injection or absorption of dynamic reactive power to support steady-state and transient voltage conditions. Similar to a synchronous condenser, an SVC has a current injection capability that translates to a reactive power capability based on terminal voltage. For this reason, a power electronics resource like a SVC connected to the BPS should be a Facility to which MOD-025 is applicable for reactive power capability verification.
- **STATCOM:** A SVC and STATCOM are very similar in terms of being power electronic resources connected to the BPS that provide steady-state and dynamic voltage support. The STATCOM and SVC differ in their reactive capability, particularly under off-nominal voltage conditions. Their controls are also different based on the types of equipment technologies used in the different devices. Again, the power electronics have a current injection capability that translates to reactive power capability based on voltage. For this reason, STATCOM should be a Facility to which MOD-025 is applicable for reactive power capability verification.
- **LCC HVDC:** A LCC HVDC circuit is predominantly used to transfer large amounts of active power across long distances (as well as other applications such as underground cables, etc.). LCC HVDC technology inherently consumes very large quantities of reactive power at the converters. AC filters located at the converter terminals to mitigate harmonics also provide reactive power and offset its consumption from the grid. However, ac filters are comprised of static shunt reactive devices with known reactive capability ratings that do not need verification. LCC HVDC does not have independent control of active and reactive power because there is no voltage source within the converters. For these reasons, LCC HVDC should ***not*** be a Facility to which MOD-025 is applicable for reactive power capability verification.
- **VSC HVDC:** VSC HVDC is different than LCC HVDC in that it has independent control of active and reactive power because of the independent voltage source within the converters. Therefore, these elements are able to operate in automatic voltage control, controlling their terminal voltage (or some other compensated voltage) to support scheduled voltages on the BPS. Therefore, VSC HVDC should be a Facility to which MOD-025 is applicable for reactive power capability verification.

MOD-026

The purpose of MOD-026 is to verify that the generator excitation control system or plant volt/var control function model (including the power system stabilizer model and the impedance compensator model) and the model parameters used in dynamic simulations accurately represent the generator excitation control system or plant volt/var control function behavior when assessing Bulk Electric System

(BES) reliability. The technical justification for applicability of MOD-026 recommended in Table 1 is described below:

- **Synchronous Condenser:** A synchronous condenser is a synchronous machine without a prime mover (freely rotating shaft) and therefore delivers/absorbs reactive power to the BPS based on its excitation. In essence, a synchronous condenser exhibits the same dynamic behavior as a synchronous generator from the perspectives of MOD-026. A synchronous condenser should be required to provide verified dynamic models as described in MOD-026.
- **SVC:** SVCs provide dynamic reactive power to the BPS to support grid voltage, voltage stability, and power transfers. These devices include elements and controls that can respond very quickly to grid conditions (during and after faults, for example). There are no (or minimal) moving parts in these devices, and the majority of the response is determined based on the settings programmed into the controls. It is important that these control settings are verified, and the dynamic response of the model matches reality. For these reasons, SVCs should be required to provide verified dynamic models as per the intent of MOD-026.
- **STATCOM:** STATCOMs use different technology than SVCs, but they also provide dynamic reactive power to the BPS and their response is determined based on the settings programmed into the controls. Therefore, similar to SVCs, STATCOMs should be required to provide verified dynamic models as per the intent of MOD-026.
- **LCC HVDC:** For the same reasons listed in MOD-025, LCC HVDC should ***not*** be a Facility to which MOD-026 is applicable.
- **VSC HVDC:** Similar to SVCs and STATCOMs, VSC HVDC Facilities also provide dynamic reactive power to the BPS and their response is determined based on the settings programmed into the controls. Therefore, VSC HVDC should be required to provide verified dynamic models as per the intent of MOD-026.

MOD-027

The purpose of MOD-027 is to verify that the turbine/governor and load control or active power/frequency control model and the model parameters, used in dynamic simulations that assess Bulk Electric System (BES) reliability, accurately represent generator unit real power response to system frequency variations. The technical justification for applicability of MOD-027 recommended in Table 1 is described below:

- **Synchronous Condenser:** A synchronous conderser is a dynamic reactive power resource and does not have the capability to provide active power to the BPS. It does not include a turbine-governor or active power-frequency control system. Therefore, MOD-027 is not applicable..
- **SVC:** It does not include a turbine-governor or active power-frequency control system. Therefore, SVC should ***not*** be a Facility to which MOD-027 is applicable.
- **STATCOM:** A STATCOM is a dynamic reactive power resource and does not have the capability to provide active power to the BPS. It does not include a turbine-governor or active power-frequency control system. Therefore, STATCOM should ***not*** be a Facility to which MOD-027 is applicable.
- **LCC HVDC:** Although LCC HVDC is *not* a dynamic reactive power resource, it has the capability to provide active power/frequency control to the BPS. Since its active power/frequency control system

response is determined based on the settings programmed into the controls, it should be required to provide verified dynamic models as per the intent of MOD-027.

- **VSC HVDC:** A VSC HVDC is a dynamic reactive power resource and also has the capability to provide active power/frequency control to the BPS. Since its active power/frequency control system response is determined based on the settings programmed into the controls, it should be required to provide verified dynamic models as per the intent of MOD-027.

MOD-032

MOD-032 has sufficiently comprehensive applicability to include transmission-connected dynamic reactive resources for the purposes of obtaining their modeling data. Therefore, SAMS does not recommend any changes to the applicability of MOD-032.

PRC-019

The purpose of PRC-019 is to verify coordination of generating unit Facility or synchronous condenser voltage regulating controls, limit functions, equipment capabilities and Protection System settings. The technical justification for applicability of PRC-019 recommended in Table 1 is described below:

- **Synchronous Condenser:** A synchronous condenser is protected with a number of protective functions and limiters, similar to a synchronous generator. If not properly coordinated, the limiters and protection elements could potentially limit the output or trip the machine below its rated capability. Therefore, PRC-019 should be applicable to synchronous condensers.
- **SVC:** Analogous to the synchronous machines, SVCs have voltage regulating controls, limiters, and protection functions. If not properly coordinated, the limiters and protection elements could potentially limit the output or trip the SVC below its rated capability. Therefore, PRC-019 should be applicable to SVCs.
- **STATCOM:** Analogous to the SVCs, STATCOMs have active and reactive voltage regulating controls, limiters, and protection functions. If not properly coordinated, the limiters and protection elements could potentially limit the output or trip the STATCOM below its rated capability. Therefore, PRC-019 should be applicable to STATCOMs.
- **LCC HVDC:** LCC HVDC does not have independent control of active and reactive power because there is no voltage source within the converters. To the extent that LCC HVDC has voltage regulating controls, limiters, and protection functions, they, they could potentially limit the LCC HVDC output below its rated capability if not properly coordinated. PRC-019 should be applicable to LCC HVDC due to its control and protection equipment abilities.
- **VSC HVDC:** VSC HVDC does have independent control of active and reactive power because they use voltage source converters. Analogous to the SVCs and STATCOMs, the VSC HVDC has voltage regulating controls, limiters, and protection functions. If not properly coordinated, the limiters and protection elements could potentially limit the VSC HVDC output below its rated capability. PRC-019 should be applicable to VSC HVDC due to its control and protection equipment abilities.

PRC-024

In the “Evaluating Protective Relay Settings” section of PRC-024 --Attachement 2 Item #2 states that the GO must “Evaluate voltage protective relay settings assuming that additional installed generating plant reactive support equipment (such as static VAR compensators, synchronous condensers, or capacitors) is available and operating normally.” However,this evaluation focuses on reactive power devices within the generating plant and does not include similar reactive power devices that are transmission connected.

The purpose of PRC-024 is to ensure Generator Owners set their generator protective relays such that generating units remain connected during defined frequency and voltage excursions. The technical justification for applicability of PRC-024 recommended in Table 1 is described below:

- **Synchronous Condenser:** Synchronous condensers, like synchronous generators, have frequency and voltage protective relays whose settings should not be within the ride through characteristics of PRC-024. Undervoltage and overvoltage protection, overspeed protection, etc., are all applied to a synchronous condenser since it is inherently a rotating electric machine without a prime mover. The synchronous condenser is expected to ride through grid voltage and frequency excursion events to provide dynamic voltage support and provide system inertia for stabilizing wide-area system frequency. Therefore, PRC-024 should be applicable to synchronous condensers.
- **SVC:** SVCs provide dynamic reactive power support during and immediately after a grid disturbance during the transient timeframes. In this respect, its purpose and functionalty is very similar to that of synchronous condensers (and synchronous generators). The SVC would be expected to ride through grid voltage and frequency excursion events to provide dynamic voltage supportsupport herefore, PRC-024 should be applicable to SVCs.
- **STATCOM:** STATCOMs provide dynamic reactive power support during and immediately after a grid disturbance during the transient timeframes. In this respect, its purpose and functionalty is very similar to that of synchronous condensers and SVCs. The STATCOM would be expected to ride through grid voltage and frequency excursion events to provide dynamic voltage support. PRC-024 should be applicable to STATCOM.
- **LCC HVDC:** The LCC HVDC would be expected to ride through grid voltage and frequency excursion events to provide continuity of service (i.e. maintaining MW output). Therefore, PRC-024 should not be applicable to LCC HVDC.
- **VSC HVDC:** VSC HVDC provide dynamic reactive power support during and immediately after a grid disturbance during the transient timeframes. In this respect, its purpose and functionalty is very similar to that of SVCs and STATCOMs. The VSC HVDC would be expected to ride through grid voltage and frequency excursion events to provide dynamic voltage support. Therefore, PRC-024 should be applicable to VSC HVDC.

Other Considerations

The following additional considerations were noted during the assessment. While not necessarily directly related to the assessment of applicability of elements to relevant NERC Standards, SAMS believes these additional topics are important and should be addressed.

1. Definitions for the following terms should be reviewed for potential additions and/or revisions in the NERC Glossary of Terms include, but are not limited to, the following:
    a. Generator (or Generating Facility)
    b. Generating Unit Capability[2]
    c. Dynamic Reactive Power
    d. Synchronous Condenser
    e. Static Var Compensator (SVC)
    f. Static Synchronous Compensator (STATCOM)
    g. High Voltage DC (HVDC)
    h. Line Commutated Converter (LCC) HVDC
    i. Voltage Source Converter (VSC) HVDC
    j. Flexible AC Transmission Systems (FACTS)
2. NERC SAMS and the NERC Power Plant Modeling and Verification Task Force (PPMVTF) have both identified a significant inconsistency between the intent of MOD-025-2 to "ensure that accurate information on generator…capability[3] is available for planning models used to assess Bulk Electric System (BES) reliability" and the actual results obtained during testing. MOD-025-2 does not require the full (maximum achievable) reactive capability of the resource to be reached via test. This is warranted because the testing conditions likely will limit the resource from reaching its full (maximum achievable) reactive capability before other limits are reached such as system voltage, generator terminal voltage, or auxiliary bus voltage limits. While this is reasonable for testing, the standard does not require calculations to be performed to prove that the resource could reach its full (maximum achievable) reactive capability under more favorable operating conditions (i.e. when that full reactive capability is needed for maintaining voltage schedule). Therefore, there is a significant misconception in the industry that the testing results should be used as the same data submitted for MOD-032-1 for capability of the machine. This misconception is likely leading to incorrect data being supplied for the purposes of MOD-032-1 and is driven by the requirements in MOD-025-2.

[2] This is a defined term; however, the definition is not sufficiently reflective of the term.

[3] and synchronous condenser reactive power capability

UPDATED
Standards Announcement

Project 2020-02 Transmission-connected Dynamic Reactive Resources Standard Authorization Request

Informal Comment Period Now Open through May 13, 2020

Now Available

The informal comment period for **Project 2020-02 Transmission-connected Resources Standard Authorization Request** *has been extended and is now open through* ***8 p.m. Eastern, Wednesday, May 13, 2020.***

Commenting

Use the Standards Balloting and Commenting System (SBS) to submit comments. Contact Wendy Muller regarding issues with the SBS. An unofficial Word version of the comment form is posted on the project page.

- *Contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern) for problems regarding accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out.*
- *Passwords expire every* ***6 months*** *and must be reset.*
- *The SBS* ***is not*** *supported for use on mobile devices.*
- *Please be mindful of ballot and comment period closing dates. We ask to* ***allow at least 48 hours*** *for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts* ***prior to the last day*** *of a comment/ballot period.*

Next Steps

The drafting team will review all responses received during the comment period and determine the next steps of the project**.**

For information on the Standards Development Process, refer to the Standard Processes Manual**.**

Subscribe to this project's observer mailing list by selecting "NERC Email Distribution Lists" from the "Service" drop-down menu and specify “Project 2020-02 Transmission-connected Resources observer list” in the Description Box. For more information or assistance, contact Senior Standards Developer, Chris Larson (via email) or at 404-446-9708.

Comment Report

Project Name:	2020-02 Transmission-connected Resources | Standard Authorization Request
Comment Period Start Date:	3/30/2020
Comment Period End Date:	5/13/2020
Associated Ballots:	

There were 39 sets of responses, including comments from approximately 118 different people from approximately 100 companies representing 10 of the Industry Segments as shown in the table on the following pages.

Questions

1. Do you agree with the proposed scope as described in the SAR? If you do not agree, or if you agree but have comments or suggestions for the project scope please provide your recommendation and explanation.

2. Provide any additional comments for the SAR drafting team to consider, if desired.

ATC generally agrees with the proposed scope and purpose of the SAR. However, the SAR should be modified to more clearly identify the BES nature of the equipment that is in scope and whether it qualifies as "transmission connected." The term "transmission connected" is ambiguous since many regions have different definitions for what is considered transmission. The SAR should be clarified to address this ambiguity.	

Additionally, “transmission connected” does not indicate if the dynamic reactive resource itself must be classified as BES, in accordance with NERC’s definition, to be within the SAR’s scope or if the dynamic reactive resource must simply be connected to an existing BES element to be within the SAR’s scope. ATC believes that non-BES devices should not fall within the scope of the standards affected (MOD-025, MOD-026, MOD-027, PRC-019, and PRC-024) such that a device connected to distribution facilities or other non-BES facilities (e.g. DERs or 69 kV bus) would not fall within the scope of the SAR.

ATC believes the scope of the SAR should only focus on BES dynamic reactive resources similar in nature to the existing BES definition and scope of the existing standards.

Comment

AEP objects to the SAR’s scope as currently proposed and find it to be far too open-ended, as typified by the inclusion of “all ***varieties*** of transmission-connected dynamic reactive resources that are utilized in providing ERS in the BES.” While we acknowledge that new technologies in this regard continue to emerge, more specificity is needed within the SAR to enable industry to provide meaningful feedback.

The final paragraph on page 7 of the Whitepaper expresses concern regarding an apparent “significant inconsistency” between the intent of MOD-025-2 to “ensure that accurate information on generator…capability is available for planning models used to assess Bulk Electric System (BES) reliability” and the actual results obtained during testing. The authors of the White Paper believe that misconceptions regarding generator maximum achievable reactive capability may be causing the provision of incorrect data for the purposes of MOD-032-1, driven by the requirements of MOD-025. The SAR would presumably require more robust testing on transmission-connected dynamic reactive resources, and it must be understood and acknowledged by the SDT that such testing would differ greatly from that of the generation resources currently in scope. We have provided feedback below regarding how we believe such testing impacts the standards that are in scope for this project.

MOD-026: While initial testing is reasonable, it is not realistic to perform any ongoing dynamic testing of FACTS devices after they are installed on the system. FACTS devices are dynamically tested on a RTDS simulator in the lab before field commissioning, and against the actual system during field commissioning. Results of these tests are used to validate the models provided. It is not expected that dynamic response would change on an inverter based system after initial design, thereby making subsequent tests irrelevant.

MOD-027: This standard does not apply to FACTS voltage control equipment, though it could apply to HVDC tie equipment. Frequency response and power flow contingency settings are an optional characteristic available in most manufacturers’ control systems and is not be utilized by all entities. These power flow and frequency response capabilities are tested as part of the factory testing before the unit is commissioned to insure that the capability performs correctly. No further verification is needed on HVDC equipment unless the frequency response capability is turned on and put into production.

PRC-019: Initial factory testing is sufficient, and no ongoing field testing is necessary. Factory coordination of protection elements and controls is a basic part of the design of a FACTS device. When possible, FACTS devices are tested to the full range of operation during commissioning, otherwise such testing is always performed on the RTDS during factory testing. Test results are then compiled and made available to show compliance with specifications. If changes are made in the field, then coordination studies would be required to update the documentation.

PRC-024: Once again, initial factory testing is sufficient, and no ongoing field testing is necessary. Protective relays are coordinated with the operation of the FACTS device during the design phase. The FACTS control system is operated against the RTDS model of the system during factory testing to insure that all specified transient phenomena are properly handled by the device. Many tests are run at varying voltages and frequencies to prove that the device is robust and meets standards. Test results are compiled and made available to show compliance with specifications. If changes are made in the field then coordination studies would be required to update the documentation.

Mod-025: The testing of a FACTS reactive resource may potentially (though obviously unintentionally) introduce risk to the system to which it is connected. Operating the system outside reasonable parameters is not acceptable for the purposes of testing. Testing of a FACTS reactive resource will be limited due to the constraints of the system at the time the testing is performed. It is quite possible that full output may not be obtained in either the capacitive or inductive direction (or both). Testing cannot require the disruption of the power system in the vicinity of the FACTS device, nor can it put that system at any risk due to the testing. The reason for the termination of the test at any output level should be documented in the test results with no further requirements due for further testing. As mentioned in the last paragraph of the white paper, an early termination of a test due to system constraints at the time of the test should not be construed to mean that the unit will always be limited to that maximum output. Any resulting limitation of the FACTS device in planning models would need to be determined after analysis of the cause of the limitation in the test results.

In summary, while AEP agrees (at least in part) with what the SAR seeks to achieve, we do not see a true reliability-driven need for standards on these suggested devices, certainly not to the extent as for independent generators. The existence and usage of these additional devices, by their very nature, requires their owners to perform reliability studies, calculations, and take other necessary measures to verify both their proper operation and modeling. As a result, we do not believe that adding obligations for these devices would perceptibly enhance the reliability of the BES, and would primarily be administrative in nature. We do not believe a “reliability parity” exists between the newly-suggested devices and those already within the scope of these standards, and do not believe that the standards should be revised to include these additional devices. However, if the SDT does indeed pursue such changes, we believe the SDT should revise the SAR to address the following a) pursue device-specific obligations for the newly-proposed non-generation devices, b) ensure that Violation Severity Levels for any new obligations are less than those associated with the existing obligation for Facilities comprising generation resources and c) ensure that the periodicity associated with the obligations on the additional devices are less burdensome as well.

Jodirah Green - ACES Power Marketing - 1,3,4,5,6 - MRO,WECC,Texas RE,SERC,RF, Group Name ACES Standard Collaborations

Answer	No
Document Name	

Comment

ACES has three main concerns with the proposed SAR:

1. The definition of Essential Reliability Services (ERS) is not consistent amongst the SAR, the White Paper, and other previous resources.

- The SAR states the following: Dynamic reactive resources used to provide Essential Reliability Services (ERS) in the BES include generation resources (rotating machine and inverter-based) as well as transmission connected dynamic reactive resources (power-electronics based).
- The SAMS White Paper states the following: ... essential reliability services (ERS) such as voltage control, frequency control, and ramping/balancing capability.
- The Essential Reliability Services “Tutorial” form 2014 explains Essential Reliability Services as an integral part of reliable operations to assure the protection of equipment and are the elemental “reliability building blocks” provided by generation. That includes voltage support and frequency support.

Therefore, use of “ERS” requires a NERC-approved definition to avoid any inconsistencies.

2- The Assessment of Applicability in Reliability Standards White Paper that has been supplied as a basis for this SAR is in a draft form. The submission of this SAR should be deferred until the final White Paper is published.

3- The SAR states that the Cost Impact Assessment is unknown. Cost Impacts are an important aspect to be studied. Company budget cycles are requested to be measured as a consideration in the time-extension decisions.

Daniela Atanasovski - APS - Arizona Public Service Co. - 1,3,5,6

Answer	No
Document Name	

Comment

AZPS proposes the scope be modified to include "BES" connected dynamic reactive devices instead of "transmission" connected reactive devices as not all devices connected at the transmission level are applicable to the BES. In addition, there are cases where devices connected at 69kV may be considered BES.

AZPS does not agree with all of the conclusions in the February 2019 NERC SAMS White Paper. For example, on Page 2, Table 1: Applicability of Relevant NERC Reliability Standards to Dynamic Reactive Resources, APS does not agree with the conclusion that LCC HVDC is applicable to MOD-027 or that VSC HVDC is applicable to MOD-025, MOD-026 or MOD-027. The intent of MOD-026 is to verify excitation system model and the intent of MOD-027 is to verify turbine generator model. Application of these standards to HVDC will not be appropriate. If the intent is to verify HVDC dynamic models as used in powerflow and stability studies, AZPS asserts that there should be a separate SAR for that requirement.

On Page 7, Other Considerations, Item 2 of the NERC SAMS White Paper additional complications of MOD-025 are discussed.

"NERC SAMS and the NERC Power Plant Modeling and Verification Task Force (PPMVTF) have both identified a significant inconsistency between the intent of MOD-025-2 to "ensure that accurate information on generator and synchronous condenser reactive power capability is available for planning models used to assess Bulk Electric System (BES) reliability" and the actual results obtained during testing. MOD-025-2 does not require the full (maximum achievable) reactive capability of the resource to be reached via test. This is warranted because the testing conditions likely will limit the resource from reaching its full (maximum achievable) reactive capability before other limits are reached such as system voltage, generator terminal voltage, or auxiliary bus voltage limits. While this is reasonable for testing, the standard does not require calculations to be performed to prove that the resource could reach its full (maximum achievable) reactive capability under more favorable operating conditions (i.e. when that full reactive capability is needed for maintaining voltage schedule). Therefore, there is a significant misconception in the industry that the testing results should be used as the same data submitted for MOD-032-1 for capability of the machine. This misconception is likely leading to incorrect data being supplied for the purposes of MOD-032-1 and is driven by the requirements in MOD-025-2."

AZPS asserts that it is not prudent to modify MOD-025 to include new devices when there are other issues that need to be addressed.

AZPS further notes that there is a discrepancy in the NERC SAMS White Paper as follows: On Page 2, Table 1 indicates that LCC HVDC is recommended to be applicable to PRC-024 but on Page 6, the Technical Basis for Applicability in the White Paper indicates that it should NOT be applicable to PRC-024. AZPS recommends the table should be corrected to have a N/A value.

Comment

The added benefit to reliability might not be significant to justify the inclusion of these transmission-connected resources. Reliability for these resources is currently addressed by Standards such as PRC-004, which requires Misoperations to be analyzed and reported and the development of Corrective Action Plans to remediate issues. In addition, the protection and control systems found in these transmission-connected reactive resources are not easily modified and typically are proprietary, requiring assistance from the manufacturer to change settings and test certain systems. Modifying existing protection and control systems affects warranty and is not recommended. Therefore, there is no need to retest/compare when no modifications are being made to the system. With the loss of a FACTS device, the Power System should not completely fall apart. There may be issues with voltage stability for short periods of time, such as power flow, but the system should not collapse.

NO, NCPA does not support this SAR as written.

NCPA feels the SAR needs to clearly state that GO/GOPs will not be subject to any changes to MOD-025, 26, 27 and PRC 19 and 24 Standards due to this Project 2020-02. If the SAR drafting team disagrees please state exactly why members are willing to imply it doesn't impact GO/GOPs but are unwilling to back it up by excluding GO/GOP from the SAR and future subject standards new/modified requirement(s).

As written the SAR seems straight forward. For instance it mentions (non-generation) transmission connected reactive resources, which looks like it excludes GO/GOPs. But from our experience with FERC, NERC, and WECC, unless the SAR or the Standard specifically states it is not applicable to GO/GOPs we are going to have to annually provide documentation/evidence proving that we don't own/operate transmission connected resources and compile evidence, or null evidence letters, annually proving compliance or non-applicability of the standard. This is simply another cost and time burden on NCPA, our investors, members, and customers, with zero reliability benefit.

It does not appear that the SAMS seriously considered a Reliability Guideline to address the issues identified in the White Paper. GTC believes that a Reliability Guideline would be a better initial step to address the needs identified in the White Paper without adding the administrative burden/cost of record keeping and documentation for audit purposes; therefore, GTC does not believe that a SAR is necessary at this time.

Dynamic reactive power resources have nothing to do with frequency control, which is a direct consequence of the balance of real power balances between generation and load. We believe that the inclusion of MOD-027 in the list of standards in the SAR is out of order.

PRC-019 already applies to TO-owned synchronous condensers. PRC-019 was originally deemed necessary due to miscoordination of the protection elements embedded in automatic voltage regulating system with the process control limiters which may exist in the controls. Does this miscoordination exist in the additional "all varieties of dynamic reactive resources" scope proposed? In other words, for the additional scoped elements, are the tripping elements tripping before the limiting elements limit? The driving source of need and the impetus for increasing the scope of the PRC-019 applicability is not justified in the SAR.

The detailed description does not provide sufficient detail as to the proposed extent of the modifications to existing requirements, nor does it provide insight into possible function of new requirements. It is suggested that this detail be added to direct a standard drafting team towards the specific concern to be addressed.

MOD-025 already applies to TO-owned synchronous condensers. Proportionately, are there substantial numbers of additional transmission connected reactive power resources that, if modelled, would significantly enhance the validity of a planning model? The driving source of need and the impetus for increasing the scope of the MOD-025 applicability is not justified in the SAR. Additionally, the operational limitations observed during the first 5 years of the MOD-025 testing which yielded test results that did not prove the actual reactive capabilities of the machines under test raise valid questions regarding its value - what is to say that expanding the applicability to additional equipment will yield valuable information on reactive capabilities?

The MVA applicability thresholds for MOD-026 were chosen so that approximately 80% of the connected generation in each interconnection would be drawn into the scope of the applicability. Are there sufficient quantities of other transmission connected reactive power resources whose inclusion in the applicability would significantly impact and enhance the validity of planning models?

It is suggested that the Project Scope statement be modified to limit the applicable resources to those specifically identified by the SAMs white paper. Including a statement such as “all variety of transmission connected dynamic resources is unbounded and could create confusion as to what resources are applicable.

PacifiCorp supports the proposed Standards Authorization Request to revise the “Applicability – Facilities” and “Applicability-Functional Entities” sections in the MOD-025, MOD-026, MOD-027, PRC-019 and PRC-024 reliability standards to include (non-generation) transmission-connected dynamic reactive resources. PacifiCorp also would like to submit a comment for the team members to consider that for MOD-025, testing the full range of large non-generation transmission-connected dynamic reactive devices may not be possible under normal operating conditions. Data from actual disturbances may need to be used to verify the reactive capability of these devices including high speed switching of any associated switched shunt capacitors and/or reactors that are incorporate to extend the range of the dynamic reactive device.

Laura Nelson - IDACORP - Idaho Power Company - 1

Answer	Yes
Document Name	
Comment	

Idaho Power (IPCO) supports the proposed modifications listed in the SAR for NERC Project 2020-02.

Impact to Idaho Power with regard to including synchronous condensers as applicable resources for MOD-026 is anticipated to be minimal. IPCO has performed dynamic system model validation for IPCO-owned synchronous condensers under the WECC Model Validation and Testing Policy. IPCO has PMU and DFR monitoring equipment installed on the IPCO-owned synchronous condensers; thus, model validation for MOD-026 can potentially be performed using disturbance recording data since all the machines have already under gone baseline testing.

Anticipated impact for the addition of synchronous condensers as applicable resources for PRC-024 is minimal to IPCO.

IPCO supports inclusion of the non-generation dynamic reactive resources listed in Table 1 of the NERC SAMS White Paper.

1. As far as adding other reactive or real power source model verification requirements to the NERC MOD Standards, I am OK with that. But I would like to add an expansion of the scope of the existing requirements to include generating resources with less than a 75 MVA rating, and connected at less than 100 KV, per the explanation below.

1. Based on WECC's experience since the Aug. 10, 1996 WSCC (now WECC) System Wide Outage, I would like to suggest that as part of this SAR, we include the expansion of the scope of those generating resources that need to have their dynamic models verified via MOD-026 & MOD-027, to include those single generating units 10 MVA or larger (or an aggregate facility rating of 20 MVA or larger), and connected at 60 kV and above.

The detailed analysis of the Aug. 10, 1996 WSCC System Wide Outage demonstrated the real significance that the smaller generators have in their impact to the transient stability of the WECC Interconnected System. During that Outage, it wasn't until the smaller U.S. Army Corps of Engineers McNary Hydroelectric Generators (each of the 13 units were smaller than 75 MVA) in the Pacific Northwest ran into excitation limits and tripped off-line causing a further and critical voltage sag, that the voltage oscillations on the 500 kV system started, and which eventually led to the complete voltage collapse and blackout of a major portion of the Pacific and Pacific Northwest System. Their excitation systems were modeled incorrectly at the time, and that is why the initial simulation analysis did not predict the actual response of the Interconnected System that occurred (see Transactions on Power Systems, Vol. 14, No. 3, August 1996; "Model Validation for the August 10, 1996 WSCC System Outage"). For this reason, WSCC (WECC) invoked the mandatory Generating Testing and Model Validation Policy, requiring testing of all generators connected at 60 kV and above, and rated at 10 MVA and above (or an aggregate facility rating of 20 MVA or larger). The effectiveness of this Policy was demonstrated by the analysis of subsequent system wide disturbances that demonstrated good matches between the simulated responses and the actual systems response during the disturbances (see "Generating Unit Model Validation: WECC Lessons and Moving Forward" ; 2009 IEEE Power and Energy Society Meeting, Calgary, AB, Canada, July 26-July 30, 2009). This definitely demonstrated the effectiveness of having accurate generator models for all generators 10 MVA and larger (or an aggregate facility rating of 20 MVA or larger), and connected at 60 kV and above.

In addition, a final and nearly exact match did not occur for the 1996 Outage simulations until the load of the WECC Interconnected System (typically placed on 69 kV and below modeled busses) was more accurately modeled by introducing a 20% induction motor load, along with the traditional static load previously modeled. This fact also demonstrated the extreme importance the lower voltage connected models have on the overall system response of the WECC high voltage (i.e., greater than or equal to 100 kV) Interconnected System.

And in recent years with the very large influx of renewable generation (many thousands of MWs) in California being added to the WECC System at the lower levels of 20 MVA and connected at 69 kV and below, it is even more incumbent on us to include in model testing and validation, these smaller size generating units.

Thank you.

Sincerely,

Spencer Tacke

It is recommended that the drafting team consider working with industry vendors of transmission connected nonsynchronous sources (i.e. FACTS, HVDC) to ensure that the standard requirements can be benchmarked with actual and realistic resource testing capabilities and modeling capabilities. As mentioned in the White Paper, controls for nonsynchronous sources are different based on the types of equipment technologies used in the different devices. In terms of dynamic simulation modeling of nonsynchronous sources (i.e. FACTS, HVDC), it is expected that such dynamic models would be developed by and provided by the device vendor. It is encouraged that the applicable standards promote the development of, and use of, standardized "off the shelf" dynamic simulation software models. It is likely that many Transmission Owners (TOs) rely on the services of the nonsynchronous resource (i.e. FACTS, HVDC) vendor for capability testing, protection coordination and model verification – due to the specialized nature of these resources. The proposed standards development envisioned by this SAR would likely increase a TO's reliance on support services from their nonsynchronous resource vendors, with a corresponding increase in costs.

EEI supports the proposed changes contained in the Project 2020-02 SAR. The SAR, which is supported by a comprehensive white paper developed by the System Analysis and Modeling Subcommittee (SAMS), identifies a gap in the existing body of Reliability Standards that has been created by the changing resource mix and changes in technology and transmission connected devices that are needed to support BES reliability. EEI agrees with SAMS that both rotating machines and power-electronics based resources that are capable of supporting Essential Reliability Services (ERS) should do so in a consistent manner.

I agree with the recommendation. Dynamic reactive resources, including generation resources such as rotating machinery as well as transmission connected dynamic reactive resources, both in the form of rotating machinery such as synchronous condensers, and power-electronics based devices such as SVC's and STATCOMS, affect the transmission voltages, power transfer levels and hence the reliability of the power system due to their ability to generate and absorb Mvars dynamically and in the steady state. In many cases the MVA rating of these devices can be larger than single generating units. As such the accurate representation and capability testing of such devices will contribute to the overall reliability of the BES.

BPA believes this is a timely and much needed effort to ensure transmission-connected reactive resources have validated dynamic models, and appropriate system performance. The Western Interconnection is undergoing significant transformation with its generation mix. Many of the large coal-fired and nuclear power plants have retired or are scheduled to retire. These generators are replaced with renewable plants, which are usually smaller in size. Current 75 MW threshold represented 80% of generating capacity in the Western Interconnection in 2007. However, with the retirement of large synchronous generators and addition of smaller renewable plants, the threshold is now lower. As such, BPA requests the drafting team to revisit the applicability threshold in MOD-026/27 Reliability Standards for the Western Interconnection as additional scope to this SAR.

ERCOT generally supports the concept described in the SAR. Regarding PRC-024 only, ERCOT agrees that the standard should be revised to prohibit tripping of GO-owned reactive devices outside certain defined parameters, as suggested by the SAMS whitepaper, but does *not* agree that the standard should be revised to prohibit tripping of TO-owned reactive devices. This is because, to the extent tripping of such devices outside of PRC-024's defined parameters can foreseeably cause a reliability issue, that issue should be identified in a TP's or PC's annual Planning Assessment and resolved through a Corrective Action Plan (CAP). To the extent the tripping of a TO-owned reactive device does not result in a violation of planning criteria, then requiring the TO to prevent the tripping of that device in conformance with the settings of PRC-024 would not be necessary or cost-effective.

Texas RE appreciates the SAR drafting team's efforts in addressing reliability and issues we have seen as a contributing cause to past events (e.g. STATCOM tripping off during voltage excursion during July 2015 event). Texas RE noticed, however, that the scope of the SAR focuses on "transmission-connected resources", but does not clearly address how these reactive devices will be addressed when owned by the Generator Owner (GO). This is especially pertinent for dispersed power producing resources where synchronous condensers, SVCs, and STATCOMs are frequently located behind the GSU and used to supplement the Reactive Power output of the individual generating units.

For example, Footnote 4 of PRC-024-2 states "*For voltage protective relays associated with dispersed power producing resources identified through Inclusion I4 of the Bulk Electric System definition, this requirement applies to voltage protective relays applied on the individual generating unit of the dispersed power producing resources, as well as voltage protective relays applied on equipment from the individual generating unit of the dispersed power producing resource up to the point of interconnection.*" Since the language in this footnote only addresses generating units, a synchronous condenser, SVC, or STATCOM owned by the GO is not applicable to the currently effective version of the Standard. **Texas RE recommends clarifying the SAR to ensure the modifications to applicability include GO dynamic reactive devices**.

The industry need section of the SAR needs is confusing in listing the GO-owned rotating-machine and inverter-based generating facilities that are already subject to the MOD and PRC standards listed in the SAR title. It is suggested that the need be focused only on the missing elements in the focus of the concern of this SAR. It is unclear what the term non-generation means. It is suggested that the detailed description section of the SAR provide only details of what is being proposed to be changed in the list of standard. The basis and justification references pointing to the SAMS white paper, in our opinion, do not belong in the detailed description section of what is being proposed. More specificity is suggested: e.g."modify the applicability sections to include…, modify requirements, if needed, to address these additional facility types…, modify/create new requirements to achieve specific objectives…, add glossary terms, if needed …".

1. MH believes that it is important to verify voltage and frequency ride through capability of LCC HVDC links. Given these links are large, loss of the links can be impactive to reliability – especially frequency support. Therefore, PRC-024 should be applicable to LCC links.

While the SAR is clearly focused on “reactive power resources” they’re missing an important contribution of LCC HVDC to frequency stability. The scope of the SAR should clearly address both voltage and frequency.

On page 6 of the NERC SAMS White paper it says the following for PRC-024:

“The LCC HVDC would be expected to ride through grid voltage and frequency excursion events to provide continuity of service (i.e. maintaining MW output). Therefore, PRC-024 should not be applicable to LCC HVDC”.

This statement contradicts with the SAMS recommendation in Table-1 to include LCC HVDC in PRC-024. NERC should revise this White Paper to ensure that PRC-024 is applicable to LCC HVDC.

2. MH believes MOD-25 should be applicable to LCC HVDC as well. From model verification point of view, it is important to know the behavior (MW/MVAr) over the range of operation at the inverter bus.

As more utilities begin to use PV plants as dynamic reactive power sources at night when real power is zero, it is increasingly important that this unique mode of operation is considered as the subject reliability standards are revised. In particular, MOD-025 should have provisions for reactive power capability at zero power for inverter-based resources that are capable of such operation.

While EEI supports the proposed SAR, we offer the following suggestions to ensure the project is appropriately bounded.

1. EEI suggests that the Project Scope statement be modified to limit the applicable resources to those specifically identified by the SAMs white paper.

2. While EEI supports and agrees with the finding of the SAMs white paper identified in the Consensus Building Activity section of the SAR, we disagree that the white paper qualifies as a “consensus” report given it was not vetted broadly by the Industry EEI suggest this statement be removed.

EEI also offer the following non-substantive comments for the SAR:

1. EEI suggests modifying the title of this SAR to “Modification of MOD-025, MOD-026, MOD-027, PRC-019 and PRC-024 to include Dynamic Reactive Resources.”

2. In the section that identifies Standards and SARs that should be referenced, EEI suggests that the PRC-024 SAR reference should be changed to include a reference to the BOT approved PRC-024-3 Reliability Standard. Additionally, since the PRC-019 SAR has not yet been approved by the Standards Committee, EEI suggests this reference be removed.

MISO supports comments submitted by the MRO NSRF and recommends the following clarifications to the scope of the SAR:

Implementation Plan – include the development of an implementation Plan for the initial testing and reporting of dynamic reactive resources newly introduced under the applicability of revised standards.

Definition of Essential Reliability Services (ERS) – define Essential Reliability Services (ERS) as the description of ERS has varied over time and includes some definitions which limit the focus to generation and demand resources. Examples provided below.

· The Essential Reliability Services Task Force (ERSTF) Scope Document approved by the NERC Planning and Operating Committees on March 5, 2014 defines Essential Reliability Services as "the elemental 'reliability building blocks' from resources (generation and demand) necessary to maintain Bulk Power System (BPS) reliability. ERS are operational attributes from conventional generation, such as providing reactive power to maintain system voltages and physical inertia to maintain system frequency, necessary to reliably operate the BPS."

http://www.nerc.com/comm/Other/essntlrlbltysrvcstskfrcDL/Scope_ERSTF_Final.pdf

· The October 2014 NERC Essential Reliability Services Task Force White Paper "*A Concept Paper on Essential Reliability Services that Characterizes Bulk Power System Reliability*" explains Essential Reliability Services as: "ERSs are an integral part of reliable operations to assure the protection of equipment, and are the elemental "reliability building blocks" provided by generation" including voltage support and frequency support.

· The February 2019 NERC SAMS White Paper, "*Transmission Connected Dynamic Reactive Resources and HVDC Equipment – Assessment of Applicability in Reliability Standards,"* referenced in the SAR states: "…essential reliability services (ERS) such as (emphasis added) voltage control, frequency control, and ramping/balancing capability."

AZPS recommends defining what qualifies as a "dynamic reactive resource" within the Glossary of Terms Used in NERC Reliability Standards. AZPS believes that without a definition there could be a gap in the applicability of the standard. AZPS suggests that the criteria listed on Slide 12 of "Dynamic vs. Static Resources" from the March 2017 Industry Webinar for Reactive Power Planning, NERC System Analysis and Modeling Subcommittee (SAMS) should be used as a starting point for the development of the definition.

Dynamic reactive resources:

- Adjust reactive power output automatically in real-time over a continuous range within a specified voltage bandwidth in response to grid voltage changes
- Maintain set point voltage or operate in voltage droop mode
- Many are power electronics ballots
- Can respond within electrical cycles using fast-acting controls.

AZPS suggests that the drafting team review the periodic performance of each device type within MOD-025 and recommends that the frequency be no more than every ten years.

Comment

1. Based on WECC's experience since the Aug. 10, 1996 WSCC (now WECC) System Wide Outage, I would like to suggest that as part of this SAR, we include the expansion of the scope of those generating resources that need to have their dynamic models verified via MOD-026 & MOD-027, to include those single generating units 10 MVA or larger (or an aggregate facility rating of 20 MVA or larger), and connected at 60 kV and above.

The detailed analysis of the Aug. 10, 1996 WSCC System Wide Outage demonstrated the real significance that the smaller generators have in their impact to the transient stability of the WECC Interconnected System. During that Outage, it wasn't until the smaller U.S. Army Corps of Engineers McNary Hydroelectric Generators (each of the 13 units were smaller than 75 MVA) in the Pacific Northwest ran into excitation limits and tripped off-line causing a further and critical voltage sag, that the voltage oscillations on the 500 kV system started, and which eventually led to the complete voltage collapse and blackout of a major portion of the Pacific and Pacific Northwest System. Their excitation systems were modeled incorrectly at the time, and that is why the initial simulation analysis did not predict the actual response of the Interconnected System that occurred (see Transactions on Power Systems, Vol. 14, No. 3, August 1996; "Model Validation for the August 10, 1996 WSCC System Outage"). For this reason, WSCC (WECC) invoked the mandatory Generating Testing and Model Validation Policy, requiring testing of all generators connected at 60 kV and above, and rated at 10 MVA and above (or an aggregate facility rating of 20 MVA or larger). The effectiveness of this Policy was demonstrated by the analysis of subsequent system wide disturbances that demonstrated good matches between the simulated responses and the actual systems response during the disturbances (see "Generating Unit Model Validation: WECC Lessons and Moving Forward" ; 2009 IEEE Power and Energy Society Meeting, Calgary, AB, Canada, July 26-July 30, 2009). This definitely demonstrated the effectiveness of having accurate generator models for all generators 10 MVA and larger (or an aggregate facility rating of 20 MVA or larger), and connected at 60 kV and above.

In addition, a final and nearly exact match did not occur for the 1996 Outage simulations until the load of the WECC Interconnected System (typically placed on 69 kV and below modeled busses) was more accurately modeled by introducing a 20% induction motor load, along with the traditional static load previously modeled. This fact also demonstrated the extreme importance the lower voltage connected models have on the overall system response of the WECC high voltage (i.e., greater than or equal to 100 kV) Interconnected System.

And in recent years with the very large influx of renewable generation (many thousands of MWs) in California being added to the WECC System at the lower levels of 20 MVA and connected at 69 kV and below, it is even more incumbent on us to include in model testing and validation, these smaller size generating units.

Thank you.

Sincerely,

Spencer Tacke

The Standard Draft Team should consider and implement a MVAR/MVA size threshold for validation of the dynamic reactive resources along with clarifying the BES/Non-BES discussion above.

Reclamation recommends the SAR drafting team thoughtfully assess the cost impacts associated with this SAR to effect changes in a cost-effective manner. The SAR proposes a significant increase in the scope of the affected standards, which will have a substantial impact on affected entities and should not be taken without appropriate consideration.

These comments represent the MRO NSRF membership as a whole but would not preclude members from submitting individual comments".

The use of the wording "Essential Reliability Services (ERS)" requires a NERC approved definition. There are many different pseudo explanations of what Essential Reliability Services are.

- From the 3 Nov 2014 Essential Reliability Services "Tutorial" which explains Essential Reliability Services as ERSs are an integral part of reliable operations to assure the protection of equipment and are the elemental "reliability building blocks" provided by generation. That include voltage support and frequency support.
- The SAMS White Paper states (within this SAR) "…essential reliability services (ERS) such as (emphasis added) voltage control, frequency control, and ramping/balancing capability".
- This SAR states "Dynamic reactive resources used to provide Essential Reliability Services (ERS) in the BES include generation resources (rotating machine and inverter-based) as well as transmission connected dynamic reactive resources (power-electronics based).

With the above inconsistency of what ERS is, the SAR should include the development of an Essential Reliability Services definition.

Project 2020-02 Transmission-connected Dynamic Reactive Resources

Summary Response to SAR Comments | February 2022

Introduction

The Standard Authorization Request (SAR) drafting team thanks all who provided comments during the informal comment period. All comments received were reviewed and the identified common themes are addressed below. Some comments have been reserved for consideration during the standard drafting phase of the project, including the financial impact question and risk.

1. **TCDRR definition(s) and Applicability section in standards should be clear which assets or technologies are considered a TCDRR and what is applicable within each Reliability Standard.**
   The Project 2020-02 standard drafting team (SDT) will use the definition of terms, revise applicability section(s), and revise standard language to make clear what assets/technologies are considered a transmission-connected dynamic reactive resource (TCDRR), and may define specific technologies (SVC, STATCOM, FACTS, HVDC, etc.). The SAR allows the SDT to add, modify or retire Glossary terms.

2. **The SDT should coordinate drafting a Reliability Guideline with a NERC technical committee rather than revising the standards.**
   Though there is an existing *Reliability Guideline: Reactive Power Planning (December 2016)* covering reactive power planning and related issues, there is currently not a Reliability Guideline drafted or being drafted that addresses the reliability risks outlined in the SAR or in SAMS white paper, *Transmission Connected Dynamic Reactive Resources – Assessment of Applicability in Reliability Standards*. The 2020-02 SDT is tasked with determining whether revisions to the standards will appropriately address the reliability risk outlined in the SAR and white paper.

3. **The SDT should consider defining addition terms such as essential reliability services.**
   The SAR allows the creation of new Glossary terms as part of the project scope. This can include new Glossary terms for all or some of the TCDRR noted in the SAMS white-paper. Essential reliability services is currently not a defined term in the Glossary of Terms used in NERC Reliability Standards. The SDT may consider adding new terms, such as essential reliability services, if they find it necessary as part of the project.

4. **Dynamic reactive resources located at a generation Facility should not be considered TCDRR.**
   The SAR DT agrees with this comment. When a dynamic reactive resource (e.g. FACTS device or synchronous condenser) is located at a generation Facility, the asset would be covered under the applicability of existing standards. As described in the SAR, Project 2020-02 is meant to address non-generation TCDRR under the purview of the Transmission Owner. The SDT will attempt to make this distinction clear, either in the Applicability section of revised standards or in Glossary term(s).

5. **The SDT should determine the practicality of staged testing TCDRR as part of MOD-025, MOD-026, and MOD-027 implementation before revising the standards.**
   Modeling data for synchronous condensers, FACTS and HVDC equipment is provided by the Transmission Owner to Transmission Planners & Planning Coordinators as part of MOD-032. However, the models are not subsequently validated, unless being reviewed by the Transmission Planner as part of MOD-033 following a system disturbance. MOD-025/026/027 could provide a means for the Transmission Owner to validate the models using a staged test, or verify the model(s) reflect in-service equipment by an alternate means. The Project 2020-02 SDT will coordinate and advise the SDTs for Project 2020-06 (MOD-026/027) & Project 2021-01 (MOD-025 and PRC-019) on the practicality of performing staged testing. However, the decision of whether and how to revise MOD-025, MOD-026, MOD-027 to include TCDRR will reside with those respective drafting teams.

Unofficial Nomination Form

Project 2020-02 Transmission-connected Dynamic Reactive Resources Standard Authorization Request Drafting Team

Do not use this form for submitting nominations. Use the electronic form to submit nominations for Standard Authorization Request (SAR) drafting team members by **8 p.m. Eastern, Monday, May 17, 2021.** This unofficial version is provided to assist nominees in compiling the information necessary to submit the electronic form.

Additional information is available on the project page. If you have questions, contact Senior Standards Developer, Chris Larson (via email), or at 404-446-9708.

Background

The problem of increasing amounts of reactive power being supplied by nonsynchronous sources was identified in NERC's 2017 Long-term Reliability Assessment. In response to the concern, the Planning Committee (PC) assigned the System Analysis and Modeling Subcommittee (SAMS) to study the issue. The SAMS developed the *Applicability of Transmission-Connected Reactive Devices* white paper, which was approved by the PC at its December 10-11, 2019 meeting. The PC Executive Committee reviewed the draft SAR from SAMS at its January meeting and subsequently approved the SAR by email vote ending on February 11, 2020. The SAR concerning Transmission-Connected Resources (TCR) aims to modify NERC Reliability Standards MOD-025, MOD-026, MOD-027, PRC-019 and PRC-024 to comprehensively include all types of dynamic reactive resources (including static var systems and FACTS) and DC transmission systems used to provide Essential Reliability Services (ERS) in the Bulk Electric System (BES).

Dynamic reactive resources used to provide ERS in the BES include generation resources (rotating machine and inverter-based) as well as transmission connected dynamic reactive resources (power-electronics based). Existing Reliability Standards for verifying the capability, modeling and performance of dynamic reactive resources are only applicable to Facilities comprising generation resources. Augmenting the applicability of these standards to include (nongeneration) transmission-connected reactive resources, both rotating machine (i.e. synchronous condenser) and power-electronics based, will enhance the BES reliability by ensuring that the capability, models and performance are verified and validated for all varieties of dynamic reactive resources utilized in providing ERS in the BES.

Standard(s) affected: PRC-024. MOD-025, MOD-026, MOD-027, PRC-019 revisions will be coordinated with other project teams.

By submitting a nomination form, you are indicating your willingness and agreement to actively participate in face-to-face meetings and conference calls. The time commitment for this project is expected to be one face-to-face meetings per quarter (on average two full working days each meeting) with conference calls scheduled as needed to meet the agreed upon timeline the team sets forth. Face-to-face meetings will be conducted only when CDC health guidelines permit. Team members may also have side projects, either individually or by sub-group, to present for discussion and review. Lastly, an important component of the team effort is outreach. Members of the team will be expected to conduct industry outreach during the development process to support a successful ballot. Previous drafting team experience is beneficial but not required. See the project page and nomination form for additional information.

NERC is seeking individuals who possess experience in the following areas:

- Developing and verifying dynamic models used in long-term planning assessments, specifically for transmission-connected reactive resources*
- Modeling and studying transmission-connected reactive devices during interconnection studies or long-term planning assessments
- Performing equipment capability testing for transmission-connected reactive devices and rotating machines
- Understanding the large disturbance behavior of transmission-connected reactive devices, particularly the power electronic controls that govern the performance of these devices during abnormal grid conditions

* Transmission-connected reactive resources generally refers to FACTS (Flexible AC Transmission System) devices such as Static Var Compensators (SVCs) and Static Synchronous Compensator (STATCOMs) as well as other power-electronic devices that fall in this category such as HVDC circuits and synchronous condensers.

Standards Announcement

Project 2020-02 Transmission-connected Dynamic Reactive Resources

Supplemental Nomination Period Open through May 17, 2021

Now Available

Additional nominations are being sought for Standard Authorization Request (SAR) drafting team members through **8 p.m. Eastern, Monday, May 17, 2021**.

Use the electronic form to submit a nomination and contact Wendy Muller regarding issues with the system. An unofficial Word version of the nomination form is posted on the Standard Drafting Team Vacancies page and the project page.

Background

The potential risk of increasing amounts of reactive power being supplied by nonsynchronous sources was identified in *NERC's 2017 Long-term Reliability Assessment*. In response to the concern, the Planning Committee (PC) assigned the System Analysis and Modeling Subcommittee (SAMS) to study the issue. The SAMS developed the *Applicability of Transmission-Connected Reactive Devices* white paper, which was approved by the PC at its December 2019 meeting. The PC Executive Committee reviewed the draft SAR from SAMS at its January meeting and subsequently approved the SAR by email vote ending on February 11, 2020. The SAR was posted for industry comment March 30 – May 13, 2020, and drafting team member nominations were solicited. However, the project was temporarily paused before a SAR drafting team was appointed.

By submitting a nomination form, you are indicating your willingness and agreement to actively participate in face-to-face meetings and conference calls. The time commitment for this project is expected to be one face-to-face meetings per quarter (on average two full working days each meeting) with conference calls scheduled as needed to meet the agreed upon timeline the team sets forth. Face-to-face meetings will be conducted only when CDC health guidelines permit. Team members may also have side projects, either individually or by sub-group, to present for discussion and review. Lastly, an important component of the team effort is outreach. Members of the team will be expected to conduct industry outreach during the development process to support a successful ballot. Previous drafting team experience is beneficial but not required. See the project page and nomination form for additional information.

Next Steps

The Standards Committee is expected to appoint members to the drafting team in June or July, 2021. Nominees will be notified shortly after they have been appointed.

For more information on the Standards Development Process, refer to the Standard Processes Manual.

Standard Authorization Request (SAR)

Complete and please email this form, with attachment(s) to: sarcomm@nerc.net

The North American Electric Reliability Corporation (NERC) welcomes suggestions to improve the reliability of the bulk power system through improved Reliability Standards.

Requested information			
SAR Title:	Revision of relevant Reliability Standards to include applicability of transmission-connected dynamic reactive resources		
Date Submitted:	February 24, 2020 (Revised on February 3, 2022)		
SAR Requester			
Name:	Hari Singh – Chair, System Analysis & Modeling Subcommittee (SAMS) (Revised by Project 2020-02 SAR DT)		
Organization:	Xcel Energy		
Telephone:	303-571-7095	Email:	hari.singh@xcelenergy.com
SAR Type (Check as many as apply)			
☐ New Standard ☒ Revision to Existing Standard ☒ Add, Modify or Retire a Glossary Term ☐ Withdraw/retire an Existing Standard		☐ Imminent Action/ Confidential Issue (SPM Section 10) ☐ Variance development or revision ☐ Other (Please specify)	
Justification for this proposed standard development project (Check all that apply to help NERC prioritize development)			
☐ Regulatory Initiation ☐ Emerging Risk (Reliability Issues Steering Committee) Identified ☐ Reliability Standard Development Plan		☒ NERC Standing Committee Identified ☐ Enhanced Periodic Review Initiated ☐ Industry Stakeholder Identified	
Industry Need (What Bulk Electric System (BES) reliability benefit does the proposed project provide?):			
Dynamic reactive resources used to provide essential reliability services (ERS) in the BES include generation resources (rotating machine and inverter-based) as well as transmission connected dynamic reactive resources (power-electronics based). Existing reliability standards for verifying the capability, modeling and performance of dynamic reactive resources are only applicable to Facilities comprising generation resources. Augmenting the applicability of these standards to include (non-generation) transmission-connected reactive resources – both rotating machine (i.e. synchronous condenser) and power-electronics based – will enhance the BES reliability by ensuring that the capability, models and performance is verified and validated for all varieties of dynamic reactive resources utilized in providing ERS in the BES.			

Requested information
Purpose or Goal (How does this proposed project provide the reliability-related benefit described above?):
Augment the "Applicability – Facilities" and "Applicability-Functional Entities" sections in PRC-024 reliability standard to address (non-generation) transmission-connected dynamic reactive resources – both rotating machine (i.e. synchronous condenser) and power-electronics (e.g. Flexible AC Transmission System (FACTS) based. Also modify Requirements (including applicable attachments) as needed to ensure they continue to address the additional Facilities. As needed, also define new Glossary Terms for all or some of the transmission-connected dynamic reactive devices noted in the SAMS white-paper "*Transmission Connected Dynamic Reactive Resources – Assessment of Applicability in Reliability Standards*".
Project Scope (Define the parameters of the proposed project):
Revise the "Applicability – Facilities" section, "Applicability – Functional Entities" section, and Requirements (including applicable attachments) as needed in PRC-024 reliability standard to comprehensively address all varieties of transmission-connected dynamic reactive resources that are utilized in providing ERS in the BES. The Project 2020-02 Standard Drafting Team will consider defining new terms (Glossary of Terms) and determine if revisions to PRC-024 are needed. In addition, they will coordinate revisions to other standards with the appropriate drafting teams MOD-026/027 (Project 2020-06) and PRC-019/MOD-025 (Project 2021-01).
Detailed Description (Describe the proposed deliverable(s) with sufficient detail for a drafting team to execute the project. If you propose a new or substantially revised Reliability Standard or definition, provide: (1) a technical justification[1]which includes a discussion of the reliability-related benefits of developing a new or revised Reliability Standard or definition, and (2) a technical foundation document (*e.g.* research paper) to guide development of the Standard or definition):
The "Applicability – Facilities" and "Applicability-Functional Entities" sections in PRC-024 reliability standard will be revised to address (non-generation) transmission-connected dynamic reactive resources based on the recommendations summarized in Table 1 of the SAMS white-paper "*Transmission Connected Dynamic Reactive Resources – Assessment of Applicability in Reliability Standards*". The white-paper also provides the technical justifications for the recommended revisions and the associated reliability benefits. Also modify Requirements (including applicable attachments) as needed to ensure they continue to address the additional Facilities. As needed, also define new Glossary Terms for all or some of the transmission-connected dynamic reactive devices noted as items 1.a – 1.j in the Additional Considerations section of the SAMS white-paper.
Cost Impact Assessment, if known (Provide a paragraph describing the potential cost impacts associated with the proposed project):
Unknown

[1] The NERC Rules of Procedure require a technical justification for new or substantially revised Reliability Standards. Please attach pertinent information to this form before submittal to NERC.

Requested information
Please describe any unique characteristics of the BES facilities that may be impacted by this proposed standard development project (*e.g*. Dispersed Generation Resources):
Synchronous condensers, HVDC Links (LCC or VSC), and power-electronics based transmission-connected reactive resources – also known as FACTS devices, such as Static Var Compensator (SVC), Static Synchronous Compensator (STATCOM).
To assist the NERC Standards Committee in appointing a drafting team with the appropriate members, please indicate to which Functional Entities the proposed standard(s) should apply (*e.g*. Transmission Operator, Reliability Coordinator, etc. See the most recent version of the NERC Functional Model for definitions):
Transmission Owners in addition to the existing Functional Entities
Do you know of any consensus building activities[2] in connection with this SAR? If so, please provide any recommendations or findings resulting from the consensus building activity.
"*Transmission Connected Dynamic Reactive Resources – Assessment of Applicability in Reliability Standards*" white-paper approved by SAMS members.
Are there any related standards or SARs that should be assessed for impact as a result of this proposed project? If so which standard(s) or project number(s)?
PRC-019 SAR requested by SPCS and PRC-024 SAR requested by IRPTF The Project 2020-02 Standard Drafting Team will consider defining new terms (Glossary of Terms) and determine if revisions to PRC-024 are needed. In addition, they will coordinate revisions to other standards with the appropriate drafting teams MOD-026/027 (Project 2020-06) and PRC-019/MOD-025 (Project 2021-01).
Are there alternatives (e.g. guidelines, white paper, alerts, etc.) that have been considered or could meet the objectives? If so, please list the alternatives.
No viable alternatives were found by SAMS.

Reliability Principles	
Does this proposed standard development project support at least one of the following Reliability Principles (Reliability Interface Principles)? Please check all those that apply.	
☒	1. Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk power systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☒	3. Information necessary for the planning and operation of interconnected bulk power systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk power systems shall be developed, coordinated, maintained and implemented.

[2] Consensus building activities are occasionally conducted by NERC and/or project review teams. They typically are conducted to obtain industry inputs prior to proposing any standard development project to revise, or develop a standard or definition.

Reliability Principles	
☒	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk power systems.
☐	6. Personnel responsible for planning and operating interconnected bulk power systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk power systems shall be assessed, monitored and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

Market Interface Principles	
Does the proposed standard development project comply with all of the following [Market Interface Principles]?	Enter (yes/no)
1. A reliability standard shall not give any market participant an unfair competitive advantage.	Yes
2. A reliability standard shall neither mandate nor prohibit any specific market structure.	Yes
3. A reliability standard shall not preclude market solutions to achieving compliance with that standard.	Yes
4. A reliability standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards.	Yes

SAR Type (Check as many as apply)			
☐ New Standard ☒ Revision to Existing Standard ☒ Add, Modify or Retire a Glossary Term ☐ Withdraw/retire an Existing Standard		☐ Imminent Action/ Confidential Issue (SPM Section 10) ☐ Variance development or revision ☐ Other (Please specify)	
Justification for this proposed standard development project (Check all that apply to help NERC prioritize development)			
☐ Regulatory Initiation ☐ Emerging Risk (Reliability Issues Steering Committee) Identified ☐ Reliability Standard Development Plan		☒ NERC Standing Committee Identified ☐ Enhanced Periodic Review Initiated ☐ Industry Stakeholder Identified	
Industry Need (What Bulk Electric System (BES) reliability benefit does the proposed project provide?):			
Dynamic reactive resources used to provide essential reliability services (ERS) in the BES include generation resources (rotating machine and inverter-based) as well as transmission connected dynamic reactive resources (power-electronics based). Existing reliability standards for verifying the capability, modeling and performance of dynamic reactive resources are only applicable to Facilities comprising generation resources. Augmenting the applicability of these standards to include (non-generation) transmission-connected reactive resources – both rotating machine (i.e. synchronous condenser) and			

Requested information
power-electronics based – will enhance the BES reliability by ensuring that the capability, models and performance is verified and validated for all varieties of dynamic reactive resources utilized in providing ERS in the BES.
Purpose or Goal (How does this proposed project provide the reliability-related benefit described above?):
Augment the "Applicability – Facilities" and "Applicability-Functional Entities" sections in ~~MOD-025, MOD-026, MOD-027, PRC-019 and~~ PRC-024 reliability standard~~s~~ to address (non-generation) transmission-connected dynamic reactive resources – both rotating machine (i.e. synchronous condenser) and power-electronics (e.g. Flexible AC Transmission System (FACTS) based. Also modify Requirements (including applicable attachments) as needed to ensure they continue to address the additional Facilities. As needed, also define new Glossary Terms for all or some of the transmission-connected dynamic reactive devices noted in the SAMS white-paper "*Transmission Connected Dynamic Reactive Resources – Assessment of Applicability in Reliability Standards*".
Project Scope (Define the parameters of the proposed project):
Revise the "Applicability – Facilities" section, "Applicability – Functional Entities" section, and Requirements (including applicable attachments) as needed in ~~MOD-025, MOD-026, MOD-027, PRC-019 and~~ PRC-024 reliability standard~~s~~ to comprehensively address all varieties of transmission-connected dynamic reactive resources that are utilized in providing ERS in the BES. The Project 2020-02 Standard Drafting Team will consider defining new terms (Glossary of Terms) and determine if revisions to PRC-024 are needed. In addition, they will coordinate revisions to other standards with the appropriate drafting teams MOD-026/027 (Project 2020-06) and PRC-019/MOD-025 (Project 2021-01).
Detailed Description (Describe the proposed deliverable(s) with sufficient detail for a drafting team to execute the project. If you propose a new or substantially revised Reliability Standard or definition, provide: (1) a technical justification[1] which includes a discussion of the reliability-related benefits of developing a new or revised Reliability Standard or definition, and (2) a technical foundation document (*e.g.* research paper) to guide development of the Standard or definition):
The "Applicability – Facilities" and "Applicability-Functional Entities" sections in ~~MOD-025, MOD-026, MOD-027, PRC-019 and~~ PRC-024 reliability standard~~s~~ will be revised to address (non-generation) transmission-connected dynamic reactive resources based on the recommendations summarized in Table 1 of the SAMS white-paper "*Transmission Connected Dynamic Reactive Resources – Assessment of Applicability in Reliability Standards*". The white-paper also provides the technical justifications for the recommended revisions and the associated reliability benefits. Also modify Requirements (including applicable attachments) as needed to ensure they continue to address the additional Facilities. As needed, also define new Glossary Terms for all or some of the transmission-connected dynamic reactive devices noted as items 1.a – 1.j in the Additional Considerations section of the SAMS white-paper.

[1] The NERC Rules of Procedure require a technical justification for new or substantially revised Reliability Standards. Please attach pertinent information to this form before submittal to NERC.

Requested information

Unofficial Nomination Form

Project 2020-02 Transmission-connected Dynamic Reactive Resources Generator Ride-through Standard (PRC-024-3 Replacement) Standard Drafting Team

Commented [A1]: The one-pager submitted to the SC states the nominations are for standard drafting team (not SAR DT) members. Please confirm which is correct.

Do not use this form for submitting nominations. Use the electronic form to submit nominations for standard drafting team (SDT) members by **8 p.m. Eastern, Thursday, July 14, 2022.** This unofficial version is provided to assist nominees in compiling the information necessary to submit the electronic form.

Additional information is available on the project page. If you have questions, contact Senior Standards Developer, Josh Blume (via email), or at 470-755-0346.

Background

The Standard Authorization Request (SAR) presented to the Standards Committee May 18, 2022 is meant to retire PRC-024-3 and replace it with a performance-based ride-through standard that ensures generators remain connected to the BPS during system disturbances. Specifically, the SAR focuses on the generator protection and control systems that can result in the reduction or disconnection of generating resources during these events. The SAR also ensures protection or controls that fail to ride through system events are analyzed, addressed with a corrective action plan (if possible), and reported to necessary entities for situational awareness. From a risk-based perspective, the goal of the standard is to mitigate the ongoing and systemic performance issues identified across multiple Interconnections and across many disturbances analyzed by NERC and the Regions. These issues have been identified in inverter-based resources as well as synchronous generators, with many causes of tripping entirely unrelated to voltage and frequency protection settings as dictated by the currently effective version of PRC-024.

Standard affected: PRC-024-3

Previous drafting or review team experience is beneficial, but not required. A brief description of the desired qualifications, expected commitment, and other pertinent information is included below.

SDT activities include participation in technical conferences, stakeholder communications and outreach events, periodic drafting team meetings and conference calls. Approximately one face-to-face meeting per quarter can be expected (on average three full working days each meeting) with conference calls scheduled as needed to meet the agreed-upon timeline the drafting team sets forth. NERC is seeking individuals who possess experience with PRC-024 implmentation and protective relay setting background or Generator Operator and Transmission Owner (owning dynamic reactive resources) experience.

By submitting a nomination form, you are indicating your willingness and agreement to actively participate in face-to-face meetings (held at the Atlanta, GA NERC offices) and conference calls.

Please briefly describe your experience and qualifications to serve on the requested SAR Drafting Team (Bio):	
If you are currently a member of any NERC drafting team, please list each team here: ☐ Not currently on any active SAR or standard drafting team. ☐ Currently a member of the following SAR or standard drafting team(s):	
If you previously worked on any NERC drafting team please identify the team(s): ☐ No prior NERC SAR or standard drafting team. ☐ Prior experience on the following team(s):	

Select each NERC Region in which you have experience relevant to the Project for which you are volunteering:		
☐ MRO ☐ NPCC ☐ RF	☐ SERC ☐ Texas RE ☐ WECC	☐ NA – Not Applicable

Select each Industry Segment that you represent:	
☐	1 — Transmission Owners
☐	2 — RTOs, ISOs
☐	3 — Load-serving Entities
☐	4 — Transmission-dependent Utilities
☐	5 — Electric Generators
☐	6 — Electricity Brokers, Aggregators, and Marketers
☐	7 — Large Electricity End Users
☐	8 — Small Electricity End Users
☐	9 — Federal, State, and Provincial Regulatory or other Government Entities
☐	10 — Regional Reliability Organizations and Regional Entities
☐	NA – Not Applicable

Select each Function[1] in which you have current or prior expertise:	
☐ Balancing Authority	☐ Transmission Operator
☐ Compliance Enforcement Authority	☐ Transmission Owner
☐ Distribution Provider	☐ Transmission Planner
☐ Generator Operator	☐ Transmission Service Provider
☐ Generator Owner	☐ Purchasing-selling Entity
☐ Interchange Authority	☐ Reliability Coordinator
☐ Load-serving Entity	☐ Reliability Assurer
☐ Market Operator	☐ Resource Planner
☐ Planning Coordinator	

[1] These functions are defined in the NERC Functional Model, which is available on the NERC web site.

Provide the names and contact information for two references who could attest to your technical qualifications and your ability to work well in a group:

Standards Announcement

Project 2020-02 Transmission-connected Dynamic Reactive Resources Generator Ride-through Standard (PRC-024-3 Replacement)

Drafting Team Nomination Period Open through July 14, 2022

Now Available

Nominations are being sought for standard drafting team members through **8 p.m. Eastern, July 14, 2022**.

Use the electronic form to submit a nomination. Contact Wendy Muller regarding issues using the electronic form. An unofficial Word version of the nomination form is posted on the Standard Drafting Team Vacancies page and the project page.

Previous drafting or review team experience is beneficial, but not required. A brief description of the desired qualifications, expected commitment, and other pertinent information is included below.

Standard drafting team activities include participation in technical conferences, stakeholder communications and outreach events, periodic drafting team meetings and conference calls. Approximately one face-to-face meeting per quarter can be expected (on average three full working days each meeting) with conference calls scheduled as needed to meet the agreed-upon timeline the drafting team sets forth. NERC is seeking individuals who possess experience with PRC-024 implementation and protective relay setting background or Generator Operator and Transmission Owner (owning dynamic reactive resources) experience.

By submitting a nomination form, you are indicating your willingness and agreement to actively participate in face-to-face meetings (held at the Atlanta, GA NERC offices) and conference calls.

Next Steps

The Standards Committee is expected to appoint members to the drafting team in August 2022. Nominees will be notified shortly after they have been appointed.

For more information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Standards Developer, Josh Blume (via email) or at 404-446-2593. Subscribe to this project's observer mailing list by selecting "NERC Email Distribution Lists" from the "Service" drop-down menu and specify “Project 2022-02 Transmission-connected Dynamic Reactive Resources observer list” in the Description Box.

Industry Need (What Bulk Electric System (BES) reliability benefit does the proposed project provide?):			
The ERO Enterprise has analyzed over 10 disturbances involving widespread loss of solar photovoltaic (PV) resources and has published multiple disturbance reports highlighting key findings and recommendations from these analyses. Across all events, a widespread loss of generating resources – solar PV, wind, synchronous generation, and battery energy storage systems (BESS) – have abnormally tripped, ceased current injection, or reduced power output with control interactions. Generator ride-through is a foundational essential reliability service. BPS-connected generating resources remaining connected during normal and contingency conditions is a critical component of BPS reliability. Ensuring fault ride-through capability enables dynamic reactive power support, frequency response, and other			

Requested information
services. The unexpected loss of widespread generating assets poses a significant risk to BPS reliability. The existing PRC-024-3 is an equipment settings standard focused solely on voltage and frequency protection. However, this standard is serving little to no value for ensuring BPS-connected inverter-based resources remain connected and supporting the BPS during grid disturbances. Furthermore, NERC has experienced multiple asset owners during the event analyses who have misconstrued PRC-024-3, resulting in incorrect or unnecessary protections applied to generating assets that have resulted in spurious and abnormal tripping events. The systemic tripping and reductions of inverter-based resources, in addition to notable concurrent tripping or performance from synchronous generating resources poses a risk to BPS reliability that must be addressed in a timely manner. This proposed standards project will address this known reliability risk with a more suitable performance-based standard that ensures generating resource ride-through performance for expected or planned BPS disturbances rather than focusing solely on a small subset of protections and controls that can trip generating resources.
Purpose or Goal (How does this proposed project provide the reliability-related benefit described above?):
The purpose of this SAR is to retire PRC-024-3 and replace it with a performance-based ride-through standard that ensures generators remain connected to the BPS during system disturbances. Specifically, this SAR focuses on the generator protection and control systems that can result in the reduction or disconnection of generating resources during these events. The SAR also ensures protection or controls that fail to ride through system events are analyzed, addressed with a corrective action plan (if possible), and reported to necessary entities for situational awareness. From a risk-based perspective, the goal of the standard is to mitigate the ongoing and systemic performance issues identified across multiple Interconnections and across many disturbances analyzed by NERC and the Regions. These issues have been identified in inverter-based resources as well as synchronous generators, with many causes of tripping entirely unrelated to voltage and frequency protection settings as dictated by the currently effective version of PRC-024.
Project Scope (Define the parameters of the proposed project):
The scope of this project includes the following: • Retire PRC-024-3, and create a new PRC standard or completely overhaul and replace the existing PRC-024 standard. • Creates a comprehensive, performance-based ride-through standard with the purpose of ensuring BES generating resources remain connected and providing essential reliability services during grid disturbances. • The scope of protections and controls involved in this ride-through standard shall include all generator protections and controls that affect the electrical output of the BES generating resource or plant. To be clear, the project should specify the protections and controls in scope of the ride-through performance and define the term ride-through, as necessary. This should, at a minimum, include all generator (synchronous or inverter-based) protections and controls at the individual

Requested information
generators, at the inverters, or within the plant (i.e., plant-level controls and protections or collector system protections). • The scope of the ride-through standard shall explicitly exclude auxiliary systems and their protection systems. Abnormal performance or unexpected tripping of these protections do not pose a systemic BES reliability risk. However, protections and controls directly focused on the generator and its prime mover (e.g., overspeed, power-load imbalance, overvoltage, phase jump, overcurrent) or plant-level (e.g., voltage, current, frequency, phase, etc.) have posed notable risks to BES reliability and should be addressed directly in this standard. • The new standard shall ensure that all unexpected or abnormal tripping or reductions in power output are reported by the GO to the TOP, BA, and RC.
-Detailed Description (Describe the proposed deliverable(s) with sufficient detail for a drafting team to execute the project. If you propose a new or substantially revised Reliability Standard or definition, provide: (1) a technical justification[1] which includes a discussion of the reliability-related benefits of developing a new or revised Reliability Standard or definition, and (2) a technical foundation document (*e.g.,* research paper) to guide development of the Standard or definition):
The following describe the proposed deliverable for this project: • The proposed deliverable is a new NERC standard (or significant overhaul and revision of PRC-024-3) that includes the following key elements: ▪ A performance-based approach to generator ride-through rather than an equipment settings standard. The new standard shall include requirements that BES resources shall ride through grid disturbances and include quantitative measures (see below) on expectations for ride-through that address all possible causes of tripping and power reductions from BES generating resources (particularly generator, turbine, inverter, and all plant-level protection and controls). ▪ A reporting requirement that all trips or reductions in power output are reported by the GO to the TOP, BA, and RC. ▪ A requirement that abnormal reductions in active power (i.e., tripping from protections or notable reductions from controls) are analyzed by the GO to develop a corrective action plan, if possible. Situations where corrective action plans are not able to be developed shall be reported to the TOP, BA, and RC. ▪ A clear requirement that momentary cessation, or temporary ceasing of current injection during BPS fault events, is deemed unacceptable performance for BES generating resources. Inverter-based generating resources employing momentary cessation shall develop a corrective action to mitigate its use. Legacy facilities prior to the effective date of the standard should receive an exemption; however, resources with a commercial operation date after the effective date of the standard (and possibly the PRC-024-3 implementation date) shall be

[1] The NERC Rules of Procedure require a technical justification for new or substantially revised Reliability Standards. Please attach pertinent information to this form before submittal to NERC.

Requested information

required to eliminate the use of momentary cessation within "ride through envelopes" (e.g., the existing PRC-024 "No Trip Zone").

- The terms ride-through, trip, momentary cessation, and any other relevant terms should be defined in the NERC Glossary of Terms, if deemed necessary.
- A clear requirement that prolonged plant controller interactions that impede the ability of the resource to dynamically respond to the grid disturbance and preclude the ability to fully provide essential reliability services are deemed unacceptable and should be addressed by a corrective action plan.
- A requirement that if the TOP, BA, or RC inform the GO of a tripping occurrence, cessation event, or plant controller interactions that are not reported by the GO, then the GO shall be responsible for analyzing the facility's performance during the event, developing a corrective action plan, and reporting this to the TOP, BA, and RC.

The technical justification regarding the reliability-related need and benefits of this project are described in extensive detail in multiple NERC disturbance reports. All widespread solar PV loss events analyzed by the ERO Enterprise have involved extensive tripping and causes of reduction that are largely not address by PRC-024-3, many of which are unrelated to voltage and frequency tripping entirely. Furthermore, these multiple events have also involved the loss of synchronous generators for various reasons that should be considered in the development activities of this proposed project. Key disturbance reports include:

- NERC 2021 California Disturbances Report (2022)
- NERC Odessa Disturbance Report (2021)
- NERC San Fernando Disturbance Report (2020)
- NERC Palmdale Roost and Angeles Forest Disturbances Report (2019)
- NERC Canyon 2 Fire Disturbance Report (2018)
- NERC Blue Cut Fire Disturbance Report (2017)

NERC Reliability Guideline: Improvements to Interconnection Requirements for BPS-Connected Inverter-Based Resources (2019), developed by the NERC Inverter-Based Resource Performance Working Group (IRPWG) and endorsed by the NERC Planning Committee, specifically recommends that all Transmission Owners (TOs) per FAC-001 establish or improve interconnection requirements by including quantitative requirements related to ride-through performance. Below is an excerpt from this guideline:

Quantitative requirements ensure that resources behave in a manner that supports BPS reliability and also assists the GOs and inverter manufacturers in specifying equipment to meet these requirements. These requirements may involve a performance envelope (FRT capability) that must be met by the resource, typically derived based on interconnection studies, grid codes, Reliability Standards, and other factors deemed necessary by the TO. Having these requirements ensures that the resources, particularly inverter-

Requested information
based resources, are unlikely to operate in a mode that has not been previously studied. Examples of these quantitative performance requirements include, but are not limited to, the following: • *Pre- and post-fault short-circuit strength (equivalent impedance or short-circuit ratio (SCR)-based metric)) for worst case contingency conditions* • *RMS low voltage ride-through and high voltage ride-through* • *Instantaneous transient overvoltage* • *Instantaneous change in phase angle* • *Low frequency ride-through and high frequency ride-through* • *No use of momentary cessation, by exception only* These deliverables developed by the ERO Enterprise and its stakeholder groups serve as a strong technical basis for ensuring resources successfully ride through grid disturbances and support the BPS by providing essential reliability services moving forward.
Cost Impact Assessment, if known (Provide a paragraph describing the potential cost impacts associated with the proposed project):
Incremental costs are expected for GOs that currently do not analyze the performance of their generating assets following grid disturbances, which has been shown during the NERC disturbance analyses to be a systemic reliability issue for solar PV resources in particular. GOs will need to assess their ride-through capabilities more comprehensively than in the past, which may have some associated costs. Minimal costs are associated with reporting of tripping occurrences. Facilities with abnormal or unexpected trips that can be mitigated with corrective actions will have some incremental costs; however, these improvements will help ensure adequate levels of reliability of the BES. Otherwise, cost impacts for this project are expected to be minimal.
Please describe any unique characteristics of the BES facilities that may be impacted by this proposed standard development project (*e.g.*, Dispersed Generation Resources):
BES generating resources.
To assist the NERC Standards Committee in appointing a drafting team with the appropriate members, please indicate to which Functional Entities the proposed standard(s) should apply (*e.g.*, Transmission Operator, Reliability Coordinator, etc. See the most recent version of the NERC Functional Model for definitions):
Generator Owners, Generator Operators, Reliability Coordinators, Transmission Operators, Transmission Owners, Transmission Planners, Planning Coordinators
Do you know of any consensus building activities[2] in connection with this SAR? If so, please provide any recommendations or findings resulting from the consensus building activity.

[2] Consensus building activities are occasionally conducted by NERC and/or project review teams. They typically are conducted to obtain industry inputs prior to proposing any standard development project to revise, or develop a standard or definition.

Requested information
This SAR is an outcome of ongoing analyses conducted by the ERO Enterprise regarding widespread inverter-based resource tripping events. Furthermore, the NERC IRPWG has developed comprehensive recommendations for improved performance of inverter-based resources, including the recommendation to develop comprehensive ride-through requirements.
Are there any related standards or SARs that should be assessed for impact as a result of this proposed project? If so, which standard(s) or project number(s)?
No.
Are there alternatives (e.g., guidelines, white paper, alerts, etc.) that have been considered or could meet the objectives? If so, please list the alternatives.
NERC has evaluated industry progress toward adopting the recommendations outlined in NERC guidelines, white papers, its prior Alerts, and other industry efforts. NERC believes that a nationwide standard for consistent requirements for generating resource ride-through is necessary to immediately address generating resource ride-through during grid disturbances moving forward.

Reliability Principles	
Does this proposed standard development project support at least one of the following Reliability Principles (Reliability Interface Principles)? Please check all those that apply.	
☒	1. Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk power systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☒	3. Information necessary for the planning and operation of interconnected bulk power systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk power systems shall be developed, coordinated, maintained and implemented.
☐	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk power systems.
☐	6. Personnel responsible for planning and operating interconnected bulk power systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk power systems shall be assessed, monitored and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

Market Interface Principles	
Does the proposed standard development project comply with all of the following Market Interface Principles?	Enter (yes/no)
1. A reliability standard shall not give any market participant an unfair competitive advantage.	Yes

Market Interface Principles	
2. A reliability standard shall neither mandate nor prohibit any specific market structure.	Yes
3. A reliability standard shall not preclude market solutions to achieving compliance with that standard.	Yes
4. A reliability standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards.	Yes

Identified Existing or Potential Regional or Interconnection Variances	
Region(s)/ Interconnection	Explanation

Project 2020-02 Transmission-connected Dynamic Reactive Resources Generator Ride-through Standard (PRC-024-3 Replacement) Standard Authorization Request

Do not use this form for submitting comments. Use the Standards Balloting and Commenting System (SBS) to submit comments on the **Generator Ride-through Standard (PRC-024-3 Replacement) Standard Authorization Request (SAR).** Comments must be submitted by **8 p.m. Eastern, Thursday, July 14, 2022.**

Additional information is available on the project page. If you have questions, contact Standards Developer, Josh Blume (via email), or at 470-755-0346.

Background Information

The Standard Authorization Request (SAR) presented to the Standards Committee May 18, 2022 is meant to retire PRC-024-3 and replace it with a performance-based ride-through standard that ensures generators remain connected to the BPS during system disturbances. Specifically, the SAR focuses on the generator protection and control systems that can result in the reduction or disconnection of generating resources during these events. The SAR also ensures protection or controls that fail to ride through system events are analyzed, addressed with a corrective action plan (if possible), and reported to necessary entities for situational awareness. From a risk-based perspective, the goal of the standard is to mitigate the ongoing and systemic performance issues identified across multiple Interconnections and across many disturbances analyzed by NERC and the Regions. These issues have been identified in inverter-based resources as well as synchronous generators, with many causes of tripping entirely unrelated to voltage and frequency protection settings as dictated by the currently effective version of PRC-024.

Standard affected: PRC-024-3

Questions

1. Do you agree with the proposed scope as described in the SAR? If you do not agree, or if you agree but have comments or suggestions for the project scope please provide your recommendation and explanation.

   ☐ Yes
   ☐ No

   Comments:

2. Provide any additional comments for the standard drafting team to consider, if desired.

   Comments:

Standards Announcement

Project 2020-02 Transmission-connected Dynamic Reactive Resources Generator Ride-through Standard (PRC-024-3 Replacement) | Standard Authorization Request

Formal Comment Period Open through July 14, 2022

Now Available

A 45-day formal comment period for the **Generator Ride-through Standard (PRC-024-3 Replacement) Standard Authorization Request** is open through **8 p.m. Eastern, Thursday, July 14, 2022**.

Commenting

Use the Standards Balloting and Commenting System (SBS) to submit comments. An unofficial Word version of the comment form is posted on the project page.

- *Contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern) for problems regarding accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out.*
- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*
- *Please be mindful of ballot and comment period closing dates. We ask to **allow at least 48 hours** for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts **prior to the last day** of a comment/ballot period.*

Next Steps

The drafting team will review all responses received during the comment period and determine the next steps of the project.

For more information or assistance, contact Standards Developer, Josh Blume (via email) or at 404-446-2593. Subscribe to this project's observer mailing list by selecting "NERC Email Distribution Lists" from the "Service" drop-down menu and specify “Project 2022-02 Transmission-connected Dynamic Reactive Resources observer list” in the Description Box.

AEP agrees with the concerns related to IBRs and the performance issues that have been previously noted but we do not agree that PRC-024 should be revised or replaced with ride-through obligations added for synchronous generation. AEP recommends that PRC-024 be retained as it currently is, and recommends creation of a new standard containing ride-through obligations for IBRs only. AEP does not see a reliability justification for developing ride-through obligations for synchronous generation and advises against any efforts to do so since, as also noted by EEI, such units have been seen to perform well in the various cited events.

The following comments are offered in the event that the SDT develops obligations for both synchronous generation and IBRs (contrary to our recommendation above).

The fourth bullet of the SAR's Project Scope states "protections and controls directly focused on the generator and its prime mover (e.g., overspeed, power-load imbalance, overvoltage, phase jump, overcurrent) or plant-level (e.g., voltage, current, frequency, phase, etc.) have posed notable risks to BES reliability." AEP does not agree with the proposed inclusion of overspeed and power-load imbalance, as both must be present to protect against equipment damage. Even if their presence could at times pose a reliability risk to the system, these protective functions need to be retained for the unit's own protection and continuing availability. AEP recommends removing overspeed and power-load imbalance from the SAR.

Requirement R3 in the current version of PRC-024 requires the Generator Owner to "document each known regulatory or equipment limitation that prevents an applicable generating unit with generator frequency or voltage protective relays from meeting the relay setting criteria in Requirements R1

or R2 including (but not limited to) study results, experience from an actual event, or manufacturer's advice." Care should be taken to retain this provision in any new or revised standard.

Comment	
The scope states generator overcurrent and plant-level current should be addressed in this standard. Overcurrent is addressed by PRC-025. It does not seem right to also include current in this standard. Other than the inclusion of overcurrent, the scope seems reasonable.

Comment	

The MRO NSRF in general agrees with both the concept and scope of this SAR. However, the MRO NSRF is voting no due to the following concerns:

1. *A reporting requirement that all trips or reductions in power output are reported by the GO to the TOP, BA, and RC.*

The MRO NSRF disagrees with this deliverable. The Reliability Coordinator (RC), Balancing Authority (BA) and Transmission Operator (TOP) should be responsible for determining the magnitude threshold and duration-of-time threshold for the Generator Owner (GO)/ Generator Operator (GOP) to report trips or reductions in power output. This will ensure that the RC, BA & TOP are not burdened by notifications for trips/reductions that do not affect the Bulk Electrical System (BES) and ultimately take the RC's, BA's & TOP's attention away from matters of higher priority for ensuring the reliability of the BES. In addition, it is the NSRF belief that the RC, BA & TOP currently has the ability request information about trips or reductions in power output from the GO/GOP under the regulatory framework of NERC Reliability Standard IRO-010-4 Reliability Coordinator Data Specification and Collection & NERC Reliability Standard TOP-003-4 - Operational Reliability Data.

Further, reductions in power will occur for a wide variety of reasons such as clouds passing over or the setting of the sun at a solar generation facility, a drop in wind speed at a wind generation facility, wet coal, changes in condenser circulating water temperature or discharge water temperature limits at a thermal plant, starting an additional large fan or pump, inlet air temperature changes to gas turbines, reduced water flow at a hydro plant – none of these causes of power reduction would have any relation to PRC requirements and no additional reporting other than that required by existing NERC

Standard IRO-010 & TOP-003 requirements should be necessary. The MRO NSRF believes this deliverable should say “A reporting requirement that all trips or reductions in power output in response to grid disturbances are reported by the GO as required by the applicable TOP, BA, and RC.”

2. *A requirement that abnormal reductions in active power (i.e., tripping from protections or notable reductions from controls) are analyzed by the GO to develop a corrective action plan, if possible. Situations where corrective action plans are not able to be developed shall be reported to the TOP, BA, and RC.*

The MRO NSRF disagrees with this deliverable. The MRO NSRF believes that the ‘trip’ portion of this deliverable is already an enforceable requirement under the regulatory framework of NERC Reliability Standard PRC-004-6 - Protection System Misoperation Identification and Correction.

As written, ‘*notable reductions from controls*’, lacks the detail required to provide a standard drafting team (SDT) with proper direction to develop a requirement(s). As this Standard Authorization Request (SAR) relates to dynamic ride-through performance of generators the MRO NSRF would request that the SAR SDT add an example magnitude threshold and duration-of-time threshold for ‘notable reductions from controls’. Adding the additional information will prevent any developed requirement(s) from overreaching beyond the intention of this SAR.

3. *A clear requirement that momentary cessation, or temporary ceasing of current injection during BPS fault events, is deemed unacceptable performance for BES generating resources. Inverter-based generating resources employing momentary cessation shall develop a corrective action to mitigate its use. Legacy facilities prior to the effective date of the standard should receive an exemption; however, resources with a commercial operation date after the effective date of the standard (and possibly the PRC-024-3 implementation date) shall be required to eliminate the use of momentary cessation within “ride through envelopes” (e.g., the existing PRC-024 “No Trip Zone”).*

The implementation date for NERC Reliability Standard PRC-024-3 — Frequency and Voltage Protection Settings for Generating Resources (NERC PRC-024-3) is October 01, 2022. As stated by the SAR requestors:

• “The existing PRC-024-3 is an equipment settings standard focused solely on voltage and frequency protection. However, this standard is serving little to no value for ensuring BPS-connected inverter-based resources remain connected and supporting the BPS during grid disturbances.”

• “The purpose of this SAR is to retire PRC-024-3 and replace it with a performance-based ride-through standard that ensures generators remain connected to the BPS during system disturbances.”

• “Retire PRC-024-3, and create a new PRC standard or completely overhaul and replace the existing PRC-024 standard.”

Based on these statements the MRO NSRF believes all generators with a commercial operation date prior to the effective date of requirements to be developed based on this SAR should not have to comply or retrofit. It is clear that any requirements developed based on this SAR will be different from the requirements of NERC PRC-024-3 and therefore the generators that need to comply should be adjusted accordingly.

4. The performance-based standard should include documented equipment limitation exemptions similar to NERC PRC-024-3 R3 and these should apply to all generator types rather than just carving out an exemption for the application of momentary cessation on legacy inverter-based resources (IBR) existing prior to the effective date of the standard (and possible the PRC-024-3 implementation date).   For example, if an existing turbine has frequency limitations that do not meet the requirements of the new ride-through standard, no corrective action plan should be necessary should the turbine trip in response to a frequency excursion outside of its capability. There appears to be nothing in the SAR that addresses limitations of existing equipment other than that of legacy IBRs applying momentary cessation.

5. The MRO NSRF believes that there is little justification for retiring NERC PRC-024-3 for synchronous generators and that any new standard should be focused on IBR performance issues. If the scope is to “create a comprehensive, performance-based ride-through standard with the purpose of ensuring BES generating resources remain connected and providing essential reliability services during grid disturbances”, why would only PRC-024-3 be considered for retirement rather than to include the retirement of other relay setting standards such as PRC-025-2, which has the purpose to assure that load responsive relays are set to prevent unnecessary tripping during system disturbances, and/or the elimination of GO applicability in PRC-026-1, which has the purpose to ensure that load-responsive relays are expected to not trip in response to stable power swings during non-Fault conditions? The MRO NSRF believes that if a truly comprehensive performance-based ride-through standard is created, then the regulatory burden of other relay setting standards pertaining to how generator protection responds to grid disturbances should be eliminated by retiring PRC-025-2 and eliminating the applicability of PRC-026-1 to Generator Owners. It seems that a comprehensive generator ride-through standard would apply to not only

24, 27, and 59 functions (PRC-024-3) but would also include trips of generating resources in response to 21, 50, 51, 51VR, 51VC, 67 (PRC-025-2) and/or 21, 40, ,50, 51, 78 (PRC-026-1) function operations in response to grid disturbances.

Further, and accounting for the aforementioned comments, the MRO NSRF recommends the drafting team consider whether retiring PRC-024-3 and replacing it with a performance-based ride-through standard may change, for example, the Generator no trip zones settings. This action would potentially affect PRC-006, and the SAR should open its scope to contemplate potential changes to that standard, and any other affected standard, if needed. This comment is to ensure the drafting team crafts a SAR with the necessary scoping parameters to make changes to associated standards as needed.

6. *A clear requirement that prolonged plant controller interactions that impede the ability of the resource to dynamically respond to the grid disturbance and preclude the ability to fully provide essential reliability services are deemed unacceptable and should be addressed by a corrective action plan.*

This requirement seems to be focused on eliminating some of the undesirable IBR performance issues, but the wording of this deliverable could be interpreted to apply to integrated plant or unit protection schemes that may indeed "impede the ability of the resource to dynamically respond to grid disturbances" but are designed to protect the boiler or nuclear reactor from pressure or level excursions, steam turbines from overspeed, operation at resonant frequencies or moisture intrusion, etc. GOs should be able to protect their equipment from catastrophic damage without having to implement a corrective action plan should these protection or control features impede dynamic response to grid disturbances.

Comment

We do not agree with the proposed scope described in the SAR, as more clarification of expectations and deliverables are needed. The proposed scope is not clear if the changes would require the installation of additional protection devices to our generators or switchyards and if additional DCS/computer points need to be monitored. Would the changes require third-party generator studies and at what frequency? We are concerned that these changes, which are still unclear, will require additional preventative tasks and specialized personnel necessary to perform these tasks. If the disturbance in the grid is large enough, wouldn't it be better for our generators to disconnect and/or trip to prevent equipment damage? A unit/generator restart would have a faster turnover and would be more efficient than having a damaged generator that motored because we couldn't disconnect it from the large disturbance of the grid.

In addition, it seems that we must wait until "performance" metrics are outlined and how metrics meet baseline criteria. The reference documents outline some of the criteria for measurement and submittal methods but not the full metric. The "ride through" criteria is mentioned, as a "no trip zone" in the attached document but not a clear definition of achieving that target. The process for defining the performance characteristics of a generation resources is not specified other than a system strength specification which we believe would require a separate criterion for each BES bus depending on the generation in the vicinity. It would be difficult to define and enforce and even more difficult to monitor.

The events in southern California revealed that generation went into a current cessation mode during a frequency/voltage excursion and PRC-024-3 covers this issue. The event would expand the scope from generation ride through to include any event where generation was reduced or removed from service for say auxiliary systems being removed from service. This subject might fall under PRC-004. If the tripping or reduction in generation is entirely unrelated to frequency or voltage, then we should have a separate standard that addresses this issue.

The deliverable noted is a requirement for reporting all trips and abnormal reductions in active power. In our experience most "abnormal" reductions are prime mover related. If it was intended to only require reporting an abnormal reduction or trip during a system disturbance only, it is not clear that this

deliverable is being met. We agree that generation outages due to frequency and voltage excursions should be tracked but the scope of the SAR goes well beyond that point. Why take a perfectly fine standard that addresses a known system issue and expand the scope into something that is not clearly defined. Consider expanding the scope of PRC-004 instead and include operations that affect the output of a BES Generation source and leave PRC-024-3 as a frequency and voltage ride through standard.

Pamela Hunter - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - SERC, Group Name Southern Company	
Answer	No
Document Name	
Comment	

Southern Company does not agree due to the following concerns:

1. *A reporting requirement that all trips or reductions in power output are reported by the GO to the TOP, BA, and RC.*

Southern Company disagrees with this deliverable. **The RC, BA, and TOP should be responsible parties for determining the magnitude threshold and duration-of-time thresholds GO/GOP to report trips or reductions in power output.** This will ensure that the RC, BA & TOP are not burdened by notifications for trips/reductions that do not affect the Bulk Electrical System (BES) and ultimately take their attention away from matters of higher priority for ensuring the reliability of the BES. In addition, it is the belief of Southern Company that **the RC, BA & TOP already has the ability request information about trips or reductions in power output from the GO/GOP under the regulatory framework of NERC Reliability Standard IRO-010-4 and TOP-003-4.**

2. *A requirement that abnormal reductions in active power (i.e., tripping from protections or notable reductions from controls) are analyzed by the GO to develop a corrective action plan, if possible. Situations where corrective action plans are not able to be developed shall be reported to the TOP, BA, and RC.*

Southern Company disagrees with this deliverable. **Southern Company believes that the ‘trip’ portion of this deliverable is already an enforceable requirement under the regulatory framework of NERC Reliability Standard PRC-004-6.**

As written, *‘notable reductions from controls’*, lacks the detail required to provide a standard drafting team (SDT) with proper direction to develop a requirement(s). **As this Standard Authorization Request (SAR) relates to dynamic ride-through performance of generators Southern Company requests that the SAR SDT add an example magnitude threshold and duration-of-time threshold for ‘notable reductions from controls’.** Adding the additional information will prevent any developed requirement(s) from overreaching beyond the intention of this SAR. The communication of unit derates, where necessary for system operation, is likely already being communicated where specified by the RC/BA/TOP data specifications of IRO-010 and TOP-003.

3. *A clear requirement that momentary cessation, or temporary ceasing of current injection during BPS fault events, is deemed unacceptable performance for BES generating resources.* Inverter-based generating resources employing momentary cessation shall develop a corrective action to mitigate its use. Legacy facilities prior to the effective date of the standard should receive an exemption; however, resources with a commercial operation date after the effective date of the standard (and possibly the PRC-024-3 implementation date) shall be required to eliminate the use of momentary cessation within “ride through envelopes” (e.g., the existing PRC-024 “No Trip Zone”).

The opening statement is contrary to real world expectations that the generation resource is not allowed to protect its equipment for BES system events. If this is the expectation, then the BES system should not be allowed to have fault events in the first place.

The implementation date for NERC Reliability Standard PRC-024-3 — Frequency and Voltage Protection Settings for Generating Resources (NERC PRC-024-3) is October 01, 2022. As stated by the SAR requestors:

• “The existing PRC-024-3 is an equipment settings standard focused solely on voltage and frequency protection. However, this standard is serving little to no value for ensuring BPS-connected inverter-based resources remain connected and supporting the BPS during grid disturbances.”

• “The purpose of this SAR is to retire PRC-024-3 and replace it with a performance-based ride-through standard that ensures generators remain connected to the BPS during system disturbances.”

• “Retire PRC-024-3, and create a new PRC standard or completely overhaul and replace the existing PRC-024 standard.”

Based on these statements Southern Company believes all generators with a commercial operation date prior to the effective date of requirements to be developed based on this SAR should not have to comply or retrofit. It is clear that any requirements developed based on this SAR will be different from the requirements of NERC PRC-024-3 and therefore the generators that need to comply should be adjusted accordingly.

4. The premise that there have been notable concurrent tripping or performance from synchronous generating resources due to frequency and voltage protection settings being too sensitive is flawed. There have not been increasing trends of synchronous machine protection system misoperations to justify that premise. The application of a ride through standard for synchronous machine generating plants was fully investigated during the original drafting effort of PRC-024 between 2008-2014. The conclusion of the standard drafting team, after multiple drafts, extended comment and consideration of comments from industry, direct consultation with FERC by standard drafting team members resulted in the realization that the standard could go no further than to specify a regions for restricting the tripping of those generators by protective relays for voltage-time and frequency-time areas that would cause the units to not be tripped for the majority of system events where the voltage or frequency was not normal. Further attempts to apply a ride through requirement should be abandoned for synchronous machines to avoid wasting everyone’s time by having to restate why it is not feasible for that generation type.

5. Further, there are limited modifications that can be made to the existing equipment to achieve the goal of 100% ride-thru ability to any grid disturbance. Simply passing a regulation specifying it must be done does not change the ability of the equipment to do so. The replacement of existing inverters is not feasible – the power ratings and voltage/current specifications of existing installed invertors do not match the inverters offered today. The collection system of a PV plant cannot be reconfigured economically once it is in place.

6. Any additional ride through requirements should only be applicable to equipment placed in service after changes are made to this standard which may require additional ride-thru capabilities for IBR plants. We suggest that the transmission interconnection agreements be the proper method to assure that newly connected IBR facilities are built to maximize their ride through capability.

7. The lack of a specific grid disturbance for which generating resources are to be required to ride-through is problematic. If specific disturbance characteristics are specified, the generating community might have a fighting chance to design systems to achieve the goals. The application of global “you must ride through all grid disturbance” requirements to existing equipment not designed to do so is ludicrous.

8. The SAR states that auxiliary systems and their protection systems are explicitly excluded. The sub-systems of a conventional synchronous machine generating station are essential for the normal plant operation. Without many of those sub-systems, the main generator cannot run. The sub-system may be essential to the mechanical operation of the turbine too. Any system disturbance that causes any of those sub-systems to not be available will immediately affect the turbine/generator ability to run. The controls of the generator and turbine are interlaced and interlinked with the sub-systems. They cannot be removed from affecting the entire unit operation. In effect, they cannot be separated from the generator and the unit availability. During system disturbances where sustained grid low voltage occurs, those sub-systems may or may not experience trouble. During the initial PRC-024 development, the Luminant company reported that some low voltage contactors dropped out for low voltage conditions, and others did not. In subsequent grid low voltage disturbances, it was observed that different sets of contactors dropped out. The indefinite response of magnetically sealed in contactor behavior for low voltage conditions was one of the problems with any meaningful successful application of ride-through standards to those types of facilities.

9. The SAR indicates that the desire of the standard revision is to address all possible causes of tripping and power reductions. Addressing ALL POSSIBLE CAUSES is indefinite and unachievable. No failsafe system can be built to withstand all possible causes.

10. With regard to the SAR question on alternatives, for which the SAR drafters included this text:

NERC has evaluated industry progress toward adopting the recommendations outlined in NERC guidelines, white papers, its prior Alerts, and other industry efforts. NERC believes that a nationwide standard for consistent requirements for generating resource ride-through is necessary to immediately address generating resource ride-through during grid disturbances moving forward.

Southern Company has implemented all possible inverter setting changes included in the two NERC alerts on the Loss of Solar Resources. We note that several of our units have continued to react to major grid disturbances by ceasing to generate. The communication of the adjustment of the settings, and the limitations to adjustments we have discerned, have been communicated to the parties included in the NERC alert recommendations. It is for this reason we implore the SDT to look forward rather than backward with change requirements. The electric grid is not in immediate imminent danger due to this current condition. The requirement of maximizing IBR equipment connectivity and grid disturbance resolution support is best addressed through the transmission interconnection requirements rather than through reliability standards.

Comment

Southern Indiana Gas and Electric Company d/b/a CenterPoint Energy Indiana South (SIGE) would like to thank the SAR Standards Drafting Team for the opportunity to provide feedback on Project 2020-02 “Transmission-connected Dynamic Reactive Resources Generator Ride-through Standard (PRC-024-3 Replacement).” SIGE does not agree with the proposed scope as described in the SAR and would request additional clarifications before agreeing to the proposed project.

Project 2020-02 describes a proposed deliverable of “A reporting requirement that all trips or reductions in power output are reported by the GO to the TOP, BA, and RC.” This phrasing should be specific to Protection Systems, as it is unclear at what point an entity is required to report. It should be defined whether reporting is required every time a unit trips due to any circumstance, or to which point reporting is required. For example, SIGE does not agree that reporting a trip due to weather should fall under the scope of this standard.

The use of phrasing within the existing PRC-024 standard, such as “No Trip Zone,” are beneficial because they are specific to Voltage and Frequency. These terms are needed to help regulate the standard.

SIGE does agree with the proposed deliverable of “a clear requirement that momentary cessation, or temporary ceasing of current injection during BPS fault events, is deemed unacceptable performance for BES generating resources.”

Michael Johnson - Pacific Gas and Electric Company - 1,3,5 - WECC, Group Name PG&E All Segments

Answer	No
Document Name	

Comment

PG&E agrees with the comments provided by EEI that there have been performance issues with Solar PV Inverter Based Resources (IBRs) that need to be addressed, but as indicated by EEI, PG&E does not agree the replacement of PRC-024-3 is required to address those issues.

The current PRC-024-2 Requirements have worked well for synchronous generators, and it is expected that PRC-024-3 will improve the performance of those generators in maintaining the reliable operation of the Bulk Electric System (BES). As noted by EEI, there were losses of synchronous generator in some of the six disturbances noted in the SAR, but none of those appeared to be unexpected, unusual, or a result of non-compliance with the current PRC-024 Standard.

PG&E personnel responsible for PRC-024 believe trying to add an entire set of additional Requirements for IBRs on top of the current PRC-024 Requirements, or changing the Standard to be performance based for all generators would be extremely complex to implement and maintain, and would not improve the reliability for synchronous generators. PG&E recommends IBR performance should be covered under a new Standard specifically developed for the unique characteristics of IBRs.

Christine Kane - WEC Energy Group, Inc. - 3,4,5,6, Group Name WEC Energy Group

Answer	No
Document Name	

Comment

WEC Energy Group is voting no due to the following concerns:

- "Purpose or Goal" section calls for complete replacement of PRC-024-3 to ensure generators remain connected during disturbances, but the "Industry Need" section clearly identifies this issue applies to IBR only. Industry can agree that current standard as is, is very well effective for traditional synchronous generating resources, therefore WEC believes that standard does not need to be rewritten but rather modified to cover specific IBR issues. WEC believes that statement "… notable concurrent tripping or performance from synchronous generating resources…" is not well supported by data from recent disturbances.
- Proposed "performance based" term needs to be better defined within the SAR.
- If industry recommendation is to include other protective elements or control systems, then it should be done separately and new standards should be developed. Good examples are PRC-025 and PRC-026.
- Some of the "possible causes of tripping and power reductions" listed in SAR are load responsive in nature, therefore should be addressed within existing Standards that cover load-responsive requirements.
- "Detailed Description" section indicates that momentary cessation is deemed unacceptable. Did the SAR requester confirm with all equipment manufacturers that momentary cassation can completely be eliminated? There are still inverter manufacturers that produce equipment with momentary cessation in their design because of current limiting components. The SAR suggest a corrective action plan to be developed to mitigate the issue. What if issue cannot be mitigated?

AZPS agrees with the following comments that were submitted by EEI on behalf of its members:

“The incidental operation of synchronous generators during some of the identified six NERC disturbance reports do not warrant the creation of a new ride through Reliability Standard replacing PRC-024-3 because the performance of most of the affected resources, outside of the solar PV resources, performed as designed and expected, and met the requirements of PRC-024-3.

While there were losses of synchronous generators in some of the six disturbance reports cited in the proposed SAR, none appear to be unexpected, unusual or the result of non-compliance with PRC-024”

“Additionally, if the intent of the SAR is to “create a comprehensive, performance-based ride-through standard,” development of a standard would need to account for retirement of other relay setting standards such as PRC-025-2 and PRC-026-1, to prevent duplicative requirements and compliance obligations.”

In describing the scope, the SAR states *"The scope of the ride-through standard shall explicitly exclude auxiliary systems and their protection systems. Abnormal performance or unexpected tripping of these protections do not pose a systemic BES reliability risk. However, protections and controls directly focused on the generator and its prime mover (e.g., overspeed, power-load imbalance, overvoltage, phase jump, overcurrent) or plant-level (e.g., voltage, current, frequency, phase, etc.) have posed notable risks to BES reliability and should be addressed directly in this standard."* However, auxiliary systems that in turn unexpectedly trip an entire plant pose a risk to reliability. While these systems should not be explicitly modeled, the OP, BA and RC should be in a position to understand when a facility will trip. As an absolute minimum, this information should be required from facilities currently being planned and installed.

The NAGF provides the following comments for consideration:

1. The NAGF believes that there is little justification for retiring PRC-024-3 for synchronous generators and that any new standard should be focused on IBR performance issues. Note that GOs have invested tremendous effort and money in achieving compliance with the PRC standards and are achieving the desired enhancement of BES reliability. Replacing them with something substantially different would require significant expenditures with no identifiable benefit. Any new standard should address only gaps in existing standards, as opposed to tearing down and rebuilding them.

2. Project Scope Comments:

a) Second Bullet: "Creates a comprehensive, performance-based ride-through standard with the purpose of ensuring BES generating resources remain connected and providing essential reliability services during grid disturbances."

The NAGF recommends that other relay-setting PRC standards be considered for retirement/modification beyond PRC-024-3. For example, PRC-025-2, which has the purpose to assure that load responsive relays are set to prevent unnecessary tripping during system disturbances, and PRC-026-1, which has the purpose to ensure that load-responsive relays are expected to not trip in response to stable power swings during non-Fault conditions. The NAGF believes that if a truly comprehensive performance-based ride-through standard is created, then the regulatory burden of other relay setting PRC standards pertaining to how generator protection responds to grid disturbances should be reviewed and incorporated. It seems that a comprehensive generator ride-through standard would apply to not only 24, 27, and 59 functions (PRC-024-3) but would also include trips of generating resources in response to 21, 50, 51, 51VR, 51VC, 67 (PRC-025-2) and/or 21, 40, ,50, 51, 78 (PRC-026-1) function operations in response to grid disturbances.

3. Detailed Description of Project Deliverables Comments:

a) Bullet #3: "A reporting requirement that all trips or reductions in power output are reported by the GO to the TOP, BA, and RC."

The NAGF believes that this statement is too vague or is stated imprecisely for this deliverable. Reductions in power will occur for a wide variety of reasons such as clouds passing over or the setting of the sun at a solar farm, a drop in wind speed, wet coal, changes in condenser circulating water temperature or discharge water temperature limits at a thermal plant, starting an additional large fan or pump, inlet air temperature changes to gas turbines, reduced water flow at a hydro plant – none of these causes of power reduction would have any relation to PRC requirements and no additional reporting other than that required by existing TOP requirements should be necessary. We believe this deliverable should be more focused, such as "A reporting requirement that all trips or reductions in power output in response to grid disturbances are reported by the GO to the TOP, BA, and RC."

b) Bullet #4: "A requirement that abnormal reductions in active power (i.e., tripping from protections or notable reductions from controls) are analyzed by the GO to develop a corrective action plan, if possible. Situations where corrective action plans are not able to be developed shall be reported to the TOP, BA, and RC."

The NAGF believes that such trip analysis and corrective actions are already addressed by PRC-004 and therefore this deliverable/requirement is redundant.

c) Bullet #5: "Legacy facilities prior to the effective date of the standard should receive an exemption; however, resources with a commercial operation date after the effective date of the standard (and possibly the PRC-024-3 implementation date) shall be required to eliminate the use of momentary cessation within "ride through envelopes" (e.g., the existing PRC-024 "No Trip Zone").

The NAGF supports the exemption for legacy IBR facilities. The NAGF recommends that the performance-based standard include documented equipment limitation exemptions similar to PRC-024-3 R3 and these should apply to all generator types rather than just carving out an exemption for the application of momentary cessation on legacy IBRs existing prior to the effective date of the standard (and possible the PRC-024-3 implementation date). For example, if an existing turbine has frequency limitations that do not meet the requirements of the new ride-through standard, no corrective action plan should be necessary should the turbine trip in response to a frequency excursion outside of its capability. There appears to be nothing in the SAR that addresses limitations of existing equipment other than that of legacy IBRs applying momentary cessation.

d) Bullet #7: "A clear requirement that prolonged plant controller interactions that impede the ability of the resource to dynamically respond to the grid disturbance and preclude the ability to fully provide essential reliability services are deemed unacceptable and should be addressed by a corrective action plan."

The NAGF is concerned with the potential ambiguity associated with this deliverable. This deliverable seems to be focused on eliminating some of the undesirable IBR performance issues, but the wording of this deliverable could be interpreted to apply to integrated plant or unit protection schemes that may indeed "impede the ability of the resource to dynamically respond to grid disturbances" but are designed to protect the boiler or nuclear reactor from pressure or level excursions, steam turbines from overspeed, operation at resonant frequencies or moisture intrusion, etc. Generator Owners should be able to protect their equipment from catastrophic damage without having to implement a corrective action plan should these protection or control features impede dynamic response to grid disturbances.

Comment

On the bottom of page 2, the SAR states: "The scope of protections and controls involved in this ride-through standard shall include all generator protections and controls that affect the electrical output of the BES generating resource or plant. To be clear, the project should specify the protections and controls in scope of the ride-through performance and define the term ride-through, as necessary."

Will the scope include requirements that developers/GOs of any new interconnection projects be required to provide protection and control models to the TO or PC? The SRC recommends that the SDT indicate all “protection and control equipment, including auxiliary equipment” that will affect the ride-through capabilities of the generator during disturbances. The SDT should identify the auxiliary systems that the ride-through should not affect.

On page 3, under Detailed Description, the SAR calls for “A requirement that abnormal reductions in active power (i.e., tripping from protections or notable reductions from controls) are analyzed by the GO to develop a corrective action plan, if possible. Situations where corrective action plans are not able to be developed shall be reported to the TOP, BA, and RC.”

This description reads much broader than what is described in the SAR purpose. In the purpose it is directed specifically towards “fail to ride through system events”. Is the intent of the SAR scope to create a requirement to report reductions in active energy which go beyond “fail to ride through system events” and include abnormal reductions of any cause? The SRC requests the SAR DT clarify the project scope.

On the bottom of page 3, the SAR states, “Legacy facilities prior to the effective date of the standard should receive an exemption; however, resources with a commercial operation date after the effective date of the standard.” We are concerned that there will be significant amounts of IBR facilities that will be exempt from these requirements. In addition, this seems to be at odds with the“all” language contained in the last bullet on the bottom of page 2 (and as mentioned in the SRC comments above).

In 2018, a SAR was introduced and denied by the Standards Committee to correct momentary cessation of IBRs that had no such exemption because of the risks existing facilities were causing on the BES. This SAR does not propose any solutions to address that risk. We recognize that there are some IBR installations which pre-date the technology to meet the SAR purpose. However there are already numerous amounts of IBRs in operation which can adopt new technology to meet the SAR’s purpose. A blanket exemption should not be a part of the standards and instead some form of exemption process should be utilized. Further between the time this standard may be complete and the time it takes effect due to the need for regulatory approval, which may be over two years. Numerous additional new installation of IBRs would become grandfathered which certainly can meet the ride through requirements. The SRC recommends exemptions be limited to technical infeasibility.

While EEI agrees in principal that that there have been performance issues, primarily with Solar PV Inverter Based Resources (IBRs), that need to be addressed, we do not support the retirement of PRC-024.

While there were losses of synchronous generators in some of the six disturbance reports cited in the proposed SAR, none appear to be unexpected, unusual or the result of non-compliance with PRC-024. As noted below, all of these six events linked within this SAR indicate solar PV performance problems, not synchronous generator problems.

Additionally, if the intent of the SAR is to "create a comprehensive, performance-based ride-through standard," development of a standard would need to account for retirement of other relay setting standards such as PRC-025-2 and PRC-026-1, to prevent duplicative requirements and compliance obligations.

For these reasons, we do not support the retirement of PRC-024-3. However, we offer an alternative approach in our response to question 2.

NERC 2021 California Disturbances Report (2022)

- June 24, 2021 – **Loss of 765MW of solar PV resources** (27 facilities) and 145MW of DERs (no synchronous resources lost).
- July 4, 2021 – **Loss of 605MW of solar PV resources** (33 facilities) and 46MW of DERs; 125MW; additionally, a single 125MW CT tripped due to two defective sensors as reported by the GO.
- July 28, 2021 – **Loss of 511MW of solar PV resources** (27 facilities) and 46MW of DERs (no synchronous resources lost).
- August 25, 2021 – **Loss of 583MW of solar PV resources** (30 facilities) and 212MW gas turbine tripped as a result of a correct operation of a RAS scheme. An additional gas turbine tripped during this event due to the failure of the excitation system (failed diodes). As stated in the report, the diodes were redundant but can only be detected during manual inspection. It is speculated that the redundant diodes failed as a result of the event, GO has indicated they will increase their inspections to avoid future failures.

NERC Odessa Disturbance Report (2021)

- May 9, 2021 Event – Initial fault occurred during CT startup testing when a surge arrester failed taking out one CT and causing another to run back for a total loss of 192MW. After this event **1112MW of solar PV output was lost**, in addition 36MW of output from 4 wind power plants.
- June 26, 2021 Event – Failed H-Frame structure causes the **loss of 518MW at 5 PV facilities**.

NERC San Fernando Disturbance Report (2020) July 7, 2020

- Static wire on a 230kV line failed causing the tripping of two lines on a double circuit tower. In addition, a nearby 230kV line relay mis operated. The result was the initial **loss of 205MW of solar PV output**. When trying to restore the lines, the second line tripped out causing the larger event, the **loss of 1000MW of solar PV output** (no synchronous resources lost).

NERC Palmdale Roost and Angeles Forest Disturbances Report (2019)

- April 20, 2018 (Angeles Forest) – A splice on a 500kV line failed causing a B-C phase fault which was cleared within 2.6 cycles. The fault caused the **loss of 860MW of solar PV output** in CAISO and 17MW in LADWP. In addition, a natural gas turbine tripped as a result of the fault. The report indicates the plan tripped on low fuel pressure causing the natural gas turbine to trip and the reduced output of a combined cycle steam generator to reduce output to 75MW for a total loss of 200MW. There was an additional loss of 130MW of DER output.
- May 11, 2018 (Palmdale Roost) – The disturbance was caused by a bird nest on a 500kV line that caused a line flashover (B phase to ground fault). As a result, there was a loss of **630MW of solar PV output in CAISO**, 48MW in LADWP and 33MW in IID. Additionally, there was 100MW of DER output lost (no indication of any synchronous generation lost during this event).

NERC Canyon 2 Fire Disturbance Report (2018)

- Canyon 2 Fire Disturbance, Oct. 9, 2017 – Two transmission lines faulted near Anaheim Hills, CA. The first fault occurred on a 220kV line at 12:12 PM and the second occurred at 12:14 PM on a 500kV line. The first fault resulted in the **reduction of 682MW of solar PV output**, which the second resulted in the **reduction of 937MW of solar PV output** (no indication that any synchronous generation was lost).

NERC Blue Cut Fire Disturbance Report (2017)

- On Aug. 16, 2016 AM the Blue Cut fire began in Cajon Pass, CA. As a result of the widespread fire SCE experience thirteen 500kV line faults and LADWP experienced two 287kV faults. Four of the fault events resulted in the **loss of 1,200MW of solar PV output** (no indication any synchronous generation was lost).

Ride-through is not a defined term in the NERC Glossary of Terms nor NPCC Glossary of Terms. The objective of the SAR is commendable, however the specific characteristics of the disturbances addressed by the new standard needs to be carefully defined. Usually the magnitude and duration of grid disturbances should be defined. Particular contingencies should be specified and studied to ensure those applicable reasonable foreseeable disturbances can be assessed and addressed.

Comment	

Regarding the 4th bullet in the “Project Scope” section, ERCOT believes the SAR should not exclude auxiliary systems that could impact the facility’s continued operation. The SDT should review the various types of auxiliary systems in use at in-scope facilities and determine whether to exclude any of them. ERCOT suggests revising the 4th bullet as follows:

This standard should address protections and controls directly focused on the generator and its prime mover (e.g., overspeed, power-load imbalance, overvoltage, phase jump, overcurrent) or at the plant level (e.g., voltage, current, frequency, phase, etc.) because they pose notable risks to BES reliability. The SDT will determine whether this ride-through standard may exclude auxiliary systems that do not impact the facility’s ability to maintain real and reactive power during a disturbance.

Regarding the 2nd sub-bullet in the “Detailed Description” section, ERCOT suggests the standard contain a requirement for a GO to report only trips or reductions in real power or improper reactive power response (trips or reductions within some threshold of the performance parameters established in the standard).

Regarding the 3rd sub-bullet in the “Detailed Description” section, ERCOT suggests clarifying the term “abnormal” to include trips and reductions in real power or improper reactive power response failing to meet the performance parameters established in the standard. Further, ERCOT suggests the SDT include a requirement for the GO to develop *and implement* a corrective action plan (CAP) or report to its TOP, BA and RC any CAP it cannot implement *due to technical infeasibility*. Finally, ERCOT suggests removing “if possible” because ERCOT’s proposed language (above) addresses situations where the GO cannot implement the CAP due to technical infeasibility.

Accordingly, ERCOT suggests modifying the 2nd and 3rd sub-bullets as follows:

- The proposed deliverable is a new NERC standard (or significant overhaul and revision of PRC-024-3) that includes the following key elements:
- ...

- A requirement for a GO to report to its TOP, BA and RC trips or reductions in real power or improper reactive power response (i.e., trips or reductions within a threshold of the performance parameters established in the standard).
- A requirement for a GO to: (a) analyze abnormal trips or reductions in real power or improper reactive power response (i.e., tripping from protections, notable reductions from controls, trips or reductions in real power or improper reactive power response failing to meet performance standards established in this standard); and (b) develop and implement a corrective action plan (CAP). If a GO cannot implement a CAP because it is not technical feasible to do so, the GO must report that fact to its TOP, BA, and RC.
- ...

Regarding the 4th sub-bullet in the "Detailed Description" section, ERCOT agrees with the SRC that the project should not exempt legacy facilities. Exempting legacy facilities will not address the reliability-related need this project addresses.

Please address and clearly explain the relationship between the two SARs ("Revision of relevant Reliability Standards to include applicability of transmission-connected dynamic reactive resources" approved in April, and "Generator Ride-Through Standard (PRC-024-3 Replacement)". Failure to provide this clarification will result in confusion between intents and requirements for different types of devices and may not clearly align with the earlier whitepapers and recommendations.

Additionally-please clarify that Synchronous Condensers, STATCOMs, SVCs and HVDC are not considered generator protection and control systems and should not be included in this standard. If Synchronous Condensers, STATCOMs, SVCs and HVDC are intended to be included in the standard, it needs to be revised to reflect that and include proper terminology, consideration of capability, and requirements specific to transmission-connected dynamic reactive power resources as opposed to generation resources.

Texas RE agrees with the need for this project to develop a comprehensive generator "ride-through" standard in lieu of the current PRC-024's focus solely on voltage and frequency protection settings. As the September 2021 Joint Odessa Disturbance Report for Texas Events on May 9, 2021 and June 26, 2021 ("Odessa Disturbance Report") highlighted, "the systematic nature of [Inverter-Based Resource tripping or cessation] events across multiple interconnections and a wide range of facilities, many of which are recently energized, warrants significant enhancements to the NERC Reliability Standards to address gaps in BES inverter-based resources." (Odessa Disturbance Report, at 29). These recommendations included the need for developing a new generator protection and control ride-through standard to replace the current PRC-024-3 to address continued examples of widespread tripping that are not addressed by the current PRC-024-3 requirements. Texas RE appreciates that the SAR provides an approach to capture the range of performance issues (PLL loss of synchronism, subcycle ac overvoltage protection, dc reverse current, and wind converter crowbar failures) that have resulted in widespread tripping incidents across a number of interconnections, including the ERCOT Interconnection. It further recommended that NERC do so on an expedited timeframe. Texas RE notes that this call of expedited action is even more pressing given the recent tripping of significant inverter-based resources in the ERCOT Interconnection earlier this year, continuing a pattern of generator performance issues in this area. NERC has highlighted grid transformation issues as the single greatest risk to grid reliability at the current time. Texas RE appreciates the SDT's important role, care, and commitment to addressing these performance issues in this project.

The Project 2020-02 webpage reflects that the initial project SAR, posted for industry comments on 3/30/2020, was revised and subsequently accepted by the NERC Standards Committee on 4/20/2022. A redline of the SAR accepted by the Standards Committee in April 2022 vs. the initial SAR posted in March 2020 is posted on the project page. It appears that a different Project 2020-02 SAR (prepared by NERC executives and staff) was presented to and accepted by the NERC Standards Committee a month later, on 5/18/2022. We suggest that a redline of the SAR accepted by the Standards Committee in May 2022 vs. the SAR accepted by the Standards Committee in April 2022 (or the initial SAR posted in March 2020) be added to the project page. It is not clear why the SAR submitted by the Chair of the System Analysis & Modeling Subcommittee and accepted by the Standards Committee in April 2022 was "abandoned" a month later to be replaced by the SAR submitted by NERC.

While FirstEnergy does agree that an assessment needs to be conducted to ensure reliability of the BES due to the changing mix of generating resources, we do not agree that a reliability standard should result in additional penalties for a GO if generating capacity requirements are not met due to a fuel shortage caused by unforeseen events. FirstEnergy generators already participate in the PJM capacity market and are required to provide generating capacity based on summer ICAP testing results. A generator is assessed financial penalties by PJM if it cannot meet its generating capacity requirements and therefore, we caution against a double jeopardy situation.

We also suggest the RC and BA, not the GO, should be responsible for developing a CAP if generation capacity demands are not met during periods of constrained resources. It is the responsibility of the Transmission Grid Operator (e.g., PJM), not the GO, to ensure that adequate generating resources are available during periods of constrained resources. Operating characteristics of IRBs are the cause of constrained resources and mitigation actions over-and-above PJM generating capacity requirements should not be placed on fossil generation resources.

Further, FirstEnergy supports EEI's comments, which states:

As an alternative to the proposed PRC-024 SAR, EEI suggests that a new SAR be developed to address performance issues specifically affecting IBRs. This new SAR could leverage key scope items from this proposed SAR to create a new performance- based NERC Reliability Standard that is focused on IBRs. As a suggested scope, we propose modifying this SAR as follows:

-- Trips or reductions in active power that occur because the IBR does not operate as expected (excludes cloud cover, setting sun, etc.), but not associated with protection system trips, (PRC-004 already addresses protection system tripping) are to be analyzed by the GO to develop a corrective action plan. Situations where an issue cannot be corrected, the GO shall develop a report detailing the limitations of the IBR and provide it to the responsible TOP, BA, and RC.

-- Momentary cessation, or temporary ceasing of current injection in response to grid disturbances, is deemed unacceptable for BES generating resources. Inverter-based generating resources employing momentary cessation shall develop a corrective action to mitigate its use unless the issue cannot be corrected. Legacy facilities prior to the effective date of the standard should receive an exemption; however, resources with a commercial operation date after the effective date of the standard shall be required to eliminate the use of momentary cessation during system transient disturbances where the system voltage or frequency falls within the "No Trip Zone" provided in PRC-024-3, which is subject to enforcement October 1, 2022.

-- Include the development of new terms to address terms specific to IBRs or where commonly used industry terms have created some confusion for IBR owners. E.g., No Trip Zone, trip, momentary cessation, and any other relevant terms that may require clarification within the NERC Glossary of Terms.

-- Prolonged IBR controller interactions that impede the ability of the resource to respond dynamically to the grid disturbance and preclude the ability to provide essential reliability services are deemed unacceptable and should be addressed by a corrective action plan. In situation where the GO has determined the issue cannot be corrected, a report shall be developed detailing the IBR limitation and provide it to the responsible TOP, BA and RC.

--If the TOP, BA, or RC inform the GO/IBR owner of a tripping occurrence, cessation event, or IBR controller interactions that are not reported or otherwise identified by the GO/IBR Owner, the responsible GO shall be responsible for analyzing the facility's performance during the event, developing a corrective action plan, and making this available to the TOP, BA, and RC or in the situation where the issue cannot be corrected, informing the TOP, BA and RC.

The current PRC-024-2, "No Trip Zone" is very clear and easy to understand for frequency and voltage parameters. The SAR Requesters' logic and SAR details appear to be pretty thorough, with the exception of replacing the "No Trip Zone" with "fault ride-through capabilities" as proposed in the revised SAR (dated 4/28/2022). We recommend the SAR Requesters/SAR Drafting Team expand on the proposal to eliminate "No Trip Zone" requirements, and expand the discussion regarding the replacement "fault ride-through capabilities".

The revised SAR language seems to suggest that synchronous generating resources suffer from mis-trips and mis-application of the standard due to deficiencies identified in PRC-024-3 to the same degree that inverter-based resources do. None of the six disturbance reports cited as technical justification for the SAR reference loss of synchronous generation caused by an inadequate or missing requirement within PRC-024-3. From a reliability perspective, while GO/GOPs of IBRs stand to benefit from a replacement/overhaul of PRC-024-3, there is no clear benefit to GO/GOPs of traditional synchronous generating resources. We recommend that the SAR language be revised to clearly delineate the current issues with synchronous generation resources and the current issues with IBRs driving this proposed standard modification, and how the changes are impacting each technology.

The proposed scope explicitly excludes auxiliary systems with the rationale that "abnormal performance or unexpected tripping of these protections do not pose a systemic BES reliability risk" (Page 3, "Project Scope", 4th bullet point). Components of auxiliary systems like unit auxiliary transformers (UATs) typically feature protection that are capable of taking a generator offline. Given this, there may be a heightened reliability risk if auxiliary equipment are not subject to the same requirements of the proposed standard as generator protection and controls. Auxiliary transformers (and BES GSUs) were added to the applicable equipment scope in the revision from PRC-024-2 to PRC-024-3, so an explanation is requested for why this inclusion is not being preserved.

ERCOT provides the following additional comments:

The SAR specifically identifies protections/controls posing risks to BES reliability. The proposed standard should not specify criteria for every potential quantity that may trigger a trip. Specifying voltage and frequency envelopes should suffice. Operating within those envelopes should not trigger any other plant control or protection to trip.

Not having high-resolution data limits the ability to identify the root cause of the events referenced in the SAR. High-resolution data, including data from phasor measurement units (PMUs), digital fault recorders (DFRs), and inverter-based oscillography, is critical to identify the root cause of disturbance events and, as such, necessary to develop a CAP. Additionally, high resolution data allows a better understanding of the interaction between local wind turbine ride-through control versus the facility plant controller. ERCOT believes this SAR should require data recording relating to voltage ride through and to add appropriate language to PRC-002-2.

Finally, ERCOT suggests the SDT consider IEEE 2800 when drafting a proposed standard.

If an attempt is made to define the ride through then it should consider the Bulk Electrical System (BES) as well as all the applicable/foreseeable generating resources that can potentially impact the BES.

A suggestion is made to use, consistently, just the Bulk Electrical System (BES) acronym and not to loosely interchange with BPS whose meaning is different than BES in the NPCC region (Bulk Power System as determined by Directory #1/A#10 methodology)

The SAR mentions that "Generator ride-through is a foundational essential reliability service.". To date the "ride-through" is not defined as a reliability service the same way we understand the following:

- **Frequency support** - provided through the combined interactions of synchronous inertia and frequency response, as services to arrest the decline in frequency and eventually return the frequency to the desired level
- **Ramping and Balancing** – provided through dispatch by the generating units with active power management capability and ability to respond to dispatch signals
- **Voltage Support** - provided through planning and confirmation testing of reactive power sufficiency per unique characteristics of their respective BA systems.

Having generating resources with ride-through capabilities are not a guarantee that the generating units will remain connected to the grid even less of a guarantee they will provide BES support (reliability services during BES disturbance) since BES support is also a:

- Function of static and dynamic reactive power reserve capabilities to regulate voltage at those respective points in the system
- Function of levels of conventional synchronous inertia for respective balancing area/interconnection, and initial frequency deviation following the largest contingency event for the interconnection

This SAR should only be applicable to the protection/protective functions that trip the protected equipment in response to a BES disturbance, where the disturbance conditions do not pose a risk of damage to the associated equipment, whose protection must be prioritized (similar with PRC-025-2).

Equipment protection does not amount nor have a simultaneous compounded effect on grid reliability.

The SAR statement related to the cost impact associated to this Project being expected to be minimal, should not be treated as an accurate statement as long as the entire scope of the project has not even been identified.

The current PRC-024 standard was written with conventional (rotating) generators in mind. Conventional generators are quite sensitive to generator speed (frequency) and abnormal speeds can damage, i.e. lower the life of, turbine blades. Hence the further away the frequency deviates from 60 Hz, the shorter the duration allowed for “no-trip.” In contrast, Inverter-Based Resources (IBRs) don’t have rotating parts whose speed is tied to their connection to the grid. Since IBRs are not affected by deviations in system frequency as much as conventional (rotating) generators, the SRC requests the PRC-024 SAR be revised to include a recognition for this difference as there may be different ride-through requirements for IBRs than conventional generators within the same interconnection.

In addition, to aid in industry implementation, the SRC requests the SAR include the requirement to provide some real-world examples; e.g. in Technical Rationale, to illustrate how proposed standard requirements will ensure both IBRs and conventional generators are able to ride-through faults and how, had they been in place, would have addressed past issues of inadequate ride-through capability.

Finally, the SRC requests that the SAR ask to expand the requirement in selecting a Standards Drafting Team (SDT) that is stated in Question 5 on the SAR form. The SRC agrees it is important to include entities that the standard will apply to, but in addition, entities who have a need for the information or bear responsibility to reliably operate within the bounds of the standard (even if the standard does not directly apply to them from a requirement and compliance standpoint), should also be included. The requirements set in any standard are intended to ensure the reliability of the BES as a whole which all registered entity functions have an impact or interest in. This should apply to any and all SARs and the SRC would like to ask NERC to address a change in the SAR form in the future.

Comment

Below are proposed changes for the "proposed deliverable" section of the SAR.

The proposed deliverable is a new NERC standard (or significant overhaul and revision of PRC-024-3) that includes the following key elements:

A performance-based approach to generator ride-through rather than an equipment settings standard. The new standard shall include requirements that BES resources shall ride through grid disturbances and include quantitative measures (see below) on expectations for ride-through that address all possible causes of tripping and power reductions from BES generating resources (particularly generator, turbine, inverter, and all plant-level protection and controls, including auxiliary systems).

A reporting requirement that all trips or abnormal reductions in power output are reported by the GO to the TOP, BA, and RC.

A requirement that abnormal reductions in active power (i.e., tripping from protections or notable reductions from controls) are analyzed by the GO and shall be reported to the TOP, BA, and RC.

The stated purpose of this SAR is to retire PRC-024-3 and replace it with a performance-based ride-through standard that ensures generators remain connected to the BPS during system disturbances. Additionally, the SAR will focus on the generator protection and control systems that can result in the reduction or disconnection of generating resources during these events.

As part of the development of the performance based standard or overhaul of PRC-024-3, it is recommended that the standard drafting team include and highlight specific references to the relevant IEEE Standard P2800-2022 clauses and to relevant FERC Orders (related to ride-through), where applicable. It will be important for stakeholders to discern similarities and differences between the new or revamped standard and these existing references.

We can offer another comment, related to PRC-024-3, for consideration in the development of a performance based standard or overhaul of PRC-024-3.

For PRC-024-3 applicability section 4.1.2, it mentions that it is for Transmission Owners in the Quebec Interconnection only. There are Transmission Owners outside the Quebec Interconnection that own BES generator step-up transformers (GSUs). Is PRC-024-3 intended to be applicable to Transmission Owners that own BES GSUs that are outside the Quebec Interconnection? If so, perhaps the "in the Quebec Interconnection only" should be removed from applicability section 4.1.2 in the next revision.

Comment	

Southern Company disagrees with the "Cost Impact Assessment". We feel that generation resources will need to install high speed recorders to capture data on electrical events that occur and the reaction of generation resources to said electrical event. These high speed recorders will be essential for any requirement for analysis and development of corrective action plans. Southern Company purports that it will be costly to engineer, procure and install this equipment.

Noting that IBR components capable of providing the performance characteristics are just now beginning to be developed and offered by vendors coupled with regulatory requirements for providing that performance will certainly cause equipment suppliers to increase costs to the users.

With the cause of the concern raised in this SAR being the system disturbance, perhaps a more beneficial result can be achieved by investigating the causes of the system disturbances that have been resulting in natural responses of the IBR and synchronous machine based generating stations. Our experience has been that most of the existing IBR systems that operate perfectly given a network with no disturbances.

The recent development and adoption of IEEE P2800 (Standard for Interconnection and Interoperability of Inverter-Based Resources Interconnecting with Associated Transmission Electric Power Systems) is nowhere to be found in the SAR as a resource. It is Southern Company's opinion that IEEE P2800 be fully understood and used by the SDT as a resource of what operational capability limits exist for IBRs. P2800 goes into many of the aspects that IBRs face from a performance perspective. A common issue with IBRs is loss of synchronism because of the voltage phase angle jump that can occur with system disturbances. A voltage phase angle shift jump can occur with the voltage magnitudes still within the no-trip zone, leading to momentary cessation because of loss synchronism of the IBRs synchronizing phase-locked loop control function.

The Functional Entities identified in the PRC-024 standard have no control what-so-ever of the design and performance characteristics of the Inverter Based Resource manufacturers equipment. This leads to GOs attempting to coerce the IBR manufactures after-the-fact to change equipment settings and parameters to comply with operational situations that they are either not designed to perform to or, due to the technical nature of the IBR generation process, cannot perform to. To move to a performance based standard and holding the GO accountable for the design performance of the IBRs is futile at best. The only performance criteria defined in the SAR so far is impossible for all situations, and that is “A clear requirement that momentary cessation, or temporary ceasing of current injection during BPS fault events, is deemed unacceptable performance for BES generating resources”.

Momentary Cessation Requirements for Existing Generators

While Texas RE appreciates the proposed SAR's focus on generator performance issues in general and momentary cessation issues in particular, Texas RE is concerned that the current proposed SAR would exempt facilities in commercial operation prior to the effective date of the new PRC-024-3 requirements from "the use of momentary cessation within 'ride through envelopes' (e.g., the existing PRC-024 "No Trip Zone"). (PRC-024 Standard Authorization Request, at 3-4). The Odessa Disturbance Report observed that momentary cessation issues resulted in generation loss, along with tripping issues inside of facilities during the event (Odessa Disturbance Report, at 7). In particular, the Odessa Disturbance Report noted: "legacy inverter momentary cessation setting with plant-level controller interactions prohibited quick active power recovery." (Odessa Disturbance Report, at 33). The report also noted other forms of momentary cessation issues, including settings that produced fixed reactive power injection with "no ability to control voltage post-contingency." (Odessa Disturbance Report, at 20). It further noted that "[t]his type of behavior was not known by ERCOT prior to the event analysis nor is this type of behavior supporting the BPS post-fault." (Id.).

Given the significance of these momentary cessation issues during the Odessa Disturbance event and other events over the past six years, Texas RE encourages the SDT to not limit momentary cessation performance requirements exclusively to new generation facilities. While Texas RE expects the SDT to move expeditiously with this project, Texas RE notes that the final revised standard may not be effective for several years. As a result, not only would existing generators not be covered by any momentary cessation requirements, but a number of planned generation resources would be similarly exempt. Given the growing role of inverter-based resources in the ERCOT Interconnection and others, this could result in a significant reliability gap.

Texas RE notes that momentary cessation issues are currently documented in NERC Reliability Guidelines (E.g., Reliability Guideline: BPS-Connected Inverter-Based Resource Performance (Sept. 2018) (2018 IBR Performance Guidelines). These existing guidelines note that "Existing and newly interconnecting inverter-based resources should eliminate the use of momentary cessation to the greatest possible extent." (2018 IBR Performance Guidelines, at 11). It is also important to note that one of the key findings in the Odessa Disturbance Report is that while these reliability guidelines are widely viewed and shared, entities are "not comprehensively adopting the recommendation(s) contained in those materials." (Odessa Disturbance Report, at vi). In short, a new Reliability Standard is required.

Texas RE acknowledges it may take time to review and implement settings to avoid certain momentary cessation-type performance issues. As the 2018 IBR Performance Guidelines note, however: "Existing resources may have hardware and/or software limitations based on a design philosophy using momentary cessation, and it may not be feasible to eliminate its use. For equipment limitations that cannot be addressed, PRC-024-2 Requirement R3.1 states that '[t]he [GO] shall communicate the documented regulatory or equipment limitation, or the removal of a previously documented regulatory or equipment limitation, to its Planning Coordinator and Transmission Planner within 30 calendar days.'" (2018 IBR Performance Guidelines, at 11-2). The drafting team could consider approaches that permit legacy systems lacking functionality to avoid momentary cessation issues to document those limitations for any new momentary cessation requirements developed in this project in a manner similar to the process currently provided in the existing PRC-024-3 Requirement R3.1.

Enhanced Communication Requirements

In addition to considering the incorporation of momentary cessation and other performance notification requirements as appropriate, Texas RE recommends the drafting team consider creating a new requirement for the GO to notify the GOP, in addition to the TOP, BA, and RC, regarding abnormal tripping. Since COM-001 and COM-002 do not include GO communications, an additional requirement for the GO to notify the GOP would be helpful for the GOP to have the information to communicate any GO issues via COM-001 and COM-002.

All protection and control system functions that will be in scope should be specifically listed in the standard. Guidance on complying with ride-through requirements should be provided by including detailed examples. A sufficient phase-in period should be part of the implementation plan to allow GOs time to achieve the additional coordination that will be required. Based on the defined project scope the new standard will enforce that unexpected trips, abnormal trips and reductions in power are reported to the pertinent entities. The term reduction of power needs to be defined since it is open for interpretation. Furthermore, this reporting-out could infringe on current standards like PRC-004.

If you feel that your comment has been overlooked, let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, contact Director, Standards Development Latrice Harkness (via email) or at (404) 858-8088.

Questions

1. Do you agree with the proposed scope as described in the SAR? If you do not agree, or if you agree but have comments or suggestions for the project scope, please provide your recommendation and explanation.

2. Provide any additional comments for the drafting team to consider, if desired.

The Industry Segments are:

1 — Transmission Owners

2 — RTOs, ISOs

3 — Load-serving Entities

4 — Transmission-dependent Utilities

5 — Electric Generators

6 — Electricity Brokers, Aggregators, and Marketers

7 — Large Electricity End Users

8 — Small Electricity End Users

9 — Federal, State, Provincial Regulatory or other Government Entities

10 — Regional Reliability Organizations, Regional Entities

Comment	

AEP agrees with the concerns related to IBRs and the performance issues that have been previously noted but we do not agree that PRC-024 should be revised or replaced with ride-through obligations added for synchronous generation. AEP recommends that PRC-024 be retained as it currently is, and recommends creation of a new standard containing ride-through obligations for IBRs only. AEP does not see a reliability justification for developing ride-through obligations for synchronous generation and advises against any efforts to do so since, as also noted by EEI, such units have been seen to perform well in the various cited events.

The following comments are offered in the event that the SDT develops obligations for both synchronous generation and IBRs (contrary to our recommendation above).

The fourth bullet of the SAR's Project Scope states "protections and controls directly focused on the generator and its prime mover (e.g., overspeed, power-load imbalance, overvoltage, phase jump, overcurrent) or plant-level (e.g., voltage, current, frequency, phase, etc.) have posed notable risks to BES reliability." AEP does not agree with the proposed inclusion of overspeed and power-load imbalance, as both must be present to protect against equipment damage. Even if their presence could at times pose a reliability risk to the system, these protective functions need to be retained for the unit's own protection and continuing availability. AEP recommends removing overspeed and power-load imbalance from the SAR.

Requirement R3 in the current version of PRC-024 requires the Generator Owner to "document each known regulatory or equipment limitation that prevents an applicable generating unit with generator frequency or voltage protective relays from meeting the relay setting criteria in Requirements R1 or R2 including (but not limited to) study results, experience from an actual event, or manufacturer's advice." Care should be taken to retain this provision in any new or revised standard.

Response	

Thank you for the comment. The SAR has the option to create a new standard. This (and R3) will be passed along for consideration by standard drafting team. The team has addressed this comment in the redlined SAR to reflect the suggested changes.	
Eric Sutlief - CMS Energy - Consumers Energy Company - 3,4,5 - RF	
Answer	No
Document Name	
Comment	
The scope states generator overcurrent and plant-level current should be addressed in this standard. Overcurrent is addressed by PRC-025. It does not seem right to also include current in this standard. Other than the inclusion of overcurrent, the scope seems reasonable.	
Likes 0	
Dislikes 0	
Response	
Thank you for the comment. The team agrees that there is possible overlap with PRC-025 if overcurrent related trips are included in the ride-through standard. As such, the team has modified the SAR to reflect the fact that PRC-025, and other selected relay setting standards, may be impacted by the new standard and may need to be revised.	
Kendra Buesgens - MRO - 1,2,3,4,5,6 - MRO

Comment	
The MRO NSRF in general agrees with both the concept and scope of this SAR. However, the MRO NSRF is voting no due to the following concerns: 1. *A reporting requirement that all trips or reductions in power output are reported by the GO to the TOP, BA, and RC.*	

The MRO NSRF disagrees with this deliverable. The Reliability Coordinator (RC), Balancing Authority (BA) and Transmission Operator (TOP) should be responsible for determining the magnitude threshold and duration-of-time threshold for the Generator Owner (GO)/ Generator Operator (GOP) to report trips or reductions in power output. This will ensure that the RC, BA & TOP are not burdened by notifications for trips/reductions that do not affect the Bulk Electrical System (BES) and ultimately take the RC's, BA's & TOP's attention away from matters of higher priority for ensuring the reliability of the BES. In addition, it is the NSRF belief that the RC, BA & TOP currently has the ability request information about trips or reductions in power output from the GO/GOP under the regulatory framework of NERC Reliability Standard IRO-010-4 Reliability Coordinator Data Specification and Collection & NERC Reliability Standard TOP-003-4 - Operational Reliability Data.

Further, reductions in power will occur for a wide variety of reasons such as clouds passing over or the setting of the sun at a solar generation facility, a drop in wind speed at a wind generation facility, wet coal, changes in condenser circulating water temperature or discharge water temperature limits at a thermal plant, starting an additional large fan or pump, inlet air temperature changes to gas turbines, reduced water flow at a hydro plant – none of these causes of power reduction would have any relation to PRC requirements and no additional reporting other than that required by existing NERC Standard IRO-010 & TOP-003 requirements should be necessary. The MRO NSRF believes this deliverable should say "A reporting requirement that all trips or reductions in power output in response to grid disturbances are reported by the GO as required by the applicable TOP, BA, and RC."

2. *A requirement that abnormal reductions in active power (i.e., tripping from protections or notable reductions from controls) are analyzed by the GO to develop a corrective action plan, if possible. Situations where corrective action plans are not able to be developed shall be reported to the TOP, BA, and RC.*

The MRO NSRF disagrees with this deliverable. The MRO NSRF believes that the 'trip' portion of this deliverable is already an enforceable requirement under the regulatory framework of NERC Reliability Standard PRC-004-6 - Protection System Misoperation Identification and Correction.

As written, '*notable reductions from controls*', lacks the detail required to provide a standard drafting team (SDT) with proper direction to develop a requirement(s). As this Standard Authorization Request (SAR) relates to dynamic ride-through performance of generators the MRO NSRF would request that the SAR SDT add an example magnitude threshold and duration-of-time threshold for 'notable reductions from controls'. Adding the additional information will prevent any developed requirement(s) from overreaching beyond the intention of this SAR.

3. *A clear requirement that momentary cessation, or temporary ceasing of current injection during BPS fault events, is deemed unacceptable performance for BES generating resources. Inverter-based generating resources employing momentary cessation shall*

develop a corrective action to mitigate its use. Legacy facilities prior to the effective date of the standard should receive an exemption; however, resources with a commercial operation date after the effective date of the standard (and possibly the PRC-024-3 implementation date) shall be required to eliminate the use of momentary cessation within “ride through envelopes” (e.g., the existing PRC-024 “No Trip Zone”).

The implementation date for NERC Reliability Standard PRC-024-3 — Frequency and Voltage Protection Settings for Generating Resources (NERC PRC-024-3) is October 01, 2022. As stated by the SAR requestors:

• “The existing PRC-024-3 is an equipment settings standard focused solely on voltage and frequency protection. However, this standard is serving little to no value for ensuring BPS-connected inverter-based resources remain connected and supporting the BPS during grid disturbances.”

• “The purpose of this SAR is to retire PRC-024-3 and replace it with a performance-based ride-through standard that ensures generators remain connected to the BPS during system disturbances.”

• “Retire PRC-024-3, and create a new PRC standard or completely overhaul and replace the existing PRC-024 standard.”

Based on these statements the MRO NSRF believes all generators with a commercial operation date prior to the effective date of requirements to be developed based on this SAR should not have to comply or retrofit. It is clear that any requirements developed based on this SAR will be different from the requirements of NERC PRC-024-3 and therefore the generators that need to comply should be adjusted accordingly.

4. The performance-based standard should include documented equipment limitation exemptions similar to NERC PRC-024-3 R3 and these should apply to all generator types rather than just carving out an exemption for the application of momentary cessation on legacy inverter-based resources (IBR) existing prior to the effective date of the standard (and possible the PRC-024-3 implementation date). For example, if an existing turbine has frequency limitations that do not meet the requirements of the new ride-through standard, no corrective action plan should be necessary should the turbine trip in response to a frequency excursion outside of its capability. There appears to be nothing in the SAR that addresses limitations of existing equipment other than that of legacy IBRs applying momentary cessation.

5. The MRO NSRF believes that there is little justification for retiring NERC PRC-024-3 for synchronous generators and that any new standard should be focused on IBR performance issues. If the scope is to “create a comprehensive, performance-based ride-through standard with the purpose of ensuring BES generating resources remain connected and providing essential reliability services during grid disturbances”, why would only PRC-024-3 be considered for retirement rather than to include the retirement of other relay setting

standards such as PRC-025-2, which has the purpose to assure that load responsive relays are set to prevent unnecessary tripping during system disturbances, and/or the elimination of GO applicability in PRC-026-1, which has the purpose to ensure that load-responsive relays are expected to not trip in response to stable power swings during non-Fault conditions? The MRO NSRF believes that if a truly comprehensive performance-based ride-through standard is created, then the regulatory burden of other relay setting standards pertaining to how generator protection responds to grid disturbances should be eliminated by retiring PRC-025-2 and eliminating the applicability of PRC-026-1 to Generator Owners. It seems that a comprehensive generator ride-through standard would apply to not only 24, 27, and 59 functions (PRC-024-3) but would also include trips of generating resources in response to 21, 50, 51, 51VR, 51VC, 67 (PRC-025-2) and/or 21, 40, ,50, 51, 78 (PRC-026-1) function operations in response to grid disturbances.

Further, and accounting for the aforementioned comments, the MRO NSRF recommends the drafting team consider whether retiring PRC-024-3 and replacing it with a performance-based ride-through standard may change, for example, the Generator no trip zones settings. This action would potentially affect PRC-006, and the SAR should open its scope to contemplate potential changes to that standard, and any other affected standard, if needed. This comment is to ensure the drafting team crafts a SAR with the necessary scoping parameters to make changes to associated standards as needed.

6. *A clear requirement that prolonged plant controller interactions that impede the ability of the resource to dynamically respond to the grid disturbance and preclude the ability to fully provide essential reliability services are deemed unacceptable and should be addressed by a corrective action plan.*

This requirement seems to be focused on eliminating some of the undesirable IBR performance issues, but the wording of this deliverable could be interpreted to apply to integrated plant or unit protection schemes that may indeed “impede the ability of the resource to dynamically respond to grid disturbances” but are designed to protect the boiler or nuclear reactor from pressure or level excursions, steam turbines from overspeed, operation at resonant frequencies or moisture intrusion, etc. GOs should be able to protect their equipment from catastrophic damage without having to implement a corrective action plan should these protection or control features impede dynamic response to grid disturbances.

Response

1. The applicability of the defining of a thresh hold will be considered where applicable when drafting the standard in the performance criteria. The SAR has been has been modified to reflect this quote. The information will be passed along to the standard drafting team.
2. The team will look at PRC-004 and make sure there is no overlap, this SAR focusing on performance criteria IBRs. Thank you for the proposal this will be reviewed in the standard drafting process when applicable.
3. This will be passed on to the drafting team, please refer to NAGF response to comment regarding legacy PRC-024 policy.
4. Refer to previous comment.
5. The team has considered the comments and have modified the SAR to reflect these specified standards and any other applicable standards.
6. Please refer to comment 3D in NAGF response to comment. The redlined SAR reflects this change.

Israel Perez - Salt River Project - 1,3,5,6 - WECC

Comment

We do not agree with the proposed scope described in the SAR, as more clarification of expectations and deliverables are needed. The proposed scope is not clear if the changes would require the installation of additional protection devices to our generators or switchyards and if additional DCS/computer points need to be monitored. Would the changes require third-party generator studies and at what frequency? We are concerned that these changes, which are still unclear, will require additional preventative tasks and specialized personnel necessary to perform these tasks. If the disturbance in the grid is large enough, wouldn't it be better for our generators to disconnect and/or trip to prevent equipment damage? A unit/generator restart would have a faster turnover and would be more efficient than having a damaged generator that motored because we couldn't disconnect it from the large disturbance of the grid.

In addition, it seems that we must wait until "performance" metrics are outlined and how metrics meet baseline criteria. The reference documents outline some of the criteria for measurement and submittal methods but not the full metric. The "ride through" criteria is mentioned, as a "no trip zone" in the attached document but not a clear definition of achieving that target. The process for defining the performance characteristics of a generation resources is not specified other than a system strength specification which we believe would

require a separate criterion for each BES bus depending on the generation in the vicinity. It would be difficult to define and enforce and even more difficult to monitor. The events in southern California revealed that generation went into a current cessation mode during a frequency/voltage excursion and PRC-024-3 covers this issue. The event would expand the scope from generation ride through to include any event where generation was reduced or removed from service for say auxiliary systems being removed from service. This subject might fall under PRC-004. If the tripping or reduction in generation is entirely unrelated to frequency or voltage, then we should have a separate standard that addresses this issue. The deliverable noted is a requirement for reporting all trips and abnormal reductions in active power. In our experience most "abnormal" reductions are prime mover related. If it was intended to only require reporting an abnormal reduction or trip during a system disturbance only, it is not clear that this deliverable is being met. We agree that generation outages due to frequency and voltage excursions should be tracked but the scope of the SAR goes well beyond that point. Why take a perfectly fine standard that addresses a known system issue and expand the scope into something that is not clearly defined. Consider expanding the scope of PRC-004 instead and include operations that affect the output of a BES Generation source and leave PRC-024-3 as a frequency and voltage ride through standard.

Response	
Thank you for the comment. The Project 2021-04 Modifications to PRC-002 drafting team is in charge of monitoring efforts. The drafting team will coordinate with the PRC-002 team in the future pertaining to the necessary recording devices. The metrics will be forwarded to the drafting team for their consideration. This SAR team has modified this requirement and is now only applied to grid system events. The SAR has also been modified and expanded to include IBR AUX systems. Current cessation mode would be included under generation ride-through topic.

Comment	

Southern Company does not agree due to the following concerns:

1. *A reporting requirement that all trips or reductions in power output are reported by the GO to the TOP, BA, and RC.*

Southern Company disagrees with this deliverable. **The RC, BA, and TOP should be responsible parties for determining the magnitude threshold and duration-of-time thresholds GO/GOP to report trips or reductions in power output.** This will ensure that the RC, BA & TOP are not burdened by notifications for trips/reductions that do not affect the Bulk Electrical System (BES) and ultimately take their attention away from matters of higher priority for ensuring the reliability of the BES. In addition, it is the belief of Southern Company that **the RC, BA & TOP already has the ability request information about trips or reductions in power output from the GO/GOP under the regulatory framework of NERC Reliability Standard IRO-010-4 and TOP-003-4.**

2. *A requirement that abnormal reductions in active power (i.e., tripping from protections or notable reductions from controls) are analyzed by the GO to develop a corrective action plan, if possible. Situations where corrective action plans are not able to be developed shall be reported to the TOP, BA, and RC.*

Southern Company disagrees with this deliverable. **Southern Company believes that the 'trip' portion of this deliverable is already an enforceable requirement under the regulatory framework of NERC Reliability Standard PRC-004-6.**

As written, *'notable reductions from controls'*, lacks the detail required to provide a standard drafting team (SDT) with proper direction to develop a requirement(s). **As this Standard Authorization Request (SAR) relates to dynamic ride-through performance of generators Southern Company requests that the SAR SDT add an example magnitude threshold and duration-of-time threshold for 'notable reductions from controls'.** Adding the additional information will prevent any developed requirement(s) from overreaching beyond the intention of this SAR. The communication of unit derates, where necessary for system operation, is likely already being communicated where specified by the RC/BA/TOP data specifications of IRO-010 and TOP-003.

3. *A clear requirement that momentary cessation, or temporary ceasing of current injection during BPS fault events, is deemed unacceptable performance for BES generating resources.* Inverter-based generating resources employing momentary cessation shall develop a corrective action to mitigate its use. Legacy facilities prior to the effective date of the standard should receive an exemption; however, resources with a commercial operation date after the effective date of the standard (and possibly the PRC-024-3 implementation date) shall be required to eliminate the use of momentary cessation within "ride through envelopes" (e.g., the existing PRC-024 "No Trip Zone").

The opening statement is contrary to real world expectations that the generation resource is not allowed to protect its equipment for BES system events. If this is the expectation, then the BES system should not be allowed to have fault events in the first place.

The implementation date for NERC Reliability Standard PRC-024-3 — Frequency and Voltage Protection Settings for Generating Resources (NERC PRC-024-3) is October 01, 2022. As stated by the SAR requestors:

• "The existing PRC-024-3 is an equipment settings standard focused solely on voltage and frequency protection. However, this standard is serving little to no value for ensuring BPS-connected inverter-based resources remain connected and supporting the BPS during grid disturbances."

• "The purpose of this SAR is to retire PRC-024-3 and replace it with a performance-based ride-through standard that ensures generators remain connected to the BPS during system disturbances."

• "Retire PRC-024-3, and create a new PRC standard or completely overhaul and replace the existing PRC-024 standard."

Based on these statements Southern Company believes all generators with a commercial operation date prior to the effective date of requirements to be developed based on this SAR should not have to comply or retrofit. It is clear that any requirements developed based on this SAR will be different from the requirements of NERC PRC-024-3 and therefore the generators that need to comply should be adjusted accordingly.

4. The premise that there have been notable concurrent tripping or performance from synchronous generating resources due to frequency and voltage protection settings being too sensitive is flawed. There have not been increasing trends of synchronous machine protection system misoperations to justify that premise. The application of a ride through standard for synchronous machine generating plants was fully investigated during the original drafting effort of PRC-024 between 2008-2014. The conclusion of the standard drafting team, after multiple drafts, extended comment and consideration of comments from industry, direct consultation with FERC by standard drafting team members resulted in the realization that the standard could go no further than to specify a regions for restricting the tripping of those generators by protective relays for voltage-time and frequency-time areas that would cause the units to not be tripped for the majority of system events where the voltage or frequency was not normal. Further attempts to apply a ride through requirement should be abandoned for synchronous machines to avoid wasting everyone's time by having to restate why it is not feasible for that generation type.

5. Further, there are limited modifications that can be made to the existing equipment to achieve the goal of 100% ride-thru ability to any grid disturbance. Simply passing a regulation specifying it must be done does not change the ability of the equipment to do so. The replacement of existing inverters is not feasible – the power ratings and voltage/current specifications of existing installed invertors do not match the inverters offered today. The collection system of a PV plant cannot be reconfigured economically once it is in place.

6. Any additional ride through requirements should only be applicable to equipment placed in service after changes are made to this standard which may require additional ride-thru capabilities for IBR plants. We suggest that the transmission interconnection agreements be the proper method to assure that newly connected IBR facilities are built to maximize their ride through capability.

7. The lack of a specific grid disturbance for which generating resources are to be required to ride-through is problematic. If specific disturbance characteristics are specified, the generating community might have a fighting chance to design systems to achieve the goals. The application of global "you must ride through all grid disturbance" requirements to existing equipment not designed to do so is ludicrous.

8. The SAR states that auxiliary systems and their protection systems are explicitly excluded. The sub-systems of a conventional synchronous machine generating station are essential for the normal plant operation. Without many of those sub-systems, the main generator cannot run. The sub-system may be essential to the mechanical operation of the turbine too. Any system disturbance that causes any of those sub-systems to not be available will immediately affect the turbine/generator ability to run. The controls of the generator and turbine are interlaced and interlinked with the sub-systems. They cannot be removed from affecting the entire unit

operation. In effect, they cannot be separated from the generator and the unit availability. During system disturbances where sustained grid low voltage occurs, those sub-systems may or may not experience trouble. During the initial PRC-024 development, the Luminant company reported that some low voltage contactors dropped out for low voltage conditions, and others did not. In subsequent grid low voltage disturbances, it was observed that different sets of contactors dropped out. The indefinite response of magnetically sealed in contactor behavior for low voltage conditions was one of the problems with any meaningful successful application of ride-through standards to those types of facilities.

9. The SAR indicates that the desire of the standard revision is to address all possible causes of tripping and power reductions. Addressing ALL POSSIBLE CAUSES is indefinite and unachievable. No failsafe system can be built to withstand all possible causes.

10. With regard to the SAR question on alternatives, for which the SAR drafters included this text:

NERC has evaluated industry progress toward adopting the recommendations outlined in NERC guidelines, white papers, its prior Alerts, and other industry efforts. NERC believes that a nationwide standard for consistent requirements for generating resource ride-through is necessary to immediately address generating resource ride-through during grid disturbances moving forward.

Southern Company has implemented all possible inverter setting changes included in the two NERC alerts on the Loss of Solar Resources. We note that several of our units have continued to react to major grid disturbances by ceasing to generate. The communication of the adjustment of the settings, and the limitations to adjustments we have discerned, have been communicated to the parties included in the NERC alert recommendations. It is for this reason we implore the SDT to look forward rather than backward with change requirements. The electric grid is not in immediate imminent danger due to this current condition. The requirement of maximizing IBR equipment connectivity and grid disturbance resolution support is best addressed through the transmission interconnection requirements rather than through reliability standards.

Thank you for the comment.

1. The applicability of defining a threshold will be considered where applicable when drafting the standard in the performance criteria.

2. The team will look at PRC-004 and make sure there is no overlap, this SAR focusing on performance criteria IBRs. This will be reviewed during the standard drafting process when applicable.
3. Please refer to MRO comment.
4. Concerns about the applicability of the proposed standards to synchronous generators will be passed along to standard drafting team. The SAR has the option to create a new standard.
5. The exemption will be considered based on existing facilities capability and limitations.
6. The SAR includes this. The drafting team cannot support the ride-through requirement was solely covered by interconnection agreement.
7. The performance requirements for disturbances will be determined by the standard drafting team when applicable.
8. The team agrees with the comments and recognizes the difficulty including auxiliary systems in this standard.
9. The SAR has been redlined to limit to trips or power reduction in response to grid events.
10. The standard is focused on performance and acknowledges grid disturbances.

Comment

PG&E agrees with the comments provided by EEI that there have been performance issues with Solar PV Inverter Based Resources (IBRs) that need to be addressed, but as indicated by EEI, PG&E does not agree the replacement of PRC-024-3 is required to address those issues.

The current PRC-024-2 Requirements have worked well for synchronous generators, and it is expected that PRC-024-3 will improve the performance of those generators in maintaining the reliable operation of the Bulk Electric System (BES). As noted by EEI, there were losses of synchronous generator in some of the six disturbances noted in the SAR, but none of those appeared to be unexpected, unusual, or a result of non-compliance with the current PRC-024 Standard.

PG&E personnel responsible for PRC-024 believe trying to add an entire set of additional Requirements for IBRs on top of the current PRC-024 Requirements, or changing the Standard to be performance based for all generators would be extremely complex to implement and maintain, and would not improve the reliability for synchronous generators. PG&E recommends IBR performance should be covered under a new Standard specifically developed for the unique characteristics of IBRs.

Comment	

WEC Energy Group is voting no due to the following concerns:

- “Purpose or Goal” section calls for complete replacement of PRC-024-3 to ensure generators remain connected during disturbances, but the “Industry Need” section clearly identifies this issue applies to IBR only. Industry can agree that current standard as is, is very well effective for traditional synchronous generating resources, therefore WEC believes that standard does not need to be rewritten but rather modified to cover specific IBR issues. WEC believes that statement “… notable concurrent tripping or performance from synchronous generating resources…” is not well supported by data from recent disturbances.
- Proposed “performance based” term needs to be better defined within the SAR.
- If industry recommendation is to include other protective elements or control systems, then it should be done separately and new standards should be developed. Good examples are PRC-025 and PRC-026.
- Some of the “possible causes of tripping and power reductions” listed in SAR are load responsive in nature, therefore should be addressed within existing Standards that cover load-responsive requirements.
- “Detailed Description” section indicates that momentary cessation is deemed unacceptable. Did the SAR requester confirm with all equipment manufacturers that momentary cassation can completely be eliminated? There are still inverter manufacturers that produce equipment with momentary cessation in their design because of current limiting components. The SAR suggest a corrective action plan to be developed to mitigate the issue. What if issue cannot be mitigated?

Response	

Thank you for the comment. Concerns about the applicability of the proposed standards to synchronous generators will be passed along to standard drafting team. The SAR has the option to create a new standard. By "performance based" term this SAR extends the scope of NERC PRC-024-3 from a protective settings standard to defining performance requirements of BES generating resources remain connected and providing essential reliability services during grid disturbances, something stated within the project scope. The drafting team does not think any "possible causes of tripping and power reductions" listed in this SAR are load driven. It is focused on BES Generating Resources. PRC-025 and PRC-026 have been added to the SAR for future review. Momentary cessation of legacy units will also be considered by the standards drafting team.

AZPS agrees with the following comments that were submitted by EEI on behalf of its members: "The incidental operation of synchronous generators during some of the identified six NERC disturbance reports do not warrant the creation of a new ride through Reliability Standard replacing PRC-024-3 because the performance of most of the affected resources, outside of the solar PV resources, performed as designed and expected, and met the requirements of PRC-024-3. While there were losses of synchronous generators in some of the six disturbance reports cited in the proposed SAR, none appear to be unexpected, unusual or the result of non-compliance with PRC-024" "Additionally, if the intent of the SAR is to "create a comprehensive, performance-based ride-through standard," development of a standard would need to account for retirement of other relay setting standards such as PRC-025-2 and PRC-026-1, to prevent duplicative requirements and compliance obligations."

Comment	
In describing the scope, the SAR states *"The scope of the ride-through standard shall explicitly exclude auxiliary systems and their protection systems. Abnormal performance or unexpected tripping of these protections do not pose a systemic BES reliability risk. However, protections and controls directly focused on the generator and its prime mover (e.g., overspeed, power-load imbalance, overvoltage, phase jump, overcurrent) or plant-level (e.g., voltage, current, frequency, phase, etc.) have posed notable risks to BES reliability and should be addressed directly in this standard."* However, auxiliary systems that in turn unexpectedly trip an entire plant pose a risk to reliability. While these systems should not be explicitly modeled, the OP, BA and RC should be in a position to understand when a facility will trip. As an absolute minimum, this information should be required from facilities currently being planned and installed.

The NAGF provides the following comments for consideration:

1. The NAGF believes that there is little justification for retiring PRC-024-3 for synchronous generators and that any new standard should be focused on IBR performance issues. Note that GOs have invested tremendous effort and money in achieving compliance with the PRC standards and are achieving the desired enhancement of BES reliability. Replacing them with something substantially different would require significant expenditures with no identifiable benefit. Any new standard should address only gaps in existing standards, as opposed to tearing down and rebuilding them.

2. Project Scope Comments:

a) Second Bullet: "Creates a comprehensive, performance-based ride-through standard with the purpose of ensuring BES generating resources remain connected and providing essential reliability services during grid disturbances."

The NAGF recommends that other relay-setting PRC standards be considered for retirement/modification beyond PRC-024-3. For example, PRC-025-2, which has the purpose to assure that load responsive relays are set to prevent unnecessary tripping during system disturbances, and PRC-026-1, which has the purpose to ensure that load-responsive relays are expected to not trip in response to stable power swings during non-Fault conditions. The NAGF believes that if a truly comprehensive performance-based ride-through standard is created, then the regulatory burden of other relay setting PRC standards pertaining to how generator protection responds to grid disturbances should be reviewed and incorporated. It seems that a comprehensive generator ride-through standard would apply to not only 24, 27, and 59 functions (PRC-024-3) but would also include trips of generating resources in response to 21, 50, 51, 51VR, 51VC, 67 (PRC-025-2) and/or 21, 40, ,50, 51, 78 (PRC-026-1) function operations in response to grid disturbances.

3. Detailed Description of Project Deliverables Comments:

a) Bullet #3: “A reporting requirement that all trips or reductions in power output are reported by the GO to the TOP, BA, and RC.”

The NAGF believes that this statement is too vague or is stated imprecisely for this deliverable. Reductions in power will occur for a wide variety of reasons such as clouds passing over or the setting of the sun at a solar farm, a drop in wind speed, wet coal, changes in condenser circulating water temperature or discharge water temperature limits at a thermal plant, starting an additional large fan or pump, inlet air temperature changes to gas turbines, reduced water flow at a hydro plant – none of these causes of power reduction would have any relation to PRC requirements and no additional reporting other than that required by existing TOP requirements should be necessary. We believe this deliverable should be more focused, such as “A reporting requirement that all trips or reductions in power output in response to grid disturbances are reported by the GO to the TOP, BA, and RC.”

b) Bullet #4: “A requirement that abnormal reductions in active power (i.e., tripping from protections or notable reductions from controls) are analyzed by the GO to develop a corrective action plan, if possible. Situations where corrective action plans are not able to be developed shall be reported to the TOP, BA, and RC.”

The NAGF believes that such trip analysis and corrective actions are already addressed by PRC-004 and therefore this deliverable/requirement is redundant.

c) Bullet #5: “Legacy facilities prior to the effective date of the standard should receive an exemption; however, resources with a commercial operation date after the effective date of the standard (and possibly the PRC-024-3 implementation date) shall be required to eliminate the use of momentary cessation within “ride through envelopes” (e.g., the existing PRC-024 “No Trip Zone”).

The NAGF supports the exemption for legacy IBR facilities. The NAGF recommends that the performance-based standard include documented equipment limitation exemptions similar to PRC-024-3 R3 and these should apply to all generator types rather than just carving out an exemption for the application of momentary cessation on legacy IBRs existing prior to the effective date of the standard (and possible the PRC-024-3 implementation date). For example, if an existing turbine has frequency limitations that do not meet the requirements of the new ride-through standard, no corrective action plan should be necessary should the turbine trip in response to a frequency excursion outside of its capability. There appears to be nothing in the SAR that addresses limitations of existing equipment other than that of legacy IBRs applying momentary cessation.

d) Bullet #7: “A clear requirement that prolonged plant controller interactions that impede the ability of the resource to dynamically respond to the grid disturbance and preclude the ability to fully provide essential reliability services are deemed unacceptable and should be addressed by a corrective action plan.”

The NAGF is concerned with the potential ambiguity associated with this deliverable. This deliverable seems to be focused on eliminating some of the undesirable IBR performance issues, but the wording of this deliverable could be interpreted to apply to integrated plant or unit protection schemes that may indeed “impede the ability of the resource to dynamically respond to grid disturbances” but are designed to protect the boiler or nuclear reactor from pressure or level excursions, steam turbines from overspeed, operation at resonant frequencies or moisture intrusion, etc. Generator Owners should be able to protect their equipment from catastrophic damage without having to implement a corrective action plan should these protection or control features impede dynamic response to grid disturbances.

Comment	
On the bottom of page 2, the SAR states: “The scope of protections and controls involved in this ride-through standard shall include all generator protections and controls that affect the electrical output of the BES generating resource or plant. To be clear, the project should specify the protections and controls in scope of the ride-through performance and define the term ride-through, as necessary.” Will the scope include requirements that developers/GOs of any new interconnection projects be required to provide protection and control models to the TO or PC? The SRC recommends that the SDT indicate all “protection and control equipment, including auxiliary	

equipment” that will affect the ride-through capabilities of the generator during disturbances. The SDT should identify the auxiliary systems that the ride-through should not affect. On page 3, under Detailed Description, the SAR calls for “A requirement that abnormal reductions in active power (i.e., tripping from protections or notable reductions from controls) are analyzed by the GO to develop a corrective action plan, if possible. Situations where corrective action plans are not able to be developed shall be reported to the TOP, BA, and RC.” This description reads much broader than what is described in the SAR purpose. In the purpose it is directed specifically towards “fail to ride through system events”. Is the intent of the SAR scope to create a requirement to report reductions in active energy which go beyond “fail to ride through system events” and include abnormal reductions of any cause? The SRC requests the SAR DT clarify the project scope. On the bottom of page 3, the SAR states, “Legacy facilities prior to the effective date of the standard should receive an exemption; however, resources with a commercial operation date after the effective date of the standard.” We are concerned that there will be significant amounts of IBR facilities that will be exempt from these requirements. In addition, this seems to be at odds with the“all” language contained in the last bullet on the bottom of page 2 (and as mentioned in the SRC comments above). In 2018, a SAR was introduced and denied by the Standards Committee to correct momentary cessation of IBRs that had no such exemption because of the risks existing facilities were causing on the BES. This SAR does not propose any solutions to address that risk. We recognize that there are some IBR installations which pre-date the technology to meet the SAR purpose. However there are already numerous amounts of IBRs in operation which can adopt new technology to meet the SAR’s purpose. A blanket exemption should not be a part of the standards and instead some form of exemption process should be utilized. Further between the time this standard may be complete and the time it takes effect due to the need for regulatory approval, which may be over two years. Numerous additional new installation of IBRs would become grandfathered which certainly can meet the ride through requirements. The SRC recommends exemptions be limited to technical infeasibility.

Response
Thank you for your comment. It will be considered when the standard is drafted. Models are not within the scope of this drafting team since this a performance standard. This question more refers to MOD-026 and MOD-027

The drafting team understands that the auxiliary systems are critical. However, considering that complexity of identifying the auxiliary equipment to be included in the standard, it has been decided not to include them in the scope. The team assumes that the equipment owner will take the necessary steps to make sure that the auxiliary systems will not trip unexpectedly to degrade the performance of the generation resources during systems events. The drafting team has discussed this point and will be discussing this more in-depth when drafting the standard.

The drafting team does not intend to create a requirement that goes beyond "riding through system events". The team agrees with your concern and modified the SAR accordingly to only be for grid-related disturbances.

The team shares your concern related to legacy equipment and modified the SAR to reflect the comment regarding legacy systems and exemptions.

Comment	

While EEI agrees in principal that that there have been performance issues, primarily with Solar PV Inverter Based Resources (IBRs), that need to be addressed, we do not support the retirement of PRC-024.

While there were losses of synchronous generators in some of the six disturbance reports cited in the proposed SAR, none appear to be unexpected, unusual or the result of non-compliance with PRC-024. As noted below, all of these six events linked within this SAR indicate solar PV performance problems, not synchronous generator problems.

Additionally, if the intent of the SAR is to "create a comprehensive, performance-based ride-through standard," development of a standard would need to account for retirement of other relay setting standards such as PRC-025-2 and PRC-026-1, to prevent duplicative requirements and compliance obligations.

For these reasons, we do not support the retirement of PRC-024-3. However, we offer an alternative approach in our response to question 2.

NERC 2021 California Disturbances Report (2022)

- June 24, 2021 – **Loss of 765MW of solar PV resources** (27 facilities) and 145MW of DERs (no synchronous resources lost).
- July 4, 2021 – **Loss of 605MW of solar PV resources** (33 facilities) and 46MW of DERs; 125MW; additionally, a single 125MW CT tripped due to two defective sensors as reported by the GO.
- July 28, 2021 – **Loss of 511MW of solar PV resources** (27 facilities) and 46MW of DERs (no synchronous resources lost).
- August 25, 2021 – **Loss of 583MW of solar PV resources** (30 facilities) and 212MW gas turbine tripped as a result of a correct operation of a RAS scheme. An additional gas turbine tripped during this event due to the failure of the excitation system (failed diodes). As stated in the report, the diodes were redundant but can only be detected during manual inspection. It is speculated that the redundant diodes failed as a result of the event, GO has indicated they will increase their inspections to avoid future failures.

NERC Odessa Disturbance Report (2021)

- May 9, 2021 Event – Initial fault occurred during CT startup testing when a surge arrester failed taking out one CT and causing another to run back for a total loss of 192MW. After this event **1112MW of solar PV output was lost**, in addition 36MW of output from 4 wind power plants.
- June 26, 2021 Event – Failed H-Frame structure causes the **loss of 518MW at 5 PV facilities**.

NERC San Fernando Disturbance Report (2020) July 7, 2020

- Static wire on a 230kV line failed causing the tripping of two lines on a double circuit tower. In addition, a nearby 230kV line relay mis operated. The result was the initial **loss of 205MW of solar PV output**. When trying to restore the lines, the second line tripped out causing the larger event, the **loss of 1000MW of solar PV output** (no synchronous resources lost).

NERC Palmdale Roost and Angeles Forest Disturbances Report (2019)

- April 20, 2018 (Angeles Forest) – A splice on a 500kV line failed causing a B-C phase fault which was cleared within 2.6 cycles. The fault caused the **loss of 860MW of solar PV output** in CAISO and 17MW in LADWP. In addition, a natural gas turbine tripped as a result of the fault. The report indicates the plan tripped on low fuel pressure causing the natural gas turbine to trip and the reduced output of a combined cycle steam generator to reduce output to 75MW for a total loss of 200MW. There was an additional loss of 130MW of DER output.
- May 11, 2018 (Palmdale Roost) – The disturbance was caused by a bird nest on a 500kV line that caused a line flashover (B phase to ground fault). As a result, there was a loss of **630MW of solar PV output in CAISO**, 48MW in LADWP and 33MW in IID. Additionally, there was 100MW of DER output lost (no indication of any synchronous generation lost during this event).

NERC Canyon 2 Fire Disturbance Report (2018)

- Canyon 2 Fire Disturbance, Oct. 9, 2017 – Two transmission lines faulted near Anaheim Hills, CA. The first fault occurred on a 220kV line at 12:12 PM and the second occurred at 12:14 PM on a 500kV line. The first fault resulted in the **reduction of 682MW of solar PV output**, which the second resulted in the **reduction of 937MW of solar PV output** (no indication that any synchronous generation was lost).

NERC Blue Cut Fire Disturbance Report (2017)

- On Aug. 16, 2016 AM the Blue Cut fire began in Cajon Pass, CA. As a result of the widespread fire SCE experience thirteen 500kV line faults and LADWP experienced two 287kV faults. Four of the fault events resulted in the **loss of 1,200MW of solar PV output** (no indication any synchronous generation was lost).

Comment

Ride-through is not a defined term in the NERC Glossary of Terms nor NPCC Glossary of Terms. The objective of the SAR is commendable, however the specific characteristics of the disturbances addressed by the new standard needs to be carefully defined. Usually the magnitude and duration of grid disturbances should be defined. Particular contingencies should be specified and studied to ensure those applicable reasonable foreseeable disturbances can be assessed and addressed.

Likes 0	

Dislikes 0	
Response	
Thank you for your comment. The existing SAR allows the standard drafting team to develop a term for the NERC Glossary to include the definition of "ride-through" as well as other relevant terms that might be used in the standard. The drafting team also agrees that specification of disturbance characteristics (e.g., type of fault, duration, voltage class, etc.) will be a critical part of the ride-through standard drafting process.	
Dana Showalter - Electric Reliability Council of Texas, Inc. - 2	
Answer	No

Comment	

Regarding the 4th bullet in the "Project Scope" section, ERCOT believes the SAR should not exclude auxiliary systems that could impact the facility's continued operation. The SDT should review the various types of auxiliary systems in use at in-scope facilities and determine whether to exclude any of them. ERCOT suggests revising the 4th bullet as follows:

This standard should address protections and controls directly focused on the generator and its prime mover (e.g., overspeed, power-load imbalance, overvoltage, phase jump, overcurrent) or at the plant level (e.g., voltage, current, frequency, phase, etc.) because they pose notable risks to BES reliability. The SDT will determine whether this ride-through standard may exclude auxiliary systems that do not impact the facility's ability to maintain real and reactive power during a disturbance.

Regarding the 2nd sub-bullet in the "Detailed Description" section, ERCOT suggests the standard contain a requirement for a GO to report only trips or reductions in real power or improper reactive power response (trips or reductions within some threshold of the performance parameters established in the standard).

Regarding the 3rd sub-bullet in the "Detailed Description" section, ERCOT suggests clarifying the term "abnormal" to include trips and reductions in real power or improper reactive power response failing to meet the performance parameters established in the standard. Further, ERCOT suggests the SDT include a requirement for the GO to develop *and implement* a corrective action plan (CAP) or report to its TOP, BA and RC any CAP it cannot implement *due to technical infeasibility*. Finally, ERCOT suggests removing "if possible" because ERCOT's proposed language (above) addresses situations where the GO cannot implement the CAP due to technical infeasibility.

Accordingly, ERCOT suggests modifying the 2nd and 3rd sub-bullets as follows: • The proposed deliverable is a new NERC standard (or significant overhaul and revision of PRC-024-3) that includes the following key elements: • ... • A requirement for a GO to report to its TOP, BA and RC trips or reductions in real power or improper reactive power response (i.e., trips or reductions within a threshold of the performance parameters established in the standard). • A requirement for a GO to: (a) analyze abnormal trips or reductions in real power or improper reactive power response (i.e., tripping from protections, notable reductions from controls, trips or reductions in real power or improper reactive power response failing to meet performance standards established in this standard); and (b) develop and implement a corrective action plan (CAP). If a GO cannot implement a CAP because it is not technical feasible to do so, the GO must report that fact to its TOP, BA, and RC. • ... Regarding the 4th sub-bullet in the “Detailed Description” section, ERCOT agrees with the SRC that the project should not exempt legacy facilities. Exempting legacy facilities will not address the reliability-related need this project addresses.

Response	
Thank you for the comments. The Auxiliary Systems concern has been addressed in the redlined SAR. The SAR has been modified to address reporting concerns. Thresholds may be addressed by the drafting team. Legacy systems should only be exempt if, after engineering analysis, corrective action is not possible or practical (need to define practical). The language was modified to reflect the changes regarding implementation of a Corrective Action Plan and removed "if possible".

Please address and clearly explain the relationship between the two SARs ("Revision of relevant Reliability Standards to include applicability of transmission-connected dynamic reactive resources" approved in April, and "Generator Ride-Through Standard (PRC-024-3 Replacement)". Failure to provide this clarification will result in confusion between intents and requirements for different types of devices and may not clearly align with the earlier whitepapers and recommendations. Additionally-please clarify that Synchronous Condensers, STATCOMs, SVCs and HVDC are not considered generator protection and control systems and should not be included in this standard. If Synchronous Condensers, STATCOMs, SVCs and HVDC are intended to be included in the standard, it needs to be revised to reflect that and include proper terminology, consideration of capability, and requirements specific to transmission-connected dynamic reactive power resources as opposed to generation resources.

Texas RE agrees with the need for this project to develop a comprehensive generator "ride-through" standard in lieu of the current PRC-024's focus solely on voltage and frequency protection settings. As the September 2021 Joint Odessa Disturbance Report for Texas Events on May 9, 2021 and June 26, 2021 ("Odessa Disturbance Report") highlighted, "the systematic nature of [Inverter-Based Resource tripping or cessation] events across multiple interconnections and a wide range of facilities, many of which are recently energized, warrants significant enhancements to the NERC Reliability Standards to address gaps in BES inverter-based resources." (Odessa Disturbance Report, at 29). These recommendations included the need for developing a new generator protection and control ride-through standard to replace the current PRC-024-3 to address continued examples of widespread tripping that are not addressed by the current PRC-024-3 requirements. Texas RE appreciates that the SAR provides an approach to capture the range of performance issues (PLL loss of synchronism, subcycle ac overvoltage protection, dc reverse current, and wind converter crowbar failures) that have resulted in widespread tripping incidents across a number of interconnections, including the ERCOT Interconnection. It further recommended that NERC do so on an expedited timeframe. Texas RE notes that this call of expedited action is even more pressing given the recent tripping of significant inverter-based resources in the ERCOT Interconnection earlier this year, continuing a pattern of generator performance issues in this area. NERC has highlighted grid transformation issues as the single greatest risk to grid reliability at the current time. Texas RE appreciates the SDT's important role, care, and commitment to addressing these performance issues in this project.

The Project 2020-02 webpage reflects that the initial project SAR, posted for industry comments on 3/30/2020, was revised and subsequently accepted by the NERC Standards Committee on 4/20/2022. A redline of the SAR accepted by the Standards Committee in April 2022 vs. the initial SAR posted in March 2020 is posted on the project page. It appears that a different Project 2020-02 SAR (prepared by NERC executives and staff) was presented to and accepted by the NERC Standards Committee a month later, on	

5/18/2022. We suggest that a redline of the SAR accepted by the Standards Committee in May 2022 vs. the SAR accepted by the Standards Committee in April 2022 (or the initial SAR posted in March 2020) be added to the project page. It is not clear why the SAR submitted by the Chair of the System Analysis & Modeling Subcommittee and accepted by the Standards Committee in April 2022 was "abandoned" a month later to be replaced by the SAR submitted by NERC.

While FirstEnergy does agree that an assessment needs to be conducted to ensure reliability of the BES due to the changing mix of generating resources, we do not agree that a reliability standard should result in additional penalties for a GO if generating capacity requirements are not met due to a fuel shortage caused by unforeseen events. FirstEnergy generators already participate in the PJM capacity market and are required to provide generating capacity based on summer ICAP testing results. A generator is assessed financial penalties by PJM if it cannot meet its generating capacity requirements and therefore, we caution against a double jeopardy situation. We also suggest the RC and BA, not the GO, should be responsible for developing a CAP if generation capacity demands are not met during periods of constrained resources. It is the responsibility of the Transmission Grid Operator (e.g., PJM), not the GO, to ensure that adequate generating resources are available during periods of constrained resources. Operating characteristics of IRBs are the cause of	

constrained resources and mitigation actions over-and-above PJM generating capacity requirements should not be placed on fossil generation resources.

Further, FirstEnergy supports EEI's comments, which states:

As an alternative to the proposed PRC-024 SAR, EEI suggests that a new SAR be developed to address performance issues specifically affecting IBRs. This new SAR could leverage key scope items from this proposed SAR to create a new performance- based NERC Reliability Standard that is focused on IBRs. As a suggested scope, we propose modifying this SAR as follows:

-- Trips or reductions in active power that occur because the IBR does not operate as expected (excludes cloud cover, setting sun, etc.), but not associated with protection system trips, (PRC-004 already addresses protection system tripping) are to be analyzed by the GO to develop a corrective action plan. Situations where an issue cannot be corrected, the GO shall develop a report detailing the limitations of the IBR and provide it to the responsible TOP, BA, and RC.

-- Momentary cessation, or temporary ceasing of current injection in response to grid disturbances, is deemed unacceptable for BES generating resources. Inverter-based generating resources employing momentary cessation shall develop a corrective action to mitigate its use unless the issue cannot be corrected. Legacy facilities prior to the effective date of the standard should receive an exemption; however, resources with a commercial operation date after the effective date of the standard shall be required to eliminate the use of momentary cessation during system transient disturbances where the system voltage or frequency falls within the "No Trip Zone" provided in PRC-024-3, which is subject to enforcement October 1, 2022.

-- Include the development of new terms to address terms specific to IBRs or where commonly used industry terms have created some confusion for IBR owners. E.g., No Trip Zone, trip, momentary cessation, and any other relevant terms that may require clarification within the NERC Glossary of Terms.

-- Prolonged IBR controller interactions that impede the ability of the resource to respond dynamically to the grid disturbance and preclude the ability to provide essential reliability services are deemed unacceptable and should be addressed by a corrective action plan. In situation where the GO has determined the issue cannot be corrected, a report shall be developed detailing the IBR limitation and provide it to the responsible TOP, BA and RC.

--If the TOP, BA, or RC inform the GO/IBR owner of a tripping occurrence, cessation event, or IBR controller interactions that are not reported or otherwise identified by the GO/IBR Owner, the responsible GO shall be responsible for analyzing

the facility's performance during the event, developing a corrective action plan, and making this available to the TOP, BA, and RC or in the situation where the issue cannot be corrected, informing the TOP, BA and RC.

The current PRC-024-2, "No Trip Zone" is very clear and easy to understand for frequency and voltage parameters. The SAR Requesters' logic and SAR details appear to be pretty thorough, with the exception of replacing the "No Trip Zone" with "fault ride-through capabilities" as proposed in the revised SAR (dated 4/28/2022). We recommend the SAR Requesters/SAR Drafting Team expand on the proposal to eliminate "No Trip Zone" requirements, and expand the discussion regarding the replacement "fault ride-through capabilities".

The revised SAR language seems to suggest that synchronous generating resources suffer from mis-trips and mis-application of the standard due to deficiencies identified in PRC-024-3 to the same degree that inverter-based resources do. None of the six disturbance reports cited as technical justification for the SAR reference loss of synchronous generation caused by an inadequate or missing requirement within PRC-024-3. From a reliability perspective, while GO/GOPs of IBRs stand to benefit from a replacement/overhaul of PRC-024-3, there is no clear benefit to GO/GOPs of traditional synchronous generating resources. We recommend that the SAR language be revised to clearly delineate the current issues with synchronous generation resources and the current issues with IBRs driving this proposed standard modification, and how the changes are impacting each technology.

The proposed scope explicitly excludes auxiliary systems with the rationale that "abnormal performance or unexpected tripping of these protections do not pose a systemic BES reliability risk" (Page 3, "Project Scope", 4th bullet point). Components of auxiliary systems like unit auxiliary transformers (UATs) typically feature protection that are capable of taking a generator offline. Given this, there may be a

heightened reliability risk if auxiliary equipment are not subject to the same requirements of the proposed standard as generator protection and controls. Auxiliary transformers (and BES GSUs) were added to the applicable equipment scope in the revision from PRC-024-2 to PRC-024-3, so an explanation is requested for why this inclusion is not being preserved.

ERCOT provides the following additional comments:	

The SAR specifically identifies protections/controls posing risks to BES reliability. The proposed standard should not specify criteria for every potential quantity that may trigger a trip. Specifying voltage and frequency envelopes should suffice. Operating within those envelopes should not trigger any other plant control or protection to trip. Not having high-resolution data limits the ability to identify the root cause of the events referenced in the SAR. High-resolution data, including data from phasor measurement units (PMUs), digital fault recorders (DFRs), and inverter-based oscillography, is critical to identify the root cause of disturbance events and, as such, necessary to develop a CAP. Additionally, high resolution data allows a better understanding of the interaction between local wind turbine ride-through control versus the facility plant controller. ERCOT believes this SAR should require data recording relating to voltage ride through and to add appropriate language to PRC-002-2. Finally, ERCOT suggests the SDT consider IEEE 2800 when drafting a proposed standard.

If an attempt is made to define the ride through then it should consider the Bulk Electrical System (BES) as well as all the applicable/foreseeable generating resources that can potentially impact the BES.

A suggestion is made to use, consistently, just the Bulk Electrical System (BES) acronym and not to loosely interchange with BPS whose meaning is different than BES in the NPCC region (Bulk Power System as determined by Directory #1/A#10 methodology)

The SAR mentions that "Generator ride-through is a foundational essential reliability service.". To date the "ride-through" is not defined as a reliability service the same way we understand the following:

- **Frequency support** - provided through the combined interactions of synchronous inertia and frequency response, as services to arrest the decline in frequency and eventually return the frequency to the desired level
- **Ramping and Balancing** – provided through dispatch by the generating units with active power management capability and ability to respond to dispatch signals
- **Voltage Support** - provided through planning and confirmation testing of reactive power sufficiency per unique characteristics of their respective BA systems.

Having generating resources with ride-through capabilities are not a guarantee that the generating units will remain connected to the grid even less of a guarantee they will provide BES support (reliability services during BES disturbance) since BES support is also a:

- Function of static and dynamic reactive power reserve capabilities to regulate voltage at those respective points in the system
- Function of levels of conventional synchronous inertia for respective balancing area/interconnection, and initial frequency deviation following the largest contingency event for the interconnection

This SAR should only be applicable to the protection/protective functions that trip the protected equipment in response to a BES disturbance, where the disturbance conditions do not pose a risk of damage to the associated equipment, whose protection must be prioritized (similar with PRC-025-2).

Equipment protection does not amount nor have a simultaneous compounded effect on grid reliability.

The SAR statement related to the cost impact associated to this Project being expected to be minimal, should not be treated as an accurate statement as long as the entire scope of the project has not even been identified.

As an alternative to the proposed PRC-024 SAR, EEI suggests that a new SAR be developed to address performance issues specifically affecting IBRs. This new SAR could leverage key scope items from this proposed SAR to create a new performance- based NERC Reliability Standard that is focused on IBRs. As a suggested scope, we propose modifying this SAR as follows:

- Trips or reductions in active power that occur because the IBR does not operate as expected (excludes cloud cover, setting sun, etc.), but not associated with protection system trips, (PRC-004 already addresses protection system tripping) are to be analyzed by the GO to develop a corrective action plan. Situations where an issue cannot be corrected, the GO shall develop a report detailing the limitations of the IBR and provide it to the responsible TOP, BA, and RC.
- Momentary cessation, or temporary ceasing of current injection in response to grid disturbances, is deemed unacceptable for BES generating resources. Inverter-based generating resources employing momentary cessation shall develop a corrective action to mitigate its use unless the issue cannot be corrected. Legacy facilities prior to the effective date of the standard should receive an exemption; however, resources with a commercial operation date after the effective date of the standard shall be required to eliminate the use of momentary cessation during system transient disturbances where the system voltage or frequency falls within the “No Trip Zone” provided in PRC-024-3, which is subject to enforcement October 1, 2022.

- Include the development of new terms to address terms specific to IBRs or where commonly used industry terms have created some confusion for IBR owners. E.g., No Trip Zone, trip, momentary cessation, and any other relevant terms that may require clarification within the NERC Glossary of Terms.
- Prolonged IBR controller interactions that impede the ability of the resource to respond dynamically to the grid disturbance and preclude the ability to provide essential reliability services are deemed unacceptable and should be addressed by a corrective action plan. In situation where the GO has determined the issue cannot be corrected, a report shall be developed detailing the IBR limitation and provide it to the responsible TOP, BA and RC.
- If the TOP, BA, or RC inform the GO/IBR owner of a tripping occurrence, cessation event, or IBR controller interactions that are not reported or otherwise identified by the GO/IBR Owner, the responsible GO shall be responsible for analyzing the facility's performance during the event, developing a corrective action plan, and making this available to the TOP, BA, and RC or in the situation where the issue cannot be corrected, informing the TOP, BA and RC.

Thank you for the comment.
The standard drafting team will take into consideration that IBR ride-through performance is the chief motivation behind the present PRC-024 SAR.

The points applicable to generation ride-through will be considered in the context of a revised or new generation ride-through standard. Momentary cessation is an aspect of ride-through performance. The final standard may not be specific to causes of unsatisfactory ride-through but only describe the system conditions and/or events during which generation must ride-through and what constitutes satisfactory ride-through performance. Exemptions for legacy generation and possibly other factors for which exemptions should be permitted will be considered. The team has redlined the SAR to address these concerns. The fourth point regarding interactions that affect reliability services in general may go beyond the scope of disturbance ride-through which the SAR is limited to. The SAR has been redlined to make it more specific, when the team starts to draft the standard this will be noted and considered.

Charles Yeung - Southwest Power Pool, Inc. (RTO) - 2

Comment

The current PRC-024 standard was written with conventional (rotating) generators in mind. Conventional generators are quite sensitive to generator speed (frequency) and abnormal speeds can damage, i.e. lower the life of, turbine blades. Hence the further away the frequency deviates from 60 Hz, the shorter the duration allowed for "no-trip." In contrast, Inverter-Based Resources (IBRs) don't have rotating parts whose speed is tied to their connection to the grid. Since IBRs are not affected by deviations in system frequency as much as conventional (rotating) generators, the SRC requests the PRC-024 SAR be revised to include a recognition for this difference as there may be different ride-through requirements for IBRs than conventional generators within the same interconnection. In addition, to aid in industry implementation, the SRC requests the SAR include the requirement to provide some real-world examples; e.g. in Technical Rationale, to illustrate how proposed standard requirements will ensure both IBRs and conventional generators are able to ride-through faults and how, had they been in place, would have addressed past issues of inadequate ride-through capability. Finally, the SRC requests that the SAR ask to expand the requirement in selecting a Standards Drafting Team (SDT) that is stated in Question 5 on the SAR form. The SRC agrees it is important to include entities that the standard will apply to, but in addition, entities who have a need for the information or bear responsibility to reliably operate within the bounds of the standard (even if the standard does not directly apply to them from a requirement and compliance standpoint), should also be included. The requirements set in any standard are intended to ensure the reliability of the BES as a whole which all registered entity functions have an impact or interest in. This should apply to any and all SARs and the SRC would like to ask NERC to address a change in the SAR form in the future.

Below are proposed changes for the “proposed deliverable” section of the SAR. *The proposed deliverable is a new NERC standard (or significant overhaul and revision of PRC-024-3) that includes the following key elements:* *A performance-based approach to generator ride-through rather than an equipment settings standard. The new standard shall include requirements that BES resources shall ride through grid disturbances and include quantitative measures (see below) on expectations for ride-through that address all possible causes of tripping and power reductions from BES generating resources (particularly generator, turbine, inverter, and all plant-level protection and controls, including auxiliary systems).*	

A reporting requirement that all trips or abnormal reductions in power output are reported by the GO to the TOP, BA, and RC. *A requirement that abnormal reductions in active power (i.e., tripping from protections or notable reductions from controls) are analyzed by the GO and shall be reported to the TOP, BA, and RC.*

The stated purpose of this SAR is to retire PRC-024-3 and replace it with a performance-based ride-through standard that ensures generators remain connected to the BPS during system disturbances. Additionally, the SAR will focus on the generator protection and control systems that can result in the reduction or disconnection of generating resources during these events. As part of the development of the performance based standard or overhaul of PRC-024-3, it is recommended that the standard drafting team include and highlight specific references to the relevant IEEE Standard P2800-2022 clauses and to relevant FERC Orders (related to ride-through), where applicable. It will be important for stakeholders to discern similarities and differences between the new or revamped standard and these existing references. We can offer another comment, related to PRC-024-3, for consideration in the development of a performance based standard or overhaul of PRC-024-3. For PRC-024-3 applicability section 4.1.2, it mentions that it is for Transmission Owners in the Quebec Interconnection only. There are Transmission Owners outside the Quebec Interconnection that own BES generator step-up transformers (GSUs). Is PRC-024-3 intended to be applicable to Transmission Owners that own BES GSUs that are outside the Quebec Interconnection? If so, perhaps the “in the Quebec Interconnection only” should be removed from applicability section 4.1.2 in the next revision.

Comment	

Southern Company disagrees with the "Cost Impact Assessment". We feel that generation resources will need to install high speed recorders to capture data on electrical events that occur and the reaction of generation resources to said electrical event. These high speed recorders will be essential for any requirement for analysis and development of corrective action plans. Southern Company purports that it will be costly to engineer, procure and install this equipment.

Noting that IBR components capable of providing the performance characteristics are just now beginning to be developed and offered by vendors coupled with regulatory requirements for providing that performance will certainly cause equipment suppliers to increase costs to the users.

With the cause of the concern raised in this SAR being the system disturbance, perhaps a more beneficial result can be achieved by investigating the causes of the system disturbances that have been resulting in natural responses of the IBR and synchronous machine based generating stations. Our experience has been that most of the existing IBR systems that operate perfectly given a network with no disturbances.

The recent development and adoption of IEEE P2800 (Standard for Interconnection and Interoperability of Inverter-Based Resources Interconnecting with Associated Transmission Electric Power Systems) is nowhere to be found in the SAR as a resource. It is Southern Company's opinion that IEEE P2800 be fully understood and used by the SDT as a resource of what operational capability limits exist for IBRs. P2800 goes into many of the aspects that IBRs face from a performance perspective. A common issue with IBRs is loss of synchronism because of the voltage phase angle jump that can occur with system disturbances. A voltage phase angle shift jump can

occur with the voltage magnitudes still within the no-trip zone, leading to momentary cessation because of loss synchronism of the IBRs synchronizing phase-locked loop control function. The Functional Entities identified in the PRC-024 standard have no control what-so-ever of the design and performance characteristics of the Inverter Based Resource manufacturers equipment. This leads to GOs attempting to coerce the IBR manufactures after-the-fact to change equipment settings and parameters to comply with operational situations that they are either not designed to perform to or, due to the technical nature of the IBR generation process, cannot perform to. To move to a performance based standard and holding the GO accountable for the design performance of the IBRs is futile at best. The only performance criteria defined in the SAR so far is impossible for all situations, and that is "A clear requirement that momentary cessation, or temporary ceasing of current injection during BPS fault events, is deemed unacceptable performance for BES generating resources".

Momentary Cessation Requirements for Existing Generators

While Texas RE appreciates the proposed SAR's focus on generator performance issues in general and momentary cessation issues in particular, Texas RE is concerned that the current proposed SAR would exempt facilities in commercial operation prior to the effective date of the new PRC-024-3 requirements from "the use of momentary cessation within 'ride through envelopes' (e.g., the existing PRC-024 "No Trip Zone"). (PRC-024 Standard Authorization Request, at 3-4). The Odessa Disturbance Report observed that momentary cessation issues resulted in generation loss, along with tripping issues inside of facilities during the event (Odessa Disturbance Report, at 7). In particular, the Odessa Disturbance Report noted: "legacy inverter momentary cessation setting with plant-level controller interactions prohibited quick active power recovery." (Odessa Disturbance Report, at 33). The report also noted other forms of momentary cessation issues, including settings that produced fixed reactive power injection with "no ability to control voltage post-contingency." (Odessa Disturbance Report, at 20). It further noted that "[t]his type of behavior was not known by ERCOT prior to the event analysis nor is this type of behavior supporting the BPS post-fault." (Id.).

Given the significance of these momentary cessation issues during the Odessa Disturbance event and other events over the past six years, Texas RE encourages the SDT to not limit momentary cessation performance requirements exclusively to new generation facilities. While Texas RE expects the SDT to move expeditiously with this project, Texas RE notes that the final revised standard may not be effective for several years. As a result, not only would existing generators not be covered by any momentary cessation requirements, but a number of planned generation resources would be similarly exempt. Given the growing role of inverter-based resources in the ERCOT Interconnection and others, this could result in a significant reliability gap.

Texas RE notes that momentary cessation issues are currently documented in NERC Reliability Guidelines (E.g., Reliability Guideline: BPS-Connected Inverter-Based Resource Performance (Sept. 2018) (2018 IBR Performance Guidelines). These existing guidelines note that "Existing and newly interconnecting inverter-based resources should eliminate the use of momentary cessation to the greatest possible extent." (2018 IBR Performance Guidelines, at 11). It is also important to note that one of the key findings in the Odessa Disturbance Report is that while these reliability guidelines are widely viewed and shared, entities are "not comprehensively adopting the recommendation(s) contained in those materials." (Odessa Disturbance Report, at vi). In short, a new Reliability Standard is required.

Texas RE acknowledges it may take time to review and implement settings to avoid certain momentary cessation-type performance issues. As the 2018 IBR Performance Guidelines note, however: "Existing resources may have hardware and/or software limitations based on a design philosophy using momentary cessation, and it may not be feasible to eliminate its use. For equipment limitations that cannot be addressed, PRC-024-2 Requirement R3.1 states that '[t]he [GO] shall communicate the documented regulatory or equipment limitation, or the removal of a previously documented regulatory or equipment limitation, to its Planning Coordinator and Transmission Planner within 30 calendar days.'" (2018 IBR Performance Guidelines, at 11-2). The drafting team could consider approaches that permit legacy systems lacking functionality to avoid momentary cessation issues to document those limitations for any new momentary cessation requirements developed in this project in a manner similar to the process currently provided in the existing PRC-024-3 Requirement R3.1.

Enhanced Communication Requirements

In addition to considering the incorporation of momentary cessation and other performance notification requirements as appropriate, Texas RE recommends the drafting team consider creating a new requirement for the GO to notify the GOP, in addition to the TOP, BA, and RC, regarding abnormal tripping. Since COM-001 and COM-002 do not include GO communications, an additional requirement for the GO to notify the GOP would be helpful for the GOP to have the information to communicate any GO issues via COM-001 and COM-002.

Although PRC-024-3 is not applicable to BPA by registration, the PRC-024-3 Requirements R3 and R4 do impact BPA as a Transmission Planner and Planning Coordinator and will have substantial impact to BPA's interconnection requirements. BPA encourages the drafting team to address the inconsistencies in format of how TPs and PCs receive the data. Data consistency will support more efficient and effective modeling of relay settings

All protection and control system functions that will be in scope should be specifically listed in the standard. Guidance on complying with ride-through requirements should be provided by including detailed examples. A sufficient phase-in period should be part of the implementation plan to allow GOs time to achieve the additional coordination that will be required. Based on the defined project scope the new standard will enforce that unexpected trips, abnormal trips and reductions in power are reported to the pertinent entities. The term reduction of power needs to be defined since it is open for interpretation. Furthermore, this reporting-out could infringe on current standards like PRC-004.

The Cost Impact Assessment states incremental cost impact which is not correct. Additional analyses and design changes are likely based on the widespread loss of generating resources observed.

Response
Thank you for comment. The SAR has been redlined to reflect the additional cost of high speed data recording devices, if or when required.

Industry Need (What Bulk Electric System (BES) reliability benefit does the proposed project provide?):			
The ERO Enterprise has analyzed over 10 disturbances involving widespread loss of solar photovoltaic (PV) resources and has published multiple disturbance reports highlighting key findings and recommendations from these analyses. Across all events, a widespread loss of generating resources – solar PV, wind, synchronous generation, and battery energy storage systems (BESS) – have abnormally tripped, ceased current injection, or reduced power output with control interactions. Generator ride-through is a foundational essential reliability service. BPS-connected generating resources remaining			

Requested information
connected during normal and contingency conditions is a critical component of BPS reliability. Ensuring fault ride-through capability enables dynamic reactive power support, frequency response, and other services. The unexpected loss of widespread generating assets poses a significant risk to BPS reliability. The existing PRC-024-3 is an equipment settings standard focused solely on voltage and frequency protection. However, this standard is serving little to no value in ensuring BPS-connected inverter-based resources remain connected and support the BPS during grid disturbances. Furthermore, NERC has experienced multiple asset owners during the event analyses who have misconstrued PRC-024-3, resulting in incorrect or unnecessary protections applied to generating assets that have resulted in spurious and abnormal tripping events. The systemic tripping and reductions of inverter-based resources, in addition to notable concurrent tripping or performance from synchronous generating resources, poses a risk to BPS reliability that must be addressed in a timely manner. This proposed standards project will address this known reliability risk with a more suitable performance-based standard that ensures generating resource ride-through performance for expected or planned BPS disturbances rather than focusing solely on a small subset of protections and controls that can trip generating resources.
Purpose or Goal (How does this proposed project provide the reliability-related benefit described above?):
The purpose of this SAR is to retire PRC-024-3 and replace it with a performance-based ride-through standard that ensures generators remain connected to the BPS during system disturbances. Specifically, this SAR focuses on the generator protection and control systems that can result in the reduction or disconnection of generating resources during these events. The SAR also ensures protection or controls that fail to ride through system events are analyzed, addressed with a corrective action plan (if possible), and reported to necessary entities for situational awareness. From a risk-based perspective, the goal of the standard is to mitigate the ongoing and systemic performance issues identified across multiple Interconnections and across many disturbances analyzed by NERC and the Regions. These issues have been identified in inverter-based resources as well as synchronous generators, with many causes of tripping entirely unrelated to voltage and frequency protection settings as dictated by the currently effective version of PRC-024.
Project Scope (Define the parameters of the proposed project):
The scope of this project includes the following: • Retire PRC-024-3, and create a new PRC standard or completely overhaul and replace the existing PRC-024 standard. • Allow for the possible modification or retirement of other relay-setting standards such as but not limited to PRC-006, PRC-019, PRC-025, and PRC-026, to prevent duplicative requirements and compliance obligations. • Creates a comprehensive, performance-based ride-through standard to ensure BES generating resources remain connected and providing essential reliability services during grid disturbances.

Requested information
• The scope of protections and controls involved in this ride-through standard shall include all generator protections and controls that affect the electrical output of the BES generating resource or plant. To be clear, the project should specify the protections and controls in the scope of the ride-through performance and define the term ride-through, as necessary. This should, at a minimum, include all generator (synchronous or inverter-based) protections and controls at the individual generators, at the inverters, or within the plant (i.e., plant-level controls and protections or collector system protections). • For synchronous generators, the scope of the ride-through standard shall explicitly exclude auxiliary systems and their protection systems. These protections have not posed a systemic BES reliability risk. However, protections and controls directly focused on the generator and its prime mover impacting the ride-through performance should be addressed in the standard. • For Inverter Based Resources (IBRs), auxiliary systems and their protection systems that can affect ride through performance shall be considered by the Standard Drafting Team. • The new standard shall ensure that all unexpected or abnormal tripping or reductions in power output are reported by the GO to the TOP, BA, and RC. • This team will also consider requirements for high-speed data recording relating to system events and will coordinate, as appropriate, with Project 2021-04 Modifications to PRC-002.
-Detailed Description (Describe the proposed deliverable(s) with sufficient detail for a drafting team to execute the project. If you propose a new or substantially revised Reliability Standard or definition, provide (1) a technical justification[1] that includes a discussion of the reliability-related benefits of developing a new or revised Reliability Standard or definition, and (2) a technical foundation document (*e.g.,* research paper) to guide the development of the Standard or definition):
The following describes the proposed deliverable for this project: • The proposed deliverable is a new NERC standard (or significant overhaul and revision of PRC-024-3) that includes the following key elements: ▪ A performance-based approach to generator ride-through rather than an equipment settings standard. The new standard shall include requirements that BES resources shall ride through grid disturbances and include quantitative measures (see below) on expectations for ride-through that address all possible causes of tripping and power reductions from BES generating resources (particularly generator, turbine, inverter, and all plant-level protection and controls). ▪ A reporting requirement that all trips or reductions in power output in response to grid disturbances are reported by the GO to the applicable TOP, BA, and RC ▪ A requirement that abnormal reductions in active power (i.e., tripping from protections or notable reductions from controls) in response to grid disturbances are analyzed by the GO to

[1] The NERC Rules of Procedure require a technical justification for new or substantially revised Reliability Standards. Please attach pertinent information to this form before submittal to NERC.

Requested information
develop and implement a Corrective Action Plan. Situations, where corrective action plans are not able to be developed, shall be reported to the TOP, BA, and RC. ▪ A clear requirement that momentary cessation, or temporary ceasing of current injection during BPS fault events, is deemed unacceptable performance for BES generating resources. Inverter-based generating resources employing momentary cessation shall develop a corrective action to mitigate its use. Legacy facilities that were connected before the effective date of the standard and cannot comply due to documented inherent equipment limitations, may be considered for an exemption; however, resources with a commercial operation date after the effective date of the standard (and possibly the PRC-024-3 implementation date) shall be required to eliminate the use of momentary cessation within "ride through envelopes" (e.g., the existing PRC-024 "No Trip Zone"). ▪ The terms ride-through, trip, momentary cessation, and any other relevant terms should be defined in the NERC Glossary of Terms if deemed necessary. ▪ A clear requirement that prolonged plant controller interactions that are unnecessary to protect equipment or system and impede the ability of the resource to dynamically respond to the grid disturbance and preclude the ability to fully provide essential reliability services are deemed unacceptable and should be addressed by a corrective action plan. ▪ A requirement that if the TOP, BA, or RC informs the GO of a tripping occurrence, cessation event, or plant controller interactions that are not reported by the GO, then the GO shall be responsible for analyzing the facility's performance during the event, developing a corrective action plan, and reporting this to the TOP, BA, and RC. The technical justification regarding the reliability-related need and benefits of this project are described in extensive detail in multiple NERC disturbance reports. All widespread solar PV loss events analyzed by the ERO Enterprise have involved extensive tripping and causes of reduction that is largely not addressed by PRC-024-3, many of which are unrelated to voltage and frequency tripping entirely. Furthermore, these multiple events have also involved the loss of synchronous generators for various reasons that should be considered in the development activities of this proposed project. Key disturbance reports include: • NERC 2021 California Disturbances Report (2022) • NERC Odessa Disturbance Report (2021) • NERC San Fernando Disturbance Report (2020) • NERC Palmdale Roost and Angeles Forest Disturbances Report (2019) • NERC Canyon 2 Fire Disturbance Report (2018) • NERC Blue Cut Fire Disturbance Report (2017) NERC Reliability Guideline: Improvements to Interconnection Requirements for BPS-Connected Inverter-Based Resources (2019), developed by the NERC Inverter-Based Resource Performance Working Group

Requested information
(IRPWG) and endorsed by the NERC Planning Committee, specifically recommends that all Transmission Owners (TOs) per FAC-001 establish or improve interconnection requirements by including quantitative requirements related to ride-through performance. Below is an excerpt from this guideline: *Quantitative requirements ensure that resources behave in a manner that supports BPS reliability and also assists the GOs and inverter manufacturers in specifying equipment to meet these requirements. These requirements may involve a performance envelope (FRT capability) that must be met by the resource, typically derived based on interconnection studies, grid codes, Reliability Standards, and other factors deemed necessary by the TO. Having these requirements ensures that the resources, particularly inverter-based resources, are unlikely to operate in a mode that has not been previously studied. Examples of these quantitative performance requirements include, but are not limited to, the following:* • *Pre- and post-fault short-circuit strength (equivalent impedance or short-circuit ratio (SCR)-based metric)) for worst-case contingency conditions* • *RMS low voltage ride-through and high voltage ride-through* • *Instantaneous transient overvoltage* • *Instantaneous change in phase angle* • *Low frequency ride-through and high frequency ride-through* • *No use of momentary cessation, by exception only* These deliverables developed by the ERO Enterprise and its stakeholder groups serve as a strong technical basis for ensuring resources successfully ride through grid disturbances and support the BPS by providing essential reliability services moving forward.
Cost Impact Assessment, if known (Provide a paragraph describing the potential cost impacts associated with the proposed project):
Incremental costs are expected for GOs that currently do not analyze the performance of their generating assets following grid disturbances, which has been shown during the NERC disturbance analyses to be a systemic reliability issue for solar PV resources in particular. GOs will need to assess their ride-through capabilities more comprehensively than in the past, which may have some associated costs. Minimal costs are associated with reporting of tripping occurrences. Facilities with abnormal or unexpected trips that can be mitigated with corrective actions will have some incremental costs; however, these improvements will help ensure adequate levels of reliability of the BES. Otherwise, cost impacts for this project are expected to be minimal. Additionally, if high speed data recording is not available in the required locations, entities may be required to install such equipment which would have some increased cost impact.
Please describe any unique characteristics of the BES facilities that may be impacted by this proposed standard development project (*e.g.*, Dispersed Generation Resources):
BES generating resources.

Requested information
To assist the NERC Standards Committee in appointing a drafting team with the appropriate members, please indicate to which Functional Entities the proposed standard(s) should apply (*e.g.*, Transmission Operator, Reliability Coordinator, etc. See the most recent version of the NERC Functional Model for definitions):
Generator Owners, Generator Operators, Reliability Coordinators, Transmission Operators, Transmission Owners, Transmission Planners, Planning Coordinators
Do you know of any consensus building activities[2] in connection with this SAR? If so, please provide any recommendations or findings resulting from the consensus building activity.
This SAR is an outcome of ongoing analyses conducted by the ERO Enterprise regarding widespread inverter-based resource tripping events. Furthermore, the NERC IRPWG has developed comprehensive recommendations for improved performance of inverter-based resources, including the recommendation to develop comprehensive ride-through requirements.
Are there any related standards or SARs that should be assessed for impact as a result of this proposed project? If so, which standard(s) or project number(s)?
PRC-006, PRC-019, PRC—025, PRC-026
Are there alternatives (e.g., guidelines, white paper, alerts, etc.) that have been considered or could meet the objectives? If so, please list the alternatives.
NERC has evaluated industry progress toward adopting the recommendations outlined in NERC guidelines, white papers, its prior Alerts, and other industry efforts. NERC believes that a nationwide standard for consistent requirements for generating resource ride-through is necessary to immediately address generating resource ride-through during grid disturbances moving forward.

Reliability Principles	
Does this proposed standard development project support at least one of the following Reliability Principles (Reliability Interface Principles)? Please check all those that apply.	
☒	1. Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk power systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☒	3. Information necessary for the planning and operation of interconnected bulk power systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for an emergency operation and system restoration of interconnected bulk power systems shall be developed, coordinated, maintained, and implemented.
☐	5. Facilities for communication, monitoring, and control shall be provided, used, and maintained for the reliability of interconnected bulk power systems.

[2] Consensus building activities are occasionally conducted by NERC and/or project review teams. They typically are conducted to obtain industry inputs prior to proposing any standard development project to revise, or develop a standard or definition.

Requested information	
☐	6. Personnel responsible for planning and operating interconnected bulk power systems shall be trained, and qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk power systems shall be assessed, monitored, and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

Market Interface Principles	
Does the proposed standard development project comply with all of the following Market Interface Principles?	Enter (yes/no)
1. A reliability standard shall not give any market participant an unfair competitive advantage.	Yes
2. A reliability standard shall neither mandate nor prohibit any specific market structure.	Yes
3. A reliability standard shall not preclude market solutions from achieving compliance with that standard.	Yes
4. A reliability standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards.	Yes

Requested information
services. The unexpected loss of widespread generating assets poses a significant risk to BPS reliability. The existing PRC-024-3 is an equipment settings standard focused solely on voltage and frequency protection. However, this standard is serving little to no value for ensuring BPS-connected inverter-based resources remain connected and supporting the BPS during grid disturbances. Furthermore, NERC has experienced multiple asset owners during the event analyses who have misconstrued PRC-024-3, resulting in incorrect or unnecessary protections applied to generating assets that have resulted in spurious and abnormal tripping events. The systemic tripping and reductions of inverter-based resources, in addition to notable concurrent tripping or performance from synchronous generating resources poses a risk to BPS reliability that must be addressed in a timely manner. This proposed standards project will address this known reliability risk with a more suitable performance-based standard that ensures generating resource ride-through performance for expected or planned BPS disturbances rather than focusing solely on a small subset of protections and controls that can trip generating resources.
Purpose or Goal (How does this proposed project provide the reliability-related benefit described above?):
The purpose of this SAR is to retire PRC-024-3 and replace it with a performance-based ride-through standard that ensures generators remain connected to the BPS during system disturbances. Specifically, this SAR focuses on the generator protection and control systems that can result in the reduction or disconnection of generating resources during these events. The SAR also ensures protection or controls that fail to ride through system events are analyzed, addressed with a corrective action plan (if possible), and reported to necessary entities for situational awareness. From a risk-based perspective, the goal of the standard is to mitigate the ongoing and systemic performance issues identified across multiple Interconnections and across many disturbances analyzed by NERC and the Regions. These issues have been identified in inverter-based resources as well as synchronous generators, with many causes of tripping entirely unrelated to voltage and frequency protection settings as dictated by the currently effective version of PRC-024.
Project Scope (Define the parameters of the proposed project):
The scope of this project includes the following: • Retire PRC-024-3, and create a new PRC standard or completely overhaul and replace the existing PRC-024 standard. • Allow for the possible modification or retirement of other relay setting standards such as but not limited to PRC-006, PRC-019, PRC-025, and PRC-026, to prevent duplicative requirements and compliance obligations. • Creates a comprehensive, performance-based ride-through standard with the purpose of ensuring BES generating resources remain connected and providing essential reliability services during grid disturbances. • The scope of protections and controls involved in this ride-through standard shall include all generator protections and controls that affect the electrical output of the BES generating resource

Requested information

or plant. To be clear, the project should specify the protections and controls in scope of the ride-through performance and define the term ride-through, as necessary. This should, at a minimum, include all generator (synchronous or inverter-based) protections and controls at the individual generators, at the inverters, or within the plant (i.e., plant-level controls and protections or collector system protections).

- For synchronous generators, ~~T~~the scope of the ride-through standard shall explicitly exclude auxiliary systems and their protection systems. ~~Abnormal performance or unexpected tripping of t~~These protections have ~~do~~ not posed a systemic BES reliability risk. However, protections and controls directly focused on the generator and its prime mover impacting the ride-through performance should be addressed in the standard. ~~(e.g., overspeed, power-load imbalance, overvoltage, pole out of step slipphase jump, overcurrent) or plant-level (e.g., voltage, current, frequency, phase, etc.) have posed notable risks to BES reliability and should be addressed directly in this standard.~~
- For Inverter Based Resources (IBRs), auxiliary systems and their protection systems that can affect ride through performance shall be considered by the Standard Drafting Team.
- The new standard shall ensure that all unexpected or abnormal tripping or reductions in power output are reported by the GO to the TOP, BA, and RC.
- This team will also consider requirements for high speed data recording relating to system events and will coordinate, as appropriate, with Project 2021-04 Modifications to PRC-002.

-Detailed Description (Describe the proposed deliverable(s) with sufficient detail for a drafting team to execute the project. If you propose a new or substantially revised Reliability Standard or definition, provide: (1) a technical justification[1] which includes a discussion of the reliability-related benefits of developing a new or revised Reliability Standard or definition, and (2) a technical foundation document (*e.g.,* research paper) to guide development of the Standard or definition):

The following describe the proposed deliverable for this project:

- The proposed deliverable is a new NERC standard (or significant overhaul and revision of PRC-024-3) that includes the following key elements:
  - A performance-based approach to generator ride-through rather than an equipment settings standard. The new standard shall include requirements that BES resources shall ride through grid disturbances and include quantitative measures (see below) on expectations for ride-through that address all possible causes of tripping and power reductions from BES generating resources (particularly generator, turbine, inverter, and all plant-level protection and controls).
  - A reporting requirement that all trips or reductions in power output in response to grid disturbances are reported by the GO to the applicable TOP, BA, and RC

[1] The NERC Rules of Procedure require a technical justification for new or substantially revised Reliability Standards. Please attach pertinent information to this form before submittal to NERC.

Requested information

- ~~A reporting requirement that all trips or reductions in power output are reported by the GO to the TOP, BA, and RC.~~
- A requirement that abnormal reductions in active power (i.e., tripping from protections or notable reductions from controls) in response to grid disturbances are analyzed by the GO to develop and implement a C~~c~~orrective A~~a~~ction P~~p~~lan~~, if possible~~. Situations where corrective action plans are not able to be developed shall be reported to the TOP, BA, and RC.
- A clear requirement that momentary cessation, or temporary ceasing of current injection during BPS fault events, is deemed unacceptable performance for BES generating resources. Inverter-based generating resources employing momentary cessation shall develop a corrective action to mitigate its use. Legacy facilities that were connected prior to the effective date of the standard and cannot comply due to documented inherent equipment limitations, may be considered for ~~should receive~~ an exemption; however, resources with a commercial operation date after the effective date of the standard (and possibly the PRC-024-3 implementation date) shall be required to eliminate the use of momentary cessation within "ride through envelopes" (e.g., the existing PRC-024 "No Trip Zone").
- The terms ride-through, trip, momentary cessation, and any other relevant terms should be defined in the NERC Glossary of Terms, if deemed necessary.
- A clear requirement that prolonged plant controller interactions that are unnecessary to protect equipment or system and impede the ability of the resource to dynamically respond to the grid disturbance and preclude the ability to fully provide essential reliability services are deemed unacceptable and should be addressed by a corrective action plan.
- A requirement that if the TOP, BA, or RC inform the GO of a tripping occurrence, cessation event, or plant controller interactions that are not reported by the GO, then the GO shall be responsible for analyzing the facility's performance during the event, developing a corrective action plan, and reporting this to the TOP, BA, and RC.

The technical justification regarding the reliability-related need and benefits of this project are described in extensive detail in multiple NERC disturbance reports. All widespread solar PV loss events analyzed by the ERO Enterprise have involved extensive tripping and causes of reduction that are largely not address by PRC-024-3, many of which are unrelated to voltage and frequency tripping entirely. Furthermore, these multiple events have also involved the loss of synchronous generators for various reasons that should be considered in the development activities of this proposed project. Key disturbance reports include:

PRC-006, PRC-019, PRC—025, PRC-026~~No.~~
Are there alternatives (e.g., guidelines, white paper, alerts, etc.) that have been considered or could meet the objectives? If so, please list the alternatives.
NERC has evaluated industry progress toward adopting the recommendations outlined in NERC guidelines, white papers, its prior Alerts, and other industry efforts. NERC believes that a nationwide standard for consistent requirements for generating resource ride-through is necessary to immediately address generating resource ride-through during grid disturbances moving forward.

Reliability Principles	
Does this proposed standard development project support at least one of the following Reliability Principles (Reliability Interface Principles)? Please check all those that apply.	
☒	1. Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk power systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☒	3. Information necessary for the planning and operation of interconnected bulk power systems shall be made available to those entities responsible for planning and operating the systems reliably.

[2] Consensus building activities are occasionally conducted by NERC and/or project review teams. They typically are conducted to obtain industry inputs prior to proposing any standard development project to revise, or develop a standard or definition.

Requested information	
☐	4. Plans for emergency operation and system restoration of interconnected bulk power systems shall be developed, coordinated, maintained and implemented.
☐	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk power systems.
☐	6. Personnel responsible for planning and operating interconnected bulk power systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk power systems shall be assessed, monitored and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

Market Interface Principles	
Does the proposed standard development project comply with all of the following [Market Interface Principles]?	Enter (yes/no)
1. A reliability standard shall not give any market participant an unfair competitive advantage.	Yes
2. A reliability standard shall neither mandate nor prohibit any specific market structure.	Yes
3. A reliability standard shall not preclude market solutions to achieving compliance with that standard.	Yes
4. A reliability standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards.	Yes

December 13, 2023

Project 2020-02 Modifications to PRC-024 (Generator Ride-through) Waiver

Action

- Approve the following waiver of provisions of the Standard Processes Manual (SPM) for Project 2020-02:
  - Initial formal comment and ballot period reduced from 45 days to as few as 25 calendar days, with ballot pools formed in the first 10 days and initial ballot and non-binding poll of Violation Risk Factors (VRFs) and Violation Severity Levels (VSLs) conducted during the last 10 days of the comment period (Sections 4.7 and 4.9)
  - Additional formal comment and ballot period(s) reduced from 45 days to as few as 15 calendar days, with ballot(s) conducted during the last 5 days of the comment period. (Sections 4.9 and 4.12)
  - Final ballot reduced from 10 days to 5 calendar days. (Section 4.9)

Background

The SAR ensures generators remain connected to the bulk power system (BPS) during system disturbances. Specifically, this SAR focuses on the generator protection and control systems that can result in the reduction or disconnection of generating resources during these events. The SAR also ensures that protection or controls that fail to ride through system events are analyzed, addressed with a corrective action plan (if possible), and reported to necessary entities for situational awareness. However, those items are now covered within Project 2023-02. From a risk-based perspective, the goal of the standard is to mitigate the ongoing and systemic performance issues identified across multiple Interconnections and across many disturbances analyzed by NERC and the Regions. These issues have been identified in Inverter-Based Resources (IBR) and synchronous generators, with many causes of tripping entirely unrelated to voltage and frequency protection settings as dictated by the currently effective version of PRC-024.

At the April 19, 2023 meeting, the Standards Committee (SC) accepted the most recent revised SAR submitted by the Project 2020-02 Standard Drafting Team.

NERC Standard Processes Manual Section 16.0 Waiver provides as follows:

> The SC may waive any of the provisions contained in this manual for good cause shown, but limited to the following circumstances:
>
> - In response to a national emergency declared by the United States or Canadian governments that involves the reliability of the Bulk Electric System (BES) or cyber attack on the BES;
> - Where necessary to meet regulatory deadlines;
> - Where necessary to meet deadlines imposed by the NERC Board of Trustees; or

- Where the SC determines that a modification to a proposed Reliability Standard or its requirement(s), a modification to a defined term, a modification to an Interpretation, or a modification to a variance has already been vetted by the industry through the standards development process or is so insubstantial that developing the modification through the processes contained in this manual will add significant time delay.

FERC Order 901 directs the development of new or modified reliability standards that include new requirements for disturbance monitoring, data sharing, post-event performance validation, and correction of IBR performance. This set of directives from the report comprises the first three sets of Standards Projects that must be completed and filed with FERC. This first set (disturbance monitoring data sharing and post-event performance validation and correction of IBR performance) must be filed with FERC by November 4, 2024.

NERC Standards Development has identified three active projects (2020-02, 2021-04, and 2023-02) that are directly impacted by these associated FERC directives. Project 2020-02 DT leadership and NERC staff request that the SC approve a waiver for specific provisions of the SPM regarding the length of comment periods and ballots in order to meet the November 2024 development deadline for 2020-02 as established by FERC.

Summary

Project 2020-02 DT leadership and NERC staff recommend that the SC shorten the initial formal comment and ballot period from 45 days to as few as 25 days and any additional formal comment and ballot period(s) from 45 days to as few as 15 days. In addition, Project 2020-02 DT leadership and NERC staff recommend that the SC shorten the final ballot from 10 days to 5 days.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

PRC-024-4 is posted for a 25-day formal comment period with initial ballot.

Completed Actions	Date
Standards Committee accepted revised Standard Authorization Request (SAR) for posting	April 19, 2023
Standards Committee approved waivers to the Standards Process Manual	December 13, 2023

Anticipated Actions	Date
25-day formal comment period with initial ballot	March 27 - April 22, 2024
15-day formal comment period and additional ballot	May 20 - June 4, 2024
15-day formal comment period and additional ballot	July 1 - 16, 2024
Final Ballot	July 18 - 24, 2024
Board adoption	August 14, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

None

A. Introduction

1. **Title:** Frequency and Voltage Protection Settings for Synchronous Generators and Synchronous Condensers

2. **Number:** PRC-024-4

3. **Purpose:** To assure that protection of synchronous generators and synchronous condensers do not cause tripping during defined frequency and voltage excursions in support of the Bulk Power System (BPS).

4. **Applicability:**

4.1. Functional Entities:

4.1.1. Generator Owners that apply protection listed in Sections 4.2.1 or 4.2.2.

4.1.2. Transmission Owners that apply protection listed in Section 4.2.2.

4.1.3. Transmission Owners (in the Quebec Interconnection only) that own a BES generator step-up (GSU) transformer or main power transformer (MPT)[1] and apply protection listed in Section 4.2.1.

4.1.4. Planning Coordinators (in the Quebec Interconnection only)

4.2. Facilities[2]:

4.2.1 Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip the generating resource(s); or (ii) provide signals to the generating resource(s) to trip; and are applied to the following:

4.2.1.1 Bulk Electric System (BES) synchronous generators.

4.2.1.2 BES GSU transformer(s) for synchronous generators.

4.2.1.3 High-side of the synchronous generator-connected unit auxiliary transformer[3] (UAT) installed on BES generating resource(s).

4.2.1.4 Elements that are designed primarily for the delivery of capacity from multiple synchronous generators connecting to a common bus identified in the BES Definition, Inclusion I4, to the point where those resources aggregate to greater than 75 MVA.

---

[1] For the purpose of this standard, the MPT is the power transformer that steps up voltage from multiple small synchronous generators, e.g. multiple small hydro generators connecting to a common bus.

[2] It is not required to install or activate the protections described in Facilities Section 4.2.

[3] These transformers are variously referred to as station power UAT, or station service transformer(s) used to provide overall auxiliary power to the synchronous generators. This UAT is the transformer connected on the generator bus between the low side of the GSU and the generator terminal.

4.2.1.5 MPT of multiple synchronous generators connecting to a common bus as identified in the BES Definition, Inclusion I4.

4.2.2 Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip transmission connected synchronous condensers; or (ii) provide signals to trip transmission connected synchronous condenser and are applied to the following:

4.2.2.1 BES synchronous condensers

4.2.2.2 BES step-up transformer(s) for synchronous condensers.

4.2.2.3 High-side of the synchronous condenser-connected unit auxiliary transformer (UAT).

4.2.3 **Exemptions:** Protection on all auxiliary equipment within the synchronous generator or synchronous condenser Facility.

5. **Effective Date:** See Implementation Plan for PRC-024-4

B. Requirements and Measures

R1. Each Generator Owner and Transmission Owner shall set applicable frequency protection[4] in accordance with PRC-024 Attachment 1 such that the applicable protection does not cause the synchronous generator(s) or condenser(s) to trip within the "no trip zone" during a frequency excursion with the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- Applicable frequency protection may be set to trip within a portion of the "no trip zone" for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.

M1. Each Generator Owner and Transmission Owner shall have evidence that the applicable frequency protection has been set in accordance with Requirement R1, such as dated setting sheets, calibration sheets, calculations, or other documentation.

R2. Each Generator Owner and Transmission Owner shall set applicable voltage protection[5] in accordance with PRC-024 Attachment 2, such that the applicable protection does not cause the synchronous generator(s) or condenser(s) to trip within the "no trip zone" during a voltage excursion at the high-side of the GSU or MPT, subject to the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- If the Transmission Planner allows less stringent voltage protection settings than those required to meet PRC-024 Attachment 2, then the Generator Owner or Transmission Owner may set its protection within the voltage recovery characteristics of a location-specific Transmission Planner's study.
- Applicable voltage protection may be set to trip during a voltage excursion within a portion of the "no trip zone" for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.

M2. Each Generator Owner and Transmission Owner shall have evidence that applicable voltage protection has been set in accordance with Requirement R2, such as dated setting sheets, voltage-time boundaries, calibration sheets, coordination plots, dynamic simulation studies, calculations, or other documentation.

R3. Each Generator Owner and Transmission Owner shall document each known regulatory or equipment limitation[6] that prevents an applicable synchronous generator(s) or condenser(s) with frequency or voltage protection from meeting the protection setting criteria in Requirements R1 or R2, including (but not limited to) study results, experience from an actual event, or manufacturer's advice. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

---

[4] Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip the synchronous generator(s) or condenser(s); or (ii) provide signals to the synchronous generator(s) or condenser(s) to trip.
[5] Ibid.
[6] Excludes limitations caused by the setting capability of the frequency, voltage, and volts per hertz protective relays for the synchronous generator(s) or condenser(s). This does not exclude limitations originating in the equipment protected by the relay.

3.1. The Generator Owner and Transmission Owner shall communicate the documented regulatory or equipment limitation, or the removal of a previously documented regulatory or equipment limitation, to its Planning Coordinator and Transmission Planner within 30 calendar days of any of the following:

- Identification of a regulatory or equipment limitation.
- Repair of the equipment causing the limitation that removes the limitation.
- Replacement of the equipment causing the limitation with equipment that removes the limitation.
- Creation or adjustment of an equipment limitation caused by consumption of the cumulative turbine life-time frequency excursion allowance.

M3. Each Generator Owner and Transmission Owner shall have evidence that it has documented and communicated any known regulatory or equipment limitations that resulted in an exception to Requirements R1 or R2 in accordance with Requirement R3, such as a dated email or letter that contains such documentation as study results, experience from an actual event, or manufacturer's advice.

R4. Each Generator Owner and Transmission Owner shall provide its applicable protection settings associated with Requirements R1 and R2 to the Planning Coordinator or Transmission Planner that models the associated synchronous generator(s) or condenser(s) within 60 calendar days of receipt of a written request for the data and within 60 calendar days of any change to those previously requested settings unless directed by the requesting Planning Coordinator or Transmission Planner that the reporting of protection setting changes is not required. *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

M4. Each Generator Owner and Transmission Owner shall have evidence that it communicated applicable protection settings in accordance with Requirement R4, such as dated e-mails, correspondence or other evidence and copies of any requests it has received for that information.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- The Generator Owner and Transmission Owner shall keep data or evidence of Requirements R1 through R4 for five years or until the next audit, whichever is longer.
- If a Generator Owner or Transmission Owner is found non-compliant, the Generator Owner or Transmission Owner shall keep information related to the non-compliance until mitigation is complete and approved for the time period specified above, whichever is longer.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	**Moderate VSL**	**High VSL**	**Severe VSL**
R1.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable frequency protection so that it does not trip according to Requirement R1.
R2.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable voltage protection so that it does not trip according to Requirement R2.
R3.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 30 calendar days but less than or equal to 60 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 60 calendar days but less than or equal to 90 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 90 calendar days but less than or equal to 120 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner failed to document any known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2. OR The Generator Owner or Transmission Owner failed to communicate the documented limitation to its Planning Coordinator and Transmission Planner within 120 calendar

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
				days of identifying the limitation.
R4.	The Generator Owner or Transmission Owner provided its protection settings more than 60 calendar days but less than or equal to 90 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner provided protection settings more than 60 calendar days but less than or equal to 90 calendar days of a written request.	The Generator Owner or Transmission Owner provided its protection settings more than 90 calendar days but less than or equal to 120 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner provided protection settings more than 90 calendar days but less than or equal to 120 calendar days of a written request.	The Generator Owner or Transmission Owner provided its protection settings more than 120 calendar days but less than or equal to 150 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner or provided protection settings more than 120 calendar days but less than or equal to 150 calendar days of a written request.	The Generator Owner or Transmission Owner failed to provide its protection settings within 150 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner failed to provide protection settings within 150 calendar days of a written request.

D. Regional Variances

D.A. Variance for the Quebec Interconnection

This Variance replaces Requirement R2 of the continent-wide standard in its entirety and adds a new requirement, Requirement D.A.5., applicable to Planning Coordinators in the Quebec Interconnection.

This Variance replaces continent-wide Requirement R2 in its entirety with the following:

D.A.2. Each Generator Owner and Transmission Owner shall set applicable voltage protection[6] in accordance with PRC-024 Attachment 2B, such that the applicable protection does not cause the synchronous generator(s) or condenser(s) to trip within the "no trip zone" during a voltage excursion at the high-side of the GSU or MPT, subject to the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- For newly designated strategic power plants, applicable protections must comply with the high voltage durations for such plants within 48 calendar months of the notification made pursuant to Requirement D.A.5. During this transition period, voltage protections must at least comply with the high voltage durations for "all power plants".
- Synchronous generator(s) are permitted to be set to trip during a voltage excursion bounded by the "no trip zone" of PRC-024 Attachment 2B for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.
- If the Transmission Planner allows less stringent voltage protection settings than those required to meet PRC-024 Attachment 2B, then the Generator Owner or Transmission Owner may set its protection within the voltage recovery characteristics of a location-specific Transmission Planner's study.

M.D.A.2. Each Generator Owner and Transmission Owner shall have evidence that applicable voltage protection has been set in accordance with Requirement R2, such as dated setting sheets, voltage-time boundaries, calibration sheets, coordination plots, dynamic simulation studies, calculations, or other documentation.

This Variance adds the following Requirement:

D.A.5 Each Planning Coordinator shall designate, at least once every five calendar years, the strategic power plants that must comply with Attachment 2B and notify, within 30 calendar days of its designation, each Generator Owner or Transmission Owner that owns facilities[7] in the

[7] Facilities in the strategic power plants include facilities with synchronous generator(s) from the generator up to and including the MPT or GSU.

strategic power plants. *[Violation Risk Factor: Medium] [Time Horizon: Long-term planning]*

M.D.A.5 Each Planning Coordinator shall have evidence that it designated, at least once every five calendar years, strategic power plants in accordance with Requirement D.A.5, Part 5 and shall have dated evidence that each Generator Owner or Transmission Owner has been notified in accordance with Requirement D.A.5, part 5.2. Evidence may include, but is not limited to letters, emails, electronic files, or hard copy records demonstrating transmittal of information.

Violation Severity Levels

This Variance adds a VSL for D.A.5 and modifies the VSL for R2 as follows:

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
D.A.2.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable voltage protection so that it does not trip in accordance with Requirement D.A.2. OR The Generator Owner or Transmission Owner set its applicable voltage protection in accordance with Requirement D.A.2 but, for strategic power plants, failed to do so within 48 months of notification.
D.A.5.	N/A	The Planning Coordinator designated strategic power plants at least once every five calendar years but notified each Generator Owner or Transmission Owner that owns facilities in the strategic power plants between 31 days and 45 days after its designation.	The Planning Coordinator designated strategic power plants at least once every five calendar years but notified each Generator Owner or Transmission Owner that owns facilities in the strategic power plants between 46 days and 60 days after its designation.	The Planning Coordinator failed to designate, at least once every five years, the strategic power plants that must comply with Attachment 2B. OR The Planning Coordinator failed to notify, each Generator Owner or Transmission Owner that owns facilities in the strategic power plants or notified them more than 60 days after its designation.

<60.5	Continuous operation	> 59.5	Continuous operation

Table 1.2

[8] The figures do not visually represent the "no trip zone" boundaries before 0.1 seconds and after 10,000 seconds. The Frequency Boundary Data Points Table defines the entirety of the "no trip zone" boundaries.

[9] Frequency is calculated over a window of time. While the frequency boundaries include the option to trip instantaneously for frequencies outside the specified range, this calculation should occur over a time window. Typical window/filtering lengths are three to six cycles (50 – 100 milliseconds). Instantaneous trip settings based on instantaneously calculated frequency measurement is not permissible.

<1.10	4.00	≥ 0.90	4.00

Table 2.2

[8] Voltage at the high-side of the GSU or MPT.

Attachment 2A: Voltage Boundary Clarifications
(Eastern, Western, and ERCOT Interconnections)

Boundary Details:

1. Unless otherwise specified by the Transmission Planner, the per unit voltage base for these boundaries is the nominal transmission system voltage (e.g., 100 kV, 115 kV, 138 kV, 161 kV, 230 kV, 345 kV, 400 kV, 500 kV, 765 kV, etc.).
2. The values in the table represent the minimum time durations allowed for specified voltage excursion thresholds.
3. When evaluating volts per hertz protection, either assume a system frequency of 60 Hertz or the magnitude of the high voltage boundary can be adjusted in proportion to deviations of frequency below 60 Hertz.
4. Voltages in the boundaries assume RMS fundamental frequency phase-to-ground or phase-to-phase per unit voltage.
5. For applicability to PRC-024, the “no trip zone” ends at 4 seconds.

Evaluating Protection Settings

The voltage values in the Attachment 2 voltage boundaries are voltages at the high-side of the GSU/MPT. For resources with multiple stages of step up to reach interconnecting voltage, this is the high-side of the transformer with a low side below 100kV and a high-side 100kV or above**.** When evaluating protection settings, consider the voltage differences between where the protection is measuring voltage and the high-side of the GSU/MPT. A steady state calculation or dynamic simulation may be used.

If using a steady state calculation or dynamic simulation, use the following conditions when evaluating protection settings:

a. The most probable real and reactive loading conditions for the unit under study.
b. All installed generating plant reactive support (e.g., static VAR compensators, synchronous condensers, capacitors) equipment is available and operating normally.
c. Account for the actual tap settings of transformers between the generator terminals and the high-side of the GSU/MPT.
d. For dynamic simulations, the automatic voltage regulator is in automatic voltage control mode with associated limiters in service.

<0.75	1.00
<0.85	2.00
<0.90	30
≥0.90	continuous

Table 2

Attachment 2C
(Voltage Boundary Clarifications Quebec Interconnection)

Boundary Details:

1. The per unit voltage base for these boundaries is the nominal operating voltage (e.g., 120 kV, 161 kV, 230 kV, 315 kV, 735 kV, etc.).
2. The values in the table represent the minimum time durations allowed for specified voltage excursion thresholds.
3. When evaluating volts per hertz protection, either assume a system frequency of 60 Hertz or the magnitude of the high voltage boundary can be adjusted in proportion to deviations of frequency below 60 Hertz.
4. Voltages in the Quebec Interconnection boundaries assume positive-sequence values.

Evaluating Protection Settings

The voltage values in the Attachment 2B voltage boundaries are voltages at the high-side of the GSU/MPT. For resources with multiple stages of step up to reach interconnecting voltage, this is the high-side of the transformer that connects to the interconnecting voltage. When evaluating protection settings, consider the voltage differences between where the protection is measuring voltage and the high-side of the GSU/MPT. A steady state calculation or dynamic simulation may be used.

If using a steady state calculation or dynamic simulation, use the following conditions when evaluating protection settings:

a. The most probable real and reactive loading conditions for the unit under study.
b. All installed generating plant reactive support (e.g., static VAR compensators, synchronous condensers, capacitors) equipment is available and operating normally.
c. Account for the actual tap settings of transformers between the generator terminals and the high-side of the GSU/MPT.
d. For dynamic simulations, the automatic voltage regulator is in automatic voltage control mode with associated limiters in service.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

PRC-024-4 is posted for a 25-day formal comment period with initial ballot.

Completed Actions	Date
Standards Committee accepted revised Standard Authorization Request (SAR) for posting	April 19, 2023
Standards Committee approved waivers to the Standards Process Manual	December 13, 2023

Anticipated Actions	Date
25-day formal comment period with initial ballot	March 27, 2024 - April 22, 2024
15-day formal comment period and additional ballot	May 20, 2024 – June 4, 2024
15-day formal comment period and additional ballot	July 1, 2024 – July 16, 2024
Final Ballot	July 18, 2024 – July 24, 2024
Board adoption	August 14, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

None

A. Introduction

1. **Title:** Frequency and Voltage Protection Settings for ~~Generating Resources~~Synchronous Generators and Synchronous Condensers

2. **Number:** PRC-024-4~~3~~

3. **Purpose:** To ~~set~~ assure that protection of ~~S~~synchronous ~~G~~generators and ~~S~~synchronous ~~C~~condensers ~~generating resource(s) remain connected~~ does not cause tripping during defined frequency and voltage excursions in support of the Bulk ~~Electric System~~Power System (B~~E~~PS).

4. **Applicability:**

   4.1. Functional Entities:

   4.1.1. Generator Owners that apply protection listed in Sections 4.2.1 or 4.2.2.

   ~~**4.1.1.**~~**4.1.2.** Transmission Owners that apply protection listed in Section 4.2.2.

   ~~**4.1.2.**~~**4.1.3.** Transmission Owners (in the Quebec Interconnection only) that own a BES generator step-up (GSU) transformer or main power transformer (MPT)[1] and apply protection listed in Section 4.2.1.

   ~~**4.1.3.**~~**4.1.4.** Planning Coordinators (in the Quebec Interconnection only)

   4.2. Facilities[2]:

   4.2.1 Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip the generating resource(s); or (ii) provide signals to the generating resource(s) to ~~either~~ trip ~~or cease injecting current~~; and are applied to the following:

   4.2.1.1 Bulk Electric System (BES) synchronous generators~~generating resource(s)~~.

   4.2.1.2 BES GSU transformer(s) for synchronous generators.

   4.2.1.3 High-~~-~~side of the synchronous generator-connected unit auxiliary transformer[3] (UAT) installed on BES generating resource(s).

---

[1] For the purpose of this standard, the MPT is the power transformer that steps up voltage from multiple small synchronous generators, e.g. multiple small hydro generators connecting to a common bus. ~~the collection system voltage to the nominal transmission/interconnecting system voltage for dispersed power producing resources.~~

[2] It is not required to install or activate the protections described in Facilities Section 4.2.

[3] These transformers are variously ~~ably~~ referred to as station power UAT, or station service transformer(s) used to provide overall auxiliary power to the ~~generating resource(s)~~synchronous generators. This UAT is the transformer connected on the generator bus between the low side of the GSU and the generator terminal.

~~4.2.1.4 Individual synchronous generators utilized as dispersed power producing resource(s) identified in the BES Definition, Inclusion I4.~~

~~4.2.1.5~~4.2.1.4 Elements that are designed primarily for the delivery of capacity from ~~the individualispersed power producing resources~~ multiple synchronous generators connecting to a common bus identified in the BES Definition, Inclusion I4, to the point where those resources aggregate to greater than 75 MVA.

4.2.1.5 MPT[4] of multiple synchronous generators connecting to a common bus ~~utilized as dispersed power producing resources resource(s)~~ as identified in the BES Definition, Inclusion I4.

4.2.2 Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip tranmission connected synchronous condensers; or (ii) provide signals to trip transmission connected synchronous condenser and are applied to the following:

4.2.2.1 BES synchronous condensers

4.2.2.2 BES step-up transformer(s) for synchronous condensers.

~~4.2.1.6~~4.2.2.3 High--side of the synchronous condenser-connected unit auxiliary transformer[5] (UAT).

~~4.2.2~~4.2.3 **Exemptions:** Protection on all auxiliary equipment within the synchronous generator or synchronous condenser ~~generating~~ Facility.

5. **Effective Date:** See Implementation Plan for PRC-024-4~~3~~

~~[4] For the purpose of this standard, the MPT is the power transformer that steps up voltage from the collection system voltage to the nominal transmission/interconnecting system voltage for dispersed power producing resources.~~

~~[5] These transformers are variably referred to as station power UAT, or station service transformer(s) used to provide overall auxiliary power to the synchronous condenser~~

B. Requirements and Measures

R1. Each Generator Owner and Transmission Owner shall set ~~its~~ applicable frequency protection[6] in accordance with PRC-024 Attachment 1 such that the applicable protection does not cause the ~~generating~~ synchronous generator(s) or condenser(s) to trip ~~or cease injecting current~~ within the "no trip zone" during a frequency excursion with the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- Applicable frequency protection may be set to trip ~~or cease injecting current~~ within a portion of the "no trip zone" for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.

M1. Each Generator Owner and Transmission Owner- shall have evidence that the applicable frequency protection has been set in accordance with Requirement R1, such as dated setting sheets, calibration sheets, calculations, or other documentation.

R2. Each Generator Owner and Transmission Owner shall set ~~its~~ applicable voltage protection[7] in accordance with PRC-024 Attachment 2, such that the applicable protection does not cause the ~~generating resource~~ synchronous generator(s) or condenser(s) -to trip ~~or cease injecting current~~ within the "no trip zone" during a voltage excursion at the high--side of the GSU or MPT, subject to the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- If the Transmission Planner allows less stringent voltage protection settings than those required to meet PRC-024 Attachment 2, then the Generator Owner or Transmission Owner may set its protection within the voltage recovery characteristics of a location-specific Transmission Planner's study.
- Applicable voltage protection may be set to trip ~~or cease injecting current~~ during a voltage excursion within a portion of the "no trip zone" for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.

M2. Each Generator Owner and Transmission Owner shall have evidence that applicable voltage protection has been set in accordance with Requirement R2, such as dated setting sheets, voltage-time boundaries, calibration sheets, coordination plots, dynamic simulation studies, calculations, or other documentation.

---

[6] Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip the ~~generating resource(s)~~ synchronous generator(s) or condenser(s); or (ii) provide signals to the ~~generating resource(s)~~ synchronous generator(s) or condenser(s) to ~~either~~ trip ~~or cease injecting current~~.

[7] Ibid.

R3. Each Generator Owner and Transmission Owner shall document each known regulatory or equipment limitation[8] that prevents an applicable ~~generating resource(s)~~ synchronous generator(s) or condenser(s) with frequency or voltage protection from meeting the protection setting criteria in Requirements R1 or R2, including (but not limited to) study results, experience from an actual event, or manufacturer's advice. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

3.1. The Generator Owner and Transmission Owner shall communicate the documented regulatory or equipment limitation, or the removal of a previously documented regulatory or equipment limitation, to its Planning Coordinator and Transmission Planner within 30 calendar days of any of the following:

- Identification of a regulatory or equipment limitation.
- Repair of the equipment causing the limitation that removes the limitation.
- Replacement of the equipment causing the limitation with equipment that removes the limitation.
- Creation or adjustment of an equipment limitation caused by consumption of the cumulative turbine life-time frequency excursion allowance.

M3. Each Generator Owner and Transmission Owner shall have evidence that it has documented and communicated any known regulatory or equipment limitations that resulted in an exception to Requirements R1 or R2 in accordance with Requirement R3, such as a dated email or letter that contains such documentation as study results, experience from an actual event, or manufacturer's advice.

R4. Each Generator Owner and Transmission Owner shall provide its applicable protection settings associated with Requirements R1 and R2 to the Planning Coordinator or Transmission Planner that models the associated ~~generating resource(s)~~ synchronous generator(s) or condenser(s) within 60 calendar days of receipt of a written request for the data and within 60 calendar days of any change to those previously requested settings unless directed by the requesting Planning Coordinator or Transmission Planner that the reporting of protection setting changes is not required. *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

M4. Each Generator Owner and Transmission Owner shall have evidence that it communicated applicable protection settings in accordance with Requirement R4, such as dated e-mails, correspondence or other evidence and copies of any requests it has received for that information.

---

[8] Excludes limitations caused by the setting capability of the frequency, voltage, and volts per hertz protective relays for the ~~generating resource(s)~~ synchronous generator(s) or condenser(s). This does not exclude limitations originating in the equipment protected by the relay. ~~This also does not exclude limitations of frequency, voltage, and volts per hertz protection embedded in control systems~~.

C. Compliance

1. **Compliance Monitoring Process**

   1.1. **Compliance Enforcement Authority:** "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

   1.2. **Evidence Retention:** The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

   The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

   - The Generator Owner and Transmission Owner shall keep data or evidence of Requirements R1 through R4 for ~~3~~five years or until the next audit, whichever is longer.
   - If a Generator Owner or Transmission Owner is found non-compliant, the Generator Owner or Transmission Owner shall keep information related to the non-compliance until mitigation is complete and approved for the time period specified above, whichever is longer.

   1.3. **Compliance Monitoring and Enforcement Program:** As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable frequency protection so that it does not trip ~~or enter momentary cessation~~ according to Requirement R1.
R2.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable voltage protection so that it does not trip ~~or enter momentary cessation~~ according to Requirement R2.
R3.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 30 calendar days	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 60 calendar days	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 90 calendar days	The Generator Owner or Transmission Owner failed to document any known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2. OR The Generator Owner or Transmission Owner failed to communicate the

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
	but less than or equal to 60 calendar days of identifying the limitation.	but less than or equal to 90 calendar days of identifying the limitation.	but less than or equal to 120 calendar days of identifying the limitation.	documented limitation to its Planning Coordinator and Transmission Planner within 120 calendar days of identifying the limitation.
R4.	The Generator Owner or Transmission Owner provided its protection settings more than 60 calendar days but less than or equal to 90 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner provided protection settings more than 60 calendar days but less than or equal to 90 calendar days of a written request.	The Generator Owner or Transmission Owner provided its protection settings more than 90 calendar days but less than or equal to 120 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner provided protection settings more than 90 calendar days but less than or equal to 120 calendar days of a written request.	The Generator Owner or Transmission Owner provided its protection settings more than 120 calendar days but less than or equal to 150 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner or provided protection settings more than 120 calendar days but less than or equal to 150 calendar days of a written request.	The Generator Owner or Transmission Owner failed to provide its protection settings within 150 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner failed to provide protection settings within 150 calendar days of a written request.

D. Regional Variances

D.A. Variance for the Quebec Interconnection

~~This Variance extends the applicability of Requirements R1, R3, and R4 to Transmission Owners in the Quebec Interconnection that own a BES GSU or MPT and apply protection listed in Section 4.2.1, Facilities.~~ This Variance ~~also~~ replaces Requirement R2 of the continent-wide standard in its entirety and adds a new requirement, Requirement D.A.5., applicable to Planning Coordinators in the Quebec Interconnection.

~~In Requirements R1, R3, and R4, all references to “Generator Owner” are replaced with “Generator Owner and Transmission Owner.”~~

This Variance replaces continent-wide Requirement R2 in its entirety with the following:

D.A.2. Each Generator Owner and Transmission Owner shall set ~~its~~ applicable voltage protection[6]~~[5]~~ in accordance with PRC-024 Attachment 2B~~a~~, such that the applicable protection does not cause the ~~generating resource~~synchronous generator(s) or condenser(s) to trip ~~or cease injecting current~~ within the “no trip zone” during a voltage excursion ~~within the “no trip zone”~~ at the high-side of the GSU or MPT, subject to the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- For newly designated strategic power plants, applicable protections must comply with the high voltage durations for such plants within 48 calendar months of the notification made pursuant to Requirement D.A.5. During this transition period, voltage protections must at least comply with the high voltage durations for “all power plants”.
- ~~The generating resource(s)~~Synchronous generator(s) are permitted to be set to trip ~~or to cease injecting current~~ during a voltage excursion bounded by the “no trip zone” of PRC-024 Attachment 2B~~a~~ for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.
- If the Transmission Planner allows less stringent voltage protection settings than those required to meet PRC-024 Attachment 2B~~a~~, then the Generator Owner or Transmission Owner may set its protection within the voltage recovery characteristics of a location-specific Transmission Planner’s study.
- ~~Inverter-based resources voltage protection settings may be set to cease injecting current momentarily during a voltage excursion at the high side of the MPT, bounded by the “no trip zone” of PRC-024 Attachment 2a, under the following conditions:~~

- ~~After a minimum delay of 0.022 s, when the positive-sequence voltage exceeds 1.25 per unit (p.u.) Normal operation must resume once the voltage drops back below 1.25 p.u at the high side of the MPT.~~
- ~~After a minimum delay of 0.022 s, when the phase-to-ground root mean square (RMS) voltages exceeds 1.4 p.u., as measured at generator terminals, on one or multiple phases. Normal operation must resume once the positive-sequence voltage drops back below the 1.25 p.u. at the high side of the MPT.~~

M.D.A.2. Each Generator Owner and Transmission Owner shall have evidence that applicable voltage protection has been set in accordance with Requirement R2, such as dated setting sheets, voltage-time boundaries, calibration sheets, coordination plots, dynamic simulation studies, calculations, or other documentation.

This Variance adds the following Requirement:

D.A.5 Each Planning Coordinator shall designate, at least once every five calendar years, the strategic power plants that must comply with Attachment 2B~~a~~ and notify, within 30 calendar days of its designation, each Generator Owner or Transmission Owner that owns facilities[9] in the strategic power plants. *[Violation Risk Factor: Medium] [Time Horizon: Long-term planning]*

M.D.A.5 Each Planning Coordinator shall have evidence that it designated, at least once every five calendar years, strategic power plants in accordance with Requirement D.A.5, Part 5 and shall have dated evidence that each Generator Owner or Transmission Owner has been notified in accordance with Requirement D.A.5, part 5.2. Evidence may include, but is not limited to: letters, emails, electronic files, or hard copy records demonstrating transmittal of information.

[9] Facilities in the strategic power plants include facilities with synchronous generator(s) from the generator up to and including the MPT or GSU.

Violation Severity Levels

This Variance adds a VSL for D.A.5 and modifies the VSL for R2 as follows:

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
D.A.2.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable voltage protection so that it does not trip ~~or enter momentary cessation~~ in accordance with Requirement D.A.2. OR The Generator Owner or Transmission Owner set its applicable voltage protection in accordance with Requirement D.A.2 but, for strategic power plants, failed to do so within 48 months of notification.
D.A.5.	N/A	The Planning Coordinator designated strategic power plants at least once every five calendar years but notified each Generator Owner or Transmission Owner that owns	The Planning Coordinator designated strategic power plants at least once every five calendar years but notified each Generator Owner or Transmission Owner that owns	The Planning Coordinator failed to designate, at least once every five years, the strategic power plants that must comply with Attachment 2B~~a~~.

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
		facilities in the strategic power plants between 31 days and 45 days after its designation.	facilities in the strategic power plants between 46 days and 60 days after its designation.	OR The Planning Coordinator failed to notify, each Generator Owner or Transmission Owner that owns facilities in the strategic power plants or notified them more than 60 days after the its designation.

Table 1.2

[10] The figures do not visually represent the "no trip zone" boundaries before 0.1 seconds and after 10,000 seconds. The Frequency Boundary Data Points Table defines the entirety of the "no trip zone" boundaries.

[11] Frequency is calculated over a window of time. While the frequency boundaries include the option to trip instantaneously for frequencies outside the specified range, this calculation should occur over a time window. Typical window/filtering lengths are three to six cycles (50 – 100 milliseconds). Instantaneous trip settings based on instantaneously calculated frequency measurement is not permissible.

Table ~~1~~2.2

[8] Voltage at the high-side of the GSU or MPT.

Attachment 2A: Voltage Boundary Clarifications – Eastern, Western, and ERCOT Interconnections

Boundary Details:

1. Unless otherwise specified by the Transmission Planner, the per unit voltage base for these boundaries is the nominal transmission system voltage (e.g., 100 kV, 115 kV, 138 kV, 161 kV, 230 kV, 345 kV, 400 kV, 500 kV, 765 kV, etc.).
2. The values in the table represent the minimum time durations allowed for specified voltage excursion thresholds.
3. When evaluating volts per hertz protection, either assume a system frequency of 60 Hertz or the magnitude of the high voltage boundary can be adjusted in proportion to deviations of frequency below 60 Hertz.
4. Voltages in the boundaries assume RMS fundamental frequency phase-to-ground or phase-to-phase per unit voltage.
5. For applicability to PRC-024, the "no trip zone" ends at 4 seconds.

Evaluating Protection Settings:

The voltage values in the Attachment 2 voltage boundaries are voltages at the high~~-~~-side of the GSU/MPT. For ~~generating~~ resources with multiple stages of step up to reach interconnecting voltage, this is the high~~-~~-side of the transformer with a low side below 100kV and a high~~-~~-side 100kV or above**.** When evaluating protection settings, consider the voltage differences between where the protection is measuring voltage and the high~~-~~-side of the GSU/MPT. A steady state calculation or dynamic simulation may be used.

If using a steady state calculation or dynamic simulation, use the following conditions when evaluating protection settings:

a. The most probable real and reactive loading conditions for the unit under study.
b. All installed generating plant reactive support (e.g., static VAR compensators, synchronous condensers, capacitors) equipment is available and operating normally.
c. Account for the actual tap settings of transformers between the generator terminals and the high~~-~~-side of the GSU/MPT.
d. For dynamic simulations, the automatic voltage regulator is in automatic voltage control mode with associated limiters in service.

≥0.90	continuous	~~≥0.90~~	~~continuous~~

Table 2

Attachment 2C~~a~~: Voltage Boundary Clarifications – Quebec Interconnection

Boundary Details:

1. The per unit voltage base for these boundaries is the nominal operating voltage (e.g., 120 kV, 161 kV, 230 kV, 315 kV, 735 kV, etc.).
2. The values in the table represent the minimum time durations allowed for specified voltage excursion thresholds.
3. When evaluating volts per hertz protection, either assume a system frequency of 60 Hertz or the magnitude of the high voltage boundary can be adjusted in proportion to deviations of frequency below 60 Hertz.
4. Voltages in the Quebec Interconnection boundaries assume positive-sequence values.

Evaluating Protection Settings:

The voltage values in the Attachment 2B~~a~~ voltage boundaries are voltages at the high~~-~~-side of the GSU/MPT. For ~~generating~~ resources with multiple stages of step up to reach interconnecting voltage, this is the high~~-~~-side of the transformer that connects to the interconnecting voltage. When evaluating protection settings, consider the voltage differences between where the protection is measuring voltage and the high~~-~~-side of the GSU/MPT. A steady state calculation or dynamic simulation may be used.

If using a steady state calculation or dynamic simulation, use the following conditions when evaluating protection settings:

a. The most probable real and reactive loading conditions for the unit under study.
b. All installed generating plant reactive support (e.g., static VAR compensators, synchronous condensers, capacitors) equipment is available and operating normally.
c. Account for the actual tap settings of transformers between the generator terminals and the high~~-~~-side of the GSU/MPT.
d. For dynamic simulations, the automatic voltage regulator is in automatic voltage control mode with associated limiters in service.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

Completed Actions	Date
Standards Committee accepted revised Standard Authorization Request (SAR) for posting	April 19, 2023
Standards Committee approved waivers to the Standards Process Manual	December 13, 2023

Anticipated Actions	Date
25-day formal comment period with initial ballot	March 27 - April 22, 2024
15-day formal comment period and additional ballot	May 20 - June 4, 2024
15-day formal comment period and additional ballot	July 1 - 16, 2024
Final Ballot	July 18 - 24, 2024
Board adoption	August 14, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

Continuous Operating Region – The range of voltages, measured at the high-side of the main power transformer, that are ≥ 0.9 per unit and ≤ 1.1 per unit.

Mandatory Operating Region – The range of voltages, measured at the high-side of the main power transformer, that are > 0.1 per unit and < 0.9 per unit – or – > 1.1 and ≤ 1.2 per unit.

Permissive Operating Region – The range of voltages, measured at the high-side of the main power transformer, that is ≤ 0.1 per unit.

A. Introduction

1. **Title:** **Frequency and Voltage Ride-through Requirements for Inverter-Based Generating Resources**
2. **Number:** **PRC-029-1**
3. **Purpose:** To ensure that Inverter-Based Resources (IBRs) remain connected and perform operationally as expected to support of the Bulk Power System (BPS) during and after defined frequency and voltage excursions.
4. **Applicability:**

   4.1 Functional Entities:

   4.1.1. Generator Owner

   4.1.2. Transmission Owner[1]

   4.2 Facilities: For purposes of this standard, the term "applicable Inverter-Based Resource" or "applicable Inverter-Based Resources" refers to the following:

   4.2.1. BPS IBRs

   4.2.2. IBR Registration Criteria

5. **Effective Date:** See Implementation Plan for Project 2020-02 – PRC-029-1

[1] For owners of Voltage Source Converter – High-voltage Direct Current (VSC-HVDC) transmission facilities that are dedicated connections for IBR to the BPS

B. Requirements and Measures

R1. Each Generator Owner or Transmission Owner of an applicable IBR shall ensure that each IBR remains electrically connected and continues to exchange current in accordance with the no-trip zones and operation regions as specified in **Attachment 1** unless needed to clear a fault or a documented equipment limitation exists in accordance with **Requirement R6**. *[Violation Risk Factor: High] [Time Horizon: Operations Assessment]*

M1. Each Generator Owner and Transmission Owner shall have evidence of actual recorded data or other evidence for each applicable IBR demonstrating adherence to ride-through requirements, as specified in **Requirement R1**.

R2. Each Generator Owner or Transmission Owner of an applicable IBR shall ensure that during a System disturbance, each IBR's voltage performance adheres to the following, unless a documented equipment limitation exists in accordance with **Requirement R6**. *[Violation Risk Factor: High] [Time Horizon: Operations Assessment]*

2.1. While the voltage at the high-side of the main power transformer remains within the Continuous Operation Region as specified in **Attachment 1**, each IBR shall:

2.1.1 Continue to deliver the pre-disturbance level of active power or available active power, whichever is less, and continue to deliver active power and reactive power up to its apparent power limit.

2.1.2 If the IBR cannot deliver both active and reactive power due to a current or apparent power limit, when the applicable voltage is below 95% and still within the Continuous Operation Region, then preference shall be given to active or reactive power according to requirements specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

2.2. While voltage at the high-side of the main power transformer is within the Mandatory Operation Region as specified in **Attachment 1**, each IBR shall:

2.2.1 Exchange current, up to the maximum capability while maintaining automatic voltage regulation, on the affected phases during both symmetrical and asymmetrical voltage disturbances.

2.2.2 Adjust reactive current injection at the high-side of the main power transformer so that the magnitude of the reactive current responds to changes in voltage at the high-side of the main power transformer in accordance with default reactive prioritization unless the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator specifies a certain magnitude of reactive power response to voltage changes or specifies active power priority instead of reactive power priority.

2.3. The IBR shall not itself cause voltage at the high-side of the main power transformer to exceed the applicable **Attachment 1** Table 1 or Table 2 no-trip zone voltage thresholds and time durations in its response from Mandatory or Permissive Operation Regions to the Continuous Operating Region.

2.4. Each IBR shall restore active power output to the pre-disturbance or available level within 1.0 second when the voltage at the high-side of the main power transformer returns to the Continuous Operation Region from the Mandatory Operation Region or Permissive Operation Region (including operation in current block mode) as specified in **Attachment 1**, unless the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator specifies a lower post-disturbance active power level requirement or specifies a different post-disturbance active power restoration time.

2.5. Each IBR shall only trip to prevent equipment damage, when the voltage at the high-side of the main power transformer is outside of the no-trip zone as specified in **Attachment 1**.

M2. Each Generator Owner and Transmission Owner shall have evidence of actual recorded data or other evidence for each applicable IBR demonstrating adherence to performance requirements, as specified in **Requirement R2**, during each System disturbance which has occurred within the associated Planning Coordinator(s) area(s).

R3. Each Generator Owner or Transmission Owner of an applicable IBR shall ensure that during a transient overvoltage as a result of a switching event whereby instantaneous voltage at the high-side of the main power transformer exceeds 1.2 per unit, each IBR shall either: *[Violation Risk Factor: Lower] [Time Horizon: Operations Assessment]*

- Remain electrically connected and continue to exchange current in accordance with instantaneous transient overvoltage levels and durations specified in **Attachment 2**; or
- Remain electrically connected in current block mode in accordance with instantaneous transient overvoltage levels and durations specified in **Attachment 2**, and restart current exchange within 5 cycles of the instantaneous voltage falling below (and remaining below) 1.2 per unit.

M3. Each Generator Owner and Transmission Owner shall have evidence of actual recorded data or other evidence for each applicable IBR demonstrating adherence to performance requirements, as specified in Requirement R3, during each transient overvoltage period which has occurred within the associated Planning Coordinator(s) area(s).

R4. Each Generator Owner or Transmission Owner of an applicable IBR shall ensure each IBR remains electrically connected and continues to exchange current during a frequency excursion event whereby the frequency remains within the “no trip zone” according to **Attachment 3** and the absolute rate of change of frequency (ROCOF)[2]

[2] Rate of change of frequency (ROCOF) is calculated as the average rate of change for multiple calculated system frequencies for a time period of greater than or equal to 0.1 second. ROCOF is not calculated during the fault occurrence and clearance.

magnitude is less than or equal to 5 Hz/second. *[Violation Risk Factor: Lower] [Time Horizon: Operations Assessment]*

M4. Each Generator Owner and Transmission Owner shall have evidence of actual recorded data or other evidence for each applicable IBR demonstrating adherence to ride-through requirements, as specified in Requirement R4, during each frequency excursion event which has occurred within the associated Planning Coordinator(s) area(s).

R5. Each Generator Owner or Transmission Owner of an applicable IBR shall ensure each IBR remains electrically connected and continues to exchange current during instantaneous positive sequence voltage phase angle changes that are initiated by non-fault switching events on the transmission system and are changes of less than 25 electrical degrees at the high-side of the main power transformer. *[Violation Risk Factor: Lower] [Time Horizon: Operations Assessment]*

5.1. When the instantaneous positive sequence voltage phase angle change is more than 25 electrical degrees at the high-side of the main power transformer and is initiated by a non-fault switching event on the transmission system, the IBR may trip, but shall only trip to prevent equipment damage.

M5. Each Generator Owner and Transmission Owner shall have evidence of actual recorded data or other evidence for each applicable IBR demonstrating adherence to ride-through requirements, as specified in Requirement R5, during instantaneous positive sequence voltage phase angle changes that are changes of less than 25 electrical degrees at the high-side of the main power transformer and that such changes are not initiated by non-fault switching events.

R6. Each Generator Owner and Transmission Owner with a documented equipment limitation that would prevent an applicable IBR that is in-service by the effective date of this standard from meeting voltage ride-through requirements as detailed in Requirements R1 and R2 shall communicate each equipment limitation to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s). *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

6.1. Each Generator Owner and Transmission Owner shall include in its documentation:

6.1.1 Identifying information of the IBR (name, facility #, other)

6.1.2 Which aspects of voltage ride-through requirements that the IBR would be unable to meet

6.1.3 Identify the specific piece(s) of equipment causing the limitation

6.1.4 Information regarding any plans to repair or replace the limiting equipment that would remove the limitation (such as estimated date of repair/replacement)

6.2. Each Generator Owner and Transmission Owner with a previously communicated equipment limitation that repairs or replaces the equipment causing the limitation shall document and communicate such equipment change to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s) within 30 days of the equipment change.

M6. Each Generator Owner and Transmission Owner shall have evidence of equipment limitations, as specified in Requirement R6, documented prior to the effective date of PRC-029-1. Each Generator Owner and Transmission Owner with changes to equipment shall have evidence of communication to each associated Planning Coordinator, Transmission Planner, and Reliability Coordinator. Acceptable types of evidence may include, but are not limited to, meeting minutes, agreements, copies of procedures or protocols in effect between entities or between departments of a vertically integrated system, or email correspondence.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- Each Generator Owner and Transmission Owner shall retain evidence with each requirement in this standard for five calendar years.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to demonstrate each applicable IBR remains electrically connected and continued to exchange current in accordance with Attachment 1, unless needed to clear a fault, in accordance with Requirement R1.
R2.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to demonstrate each applicable IBR adhered to performance requirements during each System disturbance, as specified in Requirement R2.
R3.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to demonstrate each applicable IBR adhered to performance requirements during each transient overvoltage period as specified in Requirement R3.

Version History

Version	Date	Action	Change Tracking
Initial Draft	3/27/24	DRAFT	

Attachment 1: Voltage Ride-Through Criteria

Table 1: Voltage Ride-Through Requirements for AC-Connected Wind IBR

Voltage (per unit)	Minimum Ride-Through Time (sec)
≥1.200	N/A
≥1.1	1.0
≥1.05	1800
< 0.90	3.00
< 0.70	2.50
< 0.50	1.20
< 0.25	0.16
< 0.10	0.16

Table 2: Voltage Ride-Through Requirements for All Other IBR

Voltage (per unit)	Minimum Ride-Through Time (sec)
≥1.200	N/A
≥1.1	1.0
≥1.05	1800
< 0.90	6.00
< 0.70	3.00
< 0.50	1.20
< 0.25	0.32
< 0.10	0.32

1. Table 1 applies to applicable wind IBR unless connected via a dedicated VSC-HVDC transmission facility.
2. Table 2 applies to all other IBR types not covered in Table 1; including, but not limited to, the following IBR:
    a. Isolated IBR, regardless of their energy resource, interconnecting via a dedicated VSC-HVDC transmission facility.
    b. Other IBR plants or hybrid plants consisting of photovoltaic (PV) and ESS.

3. In the case of hybrid IBR consisting of wind and various other IBR technologies, the applicable table shall be based on direction by the Transmission Planner.
4. The voltage base for per unit calculation is the nominal phase-to-ground or phase-to-phase transmission system voltage unless otherwise defined by the Planning Coordinator or Transmission Planner.
5. The applicable voltage for Tables 1 and 2 is identified as the voltage max/min of phase to neutral or phase to phase fundamental root mean square (RMS) voltage at the high side of the MPT.
6. Tables 1 and 2 are only applicable when the frequency is within the no trip zone as specified in Table 3 of Attachment 3.
7. At any given voltage value, each IBR shall not trip until the time duration at that voltage exceeds the specified minimum ride-through time duration. If the voltage is continuously varying over time, it is necessary to add the duration within each band of Tables 1 and 2 over the 10-second time period to determine compliance.
8. The specified duration of the Mandatory Operation Regions and the Permissive Operation Regions in Tables 1 and 2 is cumulative over one or more disturbances within a 10 second time period.
9. The IBR may trip for more than four deviations of the applicable voltage at the high-side of the main power transformer outside of the Continuous Operation Region within any 10 second time period.
10. If the positive sequence voltage at the high-side of the main power transformer enters the Permissive Operation Region, an IBR may operate in current block mode if necessary to protect the equipment.

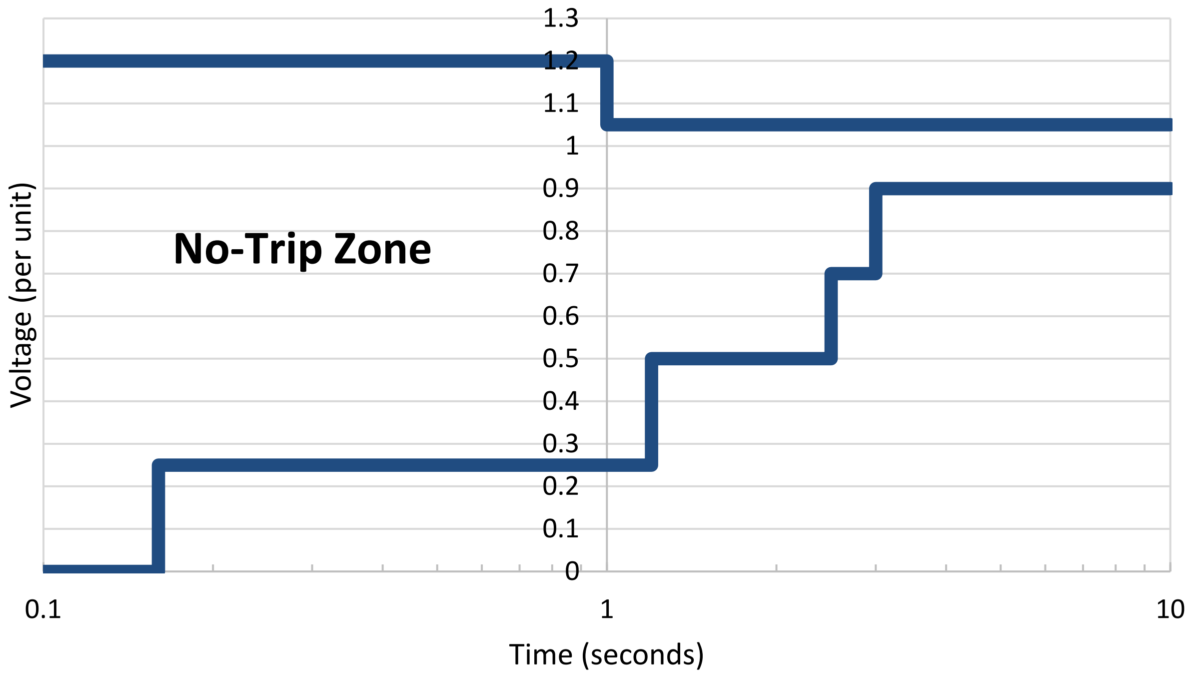

Figure 1: Voltage Ride-Through Requirements for AC-Connected Wind IBR

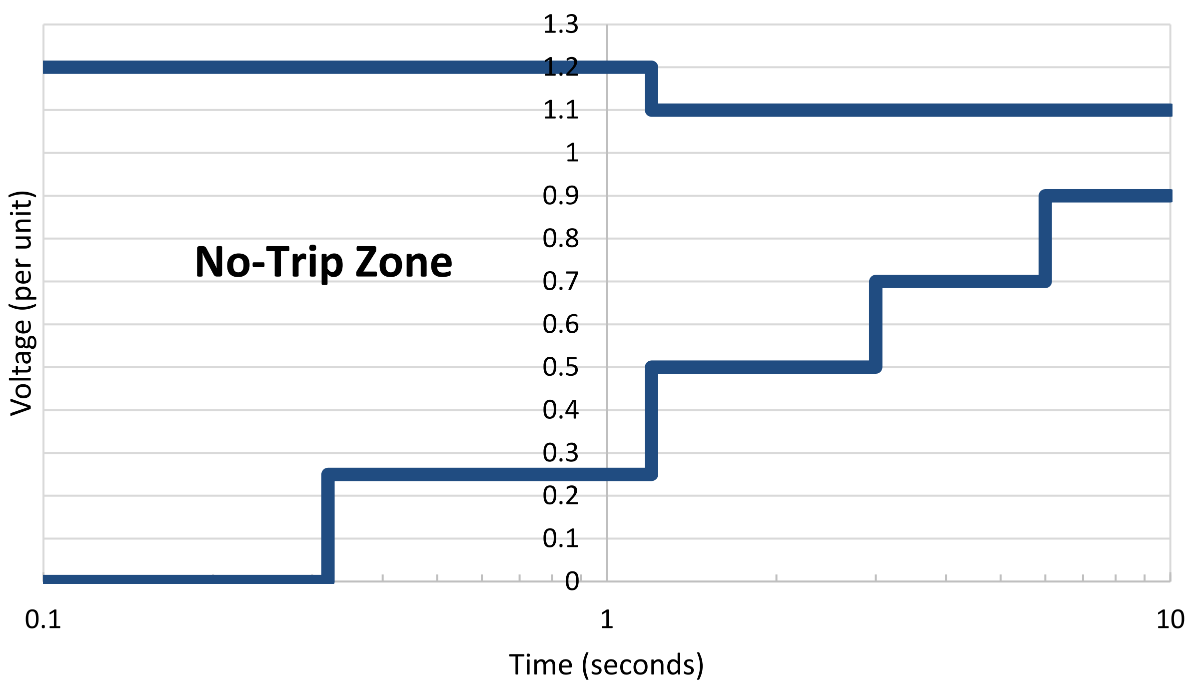

Figure 2: Voltage Ride-Through Requirements for All Other IBR

Attachment 2: Transient Overvoltage Ride-Through Criteria

Table 3: Transient Overvoltage Ride-Through Criteria

Voltage (per unit) at the high side of the MPT	Minimum Ride-Through Time (millisec)
> 1.8	May trip
> 1.7	0.2
> 1.6	1.0
> 1.4	3.0
> 1.2	15.0

1. The voltage base for per unit calculation is the nominal instantaneous phase-to-ground or phase-to-phase voltage at the high side of the MPT unless otherwise defined by the Planning Coordinator or Transmission Planner.
2. If surge protection devices are installed within the plant, the per unit voltage refers to the residual voltage with the surge arresters applied.
3. Each IBR shall not trip unless the cumulative time of one or more instances over a 1-minute time window in which the instantaneous voltage exceeds the respective voltage threshold and the minimum ride-through time.

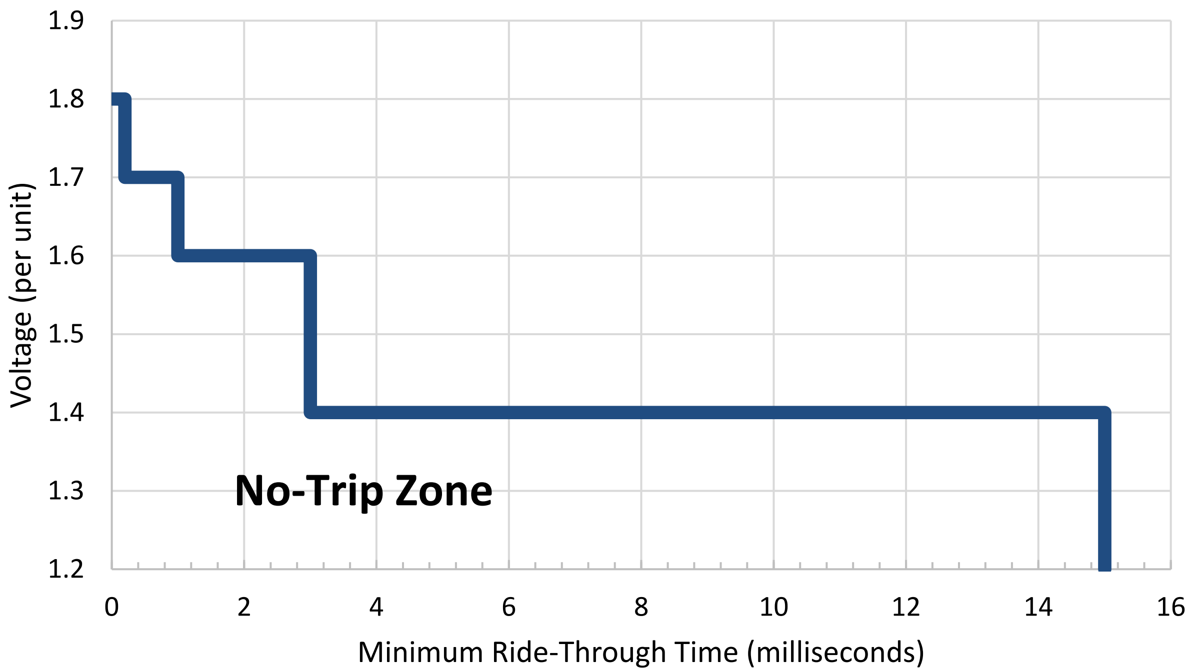

Figure 3: Transient Overvoltage Ride-Through Criteria

Attachment 3: Frequency Ride-Through Criteria

Table 4: Frequency Ride-Through Capability Requirements

Averaged System Frequency (Hz)	Minimum Ride-Through Time (sec)
≥64	May trip
≥61.8	6
> 61.5	299
> 61.2	660
< 58.8	660
< 58.5	299
< 57.0	6
< 56	May trip

1. Measurements are taken at the high-side of the main power transformer for each phase (phase to neutral).
2. Measurements are averaged over a set time period (such as 3-6 cycles) to calculate averaged system frequency at the high-side of the main power transformer.
3. Instantaneous or single points of measurement may not be used in the determination of control settings.
4. At any given frequency values, each IBR shall not trip until the time duration at that frequency exceeds the specified minimum ride-through time duration.
5. The specified durations of Table 4 are cumulative over one or more disturbances within a 15-minute time period.

Implementation Plan

Project 2020-02 Modifications to PRC-024 (Generator Ride-through)
Reliability Standards PRC-024-4 and PRC-029-1

Applicable Standard(s)

- PRC-024-4 Frequency and Voltage Protection Settings for Synchronous Generators and Synchronous Condensers
- PRC-029-1 Frequency and Voltage Ride Through Requirements for Inverter-Based Generating Resources

Requested Retirement(s)

- PRC-024-3 Frequency and Voltage Protection Settings for Generating Resources

Prerequisite Standard(s)

- PRC-028-1 Disturbance Monitoring and Reporting Requirements for Inverter-Based Resources

Proposed Definition(s)

- None

Applicable Entities

- See subject Reliability Standards.

Background

The purpose of Project 2020-02 is to modify Reliability Standard PRC-024-3 or replace it with a performance-based ride-through standard that ensures generators remain connected to the Bulk-Power System (BPS) during system disturbances. Specifically, the project focuses on using disturbance monitoring data to substantiate inverter-based resource (IBR) ride-through performance during grid disturbances. The project also ensures associated generators that fail to ride-through system events are addressed with a corrective action plan (if possible) and reported to necessary entities for situational awareness.

The purpose for this project is based on the culmination of multiple analyses conducted by the ERO Enterprise regarding widespread inverter-based resource tripping events. Furthermore, the NERC Inverter-Based Resource Performance Subcommittee[1] has developed comprehensive

[1] See documents at the NERC IRPS website: https://www.nerc.com/comm/RSTC/Pages/IRPS.aspx and the previous Inverter-Based Resource Performance Working Group website https://www.nerc.com/comm/RSTC/Pages/IRPWG.aspx

recommendations for improved performance of inverter-based resources, including the recommendation to develop comprehensive ride-through requirements.

In October 2023, FERC issued Order No. 901[2] which directs the development of new or modified Reliability Standards that include new requirements for disturbance monitoring, data sharing, post-event performance validation, and correction of IBR performance. In January 2024, NERC submitted a filing to FERC outlining a comprehensive work plan to address the directives within Order No. 901.[3] Within the work plan, NERC identified three active Standards Development projects that would need to be filed for regulatory approval with FERC by November 4, 2024. These projects include **2020-02 Modifications to PRC-024 (Generator Ride-through)**[4], **2021-04 Modifications to PRC-002-2**[5], and **2023-02 Analysis and Mitigation of BES Inverter-Based Resource Performance Issues**[6].

Project 2020-02

Proposed Reliability Standard PRC-029-1 is a new Reliability Standard that includes ride-through requirements and performance requirements for IBRs. The scope of this project was adjusted to align with associated regulatory directives from FERC Order No. 901 and the scope of the other projects related to “Milestone 2” of the NERC work plan. The components of this project’s Standard Authorization Request (SAR) that related to the inclusions of new data recording requirements are covered in Project 2021-04 and the proposed new PRC-028-1 Reliability Standard. Components of this project’s SAR that relate to analytics and corrective actions plans are covered in Project 2023-02 and the proposed new PRC-030-1 Reliability Standard.

PRC-029-1 includes requirements for Generator Owner and Transmission Owner IBR to continue to inject current and perform frequency support during a BPS disturbance. The standard also specifically requires Generator Owner and Transmission Owner IBR to prohibit momentary cessation in the no-trip zone during disturbances.

PRC-024-4 includes modifications to revise applicable facility types to remove IBR and to include synchronous condensers.

[6] See NERC Standards Development Project page for Project 2023-02; https://www.nerc.com/pa/Stand/Pages/Project-2023-02-Performance-of-IBRs.aspx

General Considerations

The ERO Enterprise acknowledges that there are IBRs currently in operation and unable to meet voltage ride-through requirements due to their inability to modify their coordinated protection and control settings. Consistent with FERC Order No. 901, a limited and documented exemption process for those IBR is appropriate and included within this Implementation Plan. Other NERC Standards Development projects will be pursued to address ongoing identification and mitigation of any potential reliability impacts to the BPS for such exemptions.

Effective Date and Phased-in Compliance Dates

The effective dates for the proposed Reliability Standards are provided below. Where the standard drafting team identified the need for a longer implementation period for compliance with a particular section of a proposed Reliability Standard (i.e., an entire Requirement or a portion thereof), the additional time for compliance with that section is specified below. The phased-in compliance dates for those particular sections represent the date that entities must begin to comply with that particular section of the Reliability Standard, even where the Reliability Standard goes into effect at an earlier date.

PRC-024-4

Where approval by an applicable governmental authority is required, Reliability Standard PRC-024-4 shall become effective on the first day of the first calendar quarter that is 6 months after the effective date of the applicable governmental authority's order approving the standard, or as otherwise provided for by the applicable governmental authority.

Where approval by an applicable governmental authority is not required, the Reliability Standard PRC-024-4 shall become effective on the first day of the first calendar quarter that is 6 months after the date the standard is adopted by the NERC Board of Trustees, or as otherwise provided for in that jurisdiction.

PRC-029-1

Where approval by an applicable governmental authority is required, Reliability Standard PRC-029-1 shall become effective on the first day of the first calendar quarter that is six months after the effective date of the applicable governmental authority's order approving the standard, or as otherwise provided for by the applicable governmental authority.

Where approval by an applicable governmental authority is not required, the Reliability Standard PRC-029-1 shall become effective on the first day of the first calendar quarter that is six months after the date the standard is adopted by the NERC Board of Trustees, or as otherwise provided for in that jurisdiction.

Compliance Date for PRC-029-1 - Requirement R6

Entities shall not be required to comply with Requirement R6 until six months after the effective date of Reliability Standard PRC-029-1. This compliance date is intended to assure equipment limitations have additional time to complete the equipment limitation process as outlined below.

Retirement Date

PRC-024-3

Reliability Standard PRC-024-3 shall be retired immediately prior to the effective date of Reliability Standards PRC-024-04 and PRC-029-1 in the particular jurisdiction in which the revised standard is becoming effective.

Equipment Limitations and Process for Requirement R6

Consistent with FERC Order No. 901, a limited and documented exemption for some legacy IBR with certain documented equipment limitations are acceptable. Per the Order, these IBRs are

> "…typically older IBR technology with hardware that needs to be physically replaced and whose settings and configurations cannot be modified using software updates – may be unable to implement the voltage ride though performance requirements."[7]

To assure compliance with Requirement R6 and alignment with FERC Order No. 901, only those IBR that are in operation as of the effective date of PRC-029-1 may be considered for potential exemption. Further, only those IBR that are unable to meet voltage ride-through requirements due to their inability to modify their coordinated protection and control settings may be considered for potential exemption.

Generator Owners with IBR that meet these criteria for equipment limitations must identify which of those IBR will be unable to meet voltage ride-through requirements, as described in Requirement R6. For each identified IBR, the associated Generator Owner must document:

- Identifying information of the IBR (name, facility #, other)
- Which aspects of voltage ride-through requirements that the IBR would be unable to meet
- Information regarding the limiting equipment
- Information regarding any plans to repair or replace the limiting equipment that would remove the limitation (such as estimated date of repair/replacement)

For each identified IBR, the associated Generator Owner must communicate the documented information listed above to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s), per the Requirement R6 no later than the effective date of Requirement R6.

[7] Order No. 901 at p. 193.

Project 2020-02 Modifications to PRC-024 (Generator Ride-through)

Do not use this form for submitting comments. Use the [Standards Balloting and Commenting System (SBS)] to submit comments on **Project 2020-02 Modifications to PRC-024 (Generator Ride-through)** by **8 p.m. Eastern, Monday, April 22, 2024.**

Additional information is available on the [project page]. If you have questions, contact Manager of Standards Development, [Jamie Calderon] (via email), or at 404-960-0568.

Background Information

The goal of Project 2020-02 is to mitigate the recent and ongoing disturbance ride-through performance issues identified across multiple Interconnections and numbers of disturbances analyzed by NERC and the Regions. These issues have been associated with Inverter-Based Resources (IBR) with many causes of their tripping or cessation unrelated to voltage and frequency protection settings requirements in the currently effective version of PRC-024, PRC-024-3. Proposed Reliability Standard PRC-024-4 includes revisions to limit its applicability to synchronous generators and synchronous condensers only and remains as a protection-based standard. A new standard, PRC-029-1, is proposed as a true disturbance ride-through Reliability Standard with applicability to inverter-based resources..

In October 2023, FERC issued Order No. 901, which directed NERC to develop new or modified existing Reliability Standards that include new requirements for disturbance monitoring, data sharing, post-event performance validation, and correction of IBR performance. Project 2020-02 was one of three projects identified by NERC that must be completed and filed with FERC by November 4, 2024 to address Order No. 901 directives. At their December 2023 meeting, the Standards Committee approved a waiver for Project 2020-02, allowing formal comment periods to be reduced from 45 days to 25 calendar days, ballot pools reduced from 30 days to as few as 10 days, and final ballot periods to be reduced from 10 days to as few as 5 calendar days.

Questions

1. Do you agree with the need for creating a new Standard (PRC-029-1) to address gaps the Inverter-Based Resource Performance Subcommittee (IRPSC) identified within the PRC-024-3 Project 2020-02 SAR and to address the expectations of FERC Order No. 901?

   ☐ Yes
   ☐ No

   Comments:

2. Do you agree that the language within PRC-029-1 requirements R1, R2, and R6 regarding IBR plant-level performance during grid voltage disturbances is clear?

☐ Yes
☐ No

Comments:

3. Do you agree with the drafting team's proposals for including IBR transient overvoltage, frequency, ROCOF, and instantaneous voltage phase-angle jump ride-through performance criteria in PRC-029-1 Requirements R3, R4, and R5?

☐ Yes
☐ No

Comments:

4. Provide any additional comments for the Drafting Team to consider, if desired.

Comments:

Technical Rationale

Project 2020-02 Modifications to PRC-024 (Generator Ride-through)

PRC-024-4 – Frequency and Voltage Protection Settings for Synchronous Generators and Synchronous Condensers

General Rationale

The drafting team proposes to modify PRC-024-3 to retain the Reliability Standard as a protection-based standard with applicability to only synchronous generators and synchronous condensers. This proposal is a consequence of both the different natures of synchronous and inverter-based generation resources and several recent events exhibiting significant IBR ride-through deficiencies. The behavior of rotating synchronous generators during faults and other disturbances on the transmission system is well established and understood in comparison to IBR generation. The disturbance ride-through vulnerabilities of synchronous generators are pole slipping instability and undervoltage dropout of critical plant auxiliary equipment, leading to tripping of a generator. Pole slipping can be managed by active power dispatch and system condition constraints, and is outside the scope of PRC-024-3. Undervoltage dropout of critical auxiliary equipment is also outside the scope of PRC-024-3 because of complexities associated with auxiliary systems and how such equipment behaves under low voltage conditions.

The Project 2020-02 Standard Authorization Request (SAR) notes that auxiliary equipment has not posed a ride-through risk and the SAR specifically excludes modifications in PRC-024-3 for auxiliary equipment. Over-frequency protection, under-frequency protection, and voltage protection may or may not be applied to synchronous generating units. If applied however, settings should be coordinated between the needs of generating unit protection, reasonable expected excursions of system frequency and voltage in a straightforward fashion, e.g., as no-trip zones within PRC-024-3 attachments, as well as the coordination of generating unit capabilities, voltage regulating controls, and protection within PRC-019-2. Excitation and governing controls affect synchronous generator ride-through behavior to some degree but because of progressive improvement, standardization, and level of maturity of these controls, they are rarely if ever cause unnecessary tripping during disturbances.

In addition, there are other existing NERC standards to prevent unnecessary tripping of the generators during a system disturbance such as PRC-025-2 “Generator Relay Loadability”, and PRC-026-2 “Relay Performance During Stable Power Swings”. For these reasons, there is no need to impose actual disturbance ride-through requirements on synchronous units and only include restrictions for frequency and voltage protection setting ranges as maintained in PCR-024-4.

Rationale for Applicability Section (4.0)

Functional Entities (4.1)

The functional entity responsible for setting frequency, voltage, and volts per hertz protection for synchronous generators and synchronous condensers is the Generator Owner (GO) and Transmission

Owner (TO). Planning Coordinators (PC) are also retained as applicable entities but are only in the Quebec Interconnection. Modifications are proposed in PRC-024-4 to expand functional entity applicability to includes those Transmission Owners that apply protection, as listed in new Facility applicability section 4.2.2.

Facilities (4.2)

Applicability Facilities subparts in Section 4.1.1 were modified to restrict PRC-024-4 to synchronous generators. Section 4.2.2 was added as new subparts to identify which synchronous condensers and equipment.

Rationale for Requirements R1 through R4

Modifications were made to Requirements R1, R2, R3, and R4 to include the Transmission Owner as an functional entity applicable to each requirement.

Modifications were made to Requirements R1, R2, R3, and R4 to include language for synchronous condensers and to remove language that relates to inverter-based resource functionality (i.e., “cease injecting current”).

NERC
NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Technical Rationale

Project 2020-02 Modifications to PRC-024 (Generator Ride-through)

PRC-029-1 – Frequency and Voltage Ride-Through Requirements for Inverter-Based Generating Resources

General Rationale

The drafting team has created a new Reliability Standard (PRC-029-1) to address inverter-based resource (IBR) disturbance ride-through performance criteria. This proposal is a consequence of both the different natures of synchronous and inverter-based generation resources and several recent events exhibiting significant IBR ride-through deficiencies. The proposed PRC-029-1 coincides with ride-through requirements of IEEE 2800 but is structured to follow language from FERC Order No. 901, which states that "NERC has the discretion to consider during its standards development process whether and how to reference IEEE standards in the new or modified Reliability Standards."[1]

The lack of standardization of IBR technology (equipment/controller behavior) has created reliability challenges associated with the interconnection of IBR facilities to the power grid. The nature of the fast switching of power electronics of IBR generation and the electronic interface to the transmission system is such that disturbance ride-through behavior is largely determined by manufacturer-specific equipment and controls system designs. These controls may be programmed but also have more restrictive limits on current, both in magnitude and duration. IBR responses to grid disturbances are highly controlled and managed by using fast switching of power electronics devices dependent upon manufacturer specific control system design that can be programmed in many ways and with various and concurrent ride--through performance objectives. Rather than attempting to restrict the myriad of control approaches, protections, and settings, it is more straightforward to require ride-through during defined frequency and voltage excursions.

In contrast to synchronous generation, the need for IBR ride-through requirements has been heightened by recent events during which IBRs have not met PRC-024-3 frequency and voltage ride-through expectations, often due to controls and protection only indirectly associated with the system voltage and frequency excursions. In addition to ride-through, there is the question of what IBRs should be doing as they ride-through. IBR responses to system disturbances can be beneficial or detrimental to both their own ride-through and system reliability, often depending on adjustable control settings. Thus, it is essential to set expectations on performance during ride-through as well as ride-through capability.

IBR do not provide inertia or short circuit contributions, unlike synchronous machines. The drafting team thinks that IBR should compensate for their lack of inertia and short circuit contributions with wider

[1] P 195, FERC Order No. 901; https://elibrary.ferc.gov/eLibrary/filelist?accession_number=20231019-3157&optimized=false; October 17, 2023

tolerances for frequency and voltage excursions. This is the reason for the differences in the frequency and voltage tables and graphs between the two standards.

The proposed PRC-029 must be understood as an event-based standard. Compliance with PRC-029 is determined from IBR ride-through performance during transmission system events in the field and not from interconnection studies, transmission planning studies, operational planning studies, or from IBR models. An IBR becomes noncompliant with PRC-029 only when an event in the field occurs that shows that one or more requirements were not satisfied. This intent is clarified by *Operations Assessment* as the Time Horizon designation of requirements R1-R5.

FERC Order No. 901 Directives

PRC-029-1 is proposed in consideration of directives from FERC Order No. 901 that were assigned to the Project 2020-02 drafting team. The following directives were assigned to this drafting team for inclusion in this Standards Project (paragraph numbers of the FERC Order are included for reference):

- Paragraph 190: “Pursuant to section 215(d)(5) of the FPA, we adopt the NOPR proposal and direct NERC to develop new or modified Reliability Standards that require registered IBR generator owners and operators to use appropriate settings (i.e., inverter, plant controller, and protection) to ride through frequency and voltage system disturbances and that permit IBR tripping only to protect the IBR equipment in scenarios similar to when synchronous generation resources use tripping as protection from internal faults.”
- Paragraph 190: “The new or modified Reliability Standards must require registered IBRs to continue to inject current and perform frequency support during a Bulk-Power System disturbance.”
- Paragraph 190: “Any new or modified Reliability Standard must also require registered IBR generator owners and operators to prohibit momentary cessation in the no-trip zone during disturbances.”
- Paragraph 190: “NERC must submit new or modified Reliability Standards that establish IBR performance requirements, including requirements addressing frequency and voltage ride through, post-disturbance ramp rates, phase lock loop synchronization, and other known causes of IBR tripping or momentary cessation.”
- Paragraph 193: “Therefore, we direct NERC through its standard development process to determine whether the new or modified Reliability Standards should provide for a limited and documented exemption for certain registered IBRs from voltage ride through performance requirements.”
- Paragraph 193: “Further, we direct NERC to ensure that any such exemption would be applicable for only existing equipment that is unable to meet voltage ride-through performance. When such existing equipment is replaced, the exemption would no longer apply, and the new equipment must comply with the appropriate IBR performance requirements specified in the Reliability Standards (e.g., voltage and frequency ride through, phase lock loop, ramp rates, etc.).”

- Paragraph 193: "Finally, we direct NERC, through its standard development process, to require the limited and documented exemption list (i.e., IBR generator owner and operator exemptions) to be communicated with their respective Bulk-Power System planners and operators (e.g., the IBR generator owner's or operator's planning coordinator, transmission planner, reliability coordinator, transmission operator, and balancing authority)."
- Paragraph 199: "Pursuant to section 215(d)(5) of the FPA, we modify the NOPR proposal. To the extent NERC determines that a limited and documented exemption for those registered IBRs currently in operation and unable to meet voltage ride-through requirements is appropriate due to their inability to modify their coordinated protection and control settings, we direct NERC to develop new or modified Reliability Standards to mitigate the reliability impacts to the Bulk-Power System of such an exemption."
- Paragraph 208: "Pursuant to section 215(d)(5) of the FPA, we adopt the NOPR proposal and direct NERC to develop and submit to the Commission for approval new or modified Reliability Standards that require post-disturbance ramp rates for registered IBRs to be unrestricted and not programmed to artificially interfere with the resource returning to a pre-disturbance output level in a quick and stable manner after a Bulk-Power System."
- Paragraph 209: "The proposed new or modified Reliability Standards must require registered IBRs to ride through momentary loss of synchronism during Bulk-Power System disturbances and require registered IBRs to continue to inject current into the Bulk-Power System at pre-disturbance levels during a disturbance, consistent with the IBR Interconnection Requirements Guideline and Canyon 2 Fire Event Report recommendations."
- Paragraph 209: "Related to ACP/SEIA's comment recommending to revise the directive to require generators to maintain synchronism where possible and continue to inject current to support system stability, we direct NERC, through its standard development process, to consider whether there are conditions that may limit generators to maintain synchronism."
- Paragraph 226: "Further, we believe that there is a need to have all of the directed Reliability Standards effective and enforceable well in advance of 2030 and direct NERC to ensure that the associated implementation plans sequentially stagger the effective and enforceable dates to ensure an orderly industry transition for complying with the IBR directives in this final rule prior to that date." (*pertains multiple projects*)

Rationale for Applicability Section (4.0)

Functional Entities (4.1)

The functional entity responsible for assuring acceptable ride-through performance of IBR is the Generator Owner (GO) and Transmission Owner (TO).

Facilities (4.2)

Applicability Facilities includes only those IBR that also meet NERC registration criteria. Language used within PRC-029-1 applicability only refers to IBR as a whole plant/facility. Consistent with FERC Order No. 901, IBR performance is based on the overall IBR plant and disturbance monitoring equipment requirements established under the proposed PRC-028-1. Requirements within PRC-029-1 do not apply to individual inverter units or measurements taken at individual inverter unit terminals.

Rationale for Requirement R1

The objective of Requirement R1 is to ensure an applicable IBR will ride-through a grid voltage disturbance consistent with the no-trip zone and Operation Regions specified in **Attachment 1**. IBR must be able to demonstrate performance that they remain electrically connected, i.e., shall not trip, and continue to exchange current, i.e., shall not enter momentary cessation.

The drafting team determined that the definition of “no-trip zones” and “Operation Regions” should be consistent with those terms as used within IEEE 2800-2022. Additionally, the team determined the voltage thresholds of each Operation Region are based on measurements taken on the high-side of the main power transformer in PRC-029-1.

Exceptions to **Attachment 1** performance criteria are allowable when 1) an IBR needs to trip to clear a fault within its zone of protection, and 2) a documented equipment limitation prevents an IBR from riding through the disturbance in accordance with Requirement R6.

Rationale for Requirement R2

In addition to having minimum voltage ride-through capability specified in Requirement R1, an applicable IBR is also required to adhere to certain voltage ride-through performance criteria during a system disturbance. Acceptable performance criteria is dependent on the Operation Region that an IBR is presently in, or it’s change from one Operation Region to another Operation Region. Requirement R2 includes specific performance criteria and is needed to assure consistent IBR performance during each Operation Region in **Attachment 1**.

Rationale for Requirement R2.1

This subpart of Requirement 2 ensures, when the voltage at the high-side of the main power transformer (MPT) recovers to the Continuous Operation Region from either the Mandatory Operation Region or the Permissive Operation Region, an IBR is expected to deliver the pre-disturbance level of active power or available active power, whichever is less. This requires an IBR to exit the “High Voltage Ride Through (HVRT)” or “Low Voltage Ridge Through (LVRT)” modes properly such that it does not cause reduction in the active power when the system already recovers the voltage within the Continuous Operation Region.

When the voltage at the high-side of the MPT is greater than 0.9 per-unit and less than 0.95 per-unit, IBRs are expected to exit the LVRT mode and come back to “normal operating mode”. If an IBR has a default total current limit of 1.0 per-unit, the apparent power production of an IBR will be limited to be below 1.0 per-unit (e.g., the per-unit value of IBR terminal voltage). In such case, IBR needs to configure a preference setting, either to maintain pre-disturbance active power or maximize the reactive power in order to further help with voltage recovery, according to requirements specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

Rationale for Requirement R2.2

This subpart of Requirement 2 ensures when the voltage at the high-side of the MPT is within the Mandatory Operation Region, IBRs are expected to enter the HVRT and LVRT mode such that it will inject or absorb reactive current proportional to the level of terminal voltage deviations it measures. IBR shall follow Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator specified certain magnitude of reactive power response to voltage changes, if available.

By default, reactive current prioritization shall be configured unless Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator requires active power priority.

Rationale for Requirement R2.3

This subpart of Requirement 2 ensures when a fault is cleared on the transmission system, the voltage regulators of connected IBRs must adjust the reactive current injection to restore the transmission system voltage to the pre-disturbance voltage as defined by the automatic voltage regulator (AVR) setpoint. The drafting team acknowledges that tuning of the AVR requires a balance between multiple competing physical factors, e.g., rise time, overshoot, and transient stability. However, it is anticipated that IBR controls will be tuned to allow for a stable post-disturbance voltage recovery without causing excessive overshoot or undershoot of the setpoint. When such overshoots do occur, they must not exceed the magnitude and duration of the applicable table given in **Attachment 1**. Furthermore, this standard anticipates that control system tuning to prevent such over/under voltages will focus on the speed at which the controller responds to setpoint changes rather than on the magnitude of the reactive current response. For example, reductions in k-factor to prevent over/under voltages should only be considered as a last resort.

Rationale for Requirement R2.4

This subpart of Requirement 2 ensures that IBR returns to effective pre-disturbance operation unless otherwise specified or needed by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

Rationale for Requirement R2.5

This subpart of Requirement 2 ensures that voltage protection settings of IBR are based on maximum equipment capabilities rather than settings based directly on, or just outside, of the no-trip zone.

Rationale for Requirement R3

The objective of Requirement R3 is to provide transient overvoltage ride-through for IBR during the non-fault switching event. Voltage transients are commonly occurring on the BPS due to switching actions, fault clearing, lightning, etc. IBR shall ride-through the transient overvoltage condition specified in **Attachment 2** during the non-fault switching events in the transmission systems. During this transient overvoltage event, IBRs should continue to inject current, but it does not have to respond to transient overvoltage, i.e., enter reactive priority mode and/or change magnitude of current output.

If necessary, IBRs may operate in current blocking mode, when instantaneous voltage exceeds 1.2 p.u., to help ensure stable response that does not lead to tripping and to eliminate the IBR as a possible cause for the overvoltage. If IBRs operate in the current blocking mode, it shall restart current exchange in less than or equal to five cycles following instantaneous voltage falling below, and remaining below, 1.2 p.u. This is different than momentary cessation, which involves a resource returning over a longer time frame with a specified delay and ramp rate.

The drafting team notes that IBR should not be set to trip on an instantaneous, unfiltered voltage measurements, except due to known equipment limitations.

Rationale for Requirement R4

The objective of Requirement R4 is to ensure that IBR remains electrically connected and exchanging current during a frequency excursion event.

Grid frequency reflects the balance of system generation and load. A system event that causes a generation/load imbalance will cause system frequency to deviate from nominal. The system may experience an over-frequency event (in the case of more generation than load) or an under-frequency event (in the case of less generation than load). Inertia resists the deviation from nominal frequency, giving the operators additional time to rebalance generation and load. System inertia depends on the amount of rotating mass connected to the system (such as the synchronous generators or motors). The larger the system inertia, the slower the system frequency will deviate from the nominal value and the lower the grid Rate Of Change Of Frequency (ROCOF), giving more time to try to rebalance generation and load. Also, higher system inertia may minimize the risk of Cascading generation loss caused by the operation of generator frequency protection.

A reduction in system inertia is an inevitable consequence of a power system transiting toward more IBR and less synchronous generators. As discussed in the previous paragraph, less system inertia means the frequency will deviate from the nominal value more quickly during a generation/load imbalance event and will expose the system to a higher ROCOF. A wider frequency ride-through capability for IBR may be required to avoid the risk of widespread tripping. To reduce the risk of widespread IBR tripping during frequency disturbances, and more generally to ensure the reliability of future grids with high IBR penetration, the drafting team proposes a 6-second frequency ride-through capability requirement for frequencies in the ranges of 61.8Hz to 64Hz or 57.0Hz to 56.0Hz range. The proposed 6-second time frame of the frequency ride-through capability requirement is beyond the IEEE 2800 standard frequency ride-through requirement and beyond frequency ride-through requirements for synchronous machines under proposed PRC-024-4.

IBR lacks the inertia and short circuit contributions of synchronous machines. To compensate for the lack of inertia and short circuit contributions, they should have wider tolerances for frequency and voltage excursions to meet the future power system with a higher percentage of IBR. Synchronous resources are more sensitive to frequency deviations than IBR resources. All IBR resources (except for type 3 wind turbines) interface to the grid through fast switching of power electronics devices. These power electronic devices are much less sensitive to the transmission system frequency excursion than non-hydraulic turbine synchronous resources (steam turbines and combustion turbines). In the case of the non-hydraulic turbine synchronous resources, the turbine is usually considered to be more restrictive than the generator in limiting IBR frequency ride-through because of possible mechanical resonances in the many stages of turbine blades. Off-nominal frequencies may bring blade vibrational frequencies closer to a mechanical resonate frequency and cause damage due to the vibration stresses. However, inverter-interfaced-IBR does not share this vibrational failure mode. Therefore, IBR should be capable of riding through the increased proposed 6-second frequency ride-through requirement without risk of equipment damage or need for frequency protection to operate.

Requirement R4 does not prescribe specific frequency protection settings for IBR equipment. IBR frequency protection settings should only be set to protect the IBR from damage caused by operation at off-nominal frequency. An IBR owner must ensure that the IBR frequency protection does not prevent an IBR from meeting the R4 ride-through requirement.

This standard requires that IBR remains electrically connected and continues to exchange current during a frequency excursion event in which the frequency remains within the no-trip zone\ according to **Attachment 3** and the absolute ROCOF magnitude is less than or equal to 5 Hz/second. Some IBR controllers and their ability to remain electrically connected and continue to exchange current to the grid are sensitive to ROCOF during a frequency excursion event. If needed to maintain the stability of the IBR or prevent equipment damage, the R4 requirement allows the IBR to trip for an absolute ROCOF exceeding 5Hz/sec within the no-trip zone as shown in **Attachment 3**. Failure to ride-through due to ROCOF exceeding 5Hz/sec shall only be allowed during a generator/load imbalance event that causes the frequency to deviate from nominal.

The ROCOF protection should not operate at the onset of a fault, during a fault, or at fault clearance, i.e., it should be disabled for faults. The IBR shall ride-through any system disturbance while the voltage at the high side of the main power transformer remains within the no-trip zones as specified in **Attachment 1**. Furthermore, to reduce the risk of IBR tripping on ROCOF protection, ROCOF shall be calculated as the average rate of change for multiple calculated system frequencies for some time greater than or equal to 0.1 seconds.

Rationale for Requirement R5

The objective of Requirement R5 is to ensure IBR remains electrically connected and exchanging current during instantaneous positive sequence voltage phase angle changes initiated by certain non-fault switching events.

Unlike synchronous generators, for which the synchronization mechanism to the grid is naturally preserved by the inertia, the grid following voltage source inverters (VSI) used for the majority of existing IBR facilities are equipped with the Phase-lock-loop (PLL) device for synchronization purposes. A typical synchronous reference frame PLL schematic is given in Fig. 1, where the three-phase voltages in the abc reference frame (v_a, v_b, and v_c) are transformed to the dq frame (v_d’ and v_q’) by the Park’s transformation and the phase angle θ is controlled by a feedback loop that regulates the q component to zero.

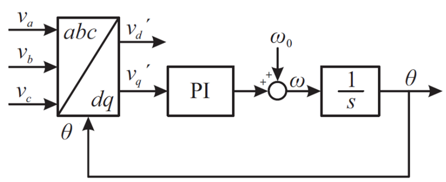

Figure 1: Schematic Diagram of a Synchronous Reference Frame PLL

Commented [JC1]: Please confirm where these example figures came from and if we can cite them in our document. Are these public?

When the inverter operates in the steady state, it is locked to the grid voltage via the PLL, assuming the PI controller is well tuned. In this case the phase displacement between the grid voltage and that measured by the PLL, Δθ is zero, as shown in Fig. 2.

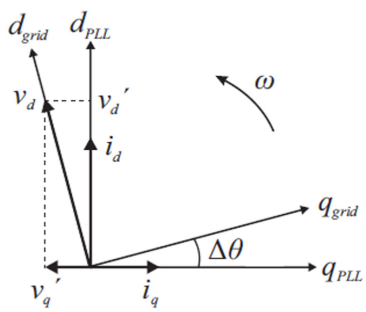

Figure 2: Phasor Diagram of Grid Voltage and Current

When a grid disturbance occurs, such as a close-in fault or a relatively large switching event, the grid voltage may experience a rapid phase angle shift. In such cases, the phase displacement Δθ can be large enough to pose challenges for the PLL to track the terminal voltage, cause control instability within the inverter, such as the inner current control loop or the DC link control loop, and even lead to tripping of the inverter due to the malfunction of the controls.

Since phase angle jumps are common occurrences on the BPS, this standard requires the IBR to be designed and operated to ride-through a minimum phase angle jump of 25 electrical degrees. This is a typical value and aligns with the requirement in IEEE 2800 2022. Furthermore, for a phase angle jump of 25 degrees or more, the IBR shall only trip to prevent equipment damage.

Some IBR equipment has PLL loss of synchronism protection, referring to a protective function that operates when the angle displacement Δθ exceeds a threshold for a predetermined period of time (on the order of a couple of milliseconds). Historically, this protection has been used by some inverter manufacturers, especially for inverters in distribution systems. For the IBR connected to the BPS, this protection function should be disabled. If it is enabled, the phase angle jump protection setting shall be configured such that the IBR shall only trip to prevent equipment damage.

Rationale for Requirement R6

The objective of Requirement R5 is to ensure legacy IBR may need to obtain an exemption to the voltage ride-through requirements if hardware replacements or other costly upgrades would be necessary to comply with Requirements R1 or Requirement R2. This provision allows such exemptions as long as such limitations are documented and communicated to the Planning Coordinator, and Reliability Coordinator of the respective footprints in which the IBR project is located. The Planning Coordinator, and Reliability Coordinator will then need to take the voltage ride-through limitations into account in planning and operations.

Limitations must not be construed as complete exemptions from the applicable **Attachment 1** table but must be specific as to which voltage band(s) and associated duration(s) cannot be satisfied or specific as to the number of cumulative voltage deviations within a ten-second time period that the equipment can ride-through if less than four. Limitation descriptions should identify the specific equipment and explain the characteristic(s) of that equipment that prevent ride-through. If any equipment limitation is removed or otherwise corrected, it is likewise necessary to communicate to the Planning Coordinator, and Reliability Coordinator of this.

FERC Order No. 901 states that this provision would be limited to exempting “certain registered IBRs from voltage ride-through performance requirements.” This is the reason that no similar provisions are included for exemptions for frequency, rate-of-change-of-frequency (ROCOF) ,phase angle change ride-through requirements.

Violation Risk Factor and Violation Severity Level Justifications

Project 2020-02 Modifications to PRC-024 (Generator Ride-through)
PRC-024-4

This document provides the standard drafting team's (SDT's) justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-024-4. Each requirement is assigned a VRF and a VSL. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the Electric Reliability Organizations (ERO) Sanction Guidelines. The SDT applied the following NERC criteria and FERC Guidelines when developing the VRFs and VSLs for the requirements.

NERC Criteria for Violation Risk Factors

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to BulkPower System instability, separation, or a cascading sequence of failures, or could place the Bulk-Power System at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to BulkPower System instability, separation, or a cascading sequence of failures, or could place the Bulk-Power System at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the Bulk-Power System, or the ability to effectively monitor and control the Bulk-Power System. However, violation of a medium risk requirement is unlikely to lead to Bulk- Power System instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the BulkPower System, or the ability to effectively monitor, control, or restore the BulkPower System. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to Bulk Power System instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk-Power System, or the ability to effectively monitor and control the Bulk-Power System; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk-Power System, or the ability to effectively monitor, control, or restore the Bulk-Power System.

FERC Guidelines for Violation Risk Factors

Guideline (1) – Consistency with the Conclusions of the Final Blackout Report

FERC seeks to ensure that VRFs assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System. In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief.

Guideline (2) – Consistency within a Reliability Standard
FERC expects a rational connection between the sub-Requirement VRF assignments and the main Requirement VRF assignment.

Guideline (3) – Consistency among Reliability Standards
FERC expects the assignment of VRFs corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) – Consistency with NERC's Definition of the Violation Risk Factor Level
Guideline (4) was developed to evaluate whether the assignment of a particular VRF level conforms to NERC's definition of that risk level.

Guideline (5) – Treatment of Requirements that Co-mingle More Than One Obligation
Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

NERC Criteria for Violation Severity Levels

VSLs define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple "degrees" of noncompliant performance and may have only one, two, or three VSLs.

VSLs should be based on NERC's overarching criteria shown in the table below:

Lower VSL	Moderate VSL	High VSL	Severe VSL
The performance or product measured almost meets the full intent of the requirement.	The performance or product measured meets the majority of the intent of the requirement.	The performance or product measured does not meet the majority of the intent of the requirement, but does meet some of the intent.	The performance or product measured does not substantively meet the intent of the requirement.

FERC Order of Violation Severity Levels

The FERC VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in the standard meet the FERC Guidelines for assessing VSLs:

Guideline (1) – Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline (2) – Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a "binary" type requirement must be a "Severe" VSL.
Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline (3) – Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline (4) – Violation Severity Level Assignment Should Be Based on a Single Violation, Not on a Cumulative Number of Violations

Unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

The VRF did not change from the previously FERC approved PRC-024-3 Reliability Standard.

VSLs for PRC-024-4, Requirement R1			
Lower	**Moderate**	**High**	**Severe**
N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable frequency protection so that it does not trip according to Requirement R1.

VSL Justifications for PRC-024-4, Requirement R1	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement adds a functional entity. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	The proposed VSLs are binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VSL Justifications for PRC-024-4, Requirement R1	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

The VRF did not change from the previously FERC approved PRC-024-3 Reliability Standard.

VSLs for PRC-024-4, Requirement R2			
Lower	**Moderate**	**High**	**Severe**
N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable voltage protection so that it does not trip according to Requirement R2.

VSL Justifications for PRC-024-4, Requirement R2	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement adds a functional entity. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties <u>Guideline 2a</u>: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent <u>Guideline 2b</u>: Violation Severity Level Assignments that Contain Ambiguous Language	The proposed VSLs are binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VSL Justifications for PRC-024-4, Requirement R2	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

The VRF did not change from the previously FERC approved PRC-024-3 Reliability Standard.

VSLs for PRC-024-4, Requirement R3			
Lower	**Moderate**	**High**	**Severe**
The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 30 calendar days but less than or equal to 60 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 60 calendar days but less than or equal to 90 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 90 calendar days but less than or equal to 120 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner failed to document any known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2. OR The Generator Owner or Transmission Owner failed to communicate the documented limitation to its Planning Coordinator and Transmission Planner within 120 calendar days of identifying the limitation.

VSL Justifications for PRC-024-4, Requirement R3	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement adds a functional entity. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.

FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

Violation Risk Factor and Violation Severity Level Justifications

Project 2020-02 Modifications to PRC-024 (Generator Ride-through)
PRC-029-1

This document provides the standard drafting team's (SDT's) justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-029-1. Each requirement is assigned a VRF and a VSL. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the Electric Reliability Organizations (ERO) Sanction Guidelines. The SDT applied the following NERC criteria and FERC Guidelines when developing the VRFs and VSLs for the requirements.

NERC Criteria for Violation Risk Factors

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to BulkPower System instability, separation, or a cascading sequence of failures, or could place the Bulk-Power System at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to BulkPower System instability, separation, or a cascading sequence of failures, or could place the Bulk-Power System at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the Bulk-Power System, or the ability to effectively monitor and control the Bulk-Power System. However, violation of a medium risk requirement is unlikely to lead to Bulk- Power System instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the BulkPower System, or the ability to effectively monitor, control, or restore the BulkPower System. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to Bulk Power System instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement
A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk-Power System, or the ability to effectively monitor and control the Bulk-Power System; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk-Power System, or the ability to effectively monitor, control, or restore the Bulk-Power System.

FERC Guidelines for Violation Risk Factors

Guideline (1) – Consistency with the Conclusions of the Final Blackout Report
FERC seeks to ensure that VRFs assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System. In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief.

Guideline (2) – Consistency within a Reliability Standard

FERC expects a rational connection between the sub-Requirement VRF assignments and the main Requirement VRF assignment.

Guideline (3) – Consistency among Reliability Standards

FERC expects the assignment of VRFs corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) – Consistency with NERC's Definition of the Violation Risk Factor Level

Guideline (4) was developed to evaluate whether the assignment of a particular VRF level conforms to NERC's definition of that risk level.

Guideline (5) – Treatment of Requirements that Co-mingle More Than One Obligation

Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

NERC Criteria for Violation Severity Levels

VSLs define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple “degrees” of noncompliant performance and may have only one, two, or three VSLs.

VSLs should be based on NERC’s overarching criteria shown in the table below:

Lower VSL	Moderate VSL	High VSL	Severe VSL
The performance or product measured almost meets the full intent of the requirement.	The performance or product measured meets the majority of the intent of the requirement.	The performance or product measured does not meet the majority of the intent of the requirement, but does meet some of the intent.	The performance or product measured does not substantively meet the intent of the requirement.

FERC Order of Violation Severity Levels

The FERC VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in the standard meet the FERC Guidelines for assessing VSLs:

Guideline (1) – Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline (2) – Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a “binary” type requirement must be a “Severe” VSL.
Do not use ambiguous terms such as “minor” and “significant” to describe noncompliant performance.

Guideline (3) – Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline (4) – Violation Severity Level Assignment Should Be Based on a Single Violation, Not on a Cumulative Number of Violations

Unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the “default” for penalty calculations.

VRF Justifications for PRC-029-1, Requirement R1	
Proposed VRF	**High**
NERC VRF Discussion	A VRF of High is appropriate as applicable generating resources must be able to ride-through system disturbances. Failure to ride-through has been documented in multiple NERC reports leading to exacerbated system conditions, resulting in the electrical disconnecting of additional generation and widespread outages.
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is in line with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The assignment of High VRF is consistent with the VRF assignments for other requirements in the proposed Reliability Standard. This requirement has only a main VRF and no different sub-requirement VRFs.
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	Similar requirements in PRC-024-3 are identified as Medium but are based on equipment protection setting documentation rather than actual, recorded performance during a grid disturbance. Therefore, this VRF is in line with other VRFs that address similar reliability goals in different Reliability Standards.
FERC VRF G4 Discussion Guideline 4- Consistency with NERC Definitions of VRFs	This VRF is in line with the definition of a High VRF requirement per the criteria filed with FERC as part of the ERO’s Sanctions Guidelines.
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not co-mingle a higher risk reliability objective and a lesser risk reliability objective.

VSLs for PRC-029-1, Requirement R1			
Lower	**Moderate**	**High**	**Severe**
N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to demonstrate each applicable IBR remains electrically connected and continued to exchange current in accordance with Attachment 1, unless needed to clear a fault, in accordance with Requirement R1.

VSL Justifications for PRC-029-1, Requirement R1	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement is new. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	The proposed VSLs are binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VSL Justifications for PRC-029-1, Requirement R1	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

VRF Justifications for PRC-029-1, Requirement R2	
Proposed VRF	**High**
NERC VRF Discussion	A VRF of High is appropriate as applicable generating resources must be able to ride-through system disturbances. Failure to ride-through has been documented in multiple NERC reports leading to exacerbated system conditions, resulting in the electrical disconnecting of additional generation and widespread outages.
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is in line with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The assignment of High VRF is consistent with the VRF assignments for other requirements in the proposed Reliability Standard. This requirement has only a main VRF and no different sub-requirement VRFs.
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	Similar requirements in PRC-024-3 are identified as Medium but are based on equipment protection setting documentation rather than actual, recorded performance during a grid disturbance. Therefore, this VRF is in line with other VRFs that address similar reliability goals in different Reliability Standards.
FERC VRF G4 Discussion Guideline 4- Consistency with NERC Definitions of VRFs	This VRF is in line with the definition of a High VRF requirement per the criteria filed with FERC as part of the ERO's Sanctions Guidelines.
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not co-mingle a higher risk reliability objective and a lesser risk reliability objective.

VSLs for PRC-029-1, Requirement R2			
Lower	**Moderate**	**High**	**Severe**
N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to demonstrate each applicable IBR adhered to performance requirements during each System disturbance, as specified in Requirement R2.

VSL Justifications for PRC-029-1, Requirement R2	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement is new. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties <u>Guideline 2a</u>: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent <u>Guideline 2b</u>: Violation Severity Level Assignments that Contain Ambiguous Language	The proposed VSLs are binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VSL Justifications for PRC-029-1, Requirement R2	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

VRF Justifications for PRC-029-1, Requirement R3	
Proposed VRF	**Lower**
NERC VRF Discussion	A VRF of Lower is appropriate that if violated, it would not be expected to adversely affect the electrical state or capability of the Bulk-Power System.
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is in line with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The assignment of Lower VRF is consistent with the VRF assignments for other requirements in the proposed Reliability Standard. This requirement has only a main VRF and no different sub-requirement VRFs.
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	This VRF is in line with other VRFs that address similar reliability goals in different Reliability Standards.
FERC VRF G4 Discussion Guideline 4- Consistency with NERC Definitions of VRFs	This VRF is in line with the definition of a Lower VRF requirement per the criteria filed with FERC as part of the ERO’s Sanctions Guidelines.
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not co-mingle a higher risk reliability objective and a lesser risk reliability objective.

VSLs for PRC-029-1, Requirement R3			
Lower	**Moderate**	**High**	**Severe**
N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to demonstrate each applicable IBR adhered to performance requirements during each transient overvoltage period as specified in Requirement R3.

VSL Justifications for PRC-029-1, Requirement R3	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement is new. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties <u>Guideline 2a</u>: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent <u>Guideline 2b</u>: Violation Severity Level Assignments that Contain Ambiguous Language	The proposed VSLs are binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VSL Justifications for PRC-029-1, Requirement R3	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

VRF Justifications for PRC-029-1, Requirement R4	
Proposed VRF	**Lower**
NERC VRF Discussion	A VRF of Lower is appropriate that if violated, it would not be expected to adversely affect the electrical state or capability of the Bulk-Power System.
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is in line with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The assignment of Lower VRF is consistent with the VRF assignments for other requirements in the proposed Reliability Standard. This requirement has only a main VRF and no different sub-requirement VRFs.
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	This VRF is in line with other VRFs that address similar reliability goals in different Reliability Standards.
FERC VRF G4 Discussion Guideline 4- Consistency with NERC Definitions of VRFs	This VRF is in line with the definition of a Lower VRF requirement per the criteria filed with FERC as part of the ERO’s Sanctions Guidelines.
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not co-mingle a higher risk reliability objective and a lesser risk reliability objective.

VSLs for PRC-029-1, Requirement R4			
Lower	**Moderate**	**High**	**Severe**
N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to demonstrate each applicable IBR adhered to performance requirements during each frequency excursion event, as specified in Requirement R4.

VSL Justifications for PRC-029-1, Requirement R4	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement is new. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties <u>Guideline 2a</u>: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent <u>Guideline 2b</u>: Violation Severity Level Assignments that Contain Ambiguous Language	The proposed VSLs are binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VSL Justifications for PRC-029-1, Requirement R4	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

VRF Justifications for PRC-029-1, Requirement R5	
Proposed VRF	**Lower**
NERC VRF Discussion	A VRF of Lower is appropriate that if violated, it would not be expected to adversely affect the electrical state or capability of the Bulk-Power System.
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is in line with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The assignment of Lower VRF is consistent with the VRF assignments for other requirements in the proposed Reliability Standard. This requirement has only a main VRF and no different sub-requirement VRFs.
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	This VRF is in line with other VRFs that address similar reliability goals in different Reliability Standards.
FERC VRF G4 Discussion Guideline 4- Consistency with NERC Definitions of VRFs	This VRF is in line with the definition of a Lower VRF requirement per the criteria filed with FERC as part of the ERO's Sanctions Guidelines.
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not co-mingle a higher risk reliability objective and a lesser risk reliability objective.

VSLs for PRC-029-1, Requirement R5			
Lower	**Moderate**	**High**	**Severe**
N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to demonstrate each applicable IBR adhered to performance requirements during each instantaneous positive sequence voltage phase angle change of less than 25 electrical degrees, as specified in Requirement R5.

VSL Justifications for PRC-029-1, Requirement R5	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement is new. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties <u>Guideline 2a</u>: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent <u>Guideline 2b</u>: Violation Severity Level Assignments that Contain	The proposed VSLs are binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VSL Justifications for PRC-029-1, Requirement R5	
Ambiguous Language	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

VRF Justifications for PRC-029-1, Requirement R6	
Proposed VRF	**Lower**
NERC VRF Discussion	A VRF of Lower is appropriate that if violated, it would not be expected to adversely affect the electrical state or capability of the Bulk-Power System.
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is in line with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The assignment of Lower VRF is consistent with the VRF assignments for other requirements in the proposed Reliability Standard. This requirement has only a main VRF and no different sub-requirement VRFs.
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	This VRF is in line with other VRFs that address similar reliability goals in different Reliability Standards.
FERC VRF G4 Discussion Guideline 4- Consistency with NERC Definitions of VRFs	This VRF is in line with the definition of a Lower VRF requirement per the criteria filed with FERC as part of the ERO's Sanctions Guidelines.
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not co-mingle a higher risk reliability objective and a lesser risk reliability objective.

VSLs for PRC-029-1, Requirement R6			
Lower	**Moderate**	**High**	**Severe**
The Generator Owner or Transmission Owner with a previously communicated equipment limitation that repairs or replaces the documented limiting equipment but failed to document and communicate the change to its Planning Coordinator, Transmission Planner, and Reliability Coordinator more than 30 calendar days but less than or equal to 60 calendar days after the change to the equipment.	The Generator Owner or Transmission Owner with a previously communicated equipment limitation that repairs or replaces the documented limiting equipment but failed to document and communicate the change to its Planning Coordinator, Transmission Planner, and Reliability Coordinator more than 60 calendar days but less than or equal to 90 calendar days after the change to the equipment.	The Generator Owner or Transmission Owner with a previously communicated equipment limitation that repairs or replaces the documented limiting equipment but failed to document and communicate the change to its Planning Coordinator, Transmission Planner, and Reliability Coordinator more than 90 calendar days but less than or equal to 120 calendar days after the change to the equipment.	The Generator Owner or Transmission Owner failed to document evidence of equipment limitations consistent with Requirement R6 and prior to the effective date of PRC 029 1 Requirement R6. OR The Generator Owner or Transmission Owner with a previously communicated equipment limitation that repairs or replaces the documented limiting equipment but failed to document and communicate the change to its Planning Coordinator, Transmission Planner, and Reliability Coordinator more than 120 calendar days after the change to the equipment.

VSL Justifications for PRC-029-1, Requirement R6	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the	The requirement is new. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.

VSL Justifications for PRC-029-1, Requirement R6	
Current Level of Compliance	
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	The proposed VSLs are binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Standards Announcement

Project 2020-02 Modifications to PRC-024 (Generator Ride-through) | PRC-024-4 and PRC-029-1

Formal Comment Period Open through April 22, 2024
Ballot Pools Forming through April 5, 2024

Now Available

A 25-day formal comment period for **Project 2020-02 Modifications to PRC-024 (Generator Ride-through)**, is open through **8 p.m. Eastern, Monday, April 22, 2024**.

The Standards Committee approved waivers to the Standard Processes Manual at their December 2023 meeting. These waivers were sought by NERC Standards staff for reduced formal comment and ballot periods. This will assist the drafting teams in expediting the standards development process due to firm timeline expectations set by FERC Order 901. *FERC Order 901 was issued under* Docket No. RM22-12-000 *on October 19, 2023.*

Reminder Regarding Corporate RBB Memberships

Under the NERC Rules of Procedure, each entity and its affiliates is collectively permitted one voting membership per Registered Ballot Body Segment. Each entity that undergoes a change in corporate structure (such as a merger or acquisition) that results in the entity or affiliated entities having more than the one permitted representative in a particular Segment must withdraw the duplicate membership(s) prior to joining new ballot pools or voting on anything as part of an existing ballot pool. Contact ballotadmin@nerc.net to assist with the removal of any duplicate registrations.

Commenting

Use the Standards Balloting and Commenting System (SBS) to submit comments. An unofficial Word version of the comment form is posted on the project page.

Ballot Pools

Ballot pools are being formed through **8 p.m. Eastern, Friday, April 5, 2024.** Registered Ballot Body members can join the ballot pools here.

- *Contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern) for problems regarding accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out.*
- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*

- *Please be mindful of ballot and comment period closing dates. We ask to* ***allow at least 48 hours*** *for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts* ***prior to the last day*** *of a comment/ballot period.*

Next Steps

Initial ballots for the standards and implementation plan, as well as non-binding polls of the associated Violation Risk Factors and Violation Severity Levels will be conducted **April 12 - 22, 2024**.

For information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Manager of Standards Development, Jamie Calderon (via email) or at 404-960-0568 Subscribe to this project's observer mailing list by selecting "NERC Email Distribution Lists" from the "Service" drop-down menu and specify “Project 2020-02 Modifications to PRC-024 (Generator Ride-through) observer list” in the Description Box.

There were 79 sets of responses, including comments from approximately 180 different people from approximately 111 companies representing 10 of the Industry Segments as shown in the table on the following pages.

Questions

1. Do you agree with the need for creating a new Standard (PRC-029-1) to address gaps the Inverter-Based Resource Performance Subcommittee (IRPSC) identified within the PRC-024-3 Project 2020-02 SAR and to address the expectations of FERC Order No. 901?

2. Do you agree that the language within PRC-029-1 requirements R1, R2, and R6 regarding IBR plant-level performance during grid voltage disturbances is clear?

3. Do you agree with the drafting team's proposals for including IBR transient overvoltage, frequency, ROCOF, and instantaneous voltage phase-angle jump ride-through performance criteria in PRC-029-1 Requirements R3, R4, and R5?

4. Provide any additional comments for the Drafting Team to consider, if desired.

Constellation does not agree with creating a new IBR specific standard (PRC-29) to address the gaps in the Inverter-Based Resource. While Constellation recognizes that there has been some grid disturbance in the Odessa/California/Utah regions in the past couple years as a result of some IBRs not performing as intended, the creation of a new standard is a quick reaction without ensuring existing equipment's are capable to fully comply. Comment	

Texas RE supports creating a new standard to address Inverter-Based Resources (IBR) gaps identified. Texas RE is concerned, however, with the structure of the standard as it is presently proposed.

As currently drafted, the proposed PRC-029-1 would wholly eliminate existing frequency and voltage protection setting verification requirements for IBR resources. Texas RE submits that this is contrary to FERC's intent in directing NERC to develop a comprehensive ride-through standard for IBR resources. FERC Order No. 901 explicitly directs NERC to draft a standard "that require[s] IBR generator owners and operators to use appropriate settings (i.e., inverter, plant controller, and protection) to ride through frequency and voltage system excursions and that permit IBR tripping only to protect IBR equipment in scenarios similar to when synchronous generation resources use tripping as protection from internal faults." (Order No, 901, paragraph 190). FERC's intent behind the order was to expand the scope of applicable devices beyond protection system equipment subject to the current PRC-024 requirements to embrace a range of devices that can trip an IBR facility (inverters, plant controller, etc.). The ultimate goal is to better ensure that IBRs provide reliable performance during voltage and frequency excursions.

Texas RE submits, however, that FERC did not intent to exclude IBR entities from the existing verification processes or significant limit the ability of the ERO to review protection system settings prior to an actual disturbance event. In its order, FERC specifically referenced the 2021 Odessa Disturbance Report jointly prepared by NERC and Texas RE staff ("2021 Odessa Disturbance Report"). The 2021 Odessa Disturbance Report in turn called for the development of a ride-through standard to replace PRC-024-3 because "the events analyzed by NERC regarding fault-induced reductions in solar PV output and wind output have identified issues with controls and protections unrelated to voltage and frequency." (2021 Odessa Report, at 29). While calling for a more comprehensive standard, however, the report simultaneously identified pervasive issues with protection system settings within the scope of the current PRC-024 standards. The report noted: "Numerous plant owner/operators have stated that they do not have sufficient technical staff on hand to interpret the results and will simply install what the consultant recommends. This is leading to poorly coordinated protection systems within the facility, causing unreliable performance from BPS-connected solar PV facilities in multiple interconnections." (2021 Odessa Report, at 17 (emphasis added)). In short, while acknowledging that the current PRC-024 standard is overly narrow, FERC and the various reports FERC references make clear that protection system verification failures remain an important contributing factor in the numerous disturbance events involving IBRs over the past few years.

As proposed, PRC-029-1 would result in a reliability gap by requiring that protection system settings no longer require verification. The Standard Drafting Team (SDT) explains in the draft PRC-029-1 Technical Rationale that "[a]n IBR becomes noncompliant with PRC-029 only when an event in the field occurs that shows that one or more requirements were not satisfied." Under the SDT's proposed approach, therefore, the existing PRC-024 protection system setting verification requirements would be eliminated and the sole mechanism to verify performance would be an IBR's failure to perform during a disturbance event. Texas RE posits that this approach is inconsistent with the intent of FERC's order to expand the applicable devices and settings that an IBR-entity must ensure are properly set to avoid unnecessary tripping during events. It is also inconsistent with findings that entities continue to experience issues properly setting (and verifying) existing protection systems within the scope of the current PRC-024 requirements.

Rather than pursue this approach, Texas RE suggests that the SDT consider retaining the existing protection system verification requirements as a foundational step, but augment those requirements with a general performance standard. Moreover, while Texas RE does not believe the SDT needs or should develop a comprehensive and prescriptive list of devices that must be appropriate set and coordinated to ensure IBR performance, the SDT should consider which measures and evidence would be appropriate for the GO and TO to demonstrate that its settings meet the various no-trip zone parameters described in Attachment 1. This should include sufficient evidence to show that protection system settings are properly set to not trip within appropriate no trip zones, as well as that other settings for inverters, plant controllers, and other devices are properly coordinated. Such clarity will ensure that at least minimum performance can be audited and verified prior to a disturbance event – the goal of the standards process.

Additionally, Texas RE noticed during the webinar, SDT stated that the requirements do not apply to individual IBR units. Requirement R1 seems to indicate that each IBR unit needs to remain electrically connected and continue to exchange current in accordance with the no-trip zones and operation regions.

Lastly, Texas RE recommends the SDT consider changing 'each IBR' to 'each IBR Facility' for all the Requirements.

Comment

A performance standard should be based on function not technology type which is always changing. An IBR generation facility should meet the same performance threshold as traditional generation, with additional support devices as necessary incorporated into the facility design to meet the same level of performance as a traditional unit.

PRC-024-3 has not been in effect long enough to be deemed inadequate to address "gaps" and issues described in IBR disturbance reports. It became effective on 10/1/2022, which was long after major disturbances occurred, and as written, covers major causes of IBR disturbances such as voltage, frequency, and momentary cessation. Most importantly, the Standard clearly stated applicability to individual IBR units and it clearly stated no-trip zones. The Standard could have been modified to include and cover other recommendations from the disturbance report such as PLL protection and ramp rate mis-coordination.

A major concern with the separate Standards, as drafted, is that ride through performance is not required for synchronous generators under PRC-024-4, but it is for IBRs under PRC-029. PRC-02-4 simply requires protective relays to be set so they do not trip the generator within specified bounds, but it allows a resource to trip offline for other reasons. PRC-024-4 also allows a plant to trip if protection systems trip auxiliary plant equipment, per section 4.2.3. In contrast, PRC-029 requires IBRs to remain electrically connected and to continue to exchange current within the specified voltage and frequency bounds. Said another way, an IBR and a synchronous resource could both trip during the same disturbance, and the IBR would be in violation of PRC-029 but the synchronous generator would not be in violation of PRC-024-4, as long as the synchronous generator did not trip due to the settings of its protection system.

To ensure grid reliability and resilience, all resources including IBRs and synchronous resources should ride through grid disturbances. The failure of synchronous generators to ride through grid disturbances threatens grid reliability as much or more than the failure of IBRs, as synchronous resources are often producing at a higher level of output, are more typically relied on as capacity resources, and often take longer to come back online and ramp up to full output if they trip due to a disturbance.

FERC Order 901 directed NERC to treat IBR resources similarly to how NERC Standards treat synchronous generators, writing that the IBR Standard should “permit IBR tripping only to protect the IBR equipment in scenarios similar to when synchronous generation resources use tripping as protection from internal faults."{C}[1] Allowing synchronous generators to trip but requiring IBRs to ride through the same or similar disturbance could be challenged at FERC as undue discrimination.

Not requiring ride-through performance from synchronous generators is also at odds with the intent for this project that NERC stated in its February 2023 comments on the FERC proposed rulemaking that led to Order 901: "A comprehensive, performance-based ride-through standard is needed to assure future grid reliability. To that end, NERC re-scoped an existing project, Project 2020-02 Modifications to PRC-024 (Generator Ride-through), to revise or replace current Reliability Standard PRC-024- 3 with a standard that will require ride-through performance from all generating resources."[2] FERC's Order 901 also noted NERC's statement that this project would require ride-through performance from all generating resources,[3] so a failure to require ride-through performance from synchronous generators may be contrary to both NERC and FERC's intent.

The drafting team should make PRC-024-4 a ride-through performance requirement like PRC-029, or alternatively create a single standard that applies to both types of resources (with any necessary clarifications or minor differences in requirements to reflect the differences in IBR and synchronous generator technologies).

While AEP agrees with creating PRC-029-1 to address the identified gaps, AEP recommends the SDTs for PRC-028, PRC-029 and PRC-030 review each proposed standard obligations to ensure there is a consistent, integrated plan across these projects and standards to achieve the goal of correcting the past performance of Invertor-Based Resources and IBR units. Having a coherent strategy document that explains how these three standards complement each other (and not be duplicative) would be beneficial.

FirstEnergy supports the need for the new standard (PRC-029-1).	

In addition, FE supports EEI's comments which state:

EEI agrees with most of the proposed language in Requirements R1, R2 and R6; however, the phrase "of an applicable IBR" should be removed. Applicability is defined in the Applicability Section of the standard and anything more is unnecessary and redundant.

Additionally, Requirement R2, subpart 2.5 could be understood to mean that IBRs whenever the voltage at the high-side of the main power transformer is within the no-trip zone, as specified in Attachment 1, must not trip even if it might lead to equipment damage. We offer the following proposed edits in boldface to Requirement R2, subpart 2.5 to clarify the requirement. NERC Reliability Standards should never mandate that equipment run to failure.

2.5 **Each IBR shall only trip to prevent equipment damage, W**hen**ever** the voltage at the high-side of the main power transformer is within **of** the no-trip zone, as specified in Attachment 1, **each IBR shall continue to operate except when the continued operation of the IBR would lead to equipment damage**.

Black Hills Corporation agrees that there is a gap in PRC-024-3 regarding performance of inverter-based resources (IBR). However, more consideration should be given to creating "protection-based" Standards for IBR, whether as an update to existing Standard PRC-024-3 or new Standard PRC-029-1 rather than the "event-based" approach currently being taken in PRC-029-1.

PGE requests that the Standard Drafting Team (SDT) add clarity regarding Attachment A: Voltage Boundary Clarifications, Section: Evaluating Protection Settings, a. The most probable real and reactive loading conditions for the unit under study.

Loading conditions vary depending on the type of unit, location, time of year, etc. How should an entity assess “most probable” loading conditions? Are entities being required to account for the worst case scenarios providing the greatest voltage change(s), not just a probable condition that may represent little to no significant voltage difference?

PGE also notes that the Table References and Figure References are not aligned

Comment	

Southern Company believes that separating synchronous machine facilities from IBR facilities simplifies the complication that would exist by addressing both types of facilities in the same standard. While the existing "legacy" facilities have demonstrated imperfect ride-through performance (reactions) during system initiated disturbances, Southern believes that the application of ride-through requirements should only be applicable to facilities designed, built, and commissioned after the development of such a standard. The existing "legacy" facilities were not designed or built to achieve the desired ride-through performance that is specified in PRC-029-1, requirements R1-R5 of this proposed standard, and should not be subject to those requirements. The demonstrated performance, while not matching the ideal performance dictated by this proposed standard, is not catastrophic to the interconnection. The notion that generator owners have not taken any actions to improve the reaction of the legacy facilities to system disturbances is false. Southern Company has reviewed and modified control and protection settings for inverter operations at multiple facilities since the issuance of the first two NERC Alerts on the Loss of Solar facilities and during the multiple disturbance analysis evaluations. Addressing the desired performance with new facilities which will have the component design and control strategies sufficient to meet the desired performance should be a measure adequate to address the frequency control, voltage control, and stability needs and concerns of the interconnection.

Perhaps a more reasonable approach towards achieving better IBR facility ride through performance during system disturbance events, is to require evaluations with every instance of a plant output hiccup. The proposed required evaluation process in PRC-030, requiring corrective action plans to minimize/eliminate/eradicate the reason for the hiccup, would address, where possible, action taken through control or protection system setting changes, or through hardware changes - for equipment placed in service after the effective date of this draft standard).

Southern would offer general concerns with synchronizing language across all draft standards. For example, M1 states: *"shall have evidence of actual recorded data or other evidence for each applicable IBR demonstrating adherence to ride-through requirements"*. This seems like an opportunity to clarify by explicitly referencing standard(s) addressing data collection. This example repeats in some form in each "M" paragraph. Should the evidence of actual recorded data in M1 and other measures synch up with the phased in approach to PRC-028?

Finally, Southern Company supports EEI and NAGF comments.

Comment

NextEra aligns with EEI's comments:

EEI supports the development of a new Reliability Standard to address gaps in Inverter-Based Resource Performance and while the SAR does not include any language that specifically addresses FERC Order No. 901, EEI has no concerns with the SDT adjusting PRC-029 in line with the directives contained in this Order.

Yes, generator ride-through is an essential reliability service and the changing generation technology to inverter-based has led to the need for improved, applicable, appropriate, and technically accurate requirements that suit IBRs. However, it is critically important that the implementation of these requirements consider all stakeholder needs and capture important technical considerations so that the requirements sufficiently mitigate risks without causing unnecessary costs or burdens on any responsible entity.

2. Do you agree that the language within PRC-029-1 requirements R1, R2, and R6 regarding IBR plant-level performance during grid voltage disturbances is clear?

Darcy O'Connell - California ISO - 2, Group Name ISO/RTO Council (IRC) Standards Review Committee	
Answer	No
Document Name	
Comment	

The ISO/RTO Council (IRC) Standards Review Committee (SRC) recommends the following modifications to improve the clarity and better convey the intent of the standard.

Recommended changes to R1:

"…as specified in Attachment 1 except when needed to clear a fault or a documented **and communicated** equipment limitation exists in accordance with **Requirement R6."**

Each Generator Owner or Transmission Owner of an applicable IBR shall ensure that each IBR remains electrically connected and continues to exchange current in accordance with the no-trip zones and operation regions as specified in Attachment 1 unless needed to clear a fault or a documented equipment limitation exists in accordance with Requirement R6.

Recommended changes to M1:

"…demonstrating adherence to ride-through requirements, as specified in Requirement R1**, or shall have evidence of a documented and communicated equipment limitation, as specified in Requirement R6**."

Recommended changes to R2:

"…each IBR's voltage performance adheres to the following, unless a documented **and communicated** equipment limitation exists…"

The SRC recommends that the SDT to review and align the data in **Attachment 1** to ensure that the data in Tables 1 and 2 aligns with what is shown in Figures 1 and 2. Currently, the graphs in Figures 1 and 2 do not match what is indicated in the Tables. For example, rows 1-3 in Tables 1 and 2 are identical, yet Figure 2 does not match Figure 1 by indicating a Voltage Ride-Through Requirement of 1.0.

It appears that the SDT's intent is to require continuous operation between 95% and 105% voltage with a minimum ride-through time of at least 1800 seconds (half an hour) when voltage is above 105% and not exceeding 110%. If the intent is actually that equipment must be able to operate *continuously* at voltages up to 110%, then the tables and plots should be labelled with a descriptor that clearly indicates that indefinite or continuous operation is required rather than operation for a minimum ride-through time (1800 seconds). For example, a version of Table 2 that achieves the SDT's apparent intent could look like the following:

Voltage (per unit)	**Minimum Ride-Through Time (sec)**
>1.2	N/A

<=1.2 and >1.1	1.0
<=1.1 and >1.05	1800
<=1.05 and >=0.95	Continuous
<0.95 and >=0.90	Continuous*

*current limitation permitted, with active or reactive power preference as specified

<0.90 and >=0.70	6
<0.70 and >=0.50	3
<0.50 and >=0.25	1.2
<0.25	0.32

While the above comments point out areas of ambiguity in the draft standard that need to be clarified, the SRC recommends that Table 1 and Table 2 be modified to require IBR plants remain connected indefinitely when the voltage is between 1.05 and 1.1 pu. The current draft standard requires units to remain online for 1800 seconds in this range, and the logic behind this threshold is not clear. The current PRC-024 standard requires units to remain on-line indefinitely for the above range. [*All SRC entities support the comments in this paragraph except MISO*].

In addition, the SRC recommends a part be added to the standard to directly address the Permissive Operating Region, similar to what is done in Part 2.1 (for the Continuous Operation Region) and Part 2.2 (for the Mandatory Operation Region) as, the rules surrounding the Permissive Operating Region are unclear if this is not addressed. For example, there should be some linkage between the body of the standard and Attachment 1, item 10. The SRC proposes the following language for consideration (new Part 2.3):

2.3 While voltage at the high-side of the main power transformer is within the Permissive Operation Region as specified in Attachment 1, an IBR may operate in current block mode only if necessary to protect the equipment. Otherwise, each IBR shall follow the requirements for the Mandatory Operation Region in Requirement R2, Part 2.2.

Recommended changes to R6:

The SRC is concerned that Requirement R6 as proposed provides an overly broad exemption, as the standard is silent as to what criteria must be met to qualify for an exemption and contains no requirement that a Corrective Action Plan be developed or that the equipment limitations be resolved or addressed. Only notification to other entities is required. The SRC recommends that the SDT:

- Develop more specific criteria as to what qualifies as an equipment limitation[1], OR A technical justification that addresses why corrective actions will not be applied nor implemented.
- Require exemptions be submitted to NERC and/or the Regional Entities for pre-approval in order to qualify for the exemption.

The SRC suggests there should be explicit requirements to both 'document equipment limitations' and to 'communicate' those documented limitations to the appropriate parties. The SRC proposes the following modifications to address this issue:

"Each Generator Owner and Transmission Owner with a **known** equipment limitation that would prevent an applicable IBR that is in-service by the effective date of this standard from meeting voltage ride-through requirements as detailed in Requirements R1 and R2 shall **document** each equipment limitation, develop a Corrective Action Plan to address the limitation, **and communicate both the limitation and the Corrective Action Plan** to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s).

Recommended changes to M6:

Each Generator Owner and Transmission Owner shall have evidence of **known** equipment Limitations accompanied by a Corrective Action Plan, as specified in Requirement R6, **having been** documented **and communicated** to each associated Planning Coordinator, Transmission Planner, and Reliability Coordinator prior to the effective date of PRC-029-1.

Each Generator Owner and Transmission Owner with changes to equipment shall have evidence of communication to each associated Planning Coordinator, Transmission Planner, and Reliability Coordinator.

[1] *See Implementation Plan (page 4), "only those IBR that are unable to meet voltage ride-through requirements due to their inability to modify their coordinated protection and control settings may be considered for potential exemption." See Technical Rationale (page 9); i.e. specify which voltage band(s) and associated duration(s) cannot be satisfied or specific as to the number of cumulative voltage deviations within a ten-second time period that the equipment can ride-through if less than four… identify the specific equipment and explain the characteristic(s) of that equipment that prevent ride-through.*

Michael Brytowski - Great River Energy - 3

Answer	No
Document Name	Attachment 1 figures 1 and 2 .pdf

Comment

Comments: GRE requests the SDT review and align the data in **Attachment 1** so the data in Tables 1 and 2 aligns with what is shownin Figures 1 and 2. Currently, the graphs in Figures 1 and 2 do not match what is indicated in the Tables. (uploaded)

GRE recommends a part be added to the standard to directly address the Permissive Operating Region, similar to what is done in Part 2.1 (for Continuous Operation Region) and Part 2.2 (for Mandatory Operation Region) as, if left unaddressed, is unclear. For example, there should be some linkage between the body of the standard and Attachment 1, item 10. MRO NSRF proposes the following language for consideration (*new* Part 2.3):

2.3 While voltage at the high-side of the main power transformer is within the Permissive Operation Region as specified in Attachment 1, an IBR may operate in current block mode only if necessary to protect the equipment. Otherwise, each IBR shall follow the requirements for the Mandatory Operation Region in Requirement R2.2.

GRE is concerned that requirement R6 provides an overly broad exemption as written as the standard is silent as to what criteria must be met. Only notification to other reliability entities is required with no requirement to develop and implement a Corrective Action Plan. MRO NSRF recommends the SDT:

Develop more specific criteria as to what qualifies as an equipment limitation[1], OR

Require exemptions be submitted to NERC and/or the Regional Entities for approval in order to qualify for the exemption.

[1] *See Implementation Plan (page 4), i.e. "only those IBR that are unable to meet voltage ride-through requirements due to their inability to modify their coordinated protection and control settings may be considered for potential exemption." See Technical Rationale (page 9); i.e. specify which voltage band(s) and associated duration(s) cannot be satisfied or specific as to the number of cumulative voltage deviations within a ten-second time period that the equipment can ride-through if less than four… identify the specific equipment and explain the characteristic(s) of that equipment that prevent ride-through.*

R2: GRE agrees with the present flexibility that some of the IBR VRT performance could be modified to meet the individual system needs by the applicable Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator. However, some clarity may be required on how this process is initiated and what type is evidence is required to demonstrate request is received and implemented. This may be an additional requirement assigned to the Transmission Planner. Each Transmission Planner, Planning Coordinator, and Transmission Operator that jointly specifies the following voltage ride-through performance requirements within their area(s) different than those specified under R2, shall make those requirements available to each associated applicable IBR Generator Owner and Transmission Owner.

R2.5 & R5.1, et al. Each IBR shall only trip … "Trip" may be ambiguous. Does this mean disconnecting from the system to de-energize the IBR equipment, as in opening a circuit breaker? Or does it mean cease exchanging current? Or something else?

Comment	
For R1, We recommend adding language to refer to plants that were previously exchanging current before the disturbance. For example, A BESS that is fully charged would be connected to the BES, but would not be exchanging current. For R2, change "each IBR's voltage performance" to voltage ride through performance. For R6, exemptions should not be automatically allowed. This would allow for bad designs relying on an exemption. Exemptions should only be for existing or legacy units. New units should not have the option for exemption.

Comment

In the opinion of ACES, the newly proposed Glossary Terms are unnecessary and seemingly incongruous terms. For example, if the Mandatory Operating Region is required, should it not also be continuous? It is our opinion that these terms add little to no value and instead only create confusion where none was previously present. We recommend striking these new terms from the standard.

In ACES' opinion, R1 appears to be overly broad so as to require an applicable IBR to be operational at all times. This does not appear to allow for full facility outages without first having a "documented equipment limitation" per R6. Thus, as written, the GO will run the risk of non-compliance with either R1, R6, or both whenever a full facility outage of an IBR is required. Furthermore, it is unclear how R1 differs from R2 other than seeming to requiring the GO to ensure the GOP always keeps the unit online during to normal operation. We recommend striking R1 from the standard.

Additionally, we do not agree with the language of Requirement R2, Part 2.1.1. As written, R2 does not define what type of System disturbance is applicable and Part 2.1.1 requires the GO to continue producing active power at the pre-disturbance levels or its maximum capability; whichever is less. We have concerns with this approach. Namely, during an over frequency deviation event wherein the high side MPT voltage remains ≥ 0.9 p.u. and ≤ 1.1 p.u. In this instance, the frequency response algorithm within the IBR would attempt to reduce active power output. Due to the fast-acting nature of IBRs, it is likely that an IBR facility(ies) would respond to and correct such an event before a synchronous generating resource(s). However, in the aforementioned hypothetical example, to comply with R2.1.1, the IBR frequency response control would need to be either disabled or limited in its response to an over frequency System disturbance. In our opinion, this is not beneficial to the reliability of the BES. While possibly unlikely at the current time, this hypothetical scenario becomes increasingly likely as conventional synchronous generating resources are retired in favor of IBRs.

Furthermore, it is the opinion of ACES that R6 should be modified to include any potential regulatory limitations. This suggested approach is in line with the approach taken in PRC-024-4 R3. We recommend the modifying R6 as follows:

R6. Each Generator Owner and Transmission Owner shall document each known regulatory or equipment limitation that prevents an applicable IBR that is in-service by the effective date of this standard from meeting voltage or frequency ride-through requirements as detailed in Requirements R1 through R5.

6.1 Each Generator Owner and Transmission Owner shall include in its documentation:

6.1.1 Identifying information of the IBR (name, facility #, other)

6.1.2 Which aspects of voltage ride-through requirements that the IBR would be unable to meet

6.1.3 Identify the specific piece(s) of equipment causing the limitation.

6.2 The Generator Owner and Transmission Owner shall communicate the documented regulatory or equipment limitation, or the removal of a previously documented regulatory or equipment limitation, to its Planning Coordinator and Transmission Planner, and Reliability Coordinator within 30 calendar days of any of the following:

6.2.1 Identification of a regulatory or equipment limitation.

6.2.2 Repair of the equipment causing the limitation that removes the limitation.

6.2.3 Replacement of the equipment causing the limitation with equipment that removes the limitation.

Lastly, the values specified in Table 1 and Table 2 in Attachment 1 do not align with the graphs shown in Figure 1 and Figure 2, respectively.

Comment

Electric Reliability Council of Texas, Inc. (ERCOT) joins the comments of the ISO/RTO Council (IRC) Standards Review Committee (SRC) and adopts them as its own in addition to the following comments, except to the extent of any specific differences between the SRC comments and the following comments from ERCOT.

As detailed below, the currently proposed language for Requirement R1 is not clear. Additionally, ERCOT believes that plant-level requirements are insufficient because individual IBR unit performance failures continue to occur and could, in aggregate, be just as impactful or more impactful than the complete loss of an IBR plant. The performance threshold should be coordinated with the threshold in PRC-030, and ERCOT believes a reasonable threshold would be the **lesser** of either 20% of the plant's gross nameplate rating, or 20 MW. In an IBR-dominated electric system, these aggregated losses could cause unreliable operations if not corrected. The past 8-10 years have demonstrated that IBR owners will not voluntarily correct these performance issues in the absence of a mandatory reliability standard.

SDT's proposed language (ERCOT finds the bold portions unclear):

"Each Generator Owner or Transmission Owner of an applicable IBR shall ensure that **each IBR** remains electrically connected and continues to exchange current in accordance with the no-trip zones and operation regions as specified in Attachment 1 unless **needed** to clear a fault or a documented equipment limitation exists in accordance with Requirement R6."

ERCOT's proposed language:

"Each Generator Owner or Transmission Owner of an applicable IBR shall ensure that each IBR, **and its IBR units**, remains electrically connected and continues to exchange current in accordance with the no-trip zones and operation regions as specified in Attachment 1 unless **the IBR, or its IBR units, needs to be tripped** to clear a fault or a documented equipment limitation exists in accordance with Requirement R6."

In addition to the concerns with Requirement R1 noted above, ERCOT is concerned that Requirement R2 does not clarify the timeframe encompassed by the term "System disturbance." Without further clarification, "System disturbance" may be interpreted to only describe the fault itself, even though control instability may manifest itself immediately after the fault clears or during the milliseconds or seconds after the fault clears, during which time frequency and voltage support are still critical. While IEEE 2800 defines the disturbance period, and there is an expectation that an IBR will perform acceptably in the continuous operation region, Requirement R2 is not clear that "riding-through" a disturbance includes both the fault and the non-fault portions of the disturbance along with the transition from ride-through mode to a new steady-state (i.e., the post-disturbance period). ERCOT suggests a 10-second window as a bright-line criterion.

SDT's proposed language for Requirement R2.

"R2. Each Generator Owner or Transmission Owner of an applicable IBR shall ensure that during a System disturbance, each IBR's voltage performance adheres to the following, unless a documented equipment limitation exists in accordance with Requirement R6."

ERCOT's proposed language for Requirement R2:

"R2. Each Generator Owner or Transmission Owner of an applicable IBR shall ensure that during, **and up to ten seconds after,** a System disturbance, each IBR's voltage performance **and its associated IBR units'** voltage performance adheres to the following, unless a documented equipment limitation exists in accordance with Requirement R6."

For Requirement R2, Part 2.2.2, ERCOT agrees that location-specific flexibility may be needed and defined by the TP, PC, RC, and or TOP; however, the language should clearly mandate that in such instances, the established performance requirements must also be met. Additionally, the current wording does not address the possibility that reactive current "response" could be in the wrong direction if not properly configured, and the language should be clarified to address this issue. ERCOT proposes the following language for Part 2.2.2 to capture the full spectrum of current priority modes from full aggressive reactive priority mode, to a de-tuned reactive response while in reactive priority mode, to an active priority mode.

"Adjust reactive current injection at the high-side of the main power transformer so that the magnitude of the reactive current **properly** responds to changes in voltage at the high-side of the main power transformer in accordance with default reactive prioritization **or as required by** any applicable Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator **that specifies** a certain magnitude **and timeliness** of reactive power response to voltage changes, **that specifies a maximum allowed active current reduction to provide reactive current, or that specifies** active power priority instead of reactive power priority."

ERCOT also recommends including the following language to help prevent unnecessary misoperations due to the use of unfiltered measurements or instantaneous (no time delay) settings for protection systems, consistent with NERC recommendations for addressing easily preventable performance failures.

R2.2.3 "Utilize sufficient time delays or filtering methods for any voltage measurements utilized by its protection equipment to prevent unnecessary trips due to calculation errors or transients."

ERCOT finds the bolded portions of the SDT's proposed language for Requirement R2, Part 2.3 to be unclear:

"The IBR shall not itself cause voltage at the high-side of the main power transformer to exceed the applicable Attachment 1 Table 1 or Table 2 no-trip zone voltage thresholds and time durations **in its response from** Mandatory or Permissive Operation Regions to the Continuous Operating Region."

ERCOT proposes the following language to clarify the issue:

"The IBR shall not itself cause voltage at the high-side of the main power transformer to exceed the applicable Attachment 1 Table 1 or Table 2 no-trip zone voltage thresholds and time durations **in its response as it transitions from** Mandatory or Permissive Operation Regions to the Continuous Operating Region."

ERCOT would also point out that the last clause may not be necessary because the IBR should not cause high voltage at any time, and the SDT could consider the following alternative language:

"The IBR shall not itself cause voltage at the high-side of the main power transformer to exceed the applicable Attachment 1 Table 1 or Table 2 no-trip zone voltage thresholds and time durations."

Consistent with the comments above on Requirement R2, Part 2.2.2, Requirement R2, Part 2.4 should be revised as follows to clarify that the other requirements or specifications from the RC/PC/TP/TOP must still be met:

"Each IBR shall restore active power output to the pre-disturbance or available level within 1.0 second when the voltage at the high-side of the main power transformer returns to the Continuous Operation Region from the Mandatory Operation Region or Permissive Operation Region (including operation in current block mode) as specified in Attachment 1, **or as required** by any applicable Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator **that specifies** a lower post-disturbance active power level requirement or **that specifies** a different post-disturbance active power restoration time."

Requirement R2, Part 2.5 may not be clear, in light of the new defined terms, that partial trips (including trips of individual IBR units) should not be allowed. While this topic should be coordinated with PRC-030, it goes to the heart of momentary cessation in that staying connected but not supporting frequency and voltage can, in aggregate, be just as detrimental to reliability as a full trip. The SDT should consider revising Part 2.5 to ensure that it is clear that there would be a violation at a particular level (e.g., the lesser of 20% of the unit's rated output, or 20 MW) of IBR unit trips. This could be graduated in severity level starting at the 20% or 20 MW level and increasing thereafter (e.g., 20%, 40%, 60%, 80%, and above).

ERCOT's proposed language for Part 2.5: "Each IBR, **or its IBR units,** shall only trip to prevent equipment damage, when the voltage at the high-side of the main power transformer is outside of the no-trip zone as specified in Attachment 1."

ERCOT also has concerns with the SDT's proposed Requirement R6 language:

"Each Generator Owner and Transmission Owner with **a documented equipment limitation** that would prevent an applicable IBR that is in-service by the effective date of this standard from meeting voltage ride-through requirements as detailed in Requirements R1 and R2 **shall communicate each equipment limitation to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s).**"

More specifically, the first bolded phrase ("a documented equipment limitation") appears to allow complete GO/TO discretion to declare a limitation with no process for review, approval, or acceptance of the limitation by any other entity. Only a communication to the PC, TP, and RC is required. It is unclear if the SDT's intention is that at some point these documented limitations would be reviewed or evaluated under the NERC CMEP (and it is unclear what standard the limitation documentation would be held to under such a review). At a minimum, Measure M6 and/or the Technical Rationale should provide more information about what an acceptable limitation might be and guidance for CMEP staff to use in evaluating the validity of limitations and the associated documentation.

The second bolded portion ("shall communicate each equipment limitation to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s)") is necessary, but may not be effective from a reliability perspective. A mere description of a limitation sent in an email or letter would not be useful for the PC/TP/RC but would meet the letter of Requirement R6. If the purpose of the communication is for PCs, TPs, and RCs to be able to assess the limitation and incorporate it into system studies, either Requirement R6 or the Technical Rationale should clarify that the communication needs to be in a format that is acceptable and useful to the PC/TP/RC (most likely in the form of an updated model that reflects the limitation). Additional burdensome administrative requirements to cover this communication process are not suggested, but at the very least the Technical Rationale should include guidance and set expectations to ensure that the communication will be useful to ensure the reliability of the grid. Additionally, ERCOT notes that FERC Order 901 recognized that "a subset of existing registered IBRs – typically older IBR technology with hardware that needs to be physically replaced and whose settings and configurations cannot be modified using software updates – may be unable to implement the voltage ride though performance requirements directed herein." ERCOT recommends that Requirement R6 be clarified to indicate that the equipment limitation process is only available to the limited subset of IBRs described in Order 901.

Additionally, ERCOT notes that Requirement R6, Part 6.2 does not require the TO/GO to actually improve ride-through capability even when equipment is replaced:

"Each Generator Owner and Transmission Owner with a previously communicated equipment limitation that repairs or replaces the equipment causing the limitation shall document and communicate such equipment changes to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s) within 30 days of the equipment change."

Rather than focusing on communication of changes, Part 6.2 should require the TO/GO to comply with all PRC-029 requirements and should not allow any documented limitations whenever equipment is changed or replaced; this approach would better align with FERC Order 901. PRC-029 should also include a requirement that mandates the implementation of software settings changes and upgrades (that do not require replacement of physical equipment) that improve ride-through capability. This is referenced in the implementation plan, but is absent from the actual requirements in PRC-029.

Equipment limitations may also not be currently captured in dynamic models, and the list of requirements should be updated to reflect this issue. The MOD standards may not accurately account for the provision of this information to all entities that perform studies (including stability limit and IROL determination studies that RCs perform); this would constitute a reliability gap. RCs and PC/TPs must be able to assess the impact of these exemptions to be able address the reliability impact under FERC Order 901.

Finally, ERCOT notes that FERC Order 901 requires NERC to "determine whether the new or modified Reliability Standards should provide for a limited and documented exemption for certain registered IBRs from voltage ride through performance requirements. Any such exemption should be only for voltage ride-through performance for those existing IBRs that are unable to modify their coordinated protection and control settings to meet the requirements without physical modification of the IBRs' equipment." While it is clear that the SDT has determined that the standard should allow for documented exemptions for equipment limitations, the requirement language is unclear as to how or whether this exemption process is truly "limited" as required in Order 901, especially in light of the explicit reference to IBRs "that are *unable* to modify their coordinated protection and control settings to meet the requirements without physical modification of the IBRs' equipment." As ERCOT notes below, exemptions should be limited to scenarios where a responsible entity cannot otherwise achieve the necessary ride-through performance without physical equipment changes (inability to meet ride-through requirements that can be addressed simply by making software- or parameterization-type changes should not be grounds for an exemption) OR to scenarios where, even without making the remaining physical changes, the loss of a contingency would not cause instability, Cascading Outages, or uncontrolled separation that adversely impact the BPS.

Requirement 1 and 2

These requirements mention that the IBRs should respond to the voltage changes with reactive current injection during a system disturbance, however, the magnitude of this response is not identified. The magnitude and expectation of the response should be clarified due to the fact that it can vary by unit and unit capabilities.

Measures 1, 2, 3, 4, and 5

With regards to data recording, it is unclear what counts as recording? If the expectation is the same as contained in PRC-028-01 Draft 2, that should be specified; or otherwise identify alternate means of data recording.

What if an entity does not have a recorded event to show compliance with the standard and prove its ability to ride through a system event?

Comment	

NextEra aligns with EEI's comments:

EEI agrees with most of the proposed language in Requirements R1, R2 and R6; however, the phrase “of an applicable IBR” should be removed. Applicability is defined in the Applicability Section of the standard and anything more is unnecessary and redundant.

EEI also does not support Requirement R2, subpart 2.5 because it contains unneeded language, which adds confusion and implies that GOs can only trip outside of the trip zone if their equipment might become damaged. This has never been an obligation for synchronous generators, and we do not agree that this should be an obligation for IBRs. If NERC or the SDT believe that the no-trip zone needs to be expanded, they should justify such a change and present it for industry review and comment, otherwise, Requirement R2, subpart 2.5 should be deleted.

And while we support Requirement R6 and the provisions to notify PCs, TPs and RC about equipment limitations that would prevent an applicable IBR from meeting ride-through requirements as detailed in Requirements R1 and R2, the Requirement does not go far enough because there may be technical reasons why an applicable IBR is unable to meet Requirement R3 through R5, as well. To address this concern, R6 should be expanded to include Requirement R1 through R5.

Comment

In regard to R1:

Does M1 imply that actual recorded data must be kept as evidence of ride-thru compliance for every in-scope IBR, for every system disturbance? Thesame question applies to R2-M2, R3-M3, R4-M4, and R5-M5.

The disturbance characteristic must be specified in order to trigger captures of performance information for every disturbance at every IBR facility - the characteristic which defines each type of disturbance must be defined in order to capture the record.

For each of the Measures M1 - M5, what "other evidence" can demonstrate compliance with R1-R5 other than recorded data? How does the drafting team believe that generator owners can assure this performance expectation can be achieved prior to an actual event? There is no test verification that can be performed to confirm the expected performance. Consider providing some examples of what is acceptable as “other evidence”.

R1 mentions “operation regions specified in Attachment 1. R2, Part 2.1 mentions “continuous operation region as specified in Attachment 1” and Part 2.2 mentions “mandatory operation regions as specified in Attachment 1”. However, nowhere in attachment 1, is there mention of "continuous, mandatory, or permissive" operation regions.

In regard to R2:

For R2, Continuous Operation Region is not specified in Att. 1; it is merely a defined term in the draft standard. Southern Company suggests that the referenced region be shown on the graph of Att.1, or that the words from the defined term simply be placed in the sub-requirement directly rather than creating a defined term. The term region implies an area (volt-time). If the definition is simply specifying voltage level magnitude, simply state that. The definition labels are confusing; does permissive operation mean the IBR has permission to trip if the voltage is less than 0.1pu? It is observed that the values in the "mandatory operating region" match some of the borders of the "no trip zone" in Attachment 1, yet there is a time element that must be accounted for in determining if a trip is in compliance or not with the curve of Att. 1. For example, how can a long term (1-9 second) event where the voltage is 0.4pu be a Mandatory Operating Region? The voltage ride-thru curve does not specify this (for example).

Regarding the R2.2 and R2.3 requirement specifications, IBR facilities do not have per phase voltage regulation in their current designs, so the feasibility of successfully reacting to low system voltage (R2.2) with rapid reactive power injection while not possibly causing high voltage locally (R2.3) is questionable.

Regarding R2.1.1 & R2.1.2, it should also reference Interconnection Agreements (IA) limits since some IBR facilities have both solar and battery storage with an IA limit less than the aggregate sum.

Regarding R2.1.1 and R2.1.2, the idea that IBR Facility Power Plant Controllers operate to apparent power limits, is not in line with normal practices. Most PPC interfaces do not provide an apparent power reading or control function option. PPCs communicate separate MW and MVAR setpoints to all the of the site IBR Units and they follow or provide as capable the MWs and deliver MVARs up to the inverter reactive power limit.

Southern Company recommends changing wording to:

R2.1.1:Continue to deliver the predisturbance level of active power or available active power, whichever is less, and continue to deliver active p ower and reactive power up to its reactive power limit.

R2.1.2:If the IBR cannot deliver both active and reactive power due to a current or reactive power limit, when the applicable voltage is below 9 5% and still within the Continuous Operation Region, then preference shall be given to active or reactive power according to requirements spec ified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

R2.1.2 discusses giving preference to either active or reactive power based on requirements specified by transmission entities. There is some concern that this could be interpreted as a fluid preference that could require IBRs to actively configure active vs reactive capabilities.

Regarding R2.3, what happens if TOP has several lines down for maintenance in the area, which causes the part of the system the IBR facility is located, go from a strong system to a weak system?

R2.4 does not take into consideration other dynamic system conditions as a result of the fault and the effects on the PPC during a fault recovery. An example of this is Primary Frequency Response due to system frequency excursions during fault recovery. The active power recovery may be reduced or frozen during an underfrequency event while an IBR Resource is in recovery, thereby extending the time of the recovery.

R2 specifies performance for continuous and mandatory operation region, but not for permissive operation region. The performance during permissive operation region is in Attachment 1. Performance for all regions should be in Requirement R2.

Regarding R2.1.1, the first part, where IBR is required to continue to deliver the pre-disturbance level of active power or available active power, whichever is less is fine. However, the second part (and continue to deliver active power and reactive power up to its apparent power limit) is conflicting with the first part of this requirement. If the IBR plant's available active power was 50% of nameplate rating due availability of wind, solar irradiance, etc., then the second part of the requirement is stating that plant is required to produce reactive power to its apparent power limit given its available active power equal to 50% of nameplate rating. This is not correct.

In regard to R2.1, the clause 7.2.2.2 of the IEEE Std 2800 includes an exception when negative-sequence voltage is higher than certain threshold for a given time duration. Why the SDT not include this exception in the PRC-029?

In regard to R2.2, it appears the intent is to require that inject balanced current, during symmetrical faults, and unbalanced current during asymmetrical faults. However, the language is confusing. First, there is no plant level voltage regulation during a fault condition. Second, during unbalanced faults, what does a voltage regulation mean? One option is replace both Part 2.2.1 and Part 2.2.2 with following: The IBR shall inject current based on voltage deviation on high-side of main power transformer and as specified by the TP, PC, RC, or TOP.

In regard to R2.3,this requirement is confusing. Table 1 and 2 in Attachment 1 includes both low- and high-voltage thresholds. One meaning could be that the IBR shall not cause voltage to exceed LVRT threshold for a specified time duration. The true meaning is unclear. Is it correct that the intent is to focus on HVRT thresholds and time duration? The time duration for voltage > 1.2 per unit is not specified. Does this mean that IBR shall not cause overvoltage > 1.2 per unit whatsoever? If so, it needs to be written clearly.

In regard toR2.5, if there is no expectation for IBR to ride-through disturbance outside of no-trip zone, then there is no need for this requirement. For example, if voltage is zero for greater than specified time duration in Tables 1 and 2, say 1 second, then what is the point in staying connected and feeding into fault unless there is a risk of equipment damage? Additionally, there is no such expectation for frequency ride-through requirement R4.

R2.5 is not practical for the GO to determine where every individual piece of equipment would be damaged. There is no need to require tripping just before equipment damage if IEEE 2800 is guidance for equipment manufacturers.

In regard to Attachment 1:

1. There is no mention of continuous, mandatory, or permissive operation region in tables 1 and 2. Consider adding a column in tables 1 and 2 to show these operation regions.
2. For Table 1 and 2:
    - ≥1.20 should be >1.2
    - ≥1.1 should be >1.1
    - ≥1.05 should be >1.5
3. In IEEE Std 2800, the cumulative ride-through duration of 1800 second when voltage is > 1.05 is applicable to all nominal voltages except for 500kV nominal operating voltage. For 500kV nominal operating voltage, the equipment rated to 550kV (1.10 per unit) is available per ANSI C84.1. In IEEE Std 2800, see Note 1 under Table 12. Consider clarifying this in the PRC-029.
4. Note 7: A time window of 10-second is mentioned. However, when V>1.05, the ride-through duration is 1800 second, which is over a 3600-second time window in IEEE 2800.
5. Note 10: The purpose of current blocking in IEEE 2800 was not to protect the equipment but to rather to avoid tripping due to consequences of injecting current and hence, failure of ride-through.
6. Figures 1 & 2: why does the X-axis start at 0.1 second and not zero?

Finally, Southern Company supports EEI and NAGF comments.

Comment	
In 2.1.1 the "apparent power limit" is what is capable during the System disturbance correct? What is the "applicable voltage" to determine 95% in 2.1.2 (and why is per unit not used)? Where are the "requirements specified" by the TP/PC/RC/TOP and how does a GO or TO determine which one to use? If in the Planning world, the requirements should be specified in the TPL Standards. It is unclear what actions a TO/GO will take and be consistently applied. Since this is an event driven compliance review in the Operations Assessment time horizon, why would a TP or PC provide preference for active or reactive power in that timeframe? In a response study by the TP/PC, perhaps guidance on preference could be provided but it is unclear and NOT required in TPL Standards to this point. Clarity between the Tables and Figures in Attachment one needs provided to avoid confusion. Just to be clear, It appears that any new units after the effective date of this Standard have to meet all the criteria. Do the existing units with limitations have six months after the effective date of Standard to submit equipment limitations. With PRC-024-3 and PRC-024-2 already having a Requirement in place that requires limitations to be provided to the TP/PC and the industry already leaning on IRO-010 and TOP-003 for notifications, why is there a need to add an additional 6 months for Requirement R6? The RC already has communication capability with GOs.

R1:

R1 should be revised to directly clarify, or include a footnote to clarify, the statement “that each IBR remains electrically connected and continues to exchange current” with “electrically connected, i.e., shall not trip, and continue to exchange current, i.e., shall not enter momentary cessation” that was provided in the Technical Rationale.

Attachment 1:

There is a discrepancy between the definition of the Term “Mandatory Operating Region” which states “≤ 1.2 per unit” and Table 1/Figure 1 or Table 2/Figure 2 which state “≥1.200” per unit “N/A”. Please clarify if Table 1/Figure 1 and Table 2/Figure 2 should state “>1200” or if the definition of the Term “Mandatory Operating Region” should state “<1.2 per unit”.

Please clarify Figure 1 and Figure 2 to clearly show the “Continuous Operating Region”, “Mandatory Operating Region”, and “Permissive Operating Region”, along with requirements beyond 10 seconds.

Please Clarify “9. The IBR may trip for more than four deviations of the applicable voltage….” In attachment 1.

R2.5:

This requirement is beyond the purpose of the standard, which is to establish Frequency and Voltage Ride-through Requirements for Inverter - Based Generating Resources and should be removed.

Andy Thomas - Duke Energy - 1,3,5,6 - SERC,RF

Answer	No
Document Name	

Comment

Duke Energy recommends the implementation of EEI and NAGF comments.

Duke Energy does not agree that the language is clear. The language seems close to but not completely in alignment with IEEE 2800-2022. It is not clear that the -029 requirements align with the IEEE 2800 requirements, especially given that most would want to comply with both. Many times the Continuous Operation Region is associated with the voltage regulation function and the Mandatory Operation Region is associated with LVRT. This separation is not maintained in various statements within 2.1 and 2.2. It is not clear how the plant or inverters can be configured to operate as specified in R2. Overall the language seems overly prescriptive and the DT may consider less specificity and possibly even a reference to IEEE 2800 rather than trying to restate it. Voltage regulation functions are typically based on POI voltage while LVRT functions are based on inverter terminal voltage. It is not clear that the requirements recognize this difference.

Also, there are multiple references in R1 and R2 to Attachment 1 containing or representing the various Regions, but they are not graphically represented. The DT may consider revising the Att. 1 Figures (and moving the vertical axis crossing to 0.1 sec).

tt seems the industry has often misinterpreted the area outside of the No-trip Zone as an area where the plant must trip. The DT may consider specifically addressing and emphasizing in the text and on the Figure that the plant is not required to trip in this area. For example, it may be labeled May Trip Zone. To that end, it would also be helpful for the GO to submit equipment ride through limits. That is the actual equipment limits, not the various voltage protection settings. With that information, plants would have the bases to provide the maximum ride-through beyond the No-Trip Zone and still not exceed plant main and BOP equipment limits.

Response

Christine Kane - WEC Energy Group, Inc. - 3, Group Name WEC Energy Group

Answer	No
Document Name	

Comment

WEC Energy Group does not agree that the language in R1, R2, and R6 is clear for the following reasons:

R1.:

WEC disagrees with text "… shall ensure that each IBR remains connected…". How else can an entity "ensure" to remain connected other than to set voltage protection outside the no-trip zone? The requirement must state what must be done. Based on Attachment 1, this is clearly voltage protection settings function so R1 should try and match PRC-024 R1. Otherwise, this requirement is open-ended as IBR could potentially be disconnected due to other reasons and the entity will be deemed non-compliant.

The "main power transformer" should be defined in a footnote, similar to what's proposed in PRC-028. It's unclear if main power transformer represents individual IBR step-up transformer or the site step-up transformer.

The phrase "exchange current" should be listed and defined in Terms section. Confusion exists in understanding if "exchange current" applies to BESS while charging, real/reactive current components, or something else. An exception should be added to exclude BESS from the PRC-029 requirements while charging.

WEC also disagrees with M1. The only means for an entity to "ensure IBR remains connected" is to set voltage protection and voltage ride-through protection according to Attachment 1. Making sure that the settings are applied should be the measure. The "recorded data" is an inconclusive statement. If the entity applied settings outside the no-trip zone and it still tripped, which could be for various other reasons, does that mean then entity is non-compliant? What needs to be recorded and where? Does this measure now mandate additional recording capabilities in addition to PRC-030? (Same comment applies to M2, M3, and M4).

R2.:

WEC disagrees with text "…. shall ensure that each IBR remains connected…". The requirement must state what TO and GO must do. Otherwise, this requirement is open-ended without a measurable statement.

2.1: Term "Continuous Operating Region" as defined conflicts with equipment design limitations. Power transformers may not be designed for continuous operations from 0.9 and 1.1 pu. Please refer to IEEE C57.12.00, sections 4.1.6.1, 4.1.6.2 and 5.5, and ANSI C84.1. Without some specific maximum time applied, the continuous operating region will conflict with equipment limitations. Due to this wide range, entities will simply take exception to R2 and R2 will not have any positive benefit for BES reliability. There is a reason PRC-024-3 has a 4 second limit. This limitation should clearly be introduced in PRC-029. Finally, the proposed "Continuous Operating Region" range conflicts with acceptable continuous operating ranges by Transmission Operators. Many Transmission Operators classify continuous operating range from 0.95 and 1.05 pu, and consider voltage ranges from 0.9 to 0.95 pu and 1.05 to 1.1 pu as abnormal voltage ranges.

2.1.2: There is nothing that governs a TP, PC, RC or TO to specify active/reactive power prioritization.

2.3: This requirement is inconclusive. The requirement must state what TO and GO must do. Otherwise, this requirement is open-ended without a measurable statement. Something regarding "IBR gain" was briefly mentioned during the PRC-029 webinar. A wide spectrum of gains and tuning parameters exist within the IBR controls. The requirement must state what parameters are to be addressed and how to set them. Gains and tuning parameters are covered in MOD-026 and MOD-027 standards and shall not be introduced here. Another potential issue could be with AVR function within the power plant controller. AVR/PPC failure could potentially cause higher voltage outputs. AVR failure, or any equipment failure, should not be the criteria to violate the standard. WEC recommends this requirement be removed.

2.4: WEC owns and operates multiple IBR sites and it is in our experience that the limitation to the 1 second requirement will come from the power plant controller. The ramp rate capabilities of the power plant controllers are far slower than inverter ramp rates and are typically in minutes range. WEC also had an instance where the power plant controller ramp rate increase was denied by the Transmission Operator/Planner.

2.5: This requirement contradicts the meaning of established No-Trip zone. If the No-Trip zone is inadequate, then SDT should evaluate and adjust it accordingly. In addition, having protection settings applied right at the equipment damage curve is not a standard protection practice, especially if events such as voltage excursions have a cumulative effect on insulation degradation that could lead to premature failures. WEC recommends this requirement be removed.

R6.: This requirement should include and cover equipment limitations associated with R3, R4, and R5.

Comment

The NAGF provides the following comments:

a. Requirement R1 - the NAGF request clarification on the term "exchange" being used in the proposed language for Requirement R1.

b. Requirement R2 – the Terms section identified the terms: Continuous Operating Region, Mandatory Operating Region, and Permissive Operating Region but these terms are not specifically referenced in the tables for Attachment 1. The NAGF believes that the regions should be included in Attachment 1 for clarity.

c. The PRC-029-1 draft remains silent on the network condition, so it is unclear how to model the transmission system to test compliance with these requirements. One option is to assume that the transmission grid at the point of interconnection may be modeled as an ideal voltage source. Another option is to model the transmission grid as a voltage with a Thevenin impedance based on a short circuit ratio (minimum and maximum), which would consider the network condition at the point of interconnection. The NAGF requests clarity on this topic regarding testing compliance.

d. The requirement stated in R2.4 for IBRs to restore active power to the pre-disturbance or available level within 1.0 second when voltage at high-side of the main power transformer returns to Continuous Operation Region. Based on the TO studies or requirements, it is recommended that flexibility be allowed in the recovery time requirement. For example, if studies indicate that a slower ramp-rate and/or pause in the power ramp-up is beneficial then that should be allowed. The NAGF also recommends an active power recovery threshold of 90% of pre-disturbance level to account for measurement and IBR unit control uncertainties and tolerances.

e. The requirement stated in R2.1.1 must allow IBRs apparent power to be limited if the voltage is outside the normal operating range and the IBR units have reached their maximum current limit.

Comment

AZPS supports the following comments that were submitted by EEI on behalf of its members:

EEI agrees with most of the proposed language in Requirements R1, R2 and R6; however, the phrase “of an applicable IBR” should be removed. Applicability is defined in the Applicability Section of the standard and anything more is unnecessary and redundant.

EEI also does not support Requirement R2, subpart 2.5 because it contains unneeded language, which adds confusion and implies that GOs can only trip outside of the trip zone if their equipment might become damaged. This has never been an obligation for synchronous generators, and we do not agree that this should be an obligation for IBRs. If NERC or the SDT believe that the no-trip zone needs to be expanded, they should justify such a change and present it for industry review and comment, otherwise, Requirement R2, subpart 2.5 should be deleted.

And while we support Requirement R6 and the provisions to notify PCs, TPs and RC about equipment limitations that would prevent an applicable IBR from meeting ride-through requirements as detailed in Requirements R1 and R2, the Requirement does not go far enough because there may be technical reasons why an applicable IBR is unable to meet Requirement R3 through R5, as well. To address this concern, R6 should be expanded to include Requirement R1 through R5.

R2.1/2.2

This states that the TO is who decides whether Active or Reactive Power is prioritized when a limit is reached. IBR sites will curtail real power to meet the reactive power request from the controllers.

R2.4

This section would depend on the ramp rate of the units, 1.0 seconds seems extreme

M2

Will the PC's be communicating in writing to the Generator Owner every time there is a disturbance with the request for this data. How long will the data need to be held?

R4

5 hz/second is not a reasonable rate

M4

Will the PC's be communicating in writing to the Generator Owner every time there is a disturbance with the request for this data. The retention period for data is not defined.

Comment

Dominion Energy supports EEI comments. In addition, Dominion Enetgy has the following comments:

R2, Section 2.1 refers to the Continuous Opera**tion** Region as specified in Attachment 1; however the definition of Continuous Opera**ting** Region at the beginning of the standard is only applicable to voltages, measured at the high-side of the MPT that are between 0.9 PU and 1.1 PU. Does this mean that the definition of Continuous Operation Region is different from Continuous Operating Region? Or is the intent the same as the definition at the front of the standard and the “tion” should be changed to “ting”? Please clarify. This disconnect also exists in R2 and in R2.2.

R2, Section 2.1.2 and R2.4 both allude to a requirement for either the Transmission Planner, Planning Coordinator, Reliability Coordinator or Transmission Operator to provide a preference of active or reactive power if an IBR cannot deliver both due to a current or apparent power limit. The standard is not applicable to any of these listed entities and thus puts an administrative burden on the Generator Owner to contact each to determine a preference. Four entities determining the preference is three too many. A new requirement should be written directing one of the four entities to be the lead point of contact for the GO. Additionally, the standard should specify that the lead entity charged with determining the preference of active of reactive power should communicate the preference a minimum of 6 months prior to the effective date for the GO. The GO cannot put controls in place and ensure compliance until the TP, PC, RC or TOP has documented the compliance requirement.

R6, Section 6.2 is confusing since the Technical Rationale and FERC Order 901 Directives, Paragraph 193 states that “when the existing equipment is replaced, the exemption would no longer apply, and the new equipment must comply with the appropriate IBR performance requirements”. Further, FAC-002-5 considers replacement of inverters / converters or Power Plant Controllers to be “qualified changes” and would require a study before implementation. This section seems to be an unnecessary administrative step, since the FAC-002 process would require submittal of “as-built settings” for the qualified change study.

1 The language “continues to exchange current” in R1 is not clear, please explain.

2 OEMs have not been forthcoming with operating limit data/equipment trip capabilities. Due to the lack of information from OEMs, we are concerned that the following language in R2.5 will be difficult to comply with: “Each IBR shall only trip *to prevent equipment damage*, when the voltage at the high-side of the main power transformer is outside of the no-trip zone as specified in Attachment 1”.

3 The SDT should consider equipment where the manufacturer is not able to provide the limits where equipment damage can occur. For legacy equipment, this information may not be available or may be available at a very high cost to the GO. These scenarios should be included as limitations.

4· Charts in Attachment 1 should be updated to graphically show the performance regions

Rhonda Jones - Invenergy LLC - 5	
Answer	No
Document Name	
Comment	

No, Invenergy disagrees that the language within PRC-029-1 requirements R1, R2, and R6 is clear. Specifically, we offer the below comments regarding these requirements:

R2.1.1.: As currently drafted, R2.1.1. seems to ignore the changes to apparent power limits that could occur during a System disturbance. We recommended the following language:

“R2.1.1. Continue to deliver the pre-disturbance level of active power or available active power, whichever is less, and continue to deliver active power and reactive power up to *the total aggregated current rating of the IBR Units in the plant*.”

R2.1.2.: Invenergy is concerned that the language in R2.1.2. regarding the active power or reactive power preferences of TPs, PCs, RCs, or TOPs may lead to increased confusion and unintended consequences. In its place, we recommend adopting something similar to the p/q/v capability curve demonstrated in Figure 8 of IEEE 2800-2022.

R2.3.: It is unclear to us what R2.3. is requiring. Please clarify or remove.

R2.4.: The ramp rate should be based on System needs; in weaker grid conditions such rapid ramping of active power could lead to power-oscillations or small-signal instability.

R2.5.: This requirement is not auditable and is beyond the scope of the standard, which is to establish certain minimum ride-through requirements. As written, R2.5. suggests GOs should push their equipment as near to its breaking point as possible, even after the minimum ride-through requirements have been met. Thus, we ask R2.5. and similar statements throughout the draft standard be removed.

R6.: Given the technical limitations of many legacy IBRs, R6 must be thoroughly amended to allow exemptions for limitations related to frequency, rate-of-change-of-frequency, and phase angle change ride-through requirements. Consider that there are a range of possible concerns with legacy equipment and equipment already in commercial operation. At one end of the spectrum there exists legacy equipment where the manufacturer is no longer in business, or no longer produces the given IBR unit technology. In these cases, it is often infeasible to either truly document all aspects of the equipment limitations or to attempt to make any software or hardware modifications. At the other end of the spectrum there exists equipment that has been installed in recent years where software modifications may be enough to bring the units into compliance with the proposed requirements, after proper due-diligence and analyses have been performed. In between these two ends of the spectrum there is a range of possibilities.

Where available, software-only modifications are the most likely to yield meaningful reliability improvements where they are most needed while being technically and financially feasible for legacy IBRs to deploy. Indeed, the vast majority of performance issues identified with solar PV resources involved in the 2021 and 2022 Odessa disturbances (and other solar PV resources with the same inverter make/model that were not involved in the Odessa events) are being addressed in ERCOT with software-based modifications (see https://www.ercot.com/files/docs/2024/03/06/Odessa%20Update_03082024.pptx).

Thus, R6 needs a thorough rewrite to give due consideration, and acknowledgement, to these various nuances. Invenergy proposes the below modifications:

R6. Each Generator Owner and Transmission Owner with an applicable IBR that is in commercial operation prior to the effective date of this standard that is unable to meet the ride-through performance requirements detailed in Requirements R1 through R5 shall document the limitation, communicate each equipment limitation to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s), and provide a plan for making reasonable software and settings modifications that reduce or remove the limitation, if available and feasible.

6.1. Each Generator Owner and Transmission Owner shall include in its documentation, in each case as is available or can be reasonably obtained:

6.1.1. Identifying information of the IBR (name, facility #, other)

6.1.2. Current ride-through capability

6.1.3. Known ride-through limitations and documentation of such limitations

6.1.4. Reasonable software and settings modifications

6.1.5. Expected post-modification ride-through capability and documentation of any expected remaining limitations following implementation of such modifications

6.1.6. A schedule for implementing the modifications

6.2. Each Generator Owner and Transmission Owner with a previously communicated equipment limitation that makes a modification that reduces or removes such limitation shall document and communicate such modification to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s) within 30 days of the modification.

To supplement the language regarding reasonable software and settings modifications, the following language could be added to the Technical Rationale: Reasonable software and settings modifications are any available technically feasible modifications involving only software, firmware, settings, or parameterization changes that do not require physical modification of the IBR equipment and are reasonably priced.

A review of the data in Attachment 1 and Tables 1 and 2 should be performed so that they align. Currently, the graphs in Figures 1 and 2 do not match what is indicated in the Tables.

We would recommend a part be added to the standard to directly address the Permissive Operating Region, similar to what is done in Part 2.1 (for Continuous Operation Region) and Part 2.2 (for Mandatory Operation Region) as, if left unaddressed, is unclear. For example, there should be some linkage between the body of the standard and Attachment 1, item 10. The following language is provided for consideration (*new* Part 2.3):

2.3 While voltage at the high-side of the main power transformer is within the Permissive Operation Region as specified in Attachment 1, an IBR may operate in current block mode only if necessary to protect the equipment. Otherwise, each IBR shall follow the requirements for the Mandatory Operation Region in Requirement R2.2.

Comment	

Plese review and align the data in Attachement 1 so that data in Tables 1 & 2 align with Figures 1 & 2.

Also, it is recommended a part be added to the standard to directly address the Permissive Operating Region, similar to what is done in Part 2.1 (for Continuous Operation Region) and Part 2.2 (for Mandatory Operation Region) as, if left unaddressed, is unclear. For example, there should be some linkage between the body of the standard and Attachment 1, item 10. See the following proposed language for consideration (*new* Part 2.3):

2.3 While voltage at the high-side of the main power transformer is within the Permissive Operation Region as specified in Attachment 1, an IBR may operate in current block mode only if necessary to protect the equipment. Otherwise, each IBR shall follow the requirements for the Mandatory Operation Region in Requirement R2.2.

OPTION A.

Requirement R6 provides an overly broad exemption as written as the standard is silent as to what criteria must be met. Only notification to other reliability entities is required with no requirement to develop and implement a Corrective Action Plan. The SDT should consider:

- Develop more specific criteria as to what qualifies as an equipment limitation[1], OR
- Require exemptions be submitted to NERC and/or the Regional Entities for approval in order to qualify for the exemption.

OPTION B.

Leave R6 as written, apply R6 to R1 through R5.

it is recommended that there be no requirement to document limitations on legacy equipment and that this standard focuses on equipment brought into service after the implementation date.

R2: We agree with the present flexibility that some of the IBR VRT performance could be modified to meet the individual system needs by the applicable Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator. However, some clarity may be required on how this process is initiated and what type is evidence is required to demonstrate request is received and implemented. This may be an additional requirement assigned to the Transmission Planner. Each Transmission Planner, Planning Coordinator, and Transmission Operator that jointly specifies the following voltage ride-through performance requirements within their area(s) different than those specified under R2, shall make those requirements available to each associated applicable IBR Generator Owner and Transmission Owner

[1] *See Implementation Plan (page 4), i.e. “only those IBR that are unable to meet voltage ride-through requirements due to their inability to modify their coordinated protection and control settings may be considered for potential exemption.” See Technical Rationale (page 9); i.e. specify which voltage band(s) and associated duration(s) cannot be satisfied or specific as to the number of cumulative voltage deviations within*

a ten-second time period that the equipment can ride-through if less than four… identify the specific equipment and explain the characteristic(s) of that equipment that prevent ride-through.

Comment

Black Hills Corporation supports EEI's and NAGF's comments. Additionally, Black Hills Corporation has concerns regarding event-based "Measures" for Requirement R2, R3, R4 and R5 as GO will likely not have immediate knowledge of "System disturbance" or other transmission system events (transient overvoltage due to switching, frequency excursion, instantaneous positive sequence voltage phase angle changes) when they occur and data collection systems have a limited amount of storage capacity (i.e. data overwrite happens over time, in our case, data is retained for a rolling 12 months). If available data remains the "Measure" for demonstrating compliance, then consideration needs to be given to when and how GO are notified of an event, so data can be reviewed and archived for future demonstration of compliance.

- 2.1.2 refers to requirements specified by the TP, TOP, PC, RC. It is unclear what the expectation is if those requirements have not been defined.
- Is 2.2.2 is stating that the IBR shall maintain reactive power per default setpoints unless a new reactive setpoint has been requested or it's been requested to maintain a certain active power? Why wouldn't this be worded similarly to the sub-bullets in 2.1?
- 2.3: if the IBR is already responding to Mandatory or Permissive Operation regions (exceedances of Attachment 1 Table 1 or Table 2), how could it then cause an exceedance?

- R2.4 There is concern that the controls will be either unable to respond within the 1 second timeframe, or that the historical records to prove the response would not have the resolution to be meaningful.
- R 2.5: How would someone prove that an IBR tripped only to prevent equipment damage? This sub-bullet cannot be enforced.

Helen Lainis - Independent Electricity System Operator - 2

Answer	No
Document Name	Proposed change to table Q2.PNG

Comment

The IESO recommends the following modifications to the text improve clarity or to better convey intent.

With regards to R1:

"…as specified in Attachment 1 unless **not doing so is** needed to clear a fault or a documented **and communicated** equipment limitation exists in accordance with **Requirement R6."**

With regards to M1:

"…demonstrating adherence to ride-through requirements, as specified in Requirement R1**, or shall have evidence of a documented and communicated equipment limitation, as specified in Requirement R6**."

With regards to R2:

"…each IBR's voltage performance adheres to the following, unless a documented **and communicated** equipment limitation exists…"

With regards to 2.1: (and Tables 1 & 2, Figures 1 & 2):

There appears to be inconsistency between the definition of 'Continuous Operation Region', the Minimum Ride-Through Time values stated in Tables 1 & 2, and the plots in Figures 1 & 2.

It seems the intent is to have 'continuous' operation between 95% and 105% voltage, and a minimum ride-through time of at least 1800 seconds (half an hour) when voltage is above 105% and not exceeding 110%. If it is really required that equipment must be able to operate ***continuously*** at voltages up to 110%, then the tables and plots should be labelled with a descriptor that implies indefinite operation is required (i.e., continuous) rather than a minimum time (1800 seconds). For example, a version of Table 2 that achieves what seems to be intent could look like the following:

See file attached - Proposed change to table Q2

With regards to 2.5:

The IESO believes the principle of tripping only when necessary (i.e., to clear faults and to prevent equipment damage during disturbances) is important enough that it warrants a dedicated requirement. With regards to tripping during over-voltages, this principle of only tripping for equipment protection purposes may apply equally to system disturbances discussed in R2 and to switching transients as discussed in R3 (tripping for equipment protection is not presently addressed in R3, though is acknowledged in the Technical Rationale document).

With regards to R6:

The IESO suggests there should be explicit requirements to both 'document equipment limitations' and to 'communicate' those documented limitations to the appropriate parties. The following modifications are proposed:

"Each Generator Owner and Transmission Owner with a **known** equipment limitation that would prevent an applicable IBR that is in-service by the effective date of this standard from meeting voltage ride-through requirements as detailed in Requirements R1 and R2 shall **document** each equipment limitation **and communicate it** to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s).

With regards to M6:

Each Generator Owner and Transmission Owner shall have evidence of **known** equipment

limitations, as specified in Requirement R6, **having been** documented **and communicated** to each associated Planning Coordinator, Transmission Planner, and Reliability Coordinator prior to the effective date of PRC-029-1.

Each Generator Owner and Transmission Owner with changes to equipment shall have evidence of communication to each associated Planning Coordinator, Transmission Planner, and Reliability Coordinator.

Jennie Wike - Jennie Wike On Behalf of: John Merrell, Tacoma Public Utilities (Tacoma, WA), 1, 4, 5, 6, 3; - Jennie Wike, Group Name Tacoma Power

Answer	No
Document Name	

Comment

Tacoma Power does not agree that the language in the applicability section of PRC-029-1 is clear. The applicable facilities language in Section 4 is vague and difficult for entities to understand what is in scope of the Standard. Specifically, the term "BPS IBR" is broad and would encompass all transmission connected IBRs, regardless of size or interconnection voltage. Additionally, the language and formatting of the applicability sections in PRC-028, PRC-029 and PRC-030 are not consistent. These three Standards apply to the same facilities, and therefore, should use the same language. Tacoma Power recommends that Section 4 of PRC-029 and PRC-030 should be revised to align with the language proposed in Section 4 of PRC-028, as follows:

4.1. Functional Entities:

4.1.1. Transmission Owner that owns equipment as identified in section 4.2

4.1.2. Generator Owner that owns equipment as identified in section 4.2

4.2. Facilities: The Elements associated with (1) BES Inverter-Based Resources; and (2) Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

Yes. The SDT should consider citing IEEE 2800-2022 directly in the standard and consider using the IEEE 2800-2022 ride-through requirements as a means to comply with Requirements R1-R5 instead of using Attachment 1 of the standard.

Remove from R1 "*and operation regions*" since this is already required in R2.

Move R2.5 to a sub-requirement of R1, since R1 is the no-trip requirement not R2.

R2.5 should read be rearranged to be more clear, "When the voltage at the high-side of the main power transformer is outside of the no-trip zone as specified in Attachment 1, each IBR shall only trip to prevent equipment damage."

While the language is clear, the SDT explains in the draft PRC-029-1 Technical Rationale that “An IBR becomes noncompliant with PRC-029 only when an event in the field occurs that shows that one or more requirements were not satisfied.” See Question 4 comment for RF’s concerns with this approach.

Comment	
BC Hydro appreciates the drafting team's efforts and the opportunity to comment, and offers the following: 1. Requirement R2 Part 2.1.2 appears to set an additional Requirement for TP, PC, RC, or TOP to specify requirements for scenarios where an IBR cannot deliver both active and reactive power when the voltage is within the Continuous Operating Region and below 95%. BC Hydro recommends that if these are intended as mandatory or deemed as a necessary input for the IBR Owner/Operator, then these should be codified as standalone Requirement(s) against the appropriate functional entities (TP, PC, RC, or TOP suggested by the current draft). 2. The VSL Table for Requirement R1 does not reflect the allowance of a documented limitation. As drafted, it implies that a Severe VSL will be assessed in spite of a preexisting and documented equipment limitation. BC Hydro recommends that the wording be revised to clarify the compliance expectations when evaluating IBR performance.

3. Do you agree with the drafting team's proposals for including IBR transient overvoltage, frequency, ROCOF, and instantaneous voltage phase-angle jump ride-through performance criteria in PRC-029-1 Requirements R3, R4, and R5?

Thomas Foltz - AEP - 5	
Answer	No
Document Name	
Comment	

Designing an IBR plant for transient over-voltage ride-through compliance is complicated by separation of the IBR Units from MPT high side by the non-aggregated collector system including the MPT itself, frequency dependence of the collector system, GSU (i.e., pad mount transformers) and MPT transformer saturation, and surge arrestors on the collector system. DFRs triggered on TOV are essential for monitoring compliance.

Assessing IBR plant phase jump ride-through is dependent on being able to trigger DFR records on non-fault line switching events. Also, as the standard is now written, phase angle jump of any magnitude during a fault must be ridden through and it does not seem possible to determine if a ride-through failure is caused by a fault-caused phase jump exceeding 25 degrees (in which case the IBR could be compliant), or if instead there is a true non-conformity with R1. AEP is not aware if anything can be done about this, but it may be a minor point in most practical situations.

Regarding R4, the technical rationale supporting the standard seems to neglect the possibility of torsional interaction between the wind facilities where sub-synchronous control interaction could exist that can result in possible damage to the wind turbine generator shaft. Therefore, a blanket statement that an inverter-based resource is not affected by off-nominal frequencies may be an assumption that should warrant further considerations when establishing inverter-based resource, frequency ride through requirements. We believe this is supported by page 6 of the technical rationale which states *"In the case of the non-hydraulic turbine synchronous resources, the turbine is usually considered to be more restrictive than generator in limiting IBR frequency ride-through because of possible mechanical resonances in the many stages of turbine blades. Off-nominal frequencies may bring blade vibrational frequencies closer to a mechanical resonate frequency and cause damage due to the vibration stresses. However, inverter- interfaced-IBR does not share this vibrational failure mode."* Furthermore, how should phase jump be considered in R5 where synch check relay settings are greater than 25 degrees?

- R3:
  - Technical Rationale "High Voltage Ride Through and Low Voltage Ride Through" modes were not clearly defined. "Mode" implies a specific, programmed, set of actions within controls which may not be real for solar sites.
  - A GO may not know if a switching event occurs. In that case, how would a GO be expected to determine if the event in question is a switching event or not? While R6 addresses exemptions for R1 and R2 in the case that equipment or the ability to record doesn't exist in an existing site, the same may be of concern for the sub-second requirements listed in R3, 4 and 5. The same exclusions should be for the entire standard, if applicable.
- R4:
  - If the Rate of Change of Frequency is 5 Hz/second, there's concern that the level of calculation needed on parameters that may not have more than a 1/second resolution would net little reaction.
- R5:

- While R6 addresses exemptions for R1 and R2 in the case that equipment or the ability to record doesn't exist in an existing site, the same may be of concern for the sub-second requirements listed in R3, 4 and 5. The same exclusions should be for the entire standard, if applicable.

Answer	No
Document Name	
Comment	

No, Invenergy disagrees with the proposals for including IBR transient overvoltage, frequency, ROCOF, and instantaneous voltage phase-angle jump ride-through performance criteria in Requirements R3, R4, and R5. We offer the below comments regarding these Requirements:

R3: Can the drafting team provide data that demonstrates observed overvoltages during recent System events were of the TOV magnitudes and durations defined in Attachment 2 Table 3? TOVs of such scale are primarily due to the following three scenarios: 1) a lightning strike on the nearby transmission system, 2) transmission line switching transients, and 3) resonant phenomena like voltage magnification due to shunt capacitor switching on the transmission system. Measures are already in place to mitigate such events, including but not limited to proper insulation coordination and substation design, metal oxide varistors, and proper capacitor bank switching of transmission level shunt capacitors (e.g. synchronous switching or use of pre-insertion resistors to mitigate voltage magnification to the extent possible).

To support our statement above, consider an often-quoted document to support these TOV requirements in the NERC Odessa Disturbance Texas Events: May 9, 2021 and June 26, 2021 Joint NERC and Texas RE Staff Report, Dated September 2021. A detailed read of the section that is entitled Inverter Transient AC Overvoltage Tripping Persists identifies poor coordination of controls and protection as the primary driver of these events, rather than TOV conditions at the point of measurement due to switching transients or any type of resonance. What the report explains is that in some cases the IBR units force maximum reactive power output during a fault to push the network voltages up, then once the fault clears they do not pull back on the reactive power injection quickly enough, which leads to an RMS over-voltage (not switching event TOV) at the terminals of the IBR unit, and thus the IBR units tripped. This is solved by 1) proper controls and protection coordination, 2) proper IBR plant design, and 3) proper evaluation of the LVRT and HVRT ride-through capabilities of the IBR plant during the design phase of the plant.

R3 should be removed, and the focus placed on low voltage ride-through and high voltage ride-through, with an emphasis that both LVRT and HVRT performance should be tested during the design phase of a facility using validated IBR unit models based on type-testing.

R4: In the Technical Rationale, the drafting team explains that due to lower system inertia “a wider frequency ride-through capability for IBR **may** be required to avoid the risk of widespread tripping.” Can the drafting team cite more specific reasoning or data to support the expansion of the frequency ride-through capability requirement to the range of 64Hz to 56Hz, well beyond the IEEE 2800-2022 standard frequency ride-through requirement and the capabilities of many legacy IBRs?

The proposed 6-second frequency ride-through capability requirement for the ranges of 61.8Hz to 64Hz and 57Hz to 56Hz does not align with the requirements on the rest of the BES. For the foreseeable future, synchronous generators will continue to be a significant part of the grid. It is a well-established fact that such large electric machinery, which are directly connected to the grid, cannot be exposed to such large variations in frequency. Therefore, it does not seem reasonable to ask IBRs to go to such extremes.

R5: We fail to see the value of requirement R5 given the other ride-through requirements, and it’s unclear to us how an entity is to determine if the subject switching event is initiated by a fault or not. Additionally, we don’t believe the language in R5.1. regarding equipment tripping to prevent equipment damage is reasonable or auditable. We recommend Requirement R5 is removed.

Ruchi Shah - AES - AES Corporation - 5	
Answer	No
Document Name	

Comment

1 AES CE agrees that such performance criteria in R3, R4, and R5 needs to be included, but requests modifications and clarifications as requested below:

2· The language in R3 and R5 relating to “switching events” is difficult to track from the GO perspective. If such an event occurs at the Transmission Operator (TOP), we may not be aware of the need to track and assess our IBR performance as applicable to PRC-029 unless notified by the TOP. If a performance issue with an IBR is identified we would need to be informed by the TOP that a switching event occurred to assess applicability to PRC-029.

3 Please update the technical rationale to clearly state that the 5 Hz/second criteria in R4 aligns with IEEE2800.

Yes, they are needed but the understanding of what those criteria should be is not evolved sufficiently at this time. Also, large scale EMT network models are not of sufficient quality to assess the criteria in the design phase.

For example, if RoCoF is for a time period of greater than or equal to 0.1 second, it leaves the choice of sample time to the user. The plant can take the 100ms for calculations and meet the criteria. The System Operator criteria may calculate RoCoF over 500ms (as we do) and would see the plant as not meeting criteria for the same event.

The proposed RoCoF of 5Hz/s is higher than IEEE1547 Category I, II and III. Transmission Wind turbines and their capabilities are often the same as DER plants. A transmission facility just has a lot more of them. That said, we are looking to introduce higher RoCoF for DER as they may be vulnerable as we transition to a very high IBR grid.

RoCoF is not calculated during the fault occurrence and clearance? The standard would only apply for loss of a source of generation without a fault? For loss of our tieline for a fault it would not apply but loss of tieline for neighbouring RAS action it would? It is most needed when there is a fault. For a fault, we are also losing the older wind MW as they go into momentary cessation during the fault making the generation loss greater. For simple loss of supply, a high IBR grid is stronger than for a loss of supply due to fault. We apply RoCoF criteria during a fault. Our current criteria for transmission design is 2.4 Hz/s calculated over 500ms. Our current design criteria for generation facilities ride through is 4Hz/s. But it is under review in EMT studies. We do not use rolling average at this time as it is difficult to accurately calculate in PSSE. We hope to be able to move to rolling average as we increase our use of PSCAD study results for operational studies.

How does it align with the RoCoF criteria for synchronous plants? We are surveying our existing thermal plants and it is still a bit of an unknown in some areas. Our current criteria of 4Hz/s applies to all generating facilities.

The NAGF provides the following comments:

a. Requirement R3 – the NAGF notes that GOs do not have knowledge of BPS/BES "switching events" and requests that the Drafting Team (DT) consider adding a requirement for the TO/TOP to notify the GOs of such events.

b. Requirement R4:

i. The term "applicable IBR" needs clarification.

ii. Request additional clarification/justification regarding the proposed 5 Hz/second threshold.

iii. The NAGF requests clarity on how to test compliance with the TOV Ride-Through requirement during study or plant IBR design phase.

c. Requirement R5:

i. Same concern as identified for R3

ii. The requirements for phase angle shift of 25 degrees should allow IBR tripping if the post-fault system condition is drastically changed and the device protection is activated.

Christine Kane - WEC Energy Group, Inc. - 3, Group Name WEC Energy Group	
Answer	No
Document Name	
Comment	

- WEC Energy Group disagrees with R3. FERC Order 901 calls for addressing system disturbances. A switching event does not qualify as a system disturbance. In addition, disturbance events summarized this as an anti-islanding protection issue and therefore it should be stated in R3 to reduce confusion. If the SDT decides to keep R3, then R3 should include following text, "unless a documented equipment limitation exists in accordance with Requirement R6."

- WEC Energy Group agrees with inclusion of R4 with following exception: R4 should include following text, “unless a documented equipment limitation exists in accordance with Requirement R6.”
- WEC Energy Group agrees with inclusion of R5 with following exceptions:
    - R5 should include following text, “unless a documented equipment limitation exists in accordance with Requirement R6.”
    - The industry term is known as PLL Loss of Synchronism and is identified as such in disturbance reports. Therefore, R5 should adopt the same to reduce the confusion.

Andy Thomas - Duke Energy - 1,3,5,6 - SERC,RF	
Answer	No
Document Name	
Comment	

Duke Energy recommends the implementation of EEI and NAGF comments.

Duke Energy also recommends, if not already considered, to verify with OEMs that the inverters can satisfy Att 2. Figure 3 does not align with IEEE 2800 Figure 14; again, making compliance with both requirements more complicated.

The controls only respond to voltage and therefore will have no context of the initiating event as could be implied by the statements in R3 and R5. Recommend adding an exception to R3 worded in a similar format to the exception stated in 5.1.

There are several concerns with the equipment limitation exemption language in the draft of R6, and such exemptions not being allowed for R3 and R5. To justify R6 only allowing an equipment limitation exemption for existing resources to R1 and R2, and not the other requirements of PRC-029, the NERC drafting team's technical rationale document points to FERC Order 901:

The objective of Requirement R5 [sic] is to ensure legacy IBR may need to obtain an exemption to the voltage ride-through requirements if hardware replacements or other costly upgrades would be necessary to comply with Requirements R1 or Requirement R2… FERC Order No. 901 states that this provision would be limited to exempting "certain registered IBRs from voltage ride-through performance requirements." This is the reason that no similar provisions are included for exemptions for frequency, rate-of-change-of-frequency (ROCOF), phase angle change ride-through requirements.

First, the R6 equipment limitation exemption should also apply to R3, which requires ride-through for "a transient overvoltage as a result of a switching event whereby instantaneous voltage at the high-side of the main power transformer exceeds 1.2 per unit." As NERC notes, FERC Order 901 directed NERC that existing resources can have equipment limitation exemptions from voltage ride-through requirements, and remaining online during transient over-voltage is clearly a voltage ride-through requirement. Transient over-voltage can damage equipment, so allowing IBRs to protect against this damage is consistent with FERC's intent in Order 901 to only allow tripping that is necessary to protect equipment. Moreover, in many cases making existing equipment better able to withstand transient overvoltages would require replacing or modifying hardware.

For similar reasons, an equipment limitation exemption for existing resources should also apply to R5, which requires ride-through for voltage phase angle changes of less than 25 degrees. FERC Order 901 directed NERC that existing resources can have equipment limitation exemptions from voltage ride-through requirements, and remaining online during voltage phase angle changes should be interpreted as part of voltage ride-through requirements. Remaining online during phase angle changes of less than 25 degrees could be a problem for existing generators, particularly wind generators as phase angle changes can impose mechanical stresses on the wind turbine's rotating equipment. Not allowing an equipment limitation exemption for existing generators under R5 is particularly problematic as it is not typically feasible to retrofit existing wind turbines to increase their ability to withstand mechanical stresses due to phase angle changes. In such cases, making existing equipment better able to withstand voltage phase angle changes would require replacing or modifying hardware. Phase angle changes can damage equipment, so allowing IBRs to protect against this damage is consistent with FERC's intent in Order 901 to only allow tripping that is necessary to protect equipment.

Moreover, a contextual reading of Order 901 indicates FERC was mostly focused on limiting equipment limitation exemptions to existing generators that would have to physically replace or modify hardware, and not strictly limiting such exemptions to a narrow reading of what constitutes voltage ride-through requirements. Paragraph 193 in its entirety, and particularly the first sentence, explain that FERC's intent was focused on exempting existing resources that would have to physically replace or modify hardware: "we agree that a subset of existing registered IBRs –typically older IBR technology with hardware that needs to be physically replaced and whose settings and configurations cannot be modified using software updates – may be unable to implement the voltage ride though performance requirements directed herein." FERC continued by directing that "Any such exemption should be only for voltage ride-through performance for those existing IBRs that are unable to modify their coordinated protection and control settings to meet the requirements without physical modification of the IBRs' equipment."{C}[1] As explained above, equipment limitation exemptions for R3 and R5 are likely necessary to ensure some existing generators do not have to physically replace or modify hardware, and thus such exemptions are consistent with FERC's directive in Order 901.

Finally, R6 equipment limitation exemptions should be allowed for resources with signed interconnection agreements as of the effective date of the Standard, instead of resources that are in-service as of that date. Resource equipment decisions are typically locked down at the time the interconnection agreement is signed, and a change in requirements after that point can require a costly change in equipment or settings that may also trigger a material modification and resulting interconnection restudies. The implementation plan for PRC-029 indicates that the effective date for the Standard will be the first day of the first quarter six months after FERC approval. Many resources take significantly longer than that to move from a signed interconnection agreement to being placed in service, so it makes more sense to allow R6 equipment limitation exemptions for resources that have a signed interconnection agreement as of the effective date of the Standard.

{C}[1]{C} Order 901, https://www.ferc.gov/media/e-1-rm22-12-000, at paragraph 193

A premise of R3 is knowing of a transient OV, due to a switching event on the transmission system.   The Generator Owner is not going to have the intelligence to know if a transient OV is due to a switching event. So, is the GO expected to treat all OV events as non-switching events?

1. Requirement R3: The Transient Overvoltage Ride-Through requirement is just not ready to be included in a regulatory standard. The measure for this requirement is based on actual recorded data. The existing facilities may not even have recording equipment in place to measure switching transients. The IEEE P2800.2 WG has also struggled to come up with a Design Evaluation procedure to show that the plant would be able to ride-through the specified TOV ride-through requirements.
2. Requirement R4:
    - The intent of “continue to exchange current” is understood, however, the requirement is vague. During frequency excursion events, it is necessary that IBR adjusts active power output in response to frequency deviation. But these details are not necessary in NERC standards, currently. The IBR that “continues to exchange current” but not based on frequency deviation, would comply with the standard requirements, which is not ideal. The TP/PC is expected to specify IBR performance during abnormal system frequency. Hence, the requirement should read as following: Each GO or TO of an applicable IBR shall ensure each IBR remains electrically connected and continues to exchange current **as specified by TP or PC** during a frequency excursion event……
    - Why is there no exception for Volts/Hz limit? This could be an issue for type III WTG and transformer within the plant. The frequency ride-through requirement in the IEEE Std 2800 recognizes Volts/Hz limitation.
3. Requirement R5:
    - Consider revising to read as follows: Each GO or TO of an applicable IBR facility shall ensure that each IBR remains electrically connected and continues to exchange current during non-fault switching events where the instantaneous change in positive sequence voltage phase angle is less than or equal to 25 electrical degrees at the high-side of the main power transformer.
    - Has the SDT discussed how to measure “instantaneous” phase angle jump based on recorded data?
    - Part 5.1 is not necessary. The IBR may not trip because it measured phase angle jump of greater than 25 electrical degrees but may trip due to affects of such a jump in phase angle. Not sure how to even prove that equipment was at risk or not.
    - For R5, the GO will not know if a phase jump is the result of a non-fault switching event, so is the GO expected to treat all phase jump events as non-fault switching events?
    - In R5, what happens if an IBR trips due to phase angle jump while the frequency and voltage remain in the continue to operate range? IBRs will not know whether the system has experienced a fault or not.
4. Attachment 3:
    - Why does the SDT require more stringent ride-through capability compared to the IEEE Std 2800? If a certain interconnection requires stringent ride-through requirement then it should only be required for that interconnection. There is no need to extend the stringent requirements of one interconnection to all interconnections. Such an approach is implemented in the PRC-024, PRC-006, etc. Additionally, the PRC-006 specifies boundaries between which the frequency needs to remain while simulating and designing UFLS scheme. The IBR frequency ride-through coordinated with boundaries in PRC-006 should be enough.
    - Table 4:
        - Not sure what is implied by “average system frequency”. The term “average” makes sense when associated with ROCOF but not with frequency.
        - ≥64 should be >64
        - ≥61.8 should be >61.8
    - Note 1 is not necessary. Which measurement is taken on each phase?
    - Note 2: Consider replacing with following: Frequency is measured over a period of time, typically 3-6 cycles.

- Note 3: not sure which “control settings” are referred here. Consider the following from PRC-024: Instantaneous trip settings based on instantaneously calculated frequency measurement is not permissible.
- Note 5: Why did the SDT specify 15-min time period instead of 10-min time period in the IEEE Std 2800.

ROCOF and phase angle jumps:

- Some legacy IBRs have technical limitations that will prevent them from riding through ROCOF less than or equal to 5 hz / second or phase angle jumps less than 25 electrical degrees. Such IBRs need the ability to seek an exemption for these requirements.Note: ERCOT has questioned the validity of how ROCOF and phase angle jumps are measured, and whether the 5 hz / second and 25 electric degree values are accurate.
- R5 specifies that IBRs must ride through phase angle jumps initiated by **non-fault** switching events and are changes of less than 25 electrical degrees. There is an issue Southern Company has encountered on NOGRR245. ERCOT has proposed that IBRs not trip for any ROCOF or phase angle jumps during **fault** conditions. It is an understanding that IBRs should ignore ROCOF and phase angle jump values during fault conditions. Southern Company would support similar fault language in PRC-029-1, but a technical exemption would be required because some legacy IBRs are unable to distinguish between a fault and non-fault condition.

R6.1.2 discusses *“aspects of VRT requirements that the IBR would be unable to meet”.* This language could be clearer by requesting the IBR to identify actual VRT capabilities.[A1]

M6 requires evidence of equipment limitations prior to the effective date of the standard. This could be extremely challenging to meet.

Finally, Southern Company supports NAGF comments.

Rwquirement 3

PG&E believes specific requirements for the inverter capabilities should be removed from the NERC standard and left to the IEEE 2800-22 standard for inverter specifications. The utility relies on RMS measurements and does not have a means to accurately measure transient over-voltage conditions for protective relays; therefore, it would be extremely difficult for the entity to prove its compliance.

Requirement 4

Frequency ride-through limits have been raised considering that IBRs can continue to generate. For synchronous machines, it is not possible to have such a wide frequency range (as per attachment 3 copied below). When the system has majority of IBRs, the effect on synchronous machines with such wide frequency variations is unknown. Also, it would affect the underfrequency load shedding schemes.

PG&E has the following questions for the SDT to consider: Should there be separate ride through limits for Grid Forming inverters and Grid Following inverters? Would higher penetration of IBRs affect the allowable frequency ranges?

Requirement 5

PG&E believes specific requirements for the inverter capabilities should be removed from the NERC standard and left to the IEEE 2800-22 standard for inverter specifications.

PG&E has the following question for the SDT: how do we set relays or trigger a DFR for a switching/non-fault event to show compliance with the requirement?

The IESO recommends the following modifications to the text improve clarity or to better convey intent. **With regards to R4:** "…continues to exchange current during a frequency excursion event whereby the **system** frequency remains within the "no trip zone" according to…" This suggestion would differentiate the actual system frequency from, say, the frequency measurement as 'seen' by the PLL or other parts of the controls. **With regards to 5.1** As commented above, IESO believes 'not tripping except to provide equipment protection' warrants a dedicated Requirement, which may be referred to the context of other requirements, such as performance during phase angle jumps.

PGE supports EEI's comments but in addition would add clarification: For the requirement to say "may trip, but shall only trip to prevent equipment damage" does not provide clear direction. If the IBR can stand a 30 electrical degree change, is it acceptable to trip at 25.0 to prevent equipment damage? It would be preferrable to provide a safety margin before reaching the damage point. Or, is this stating that the IBR wait until 30.0 electrical degrees is reached before taking action? What is the measure for making sure an IBR does not trip at 25.0 or above except to protect the equipment? If there is nothing particularly harmful about tripping an IBR above 25.0, why not indicate that above 25.0 is not a "Must Trip Zone/Criteria"?

AZPS supports the following comments that were submitted by EEI on behalf of its members:

EEI supports the proposal to include IBR transient overvoltage, frequency, ROCOF, and instantaneous voltage phase-angle jump ride-through performance criteria in PRC-029-1 Requirements R3, R4, and R5. However, the following phrase "of an applicable IBR" should be removed from R3, R4 and R5. Applicability is defined in the Applicability Section of the standard and anything more is unnecessary and redundant.

However, please verify the ROCOF with regards to how FR data at the IBR Unit level (per the definitions proposed by 2020-06) is required to be captured (Per proposed PRC-028-1). Note that PRC-002-4 and -5 have ROCOF triggers for recording that are significantly different than 5 Hz/second. Measure 4 of PRC-029-1 has a reference to a Planning Coordinator's area but Requirement 4 has no such limitation or uses Planning Coordinator within the language. It appears that the stated ROCOF is high based on IRPT reports

(https://www.nerc.com/comm/PC/InverterBased%20Resource%20Performance%20Task%20Force%20IRPT/Fast_Frequency_Response_Concepts_and_BPS_Reliability_Needs_White_Paper.pdf). And the ROCOF definition is different from said report by the IRPTF.

Comment	

ERCOT joins the comments of the IRC SRC and adopts them as its own in addition to the following comments, except to the extent of any specific differences between the SRC comments and the following comments from ERCOT.

Footnote 2 is not clear as to whether RoCoF measurement should begin immediately or upon fault clearing. IEEE 2800.2 discussions are heading in a direction that would indicate that during fault occurrence, clearance, and recovery back to a steady-state operating point, failure to ride through should only be allowed if the voltage is beyond the requirement (i.e., the unit should not trip due to any perceived RoCoF during the entire disturbance and recovery period). This is similar for phase angle jump.

Requirement R4 may need to include language similar to that found in Requirement R5, Part 5.1 to ensure RoCoF is set to the equipment capability and is not arbitrarily set at 5 Hz/s. ERCOT also notes that the IEEE 2800-2 drafting team is identifying that there should be agreement between unit owners and planners/operators on how to measure RoCoF (at what time points, greater than or equal to .1 second) to ensure consistency in testing, model validation, application, and performance evaluation. Otherwise, such a requirement may create confusion or otherwise be unenforceable. IEEE 2800-2 also identifies the potential need for higher RoCoF requirements, which may be appropriate in smaller Interconnections.

The current language in Requirement R5 excludes voltage phase angle change of exactly 25 degrees, which is included in IEEE2800 requirements:

SDT's proposed language:

"Each Generator Owner or Transmission Owner of an applicable IBR shall ensure each IBR remains electrically connected and continues to exchange current during instantaneous positive sequence voltage phase angle changes **that are initiated by non-fault switching events on the transmission system and are changes of less than 25 electrical degrees at the high-side of the main power transformer.**"

ERCOT's proposed language:

Each Generator Owner or Transmission Owner of an applicable IBR shall ensure each IBR remains electrically connected and continues to exchange current during instantaneous positive sequence voltage phase angle **changes of 25 electrical degrees or less at the high-side of the main power transformer that are initiated by non-fault switching events on the transmission system**.

Finally, ERCOT believes that under the Violation Risk Factor guidelines, Requirements R3, R4, and R5 should have a VRF of High as they are requirements "**that, if violated, could directly cause or contribute to Bulk-Power System instability, separation, or a cascading sequence of failures, or could place the Bulk-Power System at an unacceptable risk of instability, separation, or cascading failures** . . . ."

Overall, we at ACES support Requirements R3 through R5; however, we have a minor concern with the wording of Requirement R3, Option 2. Specifically, we have concerns with the requirement to "restart current exchange within 5 cycles of the instantaneous voltage falling below (and remaining below) 1.2 per unit." For how long of a duration should the instantaneous voltage remain below 1.2 p.u. to trigger the 5 cycles wherein the IBR must resume current exchange? We recommend that the SDT consider adding a time component to the return from the transient overvoltage condition.

Initial review indicates the proposed requirements R3, R4, and R5 align with IEEE 2800, which the SRC supports.

The SRC recommends the following modifications to the text to improve clarity and to better convey the intent of the standard.

Recommended changes to R4:

"…continues to exchange current during a frequency excursion event whereby the **system** frequency remains within the "no trip zone" according to…"

This revision would clarify that the actual system frequency is the relevant measurement instead of the frequency measurement as 'seen' by the PLL or other parts of the IBR control system.

Recommended changes to R5.1

As noted above, the SRC believes 'not tripping except to provide equipment protection' warrants a dedicated Requirement, which may be referred to in the context of other requirements, such as performance during phase angle jumps.

Attachment 1 needs a few corrections.

- Figures 1 and 2 use a logarithmic time scale for the Time x-axis. This should be updated to be a regular non-logarithmic time scale.
- There are numerous inconsistencies in this standard language and Attachment 1 when compared to IEEE 2800. These should be considered and reviewed for clarity and completeness in the standard. The option to cite IEEE 2800-2022 and use the requirements in the IEEE 2800-2022 directly should be allowed over just the use of Attachment 1 (give each GO/TO the ability to use either of these guides to base their performance off of).
    - IEEE 2800 identifies the following items, but the standard does not support. Clarification/review should occur for each of these items:
        - Exceptions for Negative-sequence voltage exceeding thresholds
        - IEEE 2800 recognizes Volts/Hz limitations, but the standard does not.
        - IEEE 2800 recognizes 500kV system voltages are actually operated in the range of 525kV and therefore has equipment rated to 550kV. These 500kV operating conditions should be considered in the standard.
        - In IEEE 2800 the frequency ride-through criteria defines 10-minute time periods whereas the standard defines them in a 15 minute time period (Table 4 of Attachment 3). This should be clarified and identified.

The standard is quite vague in terms of technical limitations and documentation exemptions to the requirements. Experience has shown that this is a highly nuanced and difficult consideration. There is no language focused on software versus hardware limitations and what is allowed/expected. This could lead to inconsistent, subjective auditing practices rather than clear objective requirements and auditing.

The SRC requests several enhancements to **PRC-029**.

1. **Clarify and emphasize that documented equipment limitations under Requirement R6 must not be construed to be complete exemptions from the Requirements of PRC-029.** If entities are unable to ride-through portions of the ride-through curve, this should not automatically exempt them from complying with the balance of the ride-through curve as described in the Technical Rationale. While this is clearly expressed in the Technical Rationale for Requirement R6 (page 9), this point needs to be brought out more clearly in the PRC-029 standard itself.
2. **Expand PRC-029 to require that Corrective Action Plans be developed and implemented to remove equipment limitations within a specified timeline or require a** technical justification that addresses why corrective actions will not be applied nor implemented.
3. PRC-029 will need to explicitly require any new inverter/controller replacing older equipment to be compliant with PRC-029 rather than set to original equipment specification.
4. Applicability:In Introduction, Section 4.2.2, it is not obvious what aspect of 'IBR Registration Criteria' makes an IBR an 'applicable' IBR – is it simply that an IBR meets NERC Registration Criteria? This bullet point should be elaborated upon to ensure clarity.
5. Event-Based Standard: The SRC has concerns that this standard is an event-based standard that does not necessarily provide an assurance of reliability before events occur, such as would be provided by having an engineering analysis or results from bench-testing and real-time simulations of control equipment that indicate that successful ride through of prescribed disturbances is expected.
6. Without disturbance events that show whether IBRs perform properly, there is no way to determine if an IBR is compliant with the standard. At a minimum, the measures (e.g, M2-M5) should be extended to indicate that a statement that no such events are known to have occurred will qualify as evidence of compliance.
7. Presentation of Ride-Through Ranges: The intended ride-through requirements would be made more clear if the 'minimum ride-through times' were associated with precisely stated, *non-overlapping ranges* of voltages or frequencies, such as in the example 'Table 2' provided by the SRC in its comments above.
8. Nominal Voltages: Note #4 of Attachment 1 would be clearer if the 'nominal' system voltage values were listed as they are in Attachment 2 of PRC-024-3, i.e., "(e.g., 100 kV, 115 kV, 138 kV, 161 kV, 230 kV, 345 kV, 400 kV, 500 kV, 765 kV, etc.)"
9. Harmonize Tables, Figures, Requirements: The voltage/frequency excursion levels and the associated minimum ride-through times for all tables, figures, and any associated performance requirements that modify the requirements should be carefully reviewed and harmonized. There are presently some conflicting entries in the tables/figures.

10. PRC-029 introduces new terms. The drafting team should consider using these new terms in PRC-024 for consistency. The ranges in these definitions may be specific to IBRs due to their unique performance characteristics, but these regions serve the same purpose for synchronous generators.
    i. Term(s):
    ii. Continuous Operating Region – The range of voltages, measured at the high-side of the main power transformer, that are ≥ 0.9 per unit and ≤ 1.1 per unit.
    iii. Mandatory Operating Region – The range of voltages, measured at the high-side of the main power transformer, that are > 0.1 per unit and < 0.9 per unit – or – > 1.1 and ≤ 1.2 per unit.
    iv. Permissive Operating Region – The range of voltages, measured at the high-side of the main power transformer, that is ≤ 0.1 per unit.
11. There does not seem to be a direct explanation of how these new terms used in the Requirements are applied in Attachment 1, where the ranges for “No-Trip” and “Must-trip” are shown. the only mention of these terms in Attachment 1 appears to be in bullets 8, 9, and 10 where one or two Regions are mentioned and assumed to be understood. Additionally, these terms are not used consistently throughout the standard, as these terms are defined as “Operating Regions,” but frequently appear in the standard as “Operation Regions.” The SRC recommends that the SDT standardize on a consistent format for these terms.

R1. Each Generator Owner or Transmission Owner of an applicable IBR shall ensure that each IBR remains electrically connected and continues to exchange current in accordance with the no-trip zones and operation regions as specified in Attachment 1

Attachment 1

8. The specified duration of the Mandatory Operation Regions and the Permissive Operation Regions in Tables 1 and 2 is cumulative over one or more disturbances within a 10 second time period.

Requirements R1, R2, R3, R4, and R5 and associated Measures do not make it clear whether equipment settings or configurations that render a facility unable to meet the performance requirements constitute a non-compliance prior to the occurrence of an event where the facility fails to meet the performance requirements. An understanding of these requirements as event-based (as described in the current draft of the PRC-029-1 Technical Rationale) would only partially accomplish the risk objectives described in the SAR and in FERC order 901 as many events would not be prevented. This is particularly concerning for frequency excursion events (R4) as these events are relatively infrequent and yet widespread, potentially resulting in the failure of a multitude of IBRs to meet the performance requirements if frequency trip settings are not evaluated preemptively. As such, these requirements should make it clear that facilities are to be configured to meet performance requirements and that the relevant equipment settings should be available as evidence to show compliance.

If there are portions of the performance criteria in this standard that equipment owners cannot be expected to meet through assessment of equipment settings in the absence of an event, those portions should be addressed in separate requirements that specify corrective actions to be performed following an event rather than identify non-compliance at the time of the event.

Attachment 1, Part 2b. I assume that “ESS” means Energy Storage System? Please document or clarify.

Part 7 “ … trip …” again. Same question as in comment 2 above. The second sentence is also unclear. What is “the 10-second time period”? Is this phrase identified in Parts 8 and 9? If so, please define it before first use and use the same phrase subsequently.

Attachment 2 Part 3 “ … trip …” again. Same question as in comment 2 and Attachment 1 Part 2b above.

Attachment 3, Table 4 Part 2. I agree with averaging frequency over a set time period. But 3 cycles seems rather short to assure a reasonable frequency value, especially during fault conditions. IEEE 2800 says “… at least 0.1 sec” [6 cycles] for ROCOF, and that is probably a good target for frequency also.

Table 4 and Part 4 “ … trip …” again. Same question as in comment 2 and Attachment 1 Part 2b and 3 above.

Comment

The new or modified terms should define what the “voltage” is, RMS, Positive Sequence? Instantaneous? Etc. for Continuous Operating Region, Mandatory Operating Region and Permissive Operating Region.

In Attachment 1, bullet 3 is problematic, basing the applicable table based on direction by the Transmission Planner needs to have a specific requirement describing how that would be done. Bullet 4 is also problematic for the same reason. Bullet 8 – Mandatory Operation Regions should conform with IEEE 2800 7.2.2.4 for consecutive disturbances, and differentiate from dynamic voltage oscillations. Bullet 9 should also conform to IEEE 2899 7.2.2.4.

Comment

- It is the opinion of ACES that Section 4.2 should be modified to utilize the registration criteria as defined in the latest revision of the NERC Rules of Procedure.

Thus, we recommend the following revisions to Section 4.2:

4. Applicability:

4.1 Functional Entities:

4.1.1 Generator Owner that owns an applicable facility in Section 4.2.1.

4.1.2 Transmission Owner that owns an applicable facility in Section 4.2.3.

4.2 Facilities:

4.2.1 Either of the following Inverter-Based Resource (IBR)1 types:

4.2.1.1 BES IBR

4.2.1.2 non-BES IBR that is:

4.2.1.2.1 Connected to the Bulk Power System, and

4.2.1.2.2 Meets the criteria for a Category 2 GO facility.

4.2.2 High-voltage Direct Current (VSC-HVDC) Transmission facilities that serve as a dedicated connection for an Inverter-Based Resource meeting the criteria of 4.2.1.1

- Transmission is a defined term in the NERC Glossary of Terms. As it is currently defined, this term does not specify a voltage threshold for its applicability; therefore, we recommend capitalizing all uses of the word "transmission" within PRC-029-1 for the sake of clarity.

Comment

ERCOT joins the comments of the IRC SRC and adopts them as its own in addition to the following comments, except to the extent of any specific differences between the SRC comments and the following comments from ERCOT.

The proposed changes to PRC-024 create a reliability gap, as Type 1 and Type 2 wind turbines are not synchronous machines and would therefore no longer be required to comply with PRC-024 but are not included in PRC-029 because they are not IBRs. The SDT should consider including a specific requirement in PRC-024 or PRC-029 that addresses this technology and requires these types of units to try to meet requirements up to their equipment limitations, to notify their PC/TP/RC/TOP of such limitations, and to reflect any such limitations in their dynamic models. This will ensure that the PC/TP/RC/TOP can incorporate the expected performance of these units in their studies.

ERCOT agrees with the SDT's overall approach of ensuring that PRC-029 is clearly a performance-based standard. However, the standard is not entirely clear on this point, as the Time Horizon is "operations assessment" instead of "Real-time Operations." Additionally, the standard generally uses a structure of 'owners…shall… ensure that' instead of an 'owners….shall.. perform' structure. Structures found in other standards, such as BAL-001's 'entity…shall.. operate such that…' structure or BAL-001-TRE's 'entity….shall….meet (or exceed)' structure may also work well for PRC-029.

ERCOT notes that FERC Order 901 states, "we adopt the NOPR proposal and direct NERC to develop new or modified Reliability Standards that require registered IBR generator owners and operators to use appropriate settings (i.e., inverter, plant controller, and protection) to ride through frequency and voltage system disturbances and that permit IBR tripping **only to protect the IBR equipment** in scenarios similar to when synchronous generation resources use tripping as protection from internal faults. The new or modified Reliability Standards must require registered IBRs to continue to inject current and perform frequency support during a Bulk-Power System disturbance" (emphasis added). To meet this directive, it may be important to clearly specify that partial failures (individual IBR unit trips or abnormal responses) also fall under PRC-029.

ERCOT therefore recommends modifying the Purpose statement for PRC-029 as follows: "To ensure that Inverter-Based Resources**, and their IBR Units,** remain connected and perform operationally as expected to support the Bulk-Power System during and after defined frequency and voltage excursions."

The figures in Attachments 1, 2, and 3 appear to be intended to be graphical representations of the tables. To that extent, they are redundant (and potentially contradict what is in the tables). They may be valuable in visualizing the requirements, but they are also ambiguous in that the lines are not precisely defined, and it is not clear if ride-through is required on the lines themselves. ERCOT recommends that these figures be moved to the Technical Rationale or that Attachments 1, 2, and 3 include a clarification that the plots are for visualization purposes only and that the tables define what is actually enforceable

Item 7 in Attachment 1 should not imply that the IBR shall trip beyond the minimum duration. While the inclusion of the term "minimum" helps clarify item 7, the "shall not trip until…" language implies that the IBR shall trip once the minimum ride-through time duration has elapsed.

SDT's proposed language:

"At any given voltage value, each IBR shall not trip until the time duration at that voltage exceeds the specified minimum ride-through time duration. If the voltage is continuously varying over time, it is necessary to add the duration within each band of Tables 1 and 2 over the 10-second time period to determine compliance."

ERCOT's proposed language:

"The IBR shall ride through voltage conditions beyond those specified in Tables 1 and 2 above to the maximum extent the equipment allows. If the voltage is continuously varying over time, it is necessary to add the duration within each band of Tables 1 and 2 over the 10-second time period to determine compliance."

Similar wording should also be applied in item 3 of Attachment 2 and item 4 of Attachment 3.

ERCOT is concerned that item 10 in Attachment 1 ("If the positive sequence voltage at the high-side of the main power transformer enters the Permissive Operation Region, an IBR may operate in current block mode if necessary to protect the equipment") is inconsistent with the following directive from paragraph 190 of FERC Order 901 (as cited in the technical rationale): "Any new or modified Reliability Standard must also require registered IBR generator owners and operators to prohibit momentary cessation in the no-trip zone during disturbances."

The proposed defined terms do not seem to be appropriate for the NERC glossary, especially if they are intended to be used exclusively for IBRs. If the SDT keeps these proposed terms, the definitions should be improved to include durations in addition to voltage ranges and to note that they are only valid for application to IBRs. Furthermore, there are inconstancies between these terms and Tables 1 and 2 in Attachment 1. For example, the Continuous Operating Region is defined as 0.9-1.1 pu (inclusive), but the tables specify only a one second ride-through time for 1.1pu voltage and an 1800 second ride-through time for voltages greater than or equal to 1.05pu, which is not consistent with the concept of continuous operations. Additionally, the terms are used inconsistently in PRC-029, as the terms are defined as "Operating Regions," but frequently appear in PRC-029 as "Operation Regions."

The Technical Rationale includes the following language:

"The proposed PRC-029 must be understood as an event-based standard. Compliance with PRC-029 is determined from IBR ride-through performance during transmission system events in the field and not from interconnection studies, transmission planning studies, operational planning studies, or from IBR models."

ERCOT recommends that the SDT add basic expectations to the Technical Rationale instead of simply stating that compliance is not determined by studies. For example, GOs should design and/or test their facilities to help ensure they won't be non-compliant during an actual event. Furthermore, it would be helpful to offer advice or SDT opinions on how ride-through should be evaluated during design, interconnection, planning, and operational studies. Even though deficient performance in such studies may not be a violation of PRC-029, it makes little sense to proceed with or allow an interconnection of a plant whose simulation models indicate that it will be unable to comply with PRC-029. Such guidance in the Technical Rationale would be beneficial for industry even if the Requirements in the standard do not contain a corresponding mandate.

The Technical Rationale should describe the basis for the "6-second frequency ride-through capability requirement for frequencies in the ranges of 61.8Hz to 64Hz or 57.0Hz to 56.0Hz range," as it is unclear why this approach was chosen instead of an approach that goes all the way up to 65 Hz and down to 55 Hz for 10 seconds or only up to 63.5 Hz and down to 56.5 Hz for 5 seconds.

It is also unclear how the SDT addressed the phase lock loop (PLL) loss of synchronism concerns discussed in FERC Order 901. While there is certainly an interrelationship, certain protection systems like PLL loss of synch may not need to be enabled. Even if enabled, these systems may, if not correctly configured, require additional tuning to ensure the PLL circuit properly controls and prevents some of the other parameters from tripping the unit offline (e.g. phase angle, RoCoF, and overvoltage). The SDT should consider adding additional language to PRC-029 to clarify that phase lock loss of synchronism trips (whether directly or indirectly involved) are not allowed.

The SDT should also consider adding the following items to Attachment 1 for clarity:

11. To the extent possible, IBRs should not use these curves as the absolute voltage or frequency protection set points but should strive to exceed them up to their equipment capabilities while still ensuring adequate equipment protection.

12. IBRs are not required to trip when voltage and frequency are in the may-trip or permissive operation regions.

Additionally, ERCOT has overall concerns with the work plan pushing the planner and operator requirement changes to the final phases. FERC Order 901 states, “To the extent NERC determines that a limited and documented exemption for those registered IBRs currently in operation and unable to meet voltage ride-through requirements is appropriate due to their inability to modify their coordinated protection and control settings, we direct NERC to develop new or modified Reliability Standards to mitigate the reliability impacts to the Bulk-Power System of such an exemption. As NERC will consider the reliability impacts to the Bulk-Power System caused by an such [sic] exemption, we believe that the concerns raised by NYSRC and Indicated Trade Associations on the appropriate registered entity responsible for implementing the mitigation activities, and the nature of such mitigation, should be addressed in the NERC standards development process.”

Due to the interrelationship between these factors, the allowance for limited exemptions should be linked to the need to mitigate the impact of such exemptions, which will take time in and of itself. In addition, Order 901 directs NERC to consider the reliability impacts of such an exemption. If the SDT does not have identified quantities or models of likely exemptions to assess the impact of allowing exemptions, it is unclear how NERC is considering the reliability impacts of allowing exemptions. There must be guardrails in place to ensure that exemptions are truly limited, not open-ended, and there should be verification by means of accurate models and studies that the system can withstand the impacts of exemptions. If such studies demonstrate unreliable operations (i.e. Instability, Cascading Outages, and uncontrolled separation) would result from granting exemptions, then the exemptions should not be accepted. While ERCOT understands the impacts to generator owners, such assessment and determination should be made under FERC’s direction to ensure that the limited exemptions and risk posed by such exemptions are balanced in such a way that the system maintains Reliable Operation.

Finally, regarding the implementation plan, ERCOT does not agree with how the FERC Order 901 excerpt quoted under "Equipment Limitations and Process for Requirement R6" has been applied. The FERC Order 901 excerpt refers to "typically older IBR technology," which would exclude a majority of IBRs that are in operation today. Aligning eligibility for PRC-029-1 exemptions based on documented equipment limitations under Requirement R6 with the effective date of PRC-029-1 would allow potentially hundreds of GWs of newer IBRs to qualify for exemptions. Such an allowance could result in a failure to realize the reliability benefits FERC intended to capture, as it would allow legacy IBRs to claim exemptions even if they are ultimately capable of complying with the requirements of PRC-029. Unless there is assurance, based on validated and accurate models, that planners and operators can verify that the System can withstand the impact of allowing these exemptions, this allowing this level of potential exemptions may not allow for Reliable Operations. In such instances where exemptions may not allow for Reliable Operations, there should be additional evaluation of available physical modifications (e.g. upgrade kits, new power plant controllers, new controller cards/circuits, control communication networks, component upgrades) for IBR technology that is not approaching its end of life and or an upcoming replacement/refurbishment cycle like "typically older IBR technology" is. Additionally, IBRs that make physical modifications to achieve compliance or that have to make software changes at multiple sites may need additional implementation time when such changes require changes at each individual inverter or turbine.

ERCOT expresses appreciation for all of the SDT’s hard work in meeting an expedited timeline for developing a technically complex set of Requirements that attempts to balance elements from IEEE 2800, FERC Orders, NERC recommendations, and vast amounts of stakeholder input. The SDT is to be commended for its progress thus far on this critical standard.

For PRC-029-1 PG&E asks the SDT the following question: Does Table 1 or 2 apply to Type 4 Wind IBRs? It is unclear which table it would apply to and should be clarified since Table 1 specifies “Wind IBR” but not which types of Wind IBRs. PG&E suggests reconsidering the use of the term “trip” or “no-trip.” Per IEEE 2800-22, “trip” for IBRs may not mean the same as has been traditionally used for synchronous machines and other electric elements. For PRC-024-4 PG&E has the following question for the SDT to clarify: For Transmission Owners, does new language in sections 4.1.2 & 4.2.2 only apply to Synchronous Condensers?

Comment	

NextEra aligns with EEI's comments:

PRC-029-1 (Applicability Section) Comments: EEI does not support the Applicability Section of PRC-029-1 for the following reasons:

{C}1. Applicability details should not be contained in footnotes. Please remove footnote 1 from the Applicability Section.

{C}2. Voltage Source Converter – High-voltage Direct Current (VSC-HVDC) are not defined or justified within the Technical Rationale as to why these resources need to be added PRC-029.

{C}3. Without a justification of a need to include VSC-HVDC systems, TOs should be removed from PRC-029-1.

{C}4. EEI does not support the use of the term “BPS IBRs” because no such term exists in the NERC Glossary of Terms that might provide entities with the knowledge to know definitively which IBRs are applicable.

{C}5. EEI also does not support language that points to the registration criteria.

To address our concerns, we suggest the following changes to the Applicability Section of PRC-029-1, noting the Facilities portion of our comments utilize the recommendations from the Project 2020-06 SDT (see boldface changes below):

{C}**4. Applicability:**

{C}4.1 Functional Entities:

{C}4.1.1 Generator Owner

{C}**4.1.2** {C}**Transmission Owner (and footnote 1)**

{C}4.2 Facilities: **(1) BES Inverter-Based Resources; and (2) Non-BES Inverter Based Resources (IBRs) that that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV. For purposes of this standard, the term “applicable Inverter-Based Resource” or “applicable Inverter-Based Resources” refers to the following:**

{C}**4.2.1** {C}**BPS IBRs**

{C}**4.2.2** {C}**IBR Registration Criteria**

PRC-024 Comments: While there were no questions related to the proposed modifications to PRC-024-4, EEI does not support all of the proposed changes made to PRC-024-4. Note the following:

Applicability Section of PRC-024-4

EEI does not support changing the intent of 4.2.1.4 (Previously 4.2.1.5) to include multiple synchronous generators connecting to a common bus under the BES Definition, Inclusion I4. Since the development of the BES definition, Inclusion I4 did not include or intend to include synchronous generators. Had that been the intent, the SDT could have included synchronous generator resources in I4. Furthermore, the BES Reference Document states in Chapter I4: BES Inclusion the following:

Dispersed power producing resources are small-scale power generation technologies that use a system designed primarily for aggregating capacity providing an alternative to, or an enhancement of, the traditional electric power system. Examples could include, but are not limited to: solar, geothermal, energy storage, flywheels, wind, microturbines, and fuel cells.

While EEI is open to making modifications to the BES Definition, trying to provide interpretations within individual Applicability Sections of proposed NERC Reliability Guidelines is not the proper method to make such a change. For this reason, and since 4.2.1.4 (previously 4.2.1.5) was intended to address IBRs; this part of the Applicability Section of PRC-024-4 should be deleted.

Comments on the proposed New Definitions

EEI has no concerns with the proposed new definitions, but we do have some non-substantive comments on their usage throughout PRC-029, Implementation Plan and Technical Rationale. (See below)

{C}· Usage of the newly defined terms deviated from the defined term within PRC-029 and the Technical Rational. (i.e., Operating vs. Operations)

{C}· Incorrectly stating in the Implementation Plan that there were no newly defined terms. Please correct this error.

Continuous Operating Region – Only used once in Requirement 2.3.

{C}· Continuous Operation Region used in Requirements 2.1, 2.1.2, 2.4, & once in Attachment 1 (i.e., suggest changing the defined term to Continuous **Operation** Region or correct to Continuous **Operating** Region throughout)

{C}· Continuous Operation Region used twice in the Technical Rationale; Continuous Operating Region never used in the Technical Rationale.

Mandatory Operating Region – Never used in PRC-029

{C}· Mandatory Operation Region used in PRC-029 in Requirements 2.2, 2.3, 2.4 & once in Attachment 1 (i.e., suggest changing the defined term to Mandatory **Operation** Region or correct to Mandatory **Operating** Region throughout)

{C}· Mandatory Operation Region was used twice in Technical Rationale; Mandatory Operating Region was never used in the Technical Rational.

Permissive Operating Region – Never used in PRC-029

{C}· Permissive Operation Region used in PRC-029 in Requirements 2.3, 2.4, & used twice in Attachment 1 (i.e., suggest changing the defined term to Permissive **Operation** Region or correct to Permissive **Operating** Region throughout)

{C}· Permissive Operation Region used once in the Technical Rationale; Permissive Operating Region never used in the Technical Rationale.

Comment	

Has the MPT Volts/Hz capability been considered when considering the high voltage/low frequency curves?

For R6, the use of "repair" seems inappropriate - an equipment limitation is not equivalent to a broken part in need of repair. We suggest that "repair(s) or replace the limiting element" in R6.1.4 and R6.2 be changed to "remedy the equipment limitation".

The standard requires IBR to ride-through regardless of operating condition of the transmission system. The IBR is typically designed to ride-through for planning events, most likely defined in TPL-001 standard. Considering 24 hour/365 day operation, the transmission system may be experiencing outages beyond planning events. During such an abnormal operating condition, the IBR may not be able ride-through system disturbances as specified. The same could also be true as the transmission system changes over time, as new transmission lines are added to the transmission system and generating plants are added to or removed from the transmission system. The IBR which is designed to ride-through certain transmission network and operating conditions at the time of entering commercial operation may not be able to do so if transmission network and operating conditions change significantly over time. The standard needs to recognize such issues and grant an exception if IBR fails to ride-through.

The SDT proposes to add continuous operating region, mandatory operating region, and permissive operating region terms to the Glossary of Terms. However, these terms are specific to voltage ride-through requirements. There is no reason to limit those terms to voltage ride-through capability only. The continuous and mandatory operation region terms could be applied to frequency ride-through capability as well. Refer to IEEE 2800 to see how these terms are used for both voltage and frequency ride-through capabilities.

Continuous/mandatory/permissive operating region terms:

1. The SDT uses continuous/mandatory/permissive “operating” region as well as continuous/mandatory/permissive “operation” region. Be consistent with either “operating” or “operation” throughout the standard.
2. Following comments to align voltage ranges in Attachment 1, Tables 1 & 2:
    - Mandatory Operating Region term should read like following: The range of voltages, measured at the high-side of main power transformer, that are ≥ 0.1 per unit and < 0.9 per unit OR > 1.1 per unit and ≤ 1.2 per unit.
    - Permissive Operating Region term should read like the following: The range of voltages, measured at the high-side of main power transformer, that is ≤< 0.1 per unit.

3. These terms specify voltage threshold, but which voltage is used in these terms is in the Attachment 1. Per attachment 1, the continuous and mandatory operating regions are based on phase-to-ground or phase-to-phase voltages. But the permissive operating region is based on positive-sequence voltage. The defined terms should also make it clear which voltage thresholds are defined.

Consider revising the purpose statement as following: To ensure that Inverter-Based Resources (IBRs) remain connected and support the Bulk Power System (BPS) during and after frequency and voltage excursions events.

Transmission Owner is included as a Functional Entity in section 4. However, footnote 1 makes it confusing. Would standard only apply to Transmission Owner when it owns the VSC-HVDC transmission facility connecting isolated IBR with BPS?

Currently, PRC-029-1 allows for a GO or TO to seek an exemption from meeting voltage-ride through requirements in R1 and R2.

Southern Company believes that GOs and TOs should be able to seek exemptions from meeting frequency and voltage ride-through requirements in R1 – R5.

The proposed standard only provides for VRT exemptions. Any consideration for FRT, ROCOF, phase angle?

Comment to PRC-024-4:

Facilities section 4.2.1.1 should include I2 of the BES definition and section 4.2.1.4 be removed or reference I2 in place of I4. I4 of the BES definition was intended to point to IBRs at the time of the latest BES definition adoption in 2018 as dispersed power resources and was not intended to point to synchronous generation resources.

Opportunity to clarify that legacy IBRs must maximize capabilities:

1. For NOGRR245, it has been advocated that legacy IBRs should make software / settings changes to maximize capabilities to meet or approach the new ride-through requirements, unless such changes are unreasonably priced.
2. Southern's experience is that software / settings changes are commercially reasonable. The "unreasonably priced" language is intended to protect against price gauging from OEMs.
3. The current PRC-029-1 draft requires legacy IBRs to meet the new voltage ride-through requirements unless a documented technical limitation exists. So a legacy IBR can document an exemption and have performance capabilities less than new VRT standard. But what happens if that legacy IBR owner later learns there is an available software / setting change that would reduce or remove the limitation? The current draft need clarity to address this.
4. Southern Company supports such a software / setting deployment requirement and believes it would (1) be commercially reasonable and (2) more clearly require ride-through capability maximization.

Finally, Southern Company supports EEI and NAGF comments.

While inclusive, is PRC-024-4 Facility Section Part 4.2.1.4 applicable to synchronous generators? Inclusion 4, when written, was designed to catch the wind/solar aspects of the generation fleet. Inclusion 2 seems to be more appropriate (if not already covered in 4.2.1.1). The MPT footnote appears to be limited to Quebec TO synchronous generators and does not include a reference to synchronous condensers (4.2.2

synchronous condenser applicable facilities simply says "step-up transformer(s)"). In PRC-024-4 Requirement 2 there is a reference to "MPT" and the introduction of Transmission Owner within Requirement. It is not clear if applicable to TOs outside of Quebec based on the language provided (from Requirement R2---"…a voltage excursion at the high-side of the GSU or MPT…" which the GSU/MPT is not mentioned in applicable Facilities for synchronous condensers Section 4.2.2). In Attachment 1 there is a similar issue in that footnote 8 on page 21 mentions the high-side of the GSU or MPT—Also should be noted that Footnote 8 does not appear to have an anchor (location within document to reference the footnote). On page 22 of Attachment 2A there are references to the GSU/MPT as well. Just seeking clarification to avoid an entity having a synchronous condenser indicating no applicability because of the language. This inconsistency in language does not appear to follow items 8 ("Clear Language") and 10 ("Consistent Terminology") of the Ten Benchmarks of an Excellent Reliability Standard as referenced in the Guideline for Quality Review of NERC Reliability Standards Project Documents.

PRC-029-1- SDTs need to use the same IBR terms and not add additional descriptors. Even the title of the Standard is not consistent. Should use the proposed definitions in 2020-06 Verifications of Models and Data for Generators for clarity and consistency. There is no such Facility as "IBR Registration Criteria". Footnote 1 contains undefined terms which should be defined within this Standard if used. Because of the inconsistency in definition use, it is not clear whether this applies to the IBR or IBR Unit locations (even when stated that it does not apply to "individual inverter units or measurements takes at individual inverter unit terminals." If looking at Project 2020-06, the inverters in a "common IBR Unit configuration' as shown in Figure 2.2 and 2.3 of the Technical Rational are exactly at the individual IBR Units (see link [2020-06_IBR_Definitions_Technical_Rationale_02222024.pdf (nerc.com)]). Is "exchange current" considered the same as "inject current" which is used (various ways) in other Standards being proposed? The new terms introduced address range of voltages that may not correlate to the Tables effectively. The Continuous Operating Region definition shows to **include** 1.1 per unit and should reflect the 1800 seconds in Table 1 and Table 2 but the 1.1 voltage per unit in the Tables show only a 1 second capability (Mathemataical expression includes 1.1 per unit in the Table which it should not). Furthermore the 1.2 voltage per unit is shown to be included in the Mandatory Operating Region but NOT in the Tables. Please clarify the expectations as entities had an issue in PRC-024 setting protection on the curves when initially mandatory. With conflicting information, and Figures that are not as explicit or appear to match the Tables, WECC is concerned there may be confusion. This language does not appear to follow Item 8 ("Clear Language") and 10 of the Ten Benchmarks of an Excellent Reliability Standard as referenced in the Guideline for Quality Review of NERC Reliability Standards Project Documents.

At a minimum, bullet 2 under Attachment 1 Table 2 should mention all the types of IBR as listed in other Standards (Type 3 and type 4 of wind is covered in bullet 1, "Isolated IBR" is undefined, and 2.b. simply says "Other IBR plants" and limits hybrid to PV and "ESS" (possible typo that should be "BESS"?). The "not limited to" should remain and the SDT may say all are covered with said language but clarity could be provided by adding consistent language as used in other Standards. This inconsistency in language does not appear to follow items 10 ("Consistent Terminology") of the Ten Benchmarks of an Excellent Reliability Standard as referenced in the Guideline for Quality Review of NERC Reliability Standards Project Documents.

Attachment 1 Table 2 Bullet 3 leaves the applicability to the TP but the TP is not called out as an applicable entity and this is an Operations Assessment time horizon. In the Technical Rationale it clearly states "*Compliance with PRC-029 is determined from IBR ride-through performance during transmission system events in the field and not from* ***interconnection studies, transmission planning studies****, operational planning studies, or from IBR models*." So, if IBRs in a hybrid plant have issues, the TP is to blame for calling out the incorrect Table? TPs may very well have the studies to determine how long a ride-through should be sustained by IBRs, but there is no compliance responsibility (not saying there should be—should be responsibility properly assigned through the Standards process). Bullet 4 allows the PC or TP to change the Requirement criteria but there is no accountability if done (furthermore no notifications for awareness to those entities in the Operations side of business). The apparent responsibility does not appear to follow items 1 ("Applicability") of the Ten Benchmarks of an Excellent Reliability Standard as referenced in the Guideline for Quality Review of NERC Reliability Standards Project Documents.

"MPT" is not defined in the Standard yet used repeatedly. Clarity can be provided with a footnote or addition of a definition (not that synchronous condenser use in PRC-024-4 was unclear for MPT).

There are only Severe VSLs for Requirements R1 through R5. Clarity on where the inverter is (based on the 2020-06 drawings provided and language in this Standards Technical Rational) will be important to understand. Failure of individual IBR units (as defined in 2020-06) appears to not be addressed9unless it is intended to be addressed by the Sever VSL) and will have an impact on being complaint at the IBR level.

For each of the measures M1-M5, what “other evidence” can demonstrate compliance with R1-R5 other than recorded data? How does the drafting team believe that generator owners can assure this performance expectation can be achieved prior to an actual event? There is no test verification that can be performed to confirm the expected performance that considers every type of system disturbance that can occur.

Comment

Many references in the requirements point toward Continuous Operating Region, Mandatory Operating Region, and Permissive Operating Region "as specified in **Attachment 1**", yet Attachment 1 does not specify any of these regions. Operating Regions should be added to Attachment 1 tables and figures.

No-trip zone Figures 1 & 2 don't match the tables.

Is there a point or distinction being made by using capitalized "Systen" instead of undefined "system" in requirements?

On behalf of the SERC Generator Working Group:

Consider allowing for some period of time beyond the effective date of PRC-029 to document limitations per (R6) – contemplate the real impact to BES reliability of limitation documentation.

Consider synchronizing the phase in of PRC-028 with the measures such as M1 stating "*shall have evidence of actual recorded data*...".

For each of the measures M1-M5, what "other evidence" can demonstrate compliance with R1-R5 other than recorded data? How does the drafting team believe that generator owners can assure this performance expectation can be achieved prior to an actual event? There is no test verification that can be performed to confirm the expected performance that considers every type of system disturbance that can occur.

MP agrees with the NSRF's suggestions to enhance PRC-029, especially regarding limiting the power of equipment limitations from exempting applicable entities from compliance, expanding the applicable facilities to include IBRs of 20MVA and above, and more precisely defining applicable entities and facilities within the text of the standard.

MP also suggests that a formal definition of "Inverter-Based Resources" precede the adoption of the standard.

Comment

We are concerned that the standard refers to a defined term for IBR which has yet to be adopted in project 2020-06.

We suggest that the drafting team ensure consistent language is used in the section 4.2 "Facilities" section with the other projects such as 2021-04 (PRC-028) and 2023-02(PRC-030). Section 4.2.2 refers to IBR Registration criteria, however it is our understanding that section 4.2.1 would refer to GOs and TOs "that own equipment as identified in section 4.2" and where section 4.2 would indicate "the Elements associated with (1) BES Inverter-Based Resources; and (2) Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV." .

We question why "attachment 1" and "Requirement R6" are written in bold.

Attachment 1: should the "including, but not limited to" in table 2 include the same list (or minimally the same wording) that is found in the technical rationale of the IBR definition in project 2020-0?. For example, the IBR list in 2020-06 refers to "solar photovoltaic" whereas table 2 refers to "photovoltaic (PV)".

In what standard does the PC/TP define the applicable table in point 3 of section 2 in attachment 1? Same question for the voltage base for per unit calculation in both Attachment 1 and 2. Is there a corresponding requirement in another standard that requires the PC/TP to do this?

· Terms : Mandatory and permissive operation should be defined based on the attachment figures allowing for interconnections to use different requirements

· A-4.2.2 What is the IBR registration criteria? Add a clear reference and make sur the user understands what the IBR registration criteria is.

· B-R2-2.1 Attachment 1 only uses "no-trip zone". Define continuous operating region more clearly in the table (similar to what is done in PRC-024-4)

· B-R2-2.1.2 Can the TP ask for a mix of active/reactive power based on a predetermined ratio (currently only indicated as active or reactive).

· B-R2-2.2 Attachment 1 only uses "no-trip zone". Define "mandatory operation region" in Attachment 1.

· B-R2-2.4 Permissive operation region is not used or defined in attachment 1.

· B-R3. The document refers to an overvoltage value of 1.2pu. It should refer to a voltage exceeding the mandatory operating region in order for Interconnections to set their own overvoltage table.

· B-R3. Since R6 does not apply to this requirement, what will be done with existing IBR that cannot ride through these overvoltages ? An exemption clause is required for existing IBR that cannot be modified or upgraded.

· B-R4. The 5Hz/s value should be moved to Attachment 3 and B-R4 should only refer to the value in the Attachment.

· B-R4. Since R6 does not apply to this requirement, what will be done with existing IBR that cannot ride through these frequencies and ROCOF ? (for instance, for all the HQ connected projects, the ROCOF requirement was 4Hz/s) An exemption clause is required for existing IBR that cannot be modified or upgraded.

· B-R5. Since R6 does not apply to this requirement, what will be done with existing IBR that cannot ride through this phase angle jump ? An exemption clause is required for existing IBR that cannot be modified or upgraded.

· Attachment 1. Tables 1 and 2: Indicate what is considered as “continuous operation”, “mandatory operation” and “permissive operation” in an additional column.

· Attachment 1. HQ needs a Quebec regional variance since the Québec Interconnection has its own requirements in this regard.

· Attachment 2. Bullet 3: This sentence is hard to read. Proposed replacement: "Each IBR shall not trip unless the cumulative time of one or more instances in which the instantaneous voltage exceeds the respective voltage threshold over a 1-minute time window exceeds the minimum ride-through time"

· Attachment 2. HQ needs a Quebec regional variance since the Québec Interconnection has its own requirements in this regard.

· Attachment 3. This attachment should also include the maximum absolute ROCOF value.

· Attachment 3. HQ needs a Quebec regional variance (or the equivalent through the “regie de l’energie” approval process).

· B-R2-2.1.2 Which entity between Transmission Planner, Planning Coordinator, Reliability Coordinator and Transmission Operator has priority to specify those requirements?

· B-R2-2.4 Which entity between Transmission Planner, Planning Coordinator, Reliability Coordinator and Transmission Operator has priority to specify those requirements?

Overall comments:

1. Implementation date: 6 months is not sufficient for IBR manufacturers to meet the new standard. Instead we propose 2yrs to accommodate product development/adequacy and appropriate validation.

2. For R6, R3,R4,R5 should be included as well for the documented limitation communication (see R6 comments below).

3. For Attachment 1, for VSC-HVDC connected IBRs, it is not clear if Table 2 is applicable at the MPT on grid side or on the IBR side of HVDC (see Attachment 1 comments below)

4. For MFRT, GEV suggests to align to IEEE2800-2022 7.2.2.4 for consistency (see Attachment 1 comments below).

GEV comments to R6: The language in R6 only allows documented limitations for Requirements R1 and R2. The standard must allow for documentation of limitations for Requirements R3, R4, and R5, as some existing site equipment was not designed to these requirements originally.

GEV comments to Table 2 in Attachment 1: For VSC-HVDC connected IBRs, please clarify if Table 2 is applicable at the MPT on grid side or on the IBR side.

GEV comments to MFRT: For MFRT requirements, GE Vernova strongly suggests that this language should align to IEEE2800-2022 7.2.2.4. Exceptions from the IEEE standard that are relevant were not included, making these requirements inconsistent with 2800-2022.

EEI offers the following additional comments on both PRC-024 & PRC-029:

PRC-029-1 (Applicability Section) Comments: EEI does not support the Applicability Section of PRC-029-1 for the following reasons:

1. Applicability details should not be contained in footnotes. Please remove footnote 1 from the Applicability Section.
2. Voltage Source Converter – High-voltage Direct Current (VSC-HVDC) are not defined or justified within the Technical Rationale as to why these resources need to be added PRC-029.
3. Without a justification of a need to include VSC-HVDC systems, TOs should be removed from PRC-029-1.
4. EEI does not support the use of the term "BPS IBRs" because no such term exists in the NERC Glossary of Terms that might provide entities with the knowledge to know definitively which IBRs are applicable.
5. EEI also does not support language that points to the registration criteria.

To address our concerns, we suggest the following changes to the Applicability Section of PRC-029-1, noting the Facilities portion of our comments utilize the recommendations from the Project 2020-06 SDT (see removals (i.e., TOs, registration criteria, etc. and other text) and boldface changes below:

4. Applicability:

4.1 Functional Entities:

4.1.1 Generator Owner

Facilities:

(1) BES Inverter-Based Resources; and (2) Non-BES Inverter Based Resources (IBRs) that that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

PRC-024 Comments: While there were no questions related to the proposed modifications to PRC-024-4, EEI does not support all of the proposed changes made to PRC-024-4. Note the following:

Applicability Section of PRC-024-4

EEI does not support changing the intent of 4.2.1.4 (Previously 4.2.1.5) to include multiple synchronous generators connecting to a common bus under the BES Definition, Inclusion I4. Since the development of the BES definition, Inclusion I4 did not include or intend to include synchronous generators. Had that been the intent, the SDT could have included synchronous generator resources in I4. Furthermore, the BES Reference Document states in Chapter I4: BES Inclusion the following:

Dispersed power producing resources are small-scale power generation technologies that use a system designed primarily for aggregating capacity providing an alternative to, or an enhancement of, the traditional electric power system. Examples could include, but are not limited to: solar, geothermal, energy storage, flywheels, wind, microturbines, and fuel cells.

While EEI is open to making modifications to the BES Definition, trying to provide interpretations within individual Applicability Sections of proposed NERC Reliability Guidelines is not the proper method to make such a change. For this reason, and since 4.2.1.4 (previously 4.2.1.5) was intended to address IBRs; this part of the Applicability Section of PRC-024-4 should be deleted.

Comments on the proposed New Definitions

EEI has no concerns with the proposed new definitions, but we do have some non-substantive comments on their usage throughout PRC-029, Implementation Plan and Technical Rationale. (See below)

- Usage of the newly defined terms deviated from the defined term within PRC-029 and the Technical Rational. (i.e., Operating vs. Operations)
- Incorrectly stating in the Implementation Plan that there were no newly defined terms. Please correct this error.

Continuous Operating Region – Only used once in Requirement 2.3.

- Continuous Operation Region used in Requirements 2.1, 2.1.2, 2.4, & once in Attachment 1 (i.e., suggest changing the defined term to Continuous **Operation** Region or correct to Continuous **Operating** Region throughout)
- Continuous Operation Region used twice in the Technical Rationale; Continuous Operating Region never used in the Technical Rationale.

Mandatory Operating Region – Never used in PRC-029

- Mandatory Operation Region used in PRC-029 in Requirements 2.2, 2.3, 2.4 & once in Attachment 1 (i.e., suggest changing the defined term to Mandatory **Operation** Region or correct to Mandatory **Operating** Region throughout)
- Mandatory Operation Region was used twice in Technical Rationale; Mandatory Operating Region was never used in the Technical Rational.

Permissive Operating Region – Never used in PRC-029

- Permissive Operation Region used in PRC-029 in Requirements 2.3, 2.4, & used twice in Attachment 1 (i.e., suggest changing the defined term to Permissive **Operation** Region or correct to Permissive **Operating** Region throughout)

- Permissive Operation Region used once in the Technical Rationale; Permissive Operating Region never used in the Technical Rationale.

1. Implementation should align with PRC-028-1 proposed implementation to ensure data collecting information is available to adhere to PRC-029-1.

2. PRC-024-4 Applicability and Purpose should include asynchronous type 1 and type 2 wind since these are not IBRs and therefore not applicable to PRC-029:

4.2.1.4 Elements that are designed primarily for the delivery of capacity from the multiple synchronous generators ***or asynchronous type 1 or type 2 wind generators,*** connecting to a common bus identified in the BES Definition, Inclusion I4, to the point where those resources aggregate to greater than 75 MVA.

4.2.1.6 Type I and type II asynchronous wind generation identified in the BES Definition, Inclusion I4.

3. Suggest that the drafting team ensure consistent language is used in the section 4.2 “Facilities” section with the other projects such as Project 2021-04 (PRC-028) and 2023-02(PRC-030). We suggested the following language be included in the applicability section. Facilities: The Elements associated with (1) BES Inverter-Based Resources; and (2) Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

Comment
The NAGF provides the following additional comments for consideration: *PRC-024:* *a. Section 4.2.1.2 – Consider adding the language "Main Power Transformer (MPT)".* *b. Section 4.2.1.4 and 4.2.1.5 - Recommend that the proposed language be modified to reference BES Definition – Inclusion I2 instead of Inclusion I4 – Dispersed Power Producing Resources. The proposed new PRC-029 standard's focus is on Frequency and Voltage Ride-through Requirements for Inverter-Based Generating Resources and therefore should include a reference BES I4 resources.* *PRC-029:* *a. Terms – the NAGF requests additional clarification on how the proposed defined terms work with the proposed PRC-030. Will analysis be required for an event under the proposed PRC-029 and under PRC-030? Potential double jeopardy issue. Alternatively, if tripping is allowed under PRC-029, would an analysis still be required under PR-030?* *b. Section 4.2 - Facilities:* *i. Use of the capitalized term "Bulk Power System (BPS) Inverter-Based Resources (IBR)" should be reviewed as it is not a defined term in the NERC Glossary of Terms. In addition, it is very likely that not all Bulk Power System Inverter-Based Resources will be registered even under NERC's modified Rules of Procedure. Until the definition of Inverter-Based Resources is approved, the SDT should only use the term "inverter-based resource" if needed.* *ii. The NAGF requests clarification if IBR plants that include synchronous condensers should meet the PRC-029 requirements.* *c. Comments Related to Attachments:* *i. Attachment 1 – Recommend adding to the table a column that species what area is the Continuous Operating Region, Mandatory Operating Region and Permissive Operating Region. As currently structured, it is not clear where the different regions begin or end. If possible, the NAGF recommends a graph showing the different areas for clarity.* *ii. The abbreviations "MPT" and "ESS" are not defined within the standard/attachment. Please ensure all acronyms/initializations are fully defined for use.* *iii. If the term ESS is intended to mean Energy Storage Systems, does this also apply to water storage systems, or only Battery Energy Storage Systems? If the intent is to refer to Battery Energy Storage Systems, please modify the term used.* *iv. Attachment 1, note 3 – There does not appear to be a requirement proposed for the Transmission Planner (TP) to provide direction as stated in note 3. Request clarification on how the TP will provide such guidance/direction on the applicable table to be used.* *v. Attachment 1, Note 7 – These notes appear to state that no unit should trip in a 10 second period if voltage is fluctuating, but the summation of time interval does not appear to be 10 seconds in most instances. As an example, assuming that the SDT intends for a generator to follow the voltage for 10 seconds when it is fluctuating between .7 and .5, the unit should be allowed to trip when voltage is below the .5 level*

for 1.2 seconds. However, note 7 appears to state that there is a 10 second limit if voltage were to be below .7 for 1 second, then goes below .5 for 3 seconds, then returns to the .7 for 6 seconds. Please verify this interpretation is correct, or how this language should be understood.

vi. Attachment 1, Notes 7 and 8 – Both of these items discuss cumulative numbers in Tables 1 and 2. As worded, it is unclear if the intent is to add the numbers in Table 1 to the numbers in Table 2, or if the intent is to add the numbers in the second column of Table 1 for those resources that are considered Table 1 entities, and similar for Table 2 entities. Please clarify the wording so the intent of the standard is clear.

Comment

AZPS supports the following comments that were submitted by EEI on behalf of its members:

PRC-029-1 (Applicability Section) Comments: EEI does not support the Applicability Section of PRC-029-1 for the following reasons:

1. Applicability details should not be contained in footnotes. Please remove footnote 1 from the Applicability Section.

2. Voltage Source Converter – High-voltage Direct Current (VSC-HVDC) are not defined or justified within the Technical Rationale as to why these resources need to be added PRC-029.

3. Without a justification of a need to include VSC-HVDC systems, TOs should be removed from PRC-029-1.

4. EEI does not support the use of the term "BPS IBRs" because no such term exists in the NERC Glossary of Terms that might provide entities with the knowledge to know definitively which IBRs are applicable.

5. EEI also does not support language that points to the registration criteria.

To address our concerns, we suggest the following language in the Applicability Section of PRC-029-1, noting the Facilities portion of our comments utilize the recommendations from the Project 2020-06 SDT):

4. Applicability:

4.1 Functional Entities:

4.1.1 Generator Owner

4.2 Facilities: (1) BES Inverter-Based Resources; and (2) Non-BES Inverter Based Resources (IBRs) that that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

PRC-024 Comments: While there were no questions related to the proposed modifications to PRC-024-4, EEI does not support all of the proposed changes made to PRC-024-4. Note the following:

Applicability Section of PRC-024-4

EEI does not support changing the intent of 4.2.1.4 (Previously 4.2.1.5) to include multiple synchronous generators connecting to a common bus under the BES Definition, Inclusion I4. Since the development of the BES definition, Inclusion I4 did not include or intend to include synchronous generators. Had that been the intent, the SDT could have included synchronous generator resources in I4. Furthermore, the BES Reference Document states in Chapter I4: BES Inclusion the following:

Dispersed power producing resources are small-scale power generation technologies that use a system designed primarily for aggregating capacity providing an alternative to, or an enhancement of, the traditional electric power system. Examples could include, but are not limited to: solar, geothermal, energy storage, flywheels, wind, microturbines, and fuel cells.

While EEI is open to making modifications to the BES Definition, trying to provide interpretations within individual Applicability Sections of proposed NERC Reliability Guidelines is not the proper method to make such a change. For this reason, and since 4.2.1.4 (previously 4.2.1.5) was intended to address IBRs; this part of the Applicability Section of PRC-024-4 should be deleted.

Comments on the proposed New Definitions

EEI has no concerns with the proposed new definitions, but we do have some non-substantive comments on their usage throughout PRC-029, Implementation Plan and Technical Rationale. (See below)

- Usage of the newly defined terms deviated from the defined term within PRC-029 and the Technical Rational. (i.e., Operating vs. Operations)

- Incorrectly stating in the Implementation Plan that there were no newly defined terms. Please correct this error.

Continuous Operating Region – Only used once in Requirement 2.3.

- Continuous Operation Region used in Requirements 2.1, 2.1.2, 2.4, & once in Attachment 1 (i.e., suggest changing the defined term to Continuous Operation Region or correct to Continuous Operating Region throughout)
- Continuous Operation Region used twice in the Technical Rationale; Continuous Operating Region never used in the Technical Rationale.

Mandatory Operating Region – Never used in PRC-029

- Mandatory Operation Region used in PRC-029 in Requirements 2.2, 2.3, 2.4 & once in Attachment 1 (i.e., suggest changing the defined term to Mandatory Operation Region or correct to Mandatory Operating Region throughout)
- Mandatory Operation Region was used twice in Technical Rationale; Mandatory Operating Region was never used in the Technical Rational.

Permissive Operating Region – Never used in PRC-029

- Permissive Operation Region used in PRC-029 in Requirements 2.3, 2.4, & used twice in Attachment 1 (i.e., suggest changing the defined term to Permissive Operation Region or correct to Permissive Operating Region throughout)
- Permissive Operation Region used once in the Technical Rationale; Permissive Operating Region never used in the Technical Rationale.

If using ALL CAPS, consider RCF as the acronym. It is not that significant a metric to require capitalization of "of".

RoCoF is also used in many other jurisdictions.

FERC order:

"In other words, under certain conditions some IBRs cease to provide power to the Bulk-Power System due to how they are configured and programmed. " Yes, but PRC-024 now prohibits this. In some cases, settings in the older plants can be tweaked to improve performance but we are having trouble getting good models from the GOs. To address NERC concerns we need requirements for better models.

"some models and simulations incorrectly predict that some IBRs will ride through disturbances, i.e., maintain real power output at pre-disturbance levels and provide voltage and frequency support consistent with Reliability Standard PRC-024-3". Only if incorrectly modelled. Require better modelling to identify issues and determine mitigations. PRC-029 will not stop the problem of simulating a system that works great in the virtual world but will not perform when called upon.

Comment

Texas RE has the following additional comments for PRC-029-1:

1. Texas RE recommends the new terms included in PRC-029-1 clearly state the voltage measurements included are at the high-side of the main transformer connecting to the BPS transmission system. Texas RE suggests the following changes (in bold):

Term(s): Continuous Operating Region – The range of voltages, measured at the high-side of the **BPS** main power transformer, that are ≥ 0.9 per unit and ≤ 1.1 per unit.

Mandatory Operating Region – The range of voltages, measured at the high-side of the **BPS** main power transformer, that are > 0.1 per unit and < 0.9 per unit – or – > 1.1 and ≤ 1.2 per unit.

Permissive Operating Region – The range of voltages, measured at the high-side of the **BPS** main power transformer, that is ≤ 0.1 per unit.

2. Consider changing ‘each IBR’ to ‘each IBR Facility’ for all the requirements.

3. For consistency, consider modifying the title of the standard to (in bold):

Title: Frequency and Voltage Ride-through Requirements for Inverter-Based **Generating** Resources

4. Consider changing 4.2.1 to **BES** IBRs (instead of BPS IBRs) to be consistent with other PRC standards such as proposed reliability standards PRC-028-1 and PRC-024-4.

5. Consider changing voltage (per unit) in Attachment 1 (third row) to greater than 1.05 pu only (i.e. remove the equal 1.05 criterion). Typical BES and BPS systems are expected to operate continuously for voltage levels 0.95 – 1.05 pu.

Attachment 1 - changes

In Table 1 & Table 2 change > 1.05 to >1.05

Add the following to Table 1 and 2:

Voltage (per unit): > 0.9 Minimum Ride-Through: Continuous

Voltage (per unit): < 1.05 Minimum Ride-Through: Continuous

NERC should remain consistent with their revised Rules of Procedure by avoiding the use of “BPS IBR” terminology in the applicable facilities. This is overly broad and can lead to misinterpretation for Generator Owners who own IBRs that do and do not fit the 60 kV and 20 MVA thresholds. The third question in the Project 2020-06 comment form, copied below, is a clearer definition of IBR which NERC has determined has a material impact to the BPS. NERC should consider adopting this terminology in PRC-029

Section 4. Applicability:

4.1 Functional Entities: Generator Owner, Generator Operator

4.2 Facilities: (1) BES Inverter-Based Resources; and (2) Non-BES Inverter Based Resources (IBRs) that that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

Dominion Energy supports EEI comments. In addition, we have the following coments:

The term BPS IBRs and IBR Registration Criteria are not clear-cut Facilities. The standard should reference terms available for use in the NERC Glossary of Terms to determine applicability, such as the BES defintion. As stated in the EEI comments, the BES defintion would be the appropriate place to address defintions of this type.

The Effective Date of 6 months following approval by FERC is too short for Generator Owners and Transmission Owners that own numerous IBR generating sites, to develop internal controls and processes; and perform the necessary compliance evaluations and possible settings changes to meet the ride-through criteria. Conversely, 6 months after the effective date is too long for documenting Limitations per Requirement R6.

The documentation of limitations is typically done during the compliance analysis and study. A staggered implementation plan, that takes into account the registration and requirements for Level 2 GO registrations should be designed and implemented.

The Implementation Plan should also consider those IBRs that are approved to be built and have had their Interconnection Studies approved. The contracts for building these sites are signed years in advance with the inverters ordered. A staggered applicability for R6 should be considered that allow for projects in service prior to 2027 or 2028 to be eligible for equipment limitations and those in service after to meet the performance criteria without limitations.

The SDT explains in the draft PRC-029-1 Technical Rationale that "An IBR becomes noncompliant with PRC-029 only when an event in the field occurs that shows that one or more requirements were not satisfied." This, coupled with the removal of IBRs from PRC-024 applicability, would result in a lack of accountability until actual harm (i.e., failure to adequately support the reliability of the BES during a system event) occurs for IBRs not prepared to meet the performance requirements. There would not be auditable and enforceable requirements for owners of IBRs to proactively take action to reasonably ensure the performance requirements will be met. Reliability standards exist to prevent potential harm, which minimizes actual harm.

While RF acknowledges the observed limitations of the existing PRC-024 standard in preventing the undesirable responses of IBRs to the system disturbance events cited in the SAR, RF does not support the whole-sale elimination of frequency and voltage protection settings verification requirements for IBRs. Generator frequency protection settings verification is critical in ensuring UFLS programs are adequately coordinated with generator capabilities, and RF does not wish to rely on self-revealing events to determine where miscoordination exists between IBR frequency protection and UFLS. Unless additional verification requirements are added to PRC-029, RF believes PRC-024 should remain applicable to IBRs.

RF notes that the range of system conditions in which PRC-029 would require IBRs to remain online appear to be significantly larger than those established in PRC-024 (which would remain applicable to synchronous generators). Although the unique capabilities of IBRs may support such a large expansion for only IBR resource types, additional discussion of the technical justification for this expansion would be useful.

Regarding implementation, RF finds a 12-month implementation period acceptable.

- The new performance-based approach opens us up to a lot of issues with other tripping/cessation besides basic overvoltage/under voltage/frequency that our operations team has seen during events.
    - This protection is not modeled in basic models right now and will require substantial effort to ensure we can perform as required. AES CE requests that the Implementation Plan be modified to use a phased-in approach for existing sites to allow adequate time to prepare for these performance requirements.

Additionally, the standard and rationale is absent of language on studies/assessments that should be performed. AESCE believes that providing examples of the types of studies and assessments that should be run to ensure that resources would perform as expected is necessary for reliability and adequate implementation of this standard by GOs.

- Please provide additional clarification on acceptable limitations under R6. Language such as “hardware replacements or other costly upgrades” from the Technical rationale document is vague and open to interpretation.
- AESCE would like the SDT to consider the challenges with ensuring plants, particularly legacy operational plants, can ride through per the requirements. To ensure this or identify equipment limitations, studies and equipment information is necessary and is not available for most legacy equipment.
- First, EMT studies and RMS model studies are necessary to study plant ride-through capabilities specified in the standard. However, there are significant challenges with these models today that should be considered in the implementation and equipment limitations. Quality EMT models including all equipment information needed are not available for legacy equipment (inverters, PPCs). Many legacy inverters do not have an EMT model, and those that do have models that are not adequately validated against equipment performance. Creation of models is either not supported or can be developed at a very high cost. Models created after the inverters were initially released are of inadequate quality because the equipment is no longer able to be in a lab environment.
    - To consider this, AESCE suggests that the SDT include exceptions for legacy equipment where the performance may not be predictable due to a lack of modeling or inverter information.
- Second, not all current models are of the level of quality that they can be used to ensure that the plant will ride-through as specified in the standard. The implementation of this standard should consider the significant resources and cost to implement.
- Third, manufacturer support for GOs to ensure that IBRs only trip to prevent equipment damage as noted in R2.5 is limited for existing equipment and is unavailable for some legacy equipment. Additionally, this support has been very costly for us to obtain and will strain manufacturer resources to provide.

Considering these limitations, AESCE suggests that the SDT include exceptions for legacy equipment where 1. The performance may not be predictable due to a lack of accurate models at a reasonable cost, 2. Equipment limits may not be known or where the cost may be egregious to provide.

- Expectations for demonstrating and checking performance are unclear, please add language or examples to illustrate how the SDT believes this will happen.

Comment

Invenergy thanks the drafting team for their work and the opportunity to provide comments.

Regarding the proposed Implementation Plan for R6, six months may not be enough time to gather all applicable documentation regarding equipment limitations. There are a limited number of vendors of IBR technology that have serviced the industry, and they will be inundated with requests for documentation once the standard becomes effective.

On a final note, NERC appears to have borrowed from some of the requirements within IEEE 2800-2022 and brought them into this standard (e.g. the phase-angle jump requirement, etc.). Invenergy believes it would be incorrect to adopt such requirements until the work of IEEE Working Group p2800.2 has been completed and their recommended practice standard published. Without such an approved recommended practice standard, there is no industry-wide accepted set of procedures for verifying conformity to the borrowed requirements in PRC-029-1.

Comment

Ameren agrees with EEI's comments.

In addition, Ameren believes that ride-through requirements should be in a MOD standard instead of a PRC standard. Protection relay engineers do not have access to the necessary IBR equipment and do not have the expertise to determine the root cause of why an IBR behaved in an unexpected manner. Thus, evaluating and establishing a CAP to correct a reduction in power following a disturbance will not be performed by a relay engineer.

With regards to PRC-029 we woulkd ask:

1. Clarify and emphasize that limitations must not be construed as complete exemptions. If entities are unable to ride-through portions of the ride-through curve, this does not automatically exempt them from complying with the balance of the ride-through curve as described in the Technical Rationale. While this is clear in the Technical Rationale for Requirement R6 (page 9), this point needs to be brought out more clearly in the PRC-029 standard itself.

2. Expand PRC-029 to require Corrective Action Plans be implemented to remove equipment limitations within a specified timeline.

3. we recommend modifying Section 4 of PRC-029-1 as follows:

4. Applicability:

4.1 Functional Entities: 4.1.1 Generator Owner that owns equipment identified in section 4.2, 4.1.2 Transmission Owner that owns equipment as identified in section 4.2 Generator Owner that owns equipment identified in section 4.2.

4.2 Facilities: to include 4.2.3 Shunt static or dynamic reactive device(s) associated with IBR that either have or contribute to meeting the performance requirements.

4. The standard is event-based compliance that requires installing recorded equipment data with higher sampling rates at all applicable legacy IBR Facilities. Therefore, we suggest that the implementation plan for PRC-029 should be aligned with Project 2021-04 (PRC-028-1) for the legacy IBR. Also, we suggest having a different implementation plan for the legacy IBR from IBR connected after the approval date of PRC-029.

5. Some clarity on how these requirements would be enforced in the location where no data recording is available at the IBR facility during system events.

6. M1-M5 required GO to maintain the evidence of actual recorded data or other evidence for each applicable IBR demonstrating adherence to ride-through requirements, as specified in Requirement R1-R5. What are the criteria for selecting the event(s) that should be analyzed to demonstrate compliance with the VRT, FRT, and VRT performance requirement(s)? If the performance does not meet the requirement(s), do Generator Owner needs to present a correction action plan and provide it to each applicable Reliability Coordinator. We suggest coordinate this project 2020-02 (PRC-029) with project 2023-02(PRC-030) regarding the IBR ride-through performance analysis.

7. We suggest that the drafting team ensure consistent language is used in the section 4.2 “Facilities” section with the other projects such as Project 2021-04 (PRC-028) and 2023-02(PRC-030). We suggested the following language be included in the applicability section. Facilities: The Elements associated with (1) BES Inverter-Based Resources; and (2) Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

8. The title of the standard calls out “Inverter-Based Generating Resources”, should “Generating” be removed to be consistent?

Comment

New terms are introduced on page 2 (Continuous **Operating** Region, Mandatory **Operating** Region, Permissive **Operating** Region). Requirement R1 includes the words "**operation** regions" and R2 includes the terms "Continuous **Operation** Region" (Part 2.1) and "Mandatory **Operation** Region" (Part 2.2). We recommend the drafting team review all instances of "**operation** region" within the standard and determine if it should be changed to "**operating** region" to align with the proposed terms. Or conversely, consider if the word "Operating" within the defined terms should be changed to "Operation".

For Requirement R2:

How will the Generator Owner or Transmission Owner of an applicable IBR be made aware that a PRC-029-1 applicable "System disturbance" has occurred within their associated Planning Coordinator(s) area(s)?

Part 2.1.2 refers to "requirements [for active or reactive power preference] specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator".

Part 2.2.2 refers to a "certain magnitude of reactive power response to voltage changes" or a preference for "active power priority instead of reactive power priority" that can be specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

Part 2.4 refers to a "lower post-disturbance active power level requirement" or "different post-disturbance active power restoration time" specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

With up to four registered entity types being able to provide these preferences (spanning the operations and planning time horizons), is there a chance the Generator Owner or Transmission Owner of an applicable IBR will receive conflicting requirements? Is there a corresponding standard(s) that includes a requirement(s) for the TP, PC, RC or TOP to specify these preferences?

For Requirement R3, how will the Generator Owner or Transmission Owner of an applicable IBR know that a PRC-029-1 applicable transient overvoltage period has occurred within their associated Planning Coordinator(s) area(s)?

For Requirement R4, how will the Generator Owner or Transmission Owner of an applicable IBR know that a PRC-029-1 applicable frequency excursion event has occurred within their associated Planning Coordinator(s) area(s)?

Requirement R6 requires that a Generator Owner or Transmission Owner of an applicable IBR that has a documented equipment limitation, that prevents it from meeting voltage ride-through requirements as detailed in Requirements R1 and R2, communicate each equipment limitation to their associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s). Since the Transmission Operator is also identified in R2, it seems strange to omit the TOP from R6.

With regard to the Implementation Plan, having PRC-024-4 becoming effective six months after approval is reasonable, since this Standard's changes are primarily to limit its applicability to synchronous generators / condensers, and they should already be compliant with the existing version.

However, having PRC-029-1 become effective six months after approval is not reasonable. The technical rationale doesn't provide guidance on how to provide evidence of compliance. It can take considerable time to develop and perform the required analyses, generate potential design changes to make the required setting changes, and implement them.

We recommend providing implementation guidance or technical data showing how to demonstrate performance.

We also recommend allowing at least 24 months to achieve full compliance with the proposed requirements in PRC-029-1.

The language proposed in the Applicability section of PRC-029-1 is inadequate to define what IBR Facilities this Standard would apply to. The terms “BPS IBRs” and “IBR Registration Criteria” are too broad, vague, and undefined, and could include all IBRs interconnected to the Bulk Power System at any voltage level.

SMUD recommends the Standards Drafting Team use similar language to that proposed in NERC Standards Project 2021-04 Modifications to PRC-002 - Phase II, PRC-028-1 draft #2. If modified accordingly, the Applicability section would state:

“4.1. Functional Entities:

4.1.1. Generator Owner that owns equipment as identified in section 4.2

4.1.2. Transmission Owner that owns equipment as identified in section 4.2

4.2. Facilities: The Elements associated with (1) BES Inverter-Based Resources; and (2) Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.”

Comment

BC Hydro appreciates the drafting team’s efforts and the opportunity to comment, and offers the following:

1. The Applicability section (A.4.2 Facilities) of PRC-029-1 references BPS IBR and IBR Registration Criteria. BC Hydro suggests that the Facilities section instead use wording reflective of the proposed Category 2 GO as included in the recent revisions to the NERC Rules of Procedure.
2. BC Hydro suggests that the use of “shall” in the language of the Measures may not be appropriate as it could imply a new Requirement or expansion on the existing Requirement. The obligation of having evidence is adequately established and enforceable via the CMEP.
3. The Measure M3 of PRC-029-1 references "the associated Planning Coordinator". The associated Requirement R3 does not. BC Hydro suggests that this is not needed as there may be switching events within a PC's area that do not create overvoltage conditions to trigger R3 for certain IBRs within the PC area.

Applicability:

In Introduction, Section 4.2.2, it is not obvious what aspect of 'IBR Registration Criteria' makes an IBR an 'applicable' IBR – is it simply that an IBR meets NERC Registration Criteria? This bullet point should be elaborated to ensure clarity.

Event-Based Standard:

The IESO has concerns with this standard being an event-based standard, in that it does not necessarily provide an assurance of reliability before events occur, such as would be provided by having an engineering analysis, or bench-testing/real-time simulations of controls equipment that indicates successful ride through of prescribed disturbances is expected.

Without disturbance events that challenge the IBRs to perform properly it would be unknown if the IBR is compliant. At a minimum, the measures (e.g, M2-M5) should be extended to allow a statement that no such events are known to have occurred to 'count' as evidence of compliance.

Presentation of Ride Through Ranges:

The intended ride through requirements could be made more clear if the 'minimum ride through times' were associated with precisely stated, *non-overlapping ranges* of voltages or frequencies, such as in the example 'Table 2' provided by the IESO in the comments above, for Section 2.1.

Nominal Voltages:

To ensure clarity of intent in note #4 of Attachment 1, the 'nominal' system voltage values should be listed as they are in the existing PRC-024, i.e., "(e.g., 100 kV, 115 kV, 138 kV, 161 kV, 230 kV, 345 kV, 400 kV, 500 kV, 765 kV, etc.)"

Harmonize Tables, Figures, Requirements:

The levels of voltage/frequency excursion and the minimum ride through times for all tables, figures, and any associated performance requirements that modify the requirements at given times should be carefully reviewed and harmonized. There are presently some conflicting entries in the tables/figures.

We are concerned that the standard refers to a defined term for IBR which has yet to be adopted in project 2020-06.

We suggest that the drafting team ensure consistent language is used in the section 4.2 "Facilities" section with the other projects such as 2021-04 (PRC-028) and 2023-02(PRC-030). Section 4.2.2 refers to IBR Registration criteria, however it is our understanding that section 4.2.1

would refer to GOs and TOs “that own equipment as identified in section 4.2” and where section 4.2 would indicate “the Elements associated with (1) BES Inverter-Based Resources; and (2) Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.” .

We question why “attachment 1” and “Requirement R6” are written in bold.

Attachment 1: should the “including, but not limited to” in table 2 include the same list (or minimally the same wording) that is found in the technical rationale of the IBR definition in project 2020-0?. For example, the IBR list in 2020-06 refers to “solar photovoltaic” whereas table 2 refers to “photovoltaic (PV)”.

In what standard does the PC/TP define the applicable table in point 3 of section 2 in attachment 1? Same question for the voltage base for per unit calculation in both Attachment 1 and 2. Is there a corresponding requirement in another standard that requires the PC/TP to do this?

· Terms : Mandatory and permissive operation should be defined based on the attachment figures allowing for interconnections to use different requirements

· A-4.2.2 What is the IBR registration criteria? Add a clear reference and make sur the user understands what the IBR registration criteria is.

· B-R2-2.1 Attachment 1 only uses "no-trip zone". Define continuous operating region more clearly in the table (similar to what is done in PRC-024-4)

· B-R2-2.1.2 Can the TP ask for a mix of active/reactive power based on a predetermined ratio (currently only indicated as active or reactive).

· B-R2-2.2 Attachment 1 only uses "no-trip zone". Define "mandatory operation region" in Attachment 1.

· B-R2-2.4 Permissive operation region is not used or defined in attachment 1.

· B-R3. The document refers to an overvoltage value of 1.2pu. It should refer to a voltage exceeding the mandatory operating region in order for Interconnections to set their own overvoltage table.

· B-R3. Since R6 does not apply to this requirement, what will be done with existing IBR that cannot ride through these overvoltages ? An exemption clause is required for existing IBR that cannot be modified or upgraded.

· B-R4. The 5Hz/s value should be moved to Attachment 3 and B-R4 should only refer to the value in the Attachment.

· B-R4. Since R6 does not apply to this requirement, what will be done with existing IBR that cannot ride through these frequencies and ROCOF ? (for instance, for all the HQ connected projects, the ROCOF requirement was 4Hz/s) An exemption clause is required for existing IBR that cannot be modified or upgraded.

· B-R5. Since R6 does not apply to this requirement, what will be done with existing IBR that cannot ride through this phase angle jump ? An exemption clause is required for existing IBR that cannot be modified or upgraded.

· Attachment 1. Tables 1 and 2: Indicate what is considered as “continuous operation”, “mandatory operation” and “permissive operation” in an additional column.

· Attachment 1. HQ needs a Quebec regional variance since the Québec Interconnection has its own requirements in this regard.

· Attachment 2. Bullet 3: This sentence is hard to read. Proposed replacement: "Each IBR shall not trip unless the cumulative time of one or more instances in which the instantaneous voltage exceeds the respective voltage threshold over a 1-minute time window exceeds the minimum ride-through time"

· Attachment 2. HQ needs a Quebec regional variance since the Québec Interconnection has its own requirements in this regard.

· Attachment 3. This attachment should also include the maximum absolute ROCOF value.

· Attachment 3. HQ needs a Quebec regional variance

· B-R2-2.1.2 Which entity between Transmission Planner, Planning Coordinator, Reliability Coordinator and Transmission Operator has priority to specify those requirements?

· B-R2-2.4 Which entity between Transmission Planner, Planning Coordinator, Reliability Coordinator and Transmission Operator has priority to specify those requirements?

- Evidence Retention: We would suggest that the evidence retention period for both Standards should be changed from five years to three years, to be consistent with other NERC Standards.

- The standard is event-based compliance that required installing recorded equipment data with higher sampling rates at all applicable legacy IBR Facilities. Therefore, we recommend that the implementation plan for PRC-029 should be aligned with Project 2021-04 (PRC-028-1) for the legacy IBR. Also, we suggest have different implementation plan for the legacy IBR from IBR connected after the approval date of PRC-029.

- Some clarity how these requirements would be enforced in a location where no data recording is available at an IBR facility during system events.

- M1-M5 required the GO to maintain the evidence of actual recorded data or other evidence for each applicable IBR demonstrating adherence to ride-through requirements, as specified in Requirement R1-R5. What are the criteria for selecting the event(s) that should be analyzed to demonstrate compliance with the VRT, FRT and VRT performance requirement(s)? If the performance does not meet the requirement(s), do Generator Owner need to present a corrective action plan and provide it to each applicable Reliability Coordinator. We suggest coordinating this project 2020-02 (PRC-029) with project 2023-02(PRC-030) regarding the IBR ride-through performance analysis.

- R2: We agree with the present flexibility that some of the IBR VRT performance could be modified to meet the individual system needs by the applicable Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator. However, some clarity may be required on how this process is initiated and what type of evidence is required to demonstrate the request is received and implemented. This may be an additional requirement assigned to the Transmission Planner. Each Transmission Planner, Planning Coordinator, and Transmission Operator that jointly specifies the following voltage ride-through performance requirements within their area(s) different than those specified under R2, shall make those requirements available to each associated applicable IBR Generator Owner and Transmission Owner.

- We suggest that the drafting team ensures consistent language is used in the section 4.2 "Facilities" section with the other projects such as Project 2021-04 (PRC-028) and 2023-02(PRC-030). We suggest the following language be included in the applicability section. Facilities: The Elements associated with (1) BES Inverter-Based Resources; and (2) Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

- R3: we suggest adding to the attachment 2 how the instantaneous transient overvoltage should be calculated (such as what is the pu based on? and the minimum sampling rate?)

1. The proposed Standard refers to four different operating regions (no-trip zone, Continuous Operation Region, Mandatory Operation Region, and Permissive Operating Region). The different zones require Generator Owners to take different actions based on the number of disturbances and deviations that occur within in a 10 second period as well as the positive sequence voltage on the high side of the MPT. The ability of plant operators or inverter controls to identify, track, and respond effectively to all these variables is unrealistic. Why are these requirements not applied to non-IBR owners?
2. In R1, GOs are required to ensure that IBRs continue to "exchange current in accordance with the no-trip zones and operation regions as specified in Attachment 1." The Standard does not define the term "exchange current". Please define this term.
3. Measure 1 requires the Generator Owner and Transmission Owner to have actual recorded data for each applicable IBR demonstrating ridethrough adherence. This measure needs a timeframe for retention of the data.
4. The second half of the sentence in 2.1.1 doesn't appear to add any value to the sub-requirement. Please clarify what added operational requirement is meant by, "…and continue to deliver active power and reactive power up to its apparent power limit."
5. Requirement R2.1.2 allows four different entities to dictate each IBR's operating mode. This contradicts the requirements of VAR-001 which states that GOs must operate in voltage control mode unless exempted by the TOP. Recommend selecting one of these entities to determine the preference.

6. For overvoltage conditions greater than 140% Attachment 2 requires Generator Owners to distinguish and respond with different time delays, all less than or equal to 3 ms. Recommend requiring IBRs to delay their response to voltage excursions and program their IBRs to match the responses of synchronous machines.
7. Clarify Requirement 2.2.1 to address the expected operational response to close-in faults. Recommend the Standard specify separate performance requirements for close-in faults and more distant faults.
8. Requirement 2.2 appears to mandate that IBRs who operate in active power priority mode in the continuous operating region would be required to switch to the reactive power mode if a voltage disturbance occurs. What criteria are IBRs expected to use to determine when this switch should occur? What are IBRs expected to do if their inverters cannot be switched without software modifications?
9. The ride through requirements should all be specified in the same units of time.
10. Couldn't the voltage overshoot concerns addressed by Requirement 2.3 be addressed more reliably by slowing the response time of the IBR plant controllers to match that of synchronous generation?
11. Measure 2 requires the GO and TO to have actual recorded data during each system disturbance. Recommend establishing a timeframe for the retention of this data.
12. Measure 3 requires the GO and TO to have actual recorded data during each transient voltage event. Recommend establishing a timeframe for the retention of this data.
13. Measure 4 requires the GO and TO to have actual recorded data during each frequency excursion event. Recommend establishing a timeframe for the retention of this data.
14. Measure 5 requires the GO and TO to have actual recorded data during each positive sequence voltage phase angle changes that are less than 25 electrical degrees at the high side of the main transformer. Recommend establishing a timeframe for the retention of this data.
15. Requirement 6 has more specific requirements for an equipment limitation than is being proposed for the synchronous generators. Recommend PRC-029 reflect the wording proposed for PRC-024-4.
16. PRC-029 frequency ride-through is a single graph for all regions. The graph no trip zone is larger than the existing PRC-024 frequency no-trip zone for Eastern, Western, and ERCOT zones. The wording in the rationale is very soft (may be required). The change will cause the LFRT and HFRT settings to be updated as well as collector and transformer frequency settings. Recommend the frequency settings remain consistent with PRC-024 until the time that it is justified from grid events.

In some cases, the initial 6-month implementation period to develop a technical rationale for an exemption may be too short. This is attributable to the necessary input from the original OEM and in some cases due to the complexity associated with facilities comprised of new and old equipment. One example where this may exist are plants where a repower project may have taken place that does not replace all inverters. In a case such as this, the new equipment may meet the requirements, but the remaining existing equipment may not. This may require a detailed study to verify compliance, or perhaps instead, require some form of hybrid exemption for the site. Unlike the stated technical goal of the standard where this is a “performance based” standard, the justification for a technical exemption will require some form of a study to justify that exemption. This could lead to a greater than 6-month period in developing the exemption request. To accommodate these situations, AEP recommends an implementation period of 18 months.

PRC-029 requires that IBR’s shall ride through 110%-120% overvoltage from 0-1 seconds as seen at the high side of the main power step-up transformer. Due to voltage drop, the voltage seen at the equipment terminals can be another 5% higher leading to potential equipment damage from overvoltage. AEP suggests that the SDT consider lowering the ride through to 110% at the high side of the main step-up transformer.

There were 79 sets of responses, including comments from approximately 180 different people from approximately 111 companies representing 10 of the Industry Segments as shown in the table on the following pages.

All comments submitted can be reviewed in their original format on the project page.

If you feel that your comment has been overlooked, let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, contact Director, Standards Development Latrice Harkness (via email) or at (404) 858-8088.

Questions

1. Do you agree with the need for creating a new Standard (PRC-029-1) to address gaps the Inverter-Based Resource Performance Subcommittee (IRPSC) identified within the PRC-024-3 Project 2020-02 SAR and to address the expectations of FERC Order No. 901?

2. Do you agree that the language within PRC-029-1 requirements R1, R2, and R6 regarding IBR plant-level performance during grid voltage disturbances is clear?

3. Do you agree with the drafting team's proposals for including IBR transient overvoltage, frequency, ROCOF, and instantaneous voltage phase-angle jump ride-through performance criteria in PRC-029-1 Requirements R3, R4, and R5?

4. Provide any additional comments for the Drafting Team to consider, if desired.

1. Do you agree with the need for creating a new Standard (PRC-029-1) to address gaps the Inverter-Based Resource Performance Subcommittee (IRPSC) identified within the PRC-024-3 Project 2020-02 SAR and to address the expectations of FERC Order No. 901?

Jennifer Weber - Tennessee Valley Authority - 1,3,5,6 - SERC	
Answer	No
Document Name	
Comment	
We recommend adding these IBR related requirements to PRC-024, rather than creating a new Standard.	
Likes 0	
Dislikes 0	
Response	
Thank you for your comment. The need for a separate standard, PRC-029, is a consequence of both the different natures of synchronous and inverter-based generation and several recent events exhibiting significant IBR ride-through deficiencies and failures the causes of which are not relevant to synchronous generators. Due to the differences in the requirements between these types of generation, PRC-024 is focused on equipment settings, and PRC-029 includes performance based requirements to “ride-through” events. Please refer to the technical rationale for additional information.	
Kimberly Turco - Constellation - 6	
Answer	No
Document Name	
Comment	
Constellation does not agree with creating a new IBR specific standard (PRC-29) to address the gaps in the Inverter-Based Resource. While Constellation recognizes that there has been some grid disturbance in the Odessa/California/Utah regions in the past couple years as a result of some IBRs not performing as intended, the creation of a new standard is a quick reaction without ensuring existing equipment's are capable to fully comply.	

Kimberly Turco on behalf of Constellation Segments 5 and 6

Response	
Thank you for your comment. The scope of PRC-029 is consistent with the SAR assigned to this team and the regulatory directives from FERC Order No. 901 that were assigned to this team. The need for a separate standard, PRC-029, is a consequence of both the different natures of synchronous and inverter-based generation and several recent events exhibiting significant IBR ride-through deficiencies and failures the causes of which are not relevant to synchronous generators. We cannot take the approach of PRC-024 for IBRs because there are too many other factors and causes of IBR ride-through failure not directly related to voltage and frequency protection settings that may, and have caused ride-through deficiencies and failures.	
Rachel Coyne - Texas Reliability Entity, Inc. - 10	
Answer	No
Document Name	
Comment	
Texas RE supports creating a new standard to address Inverter-Based Resources (IBR) gaps identified. Texas RE is concerned, however, with the structure of the standard as it is presently proposed. As currently drafted, the proposed PRC-029-1 would wholly eliminate existing frequency and voltage protection setting verification requirements for IBR resources. Texas RE submits that this is contrary to FERC's intent in directing NERC to develop a comprehensive ride-through standard for IBR resources. FERC Order No. 901 explicitly directs NERC to draft a standard "that require[s] IBR generator owners and operators to use appropriate settings (i.e., inverter, plant controller, and protection) to ride through frequency and voltage system excursions and that permit IBR tripping only to protect IBR equipment in scenarios similar to when synchronous generation resources use tripping as protection from internal faults." (Order No, 901, paragraph 190). FERC's intent behind the order was to expand the scope of applicable devices beyond protection system equipment subject to the current PRC-024 requirements to embrace a range of devices that can trip an IBR facility (inverters, plant controller, etc.). The ultimate goal is to better ensure that IBRs provide reliable performance during voltage and frequency excursions. Texas RE submits, however, that FERC did not intent to exclude IBR entities from the existing verification processes or significant limit the ability of the ERO to review protection system settings prior to an actual disturbance event. In its order, FERC specifically referenced the 2021 Odessa Disturbance Report jointly prepared by NERC and Texas RE staff ("2021 Odessa Disturbance Report"). The 2021 Odessa Disturbance Report in turn called for the development of a ride-through standard to replace PRC-024-3 because "the events analyzed by NERC regarding fault-induced	

reductions in solar PV output and wind output have identified issues with controls and protections unrelated to voltage and frequency." (2021 Odessa Report, at 29). While calling for a more comprehensive standard, however, the report simultaneously identified pervasive issues with protection system settings within the scope of the current PRC-024 standards. The report noted: "Numerous plant owner/operators have stated that they do not have sufficient technical staff on hand to interpret the results and will simply install what the consultant recommends. This is leading to poorly coordinated protection systems within the facility, causing unreliable performance from BPS-connected solar PV facilities in multiple interconnections." (2021 Odessa Report, at 17 (emphasis added)). In short, while acknowledging that the current PRC-024 standard is overly narrow, FERC and the various reports FERC references make clear that protection system verification failures remain an important contributing factor in the numerous disturbance events involving IBRs over the past few years.

As proposed, PRC-029-1 would result in a reliability gap by requiring that protection system settings no longer require verification. The Standard Drafting Team (SDT) explains in the draft PRC-029-1 Technical Rationale that "[a]n IBR becomes noncompliant with PRC-029 only when an event in the field occurs that shows that one or more requirements were not satisfied." Under the SDT's proposed approach, therefore, the existing PRC-024 protection system setting verification requirements would be eliminated and the sole mechanism to verify performance would be an IBR's failure to perform during a disturbance event. Texas RE posits that this approach is inconsistent with the intent of FERC's order to expand the applicable devices and settings that an IBR-entity must ensure are properly set to avoid unnecessary tripping during events. It is also inconsistent with findings that entities continue to experience issues properly setting (and verifying) existing protection systems within the scope of the current PRC-024 requirements.

Rather than pursue this approach, Texas RE suggests that the SDT consider retaining the existing protection system verification requirements as a foundational step, but augment those requirements with a general performance standard. Moreover, while Texas RE does not believe the SDT needs or should develop a comprehensive and prescriptive list of devices that must be appropriate set and coordinated to ensure IBR performance, the SDT should consider which measures and evidence would be appropriate for the GO and TO to demonstrate that its settings meet the various no-trip zone parameters described in Attachment 1. This should include sufficient evidence to show that protection system settings are properly set to not trip within appropriate no trip zones, as well as that other settings for inverters, plant controllers, and other devices are properly coordinated. Such clarity will ensure that at least minimum performance can be audited and verified prior to a disturbance event – the goal of the standards process.

Additionally, Texas RE noticed during the webinar, SDT stated that the requirements do not apply to individual IBR units. Requirement R1 seems to indicate that each IBR unit needs to remain electrically connected and continue to exchange current in accordance with the no-trip zones and operation regions.

Lastly, Texas RE recommends the SDT consider changing 'each IBR' to 'each IBR Facility' for all the Requirements.

Thank you for your comment. The team agrees that the ability to validate the capability of each applicable IBR was not clear from the initial draft. Changes have been made to ensure the design/capability of each IBR can be validated prior to an event – in addition to retaining the event and performance-based requirements. The team does intend for each requirement to only apply at the plant/facility level; consistent with the disturbance monitoring equipment requirements within draft PRC-028. Also, the specific term identifying the applicable IBR facilities will have to await the completion of the IBR definition(s) by Project 2020-06. Changes have been made throughout the requirements and the applicability section to use only currently enforceable language.

A performance standard should be based on function not technology type which is always changing. An IBR generation facility should meet the same performance threshold as traditional generation, with additional support devices as necessary incorporated into the facility design to meet the same level of performance as a traditional unit.

Thank you for your comment. The need for a separate standard, PRC-029, is a consequence of both the different natures of synchronous and inverter-based generation and several recent events exhibiting significant IBR ride-through deficiencies and failures the causes of which are not relevant to synchronous generators. Due to the differences in the requirements between these types of generation, PRC-024 is focused on equipment settings, and PRC-029 includes performance based requirements to “ride-through” events. Please refer to the technical rationale for additional information.

PRC-024-3 has not been in effect long enough to be deemed inadequate to address “gaps” and issues described in IBR disturbance reports. It became effective on 10/1/2022, which was long after major disturbances occurred, and as written, covers major causes of IBR disturbances such as voltage, frequency, and momentary cessation. Most importantly, the Standard clearly stated applicability to individual IBR units and it clearly stated no-trip zones. The Standard could have been modified to include and cover other recommendations from the disturbance report such as PLL protection and ramp rate mis-coordination.

Thank you for your comment. The scope of PRC-029 is consistent with the SAR assigned to this team and the regulatory directives from FERC Order No. 901 that were assigned to this team. The need for a separate standard, PRC-029, is a consequence of both the different natures of synchronous and inverter-based generation and several recent events exhibiting significant IBR ride-through deficiencies and failures the causes of which are not relevant to synchronous generators. We cannot take the approach of PRC-024 for IBRs because there are too many other factors and causes of IBR ride-through failure not directly related to voltage and frequency protection settings that may, and have caused ride-through deficiencies and failures. Lastly, PRC-029 is plant/facility level based requirements and is not applicable at the individual inverter unit level.	
Alison MacKellar - Constellation - 5

Constellation does not agree with creating a new IBR specific standard (PRC-29) to address the gaps in the Inverter-Based Resource. While Constellation recognizes that there has been some grid disturbance in the Odessa/California/Utah regions in the past couple years as a result of some IBRs not performing as intended, the creation of a new standard is a quick reaction without ensuring existing equipment's are capable to fully comply. Comment	
A major concern with the separate Standards, as drafted, is that ride through performance is not required for synchronous generators under PRC-024-4, but it is for IBRs under PRC-029. PRC-02-4 simply requires protective relays to be set so they do not trip the generator within specified bounds, but it allows a resource to trip offline for other reasons. PRC-024-4 also allows a plant to trip if protection systems trip auxiliary plant equipment, per section 4.2.3. In contrast, PRC-029 requires IBRs to remain electrically connected and to continue to exchange current within the specified voltage and frequency bounds. Said another way, an IBR and a synchronous resource could both trip during the same disturbance, and the IBR would be in violation of PRC-029 but the synchronous generator would not be in violation of PRC-024-4, as long as the synchronous generator did not trip due to the settings of its protection system. To ensure grid reliability and resilience, all resources including IBRs and synchronous resources should ride through grid disturbances. The failure of synchronous generators to ride through grid disturbances threatens grid reliability as much or more than the failure of IBRs, as synchronous resources are often producing at a higher level of output, are more typically relied on as capacity resources, and often take longer to come back online and ramp up to full output if they trip due to a disturbance. FERC Order 901 directed NERC to treat IBR resources similarly to how NERC Standards treat synchronous generators, writing that the IBR Standard should “permit IBR tripping only to protect the IBR equipment in scenarios similar to when synchronous generation resources use tripping as protection from internal faults.”{C}[1] Allowing synchronous generators to trip but requiring IBRs to ride through the same or similar disturbance could be challenged at FERC as undue discrimination.	

Not requiring ride-through performance from synchronous generators is also at odds with the intent for this project that NERC stated in its February 2023 comments on the FERC proposed rulemaking that led to Order 901: "A comprehensive, performance-based ride-through standard is needed to assure future grid reliability. To that end, NERC re-scoped an existing project, Project 2020-02 Modifications to PRC-024 (Generator Ride-through), to revise or replace current Reliability Standard PRC-024- 3 with a standard that will require ride-through performance from all generating resources."[2] FERC's Order 901 also noted NERC's statement that this project would require ride-through performance from all generating resources,[3] so a failure to require ride-through performance from synchronous generators may be contrary to both NERC and FERC's intent. The drafting team should make PRC-024-4 a ride-through performance requirement like PRC-029, or alternatively create a single standard that applies to both types of resources (with any necessary clarifications or minor differences in requirements to reflect the differences in IBR and synchronous generator technologies). {C}[1]{C} Order 901, https://www.ferc.gov/media/e-1-rm22-12-000, at paragraph 190 {C}[2]{C}https://www.nerc.com/FilingsOrders/us/NERC%20Filings%20to%20FERC%20DL/Comments_IBR%20Standards%20NOPR.pdf, at 21-22 {C}[3]{C} Order 901, https://www.ferc.gov/media/e-1-rm22-12-000, at paragraph 185

Thank you for your comment. The team intends to continue evaluation of synchronous generators within the scope of the project. The team is seeking to meet regulatory timelines for IBR within FERC Order No. 901 and to address changes for IBR with the proposed PRC-029. Further, the team wants to assure that the physical differences between the technology types are fully represented in any new or modified requirements for synchronous machines and that such new or modified requirements are reasonable.

While AEP agrees with creating PRC-029-1 to address the identified gaps, AEP recommends the SDTs for PRC-028, PRC-029 and PRC-030 review each proposed standard obligations to ensure there is a consistent, integrated plan across these projects and standards to achieve the goal of correcting the past performance of Invertor-Based Resources and IBR units. Having a coherent strategy document that explains how these three standards complement each other (and not be duplicative) would be beneficial.

Comment	
FirstEnergy supports the need for the new standard (PRC-029-1). In addition, FE supports EEI's comments which state:	

EEI agrees with most of the proposed language in Requirements R1, R2 and R6; however, the phrase “of an applicable IBR” should be removed. Applicability is defined in the Applicability Section of the standard and anything more is unnecessary and redundant.

Additionally, Requirement R2, subpart 2.5 could be understood to mean that IBRs whenever the voltage at the high-side of the main power transformer is within the no-trip zone, as specified in Attachment 1, must not trip even if it might lead to equipment damage. We offer the following proposed edits in boldface to Requirement R2, subpart 2.5 to clarify the requirement. NERC Reliability Standards should never mandate that equipment run to failure.

2.5 **Each IBR shall only trip to prevent equipment damage, W**hen**ever** the voltage at the high-side of the main power transformer is within **of** the no-trip zone, as specified in Attachment 1, **each IBR shall continue to operate except when the continued operation of the IBR would lead to equipment damage**.

Response

Thank you for your comment.
Terminology: The team has removed the word “applicable” and include a reference to the applicability section of the Standard. Any IBR that cannot meet voltage ride-through requirements, and may need to trip within the no-trip zone to protect equipment, would be covered under the documented equipment limitations as covered within Requirement R4 (previous R6).
R2.5: The team agrees with removing requirements on operation outside the no-trip zone and has removed R2.5.

Comment

Black Hills Corporation agrees that there is a gap in PRC-024-3 regarding performance of inverter-based resources (IBR). However, more consideration should be given to creating “protection-based” Standards for IBR, whether as an update to existing Standard PRC-024-3 or new Standard PRC-029-1 rather than the “event-based” approach currently being taken in PRC-029-1.

Thank you for your comment. The SDT wants to avoid the complexities of OEM-specific IBR controls and protection by avoiding the protection settings issues altogether. We believe that a settings-based approach to the determination of compliance would become impractical if not impossible because of the varability of OEM designs. We cannot take the approach of PRC-024 for IBRs because there are too many other factors and causes of IBR ride-through failure not directly related to voltage and frequency protection settings that may, and have caused ride-through deficiencies and failures. A settings-based approach cannot practically address all factors and causes inherent to the various OEM designs of IBR units and plants. Some revisions were made to add clarity to capability-based requirements which require a demonstration of verified design/capability to ride-through.

PGE requests that the Standard Drafting Team (SDT) add clarity regarding Attachment A: Voltage Boundary Clarifications, Section: Evaluating Protection Settings, a. The most probable real and reactive loading conditions for the unit under study. Loading conditions vary depending on the type of unit, location, time of year, etc. How should an entity assess “most probable” loading conditions? Are entities being required to account for the worst case scenarios providing the greatest voltage change(s), not just a probable condition that may represent little to no significant voltage difference? PGE also notes that the Table References and Figure References are not aligned	
Likes 0

Response	
Thank you for your comment. The attachment describes an approach to translating per unit voltage between the low and high sides of GSUs. This is something that needs to be done if voltage protection is applied at the generator terminal. It is only a recommendation. The protection setting no-trip zone references the POI voltage. The table and figure numbers in PRC-024-4 are now corrected.

Comment	

Southern Company believes that separating synchronous machine facilities from IBR facilities simplifies the complication that would exist by addressing both types of facilities in the same standard. While the existing "legacy" facilities have demonstrated imperfect ride-through performance (reactions) during system initiated disturbances, Southern believes that the application of ride-through requirements should only be applicable to facilities designed, built, and commissioned after the development of such a standard. The existing "legacy" facilities were not designed or built to achieve the desired ride-through performance that is specified in PRC-029-1, requirements R1-R5 of this proposed standard, and should not be subject to those requirements. The demonstrated performance, while not matching the ideal performance dictated by this proposed standard, is not catastrophic to the interconnection. The notion that generator owners have not taken any actions to improve the reaction of the legacy facilities to system disturbances is false. Southern Company has reviewed and modified control and protection settings for inverter operations at multiple facilities since the issuance of the first two NERC Alerts on the Loss of Solar facilities and during the multiple disturbance analysis evaluations. Addressing the desired performance with new facilities which will have the component design and control strategies sufficient to meet the desired performance should be a measure adequate to address the frequency control, voltage control, and stability needs and concerns of the interconnection.

Perhaps a more reasonable approach towards achieving better IBR facility ride through performance during system disturbance events, is to require evaluations with every instance of a plant output hiccup. The proposed required evaluation process in PRC-030, requiring corrective action plans to minimize/eliminate/eradicate the reason for the hiccup, would address, where possible, action taken through control or protection system setting changes, or through hardware changes - for equipment placed in service after the effective date of this draft standard).

Southern would offer general concerns with synchronizing language across all draft standards. For example, M1 states: *"shall have evidence of actual recorded data or other evidence for each applicable IBR demonstrating adherence to ride-through requirements"*. This seems like an opportunity to clarify by explicitly referencing standard(s) addressing data collection. This example repeats in some form in each "M" paragraph. Should the evidence of actual recorded data in M1 and other measures synch up with the phased in approach to PRC-028?

Finally, Southern Company supports EEI and NAGF comments.

Response

Thank you for your comment.
Scope of legacy IBR and approach by the team: The scope of PRC-029 is consistent with the SAR assigned to this team and the regulatory directives from FERC Order No. 901 that were assigned to this team. There is some potential for documented limitations within Requirement R6 and the Implementation Plan for legacy equipment that cannot meet any voltage ride-through requirements (R1 and R2). Some revisions were made to clarify design capabilities would still be required.
Coordination between PRC-029 and PRC-030 drafting teams: these team have implemented changes to those drafts that triggers within PRC-030 to initiate an analysis will be evaluated against PRC-029 ride through criteria. PRC-029 established the criteria and PRC-030 includes requirements for conducting the analysis of performance after a disturbance.
Performance Measures: The compliance measures for demonstration of performance were revised from "actual recorded data" to "actual disturbance monitoring (i.e. Sequence of Event Recorder, Dynamic Disturbance Recorder, and Fault Recorder) data".

Yes, generator ride-through is an essential reliability service and the changing generation technology to inverter-based has led to the need for improved, applicable, appropriate, and technically accurate requirements that suit IBRs. However, it is critically important that the implementation of these requirements consider all stakeholder needs and capture important technical considerations so that the requirements sufficiently mitigate risks without causing unnecessary costs or burdens on any responsible entity.

2. Do you agree that the language within PRC-029-1 requirements R1, R2, and R6 regarding IBR plant-level performance during grid voltage disturbances is clear?	
Darcy O'Connell - California ISO - 2, Group Name ISO/RTO Council (IRC) Standards Review Committee	
Answer	No
Document Name	
Comment	

The ISO/RTO Council (IRC) Standards Review Committee (SRC) recommends the following modifications to improve the clarity and better convey the intent of the standard.

Recommended changes to R1:

"…as specified in Attachment 1 except when needed to clear a fault or a documented **and communicated** equipment limitation exists in accordance with **Requirement R6."**

Each Generator Owner or Transmission Owner of an applicable IBR shall ensure that each IBR remains electrically connected and continues to exchange current in accordance with the no-trip zones and operation regions as specified in Attachment 1 unless needed to clear a fault or a documented equipment limitation exists in accordance with Requirement R6.

Recommended changes to M1:

"…demonstrating adherence to ride-through requirements, as specified in Requirement R1**, or shall have evidence of a documented and communicated equipment limitation, as specified in Requirement R6**."

Recommended changes to R2:

"…each IBR's voltage performance adheres to the following, unless a documented **and communicated** equipment limitation exists…"

The SRC recommends that the SDT to review and align the data in **Attachment 1** to ensure that the data in Tables 1 and 2 aligns with what is shown in Figures 1 and 2. Currently, the graphs in Figures 1 and 2 do not match what is indicated in the Tables. For example, rows 1-3 in Tables 1 and 2 are identical, yet Figure 2 does not match Figure 1 by indicating a Voltage Ride-Through Requirement of 1.0.

It appears that the SDT's intent is to require continuous operation between 95% and 105% voltage with a minimum ride-through time of at least 1800 seconds (half an hour) when voltage is above 105% and not exceeding 110%. If the intent is actually that equipment must be able to operate *continuously* at voltages up to 110%, then the tables and plots should be labelled with a descriptor that clearly indicates that indefinite or continuous operation is required rather than operation for a minimum ride-through time (1800 seconds). For example, a version of Table 2 that achieves the SDT's apparent intent could look like the following:

Voltage (per unit)	**Minimum Ride-Through Time (sec)**
>1.2	N/A
<=1.2 and >1.1	1.0
<=1.1 and >1.05	1800
<=1.05 and >=0.95	Continuous
<0.95 and >=0.90	Continuous*

*current limitation permitted, with active or reactive power preference as specified

<0.90 and >=0.70	6
<0.70 and >=0.50	3
<0.50 and >=0.25	1.2
<0.25	0.32

While the above comments point out areas of ambiguity in the draft standard that need to be clarified, the SRC recommends that Table 1 and Table 2 be modified to require IBR plants remain connected indefinitely when the voltage is between 1.05 and 1.1 pu. The current draft standard requires units to remain online for 1800 seconds in this range, and the logic behind this threshold is not clear. The current PRC-024 standard requires units to remain on-line indefinitely for the above range. [*All SRC entities support the comments in this paragraph except MISO*].

In addition, the SRC recommends a part be added to the standard to directly address the Permissive Operating Region, similar to what is done in Part 2.1 (for the Continuous Operation Region) and Part 2.2 (for the Mandatory Operation Region) as, the rules surrounding the Permissive Operating Region are unclear if this is not addressed. For example, there should be some linkage between the body of the standard and Attachment 1, item 10. The SRC proposes the following language for consideration (new Part 2.3):

2.3 While voltage at the high-side of the main power transformer is within the Permissive Operation Region as specified in Attachment 1, an IBR may operate in current block mode only if necessary to protect the equipment. Otherwise, each IBR shall follow the requirements for the Mandatory Operation Region in Requirement R2, Part 2.2.

Recommended changes to R6:

The SRC is concerned that Requirement R6 as proposed provides an overly broad exemption, as the standard is silent as to what criteria must be met to qualify for an exemption and contains no requirement that a Corrective Action Plan be developed or that the equipment limitations be resolved or addressed. Only notification to other entities is required. The SRC recommends that the SDT:

- Develop more specific criteria as to what qualifies as an equipment limitation[1], OR A technical justification that addresses why corrective actions will not be applied nor implemented.
- Require exemptions be submitted to NERC and/or the Regional Entities for pre-approval in order to qualify for the exemption.

The SRC suggests there should be explicit requirements to both ‘document equipment limitations’ and to ‘communicate’ those documented limitations to the appropriate parties. The SRC proposes the following modifications to address this issue:

“Each Generator Owner and Transmission Owner with a **known** equipment limitation that would prevent an applicable IBR that is in-service by the effective date of this standard from meeting voltage ride-through requirements as detailed in Requirements R1 and R2 shall **document** each equipment limitation, develop a Corrective Action Plan to address the limitation, **and communicate both the limitation and the Corrective Action Plan** to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s).

Recommended changes to M6:

Each Generator Owner and Transmission Owner shall have evidence of **known** equipment Limitations accompanied by a Corrective Action Plan, as specified in Requirement R6, **having been** documented **and communicated** to each associated Planning Coordinator, Transmission Planner, and Reliability Coordinator prior to the effective date of PRC-029-1.

Each Generator Owner and Transmission Owner with changes to equipment shall have evidence of communication to each associated Planning Coordinator, Transmission Planner, and Reliability Coordinator.

[1] *See Implementation Plan (page 4), “only those IBR that are unable to meet voltage ride-through requirements due to their inability to modify their coordinated protection and control settings may be considered for potential exemption.” See Technical Rationale (page 9); i.e. specify which voltage band(s) and associated duration(s) cannot be satisfied or specific as to the number of cumulative voltage deviations within a ten-second time period that the equipment can ride-through if less than four… identify the specific equipment and explain the characteristic(s) of that equipment that prevent ride-through.*

Response

Thank you for your comment.
R1 and R2: The team revised R1 and R2 to state "an equipment limitation in accordance with Requirement R6." R6 includes requirement language to document and communicate. Measure M4 (previous M6) was revised to include "known" as well as "and communicate" with the initial documentation of an equipment limitation.
Attachment 1: Tables and Figures in Attachment 1 have been revised to add clarity on the operation regions. The range of values in row #4 of Tables 1 and 2 to clarify the continuous operation region.
R2: The team added requirement subpart 2.3 to provide clarity on the operation within the Permissive Operation Region.
R4 (Previous R6): The team added clarity to Requirement R4 and the Implementation Plan to align the documentation and communication of known equipment limitations and exemptions with Requirement R3 of PRC-024-4.

Comment

Comments: GRE requests the SDT review and align the data in **Attachment 1** so the data in Tables 1 and 2 aligns with what is shownin Figures 1 and 2. Currently, the graphs in Figures 1 and 2 do not match what is indicated in the Tables. (uploaded)

GRE recommends a part be added to the standard to directly address the Permissive Operating Region, similar to what is done in Part 2.1 (for Continuous Operation Region) and Part 2.2 (for Mandatory Operation Region) as, if left unaddressed, is unclear. For example, there should be some linkage between the body of the standard and Attachment 1, item 10. MRO NSRF proposes the following language for consideration (*new* Part 2.3):

2.3 While voltage at the high-side of the main power transformer is within the Permissive Operation Region as specified in Attachment 1, an IBR may operate in current block mode only if necessary to protect the equipment. Otherwise, each IBR shall follow the requirements for the Mandatory Operation Region in Requirement R2.2.

GRE is concerned that requirement R6 provides an overly broad exemption as written as the standard is silent as to what criteria must be met. Only notification to other reliability entities is required with no requirement to develop and implement a Corrective Action Plan. MRO NSRF recommends the SDT:

Develop more specific criteria as to what qualifies as an equipment limitation[1], OR Require exemptions be submitted to NERC and/or the Regional Entities for approval in order to qualify for the exemption. [1] *See Implementation Plan (page 4), i.e. "only those IBR that are unable to meet voltage ride-through requirements due to their inability to modify their coordinated protection and control settings may be considered for potential exemption." See Technical Rationale (page 9); i.e. specify which voltage band(s) and associated duration(s) cannot be satisfied or specific as to the number of cumulative voltage deviations within a ten-second time period that the equipment can ride-through if less than four… identify the specific equipment and explain the characteristic(s) of that equipment that prevent ride-through.* R2: GRE agrees with the present flexibility that some of the IBR VRT performance could be modified to meet the individual system needs by the applicable Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator. However, some clarity may be required on how this process is initiated and what type is evidence is required to demonstrate request is received and implemented. This may be an additional requirement assigned to the Transmission Planner. Each Transmission Planner, Planning Coordinator, and Transmission Operator that jointly specifies the following voltage ride-through performance requirements within their area(s) different than those specified under R2, shall make those requirements available to each associated applicable IBR Generator Owner and Transmission Owner.

R2.5 & R5.1, et al. Each IBR shall only trip … "Trip" may be ambiguous. Does this mean disconnecting from the system to de-energize the IBR equipment, as in opening a circuit breaker? Or does it mean cease exchanging current? Or something else?	
Likes 0	
Dislikes 0	
Response	
Thank you for your comment. The team believes that "trip" is an industry term that is generally accepted when a plant/facility disconnects and electrically isolates itself. **R2:** The team agrees with removing requirements on operation outside the no-trip zone and has removed R2.5. **R5:** Requirement R5 has also been removed.	
John Pearson - ISO New England, Inc. - 2	
Answer	No

Comment	
For R1, We recommend adding language to refer to plants that were previously exchanging current before the disturbance. For example, A BESS that is fully charged would be connected to the BES, but would not be exchanging current. For R2, change "each IBR's voltage performance" to	

voltage ride through performance. For R6, exemptions should not be automatically allowed. This would allow for bad designs relying on an exemption. Exemptions should only be for existing or legacy units. New units should not have the option for exemption.	
Likes 0	
Dislikes 0	
Response	
Thank you for your comment. **Terminology**: That the requirement states "continues to exchange" implies that the facility was exchanging current prior to the disturbance. **R2:** R2 states that the voltage performance must meet the requirements within Attachment 1. Also, ride-through is not currently defined. **R4 (Previous R6):** R4 only applies for legacy units that have already documented known equipment limitations. Refer to the Implementation Plan for additional information.

Comment	

In the opinion of ACES, the newly proposed Glossary Terms are unnecessary and seemingly incongruous terms. For example, if the Mandatory Operating Region is required, should it not also be continuous? It is our opinion that these terms add little to no value and instead only create confusion where none was previously present. We recommend striking these new terms from the standard.

In ACES' opinion, R1 appears to be overly broad so as to require an applicable IBR to be operational at all times. This does not appear to allow for full facility outages without first having a "documented equipment limitation" per R6. Thus, as written, the GO will run the risk of non-compliance with either R1, R6, or both whenever a full facility outage of an IBR is required. Furthermore, it is unclear how R1 differs from R2 other than seeming to requiring the GO to ensure the GOP always keeps the unit online during to normal operation. We recommend striking R1 from the standard.

Additionally, we do not agree with the language of Requirement R2, Part 2.1.1. As written, R2 does not define what type of System disturbance is applicable and Part 2.1.1 requires the GO to continue producing active power at the pre-disturbance levels or its maximum capability; whichever is less. We have concerns with this approach. Namely, during an over frequency deviation event wherein the high side MPT voltage remains ≥ 0.9 p.u. and ≤ 1.1 p.u. In this instance, the frequency response algorithm within the IBR would attempt to reduce active power output. Due to the fast-acting nature of IBRs, it is likely that an IBR facility(ies) would respond to and correct such an event before a synchronous generating resource(s). However, in the aforementioned hypothetical example, to comply with R2.1.1, the IBR frequency response control would need to be either disabled or limited in its response to an over frequency System disturbance. In our opinion, this is not beneficial to the reliability of the BES. While possibly unlikely at the current time, this hypothetical scenario becomes increasingly likely as conventional synchronous generating resources are retired in favor of IBRs.

Furthermore, it is the opinion of ACES that R6 should be modified to include any potential regulatory limitations. This suggested approach is in line with the approach taken in PRC-024-4 R3. We recommend the modifying R6 as follows:

R6. Each Generator Owner and Transmission Owner shall document each known regulatory or equipment limitation that prevents an applicable IBR that is in-service by the effective date of this standard from meeting voltage or frequency ride-through requirements as detailed in Requirements R1 through R5.

6.1 Each Generator Owner and Transmission Owner shall include in its documentation:

6.1.1 Identifying information of the IBR (name, facility #, other)

6.1.2 Which aspects of voltage ride-through requirements that the IBR would be unable to meet

6.1.3 Identify the specific piece(s) of equipment causing the limitation.

6.2 The Generator Owner and Transmission Owner shall communicate the documented regulatory or equipment limitation, or the removal of a previously documented regulatory or equipment limitation, to its Planning Coordinator and Transmission Planner, and Reliability Coordinator within 30 calendar days of any of the following:

6.2.1 Identification of a regulatory or equipment limitation.

6.2.2 Repair of the equipment causing the limitation that removes the limitation.

6.2.3 Replacement of the equipment causing the limitation with equipment that removes the limitation.

Lastly, the values specified in Table 1 and Table 2 in Attachment 1 do not align with the graphs shown in Figure 1 and Figure 2, respectively.

Response

Thank you for your comments.
Definitions: The team removed the terms for operating regions.
R1: Requirement R1 requires that the plant/facility must be electrically connected and exchanging current prior to the disturbance. R1 is needed to define clear boundaries for ride-through and R2 is needed to define performance for the different operation regions within the no-trip zone.
R1 and R2: The team used the defined term “voltage excursion” to align with language in PRC-024.
R2: The team added a footnote to 2.1.1 and other relevant footnotes to resolve the frequency excursion scenario.
R4 (Previous R6): The team included the *regulatory limitation* to align with PRC-024. R4 was also modied to clarify that changes to equipment that remedy the equipment limitation, that would remove the exemption.
Attachment 1: The tables and figures have been adjusted.

Kennedy Meier - Electric Reliability Council of Texas, Inc. - 2	
Answer	No

Document Name	
Comment	

Electric Reliability Council of Texas, Inc. (ERCOT) joins the comments of the ISO/RTO Council (IRC) Standards Review Committee (SRC) and adopts them as its own in addition to the following comments, except to the extent of any specific differences between the SRC comments and the following comments from ERCOT.

As detailed below, the currently proposed language for Requirement R1 is not clear. Additionally, ERCOT believes that plant-level requirements are insufficient because individual IBR unit performance failures continue to occur and could, in aggregate, be just as impactful or more impactful than the complete loss of an IBR plant. The performance threshold should be coordinated with the threshold in PRC-030, and ERCOT believes a reasonable threshold would be the **lesser** of either 20% of the plant's gross nameplate rating, or 20 MW. In an IBR-dominated electric system, these aggregated losses could cause unreliable operations if not corrected. The past 8-10 years have demonstrated that IBR owners will not voluntarily correct these performance issues in the absence of a mandatory reliability standard.

SDT's proposed language (ERCOT finds the bold portions unclear):

"Each Generator Owner or Transmission Owner of an applicable IBR shall ensure that **each IBR** remains electrically connected and continues to exchange current in accordance with the no-trip zones and operation regions as specified in Attachment 1 unless **needed** to clear a fault or a documented equipment limitation exists in accordance with Requirement R6."

ERCOT's proposed language:

"Each Generator Owner or Transmission Owner of an applicable IBR shall ensure that each IBR, **and its IBR units**, remains electrically connected and continues to exchange current in accordance with the no-trip zones and operation regions as specified in Attachment 1 unless **the IBR, or its IBR units, needs to be tripped** to clear a fault or a documented equipment limitation exists in accordance with Requirement R6."

In addition to the concerns with Requirement R1 noted above, ERCOT is concerned that Requirement R2 does not clarify the timeframe encompassed by the term "System disturbance." Without further clarification, "System disturbance" may be interpreted to only describe the fault itself, even though control instability may manifest itself immediately after the fault clears or during the milliseconds or seconds after the fault clears, during which time frequency and voltage support are still critical. While IEEE 2800 defines the disturbance period, and there is an expectation that an IBR will perform acceptably in the continuous operation region, Requirement R2 is not clear that "riding-through" a disturbance includes both the fault and the non-fault portions of the disturbance along with the transition from ride-through mode to a new steady-state (i.e., the post-disturbance period). ERCOT suggests a 10-second window as a bright-line criterion.

SDT's proposed language for Requirement R2.

"R2. Each Generator Owner or Transmission Owner of an applicable IBR shall ensure that during a System disturbance, each IBR's voltage performance adheres to the following, unless a documented equipment limitation exists in accordance with Requirement R6."

ERCOT's proposed language for Requirement R2:

"R2. Each Generator Owner or Transmission Owner of an applicable IBR shall ensure that during, **and up to ten seconds after,** a System disturbance, each IBR's voltage performance **and its associated IBR units'** voltage performance adheres to the following, unless a documented equipment limitation exists in accordance with Requirement R6."

For Requirement R2, Part 2.2.2, ERCOT agrees that location-specific flexibility may be needed and defined by the TP, PC, RC, and or TOP; however, the language should clearly mandate that in such instances, the established performance requirements must also be met. Additionally, the current wording does not address the possibility that reactive current "response" could be in the wrong direction if not properly configured, and the language should be clarified to address this issue. ERCOT proposes the following language for Part 2.2.2 to capture the full spectrum of current priority modes from full aggressive reactive priority mode, to a de-tuned reactive response while in reactive priority mode, to an active priority mode.

"Adjust reactive current injection at the high-side of the main power transformer so that the magnitude of the reactive current **properly** responds to changes in voltage at the high-side of the main power transformer in accordance with default reactive prioritization **or as required by** any applicable Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator **that specifies** a certain magnitude **and timeliness** of reactive power response to voltage changes, **that specifies a maximum allowed active current reduction to provide reactive current, or that specifies** active power priority instead of reactive power priority."

ERCOT also recommends including the following language to help prevent unnecessary misoperations due to the use of unfiltered measurements or instantaneous (no time delay) settings for protection systems, consistent with NERC recommendations for addressing easily preventable performance failures.

R2.2.3 "Utilize sufficient time delays or filtering methods for any voltage measurements utilized by its protection equipment to prevent unnecessary trips due to calculation errors or transients."

ERCOT finds the bolded portions of the SDT's proposed language for Requirement R2, Part 2.3 to be unclear:

"The IBR shall not itself cause voltage at the high-side of the main power transformer to exceed the applicable Attachment 1 Table 1 or Table 2 no-trip zone voltage thresholds and time durations **in its response from** Mandatory or Permissive Operation Regions to the Continuous Operating Region."

ERCOT proposes the following language to clarify the issue:

"The IBR shall not itself cause voltage at the high-side of the main power transformer to exceed the applicable Attachment 1 Table 1 or Table 2 no-trip zone voltage thresholds and time durations **in its response as it transitions from** Mandatory or Permissive Operation Regions to the Continuous Operating Region."

ERCOT would also point out that the last clause may not be necessary because the IBR should not cause high voltage at any time, and the SDT could consider the following alternative language:

"The IBR shall not itself cause voltage at the high-side of the main power transformer to exceed the applicable Attachment 1 Table 1 or Table 2 no-trip zone voltage thresholds and time durations."

Consistent with the comments above on Requirement R2, Part 2.2.2, Requirement R2, Part 2.4 should be revised as follows to clarify that the other requirements or specifications from the RC/PC/TP/TOP must still be met:

"Each IBR shall restore active power output to the pre-disturbance or available level within 1.0 second when the voltage at the high-side of the main power transformer returns to the Continuous Operation Region from the Mandatory Operation Region or Permissive Operation Region (including operation in current block mode) as specified in Attachment 1, **or as required** by any applicable Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator **that specifies** a lower post-disturbance active power level requirement or **that specifies** a different post-disturbance active power restoration time."

Requirement R2, Part 2.5 may not be clear, in light of the new defined terms, that partial trips (including trips of individual IBR units) should not be allowed. While this topic should be coordinated with PRC-030, it goes to the heart of momentary cessation in that staying connected but not supporting frequency and voltage can, in aggregate, be just as detrimental to reliability as a full trip. The SDT should consider revising Part 2.5 to ensure that it is clear that there would be a violation at a particular level (e.g., the lesser of 20% of the unit's rated output, or 20 MW) of IBR unit trips. This could be graduated in severity level starting at the 20% or 20 MW level and increasing thereafter (e.g., 20%, 40%, 60%, 80%, and above).

ERCOT's proposed language for Part 2.5: "Each IBR, **or its IBR units,** shall only trip to prevent equipment damage, when the voltage at the high-side of the main power transformer is outside of the no-trip zone as specified in Attachment 1."

ERCOT also has concerns with the SDT's proposed Requirement R6 language:

"Each Generator Owner and Transmission Owner with **a documented equipment limitation** that would prevent an applicable IBR that is in-service by the effective date of this standard from meeting voltage ride-through requirements as detailed in Requirements R1 and R2 **shall communicate each equipment limitation to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s).**"

More specifically, the first bolded phrase ("a documented equipment limitation") appears to allow complete GO/TO discretion to declare a limitation with no process for review, approval, or acceptance of the limitation by any other entity. Only a communication to the PC, TP, and RC is required. It is unclear if the SDT's intention is that at some point these documented limitations would be reviewed or evaluated under the NERC CMEP (and it is unclear what standard the limitation documentation would be held to under such a review). At a minimum, Measure M6 and/or the Technical Rationale should provide more information about what an acceptable limitation might be and guidance for CMEP staff to use in evaluating the validity of limitations and the associated documentation.

The second bolded portion ("shall communicate each equipment limitation to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s)") is necessary, but may not be effective from a reliability perspective. A mere description of a limitation sent in an email or letter would not be useful for the PC/TP/RC but would meet the letter of Requirement R6. If the purpose of the communication is for PCs, TPs, and RCs to be able to assess the limitation and incorporate it into system studies, either Requirement R6 or the Technical Rationale should clarify that the communication needs to be in a format that is acceptable and useful to the PC/TP/RC (most likely in the form of an updated model that reflects the limitation). Additional burdensome administrative requirements to cover this communication process are not suggested, but at the very least the Technical Rationale should include guidance and set expectations to ensure that the communication will be useful to ensure the reliability of the grid. Additionally, ERCOT notes that FERC Order 901 recognized that "a subset of existing registered IBRs – typically older IBR technology with hardware that needs to be physically replaced and whose settings and configurations cannot be modified using software updates – may be unable to implement the voltage ride though performance requirements directed herein." ERCOT recommends that Requirement R6 be clarified to indicate that the equipment limitation process is only available to the limited subset of IBRs described in Order 901.

Additionally, ERCOT notes that Requirement R6, Part 6.2 does not require the TO/GO to actually improve ride-through capability even when equipment is replaced:

"Each Generator Owner and Transmission Owner with a previously communicated equipment limitation that repairs or replaces the equipment causing the limitation shall document and communicate such equipment changes to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s) within 30 days of the equipment change."

Rather than focusing on communication of changes, Part 6.2 should require the TO/GO to comply with all PRC-029 requirements and should not allow any documented limitations whenever equipment is changed or replaced; this approach would better align with FERC Order 901. PRC-029 should also include a requirement that mandates the implementation of software settings changes and upgrades (that do not require replacement of physical equipment) that improve ride-through capability. This is referenced in the implementation plan, but is absent from the actual requirements in PRC-029.

Equipment limitations may also not be currently captured in dynamic models, and the list of requirements should be updated to reflect this issue. The MOD standards may not accurately account for the provision of this information to all entities that perform studies (including stability limit and IROL determination studies that RCs perform); this would constitute a reliability gap. RCs and PC/TPs must be able to assess the impact of these exemptions to be able address the reliability impact under FERC Order 901.

Finally, ERCOT notes that FERC Order 901 requires NERC to "determine whether the new or modified Reliability Standards should provide for a limited and documented exemption for certain registered IBRs from voltage ride through performance requirements. Any such exemption should be only for voltage ride-through performance for those existing IBRs that are unable to modify their coordinated protection and control settings to meet the requirements without physical modification of the IBRs' equipment." While it is clear that the SDT has determined that the standard should allow for documented exemptions for equipment limitations, the requirement language is unclear as to how or whether this exemption process is truly "limited" as required in Order 901, especially in light of the explicit reference to IBRs "that are *unable* to modify their coordinated protection and control settings to meet the requirements without physical modification of the IBRs' equipment." As ERCOT notes below, exemptions should be limited to scenarios where a responsible entity cannot otherwise achieve the necessary ride-through performance without physical equipment changes (inability to meet ride-through requirements that can be addressed simply by making software- or parameterization-type changes should not be grounds for an exemption) OR to scenarios where, even without making the remaining physical changes, the loss of a contingency would not cause instability, Cascading Outages, or uncontrolled separation that adversely impact the BPS.

Response

Thank you for your comments.
Evaluation of plant performance: The team is establishing plant/facility level ride-through requirements, consistent with the availability of disturbance monitoring data established within PRC-028. Further, Requirement R2 requires that the plant/facility must return to pre-disturbance values. Should the plant experience tripping of a portion of it's individual inverters, the overall plant would not be able to achieve compliance with R2. PRC-030 also include mechanisms for the entities with a wider-area view to request data, analyze performance, and establish corrective action plans.
Terminology used: The team has replaced the terms "disturbance" and "event" to use the type of excursion that is occurring. This change allows Requirement R1 to cover the time after a fault.
R2: The team agrees to some revised language in 2.2.2 to clarify the current response desired to improve performance.
R2.4 (Previous R2.3): The team clarified language in as suggested and added clarity on the voltage recovering as part of the change state.
R2.5 (Previous R2.4): Revisions included.
Previous R2.5: **R2:** The team agrees with removing requirements on operation outside the no-trip zone and has removed R2.5.
R4 (Previous R6): The team did add clarity to R4 and the implementation plan to specify what is allowable to an exemption that is consistent with the regulatory directives and assures adequate reliability can be evaluated.

Requirement 1 and 2 These requirements mention that the IBRs should respond to the voltage changes with reactive current injection during a system disturbance, however, the magnitude of this response is not identified. The magnitude and expectation of the response should be clarified due to the fact that it can vary by unit and unit capabilities. Measures 1, 2, 3, 4, and 5 With regards to data recording, it is unclear what counts as recording? If the expectation is the same as contained in PRC-028-01 Draft 2, that should be specified; or otherwise identify alternate means of data recording. What if an entity does not have a recorded event to show compliance with the standard and prove its ability to ride through a system event?

Response	

Thank you for your comments. **R1 and R2:** R2.2.2 allows for TP/PC/RC/TOP to require specific reactive current and active current magnitude as needed. The team does not intend to provide specificity of magnitude in R1 nor R2. **Measures:** The team specific language in the measures to tie disturbance monitoring data language to PRC-028-1. The team added specificity for demonstration of capability/design as well as performance. **Coordination between projects:** The team will work with the implementation plan to reflect the reality of the PRC-028 implementation.

NextEra aligns with EEI's comments: EEI agrees with most of the proposed language in Requirements R1, R2 and R6; however, the phrase “of an applicable IBR” should be removed. Applicability is defined in the Applicability Section of the standard and anything more is unnecessary and redundant. EEI also does not support Requirement R2, subpart 2.5 because it contains unneeded language, which adds confusion and implies that GOs can only trip outside of the trip zone if their equipment might become damaged. This has never been an obligation for synchronous generators, and we do not agree that this should be an obligation for IBRs. If NERC or the SDT believe that the no-trip zone needs to be expanded, they should justify such a change and present it for industry review and comment, otherwise, Requirement R2, subpart 2.5 should be deleted. And while we support Requirement R6 and the provisions to notify PCs, TPs and RC about equipment limitations that would prevent an applicable IBR from meeting ride-through requirements as detailed in Requirements R1 and R2, the Requirement does not go far enough because there may be technical reasons why an applicable IBR is unable to meet Requirement R3 through R5, as well. To address this concern, R6 should be expanded to include Requirement R1 through R5.

Response	
Thank you for your comments.	

Applicability: The team has removed the word “applicable” and include a reference to the applicability section of the Standard. Any IBR that cannot meet voltage ride-through requirements, and may need to trip within the no-trip zone to protect equipment, would be covered under the documented equipment limitations as covered within Requirement R4 (Previous R6).
R2: The team agrees with removing requirements on operation outside the no-trip zone and has removed R2.5.
R4 (Previous R6): The scope of allowable exemptions within R4 is consistent with the regulatory directives of Order No. 901. Requirements R3-R5 cannot apply.

Comment

In regard to R1:

Does M1 imply that actual recorded data must be kept as evidence of ride-thru compliance for every in-scope IBR, for every system disturbance? Thesame question applies to R2-M2, R3-M3, R4-M4, and R5-M5.

The disturbance characteristic must be specified in order to trigger captures of performance information for every disturbance at every IBR facility - the characteristic which defines each type of disturbance must be defined in order to capture the record.

For each of the Measures M1 - M5, what "other evidence" can demonstrate compliance with R1-R5 other than recorded data?   How does the drafting team believe that generator owners can assure this performance expectation can be achieved prior to an actual event? There is no test verification that can be performed to confirm the expected performance. Consider providing some examples of what is acceptable as “other evidence”.

R1 mentions “operation regions specified in Attachment 1. R2, Part 2.1 mentions “continuous operation region as specified in Attachment 1” and Part 2.2 mentions “mandatory operation regions as specified in Attachment 1”. However, nowhere in attachment 1, is there mention of "continuous, mandatory, or permissive" operation regions.

In regard to R2:

For R2, Continuous Operation Region is not specified in Att. 1; it is merely a defined term in the draft standard.   Southern Company suggests that the referenced region be shown on the graph of Att.1, or that the words from the defined term simply be placed in the sub-requirement directly rather than creating a defined term.   The term region implies an area (volt-time). If the definition is simply specifying voltage level magnitude, simply state that. The definition labels are confusing; does permissive operation mean the IBR has permission to trip if the voltage is less than

0.1pu? It is observed that the values in the "mandatory operating region" match some of the borders of the "no trip zone" in Attachment 1, yet there is a time element that must be accounted for in determining if a trip is in compliance or not with the curve of Att. 1. For example, how can a long term (1-9 second) event where the voltage is 0.4pu be a Mandatory Operating Region? The voltage ride-thru curve does not specify this (for example).

Regarding the R2.2 and R2.3 requirement specifications, IBR facilities do not have per phase voltage regulation in their current designs, so the feasibility of successfully reacting to low system voltage (R2.2) with rapid reactive power injection while not possibly causing high voltage locally (R2.3) is questionable.

Regarding R2.1.1 & R2.1.2, it should also reference Interconnection Agreements (IA) limits since some IBR facilities have both solar and battery storage with an IA limit less than the aggregate sum.

Regarding R2.1.1 and R2.1.2, the idea that IBR Facility Power Plant Controllers operate to apparent power limits, is not in line with normal practices. Most PPC interfaces do not provide an apparent power reading or control function option. PPCs communicate separate MW and MVAR setpoints to all the of the site IBR Units and they follow or provide as capable the MWs and deliver MVARs up to the inverter reactive power limit.

Southern Company recommends changing wording to:

R2.1.1:Continue to deliver the predisturbance level of active power or available active power, whichever is less, and continue to deliver active powe r and reactive power up to its reactive power limit.

R2.1.2:If the IBR cannot deliver both active and reactive power due to a current or reactive power limit, when the applicable voltage is below 95% a nd still within the Continuous Operation Region, then preference shall be given to active or reactive power according to requirements specified by t he Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

R2.1.2 discusses giving preference to either active or reactive power based on requirements specified by transmission entities. There is some concern that this could be interpreted as a fluid preference that could require IBRs to actively configure active vs reactive capabilities.

Regarding R2.3, what happens if TOP has several lines down for maintenance in the area, which causes the part of the system the IBR facility is located, go from a strong system to a weak system?

R2.4 does not take into consideration other dynamic system conditions as a result of the fault and the effects on the PPC during a fault recovery. An example of this is Primary Frequency Response due to system frequency excursions during fault recovery. The active power recovery may be reduced or frozen during an underfrequency event while an IBR Resource is in recovery, thereby extending the time of the recovery.

R2 specifies performance for continuous and mandatory operation region, but not for permissive operation region. The performance during permissive operation region is in Attachment 1. Performance for all regions should be in Requirement R2.

Regarding R2.1.1, the first part, where IBR is required to continue to deliver the pre-disturbance level of active power or available active power, whichever is less is fine. However, the second part (and continue to deliver active power and reactive power up to its apparent power limit) is conflicting with the first part of this requirement. If the IBR plant's available active power was 50% of nameplate rating due availability of wind, solar irradiance, etc., then the second part of the requirement is stating that plant is required to produce reactive power to its apparent power limit given its available active power equal to 50% of nameplate rating. This is not correct.

In regard to R2.1, the clause 7.2.2.2 of the IEEE Std 2800 includes an exception when negative-sequence voltage is higher than certain threshold for a given time duration. Why the SDT not include this exception in the PRC-029?

In regard to R2.2, it appears the intent is to require that inject balanced current, during symmetrical faults, and unbalanced current during asymmetrical faults. However, the language is confusing. First, there is no plant level voltage regulation during a fault condition. Second, during unbalanced faults, what does a voltage regulation mean? One option is replace both Part 2.2.1 and Part 2.2.2 with following: The IBR shall inject current based on voltage deviation on high-side of main power transformer and as specified by the TP, PC, RC, or TOP.

In regard to R2.3,this requirement is confusing. Table 1 and 2 in Attachment 1 includes both low- and high-voltage thresholds. One meaning could be that the IBR shall not cause voltage to exceed LVRT threshold for a specified time duration. The true meaning is unclear. Is it correct that the intent is to focus on HVRT thresholds and time duration? The time duration for voltage > 1.2 per unit is not specified. Does this mean that IBR shall not cause overvoltage > 1.2 per unit whatsoever? If so, it needs to be written clearly.

In regard toR2.5, if there is no expectation for IBR to ride-through disturbance outside of no-trip zone, then there is no need for this requirement. For example, if voltage is zero for greater than specified time duration in Tables 1 and 2, say 1 second, then what is the point in staying connected and feeding into fault unless there is a risk of equipment damage? Additionally, there is no such expectation for frequency ride-through requirement R4.

R2.5 is not practical for the GO to determine where every individual piece of equipment would be damaged. There is no need to require tripping just before equipment damage if IEEE 2800 is guidance for equipment manufacturers.

In regard to Attachment 1:

1. There is no mention of continuous, mandatory, or permissive operation region in tables 1 and 2. Consider adding a column in tables 1 and 2 to show these operation regions.
2. For Table 1 and 2:
    - ≥1.20 should be >1.2

- ≥1.1 should be >1.1
- ≥1.05 should be >1.5

3. In IEEE Std 2800, the cumulative ride-through duration of 1800 second when voltage is > 1.05 is applicable to all nominal voltages except for 500kV nominal operating voltage. For 500kV nominal operating voltage, the equipment rated to 550kV (1.10 per unit) is available per ANSI C84.1. In IEEE Std 2800, see Note 1 under Table 12. Consider clarifying this in the PRC-029.
4. Note 7: A time window of 10-second is mentioned. However, when V>1.05, the ride-through duration is 1800 second, which is over a 3600-second time window in IEEE 2800.
5. Note 10: The purpose of current blocking in IEEE 2800 was not to protect the equipment but to rather to avoid tripping due to consequences of injecting current and hence, failure of ride-through.
6. Figures 1 & 2: why does the X-axis start at 0.1 second and not zero?

Finally, Southern Company supports EEI and NAGF comments.

Thank you for your comments

Measures (events): The evidence of compliance for disturbance monitoring that are associated with voltage and frequency excursions that were System disturbances and would be identified for analysis or another trigger by an applicable entity within draft PRC-030. Evidence of disturbance monitoring of IBR associated with those disturbances would be triggered by compliance under the requirements for PRC-030.

Measures (data): The team agrees and the measures for R1 through R3 have been adjusted to include design/capability based requirements as well as the demonstration of performance during disturbances.

Attachment 1: The team agrees and has made changes to the tables and figures to include clear references to the operation regions. Explanation of the permissive operation region was added to Requirement 2. The definitions for the regions were also removed.

Exemptions: Voltage requirements R1 and R2 may have the capability for exemption of an known hardware-based limitation as detailed in the Implementation and Requirement R4 (Previous R6). The requirements include the flexibility for the IBR response based on the communication between the GO and the TP/PC.

R2 – use of reactive power: The team agrees that changes to clarify reaction power support in 2.1 was needed and made some adjustments to specify reactive power. This was broken into 2.1.1 and 2.1.2.

R2- -dynamic switching: Requirement 2.1.3 (previously 2.1.2) does not require dynamic switching between these two modes of operation. However, if that capability already exists, the operating mode would need to be specified by the TP, PC, RC, or TOP.

General operation expectations: IBR must adhere to ride through requirements and any direction as specified by their TOP(s) under any system operating condition.

R2 – clarification on frequency and voltage excursions: Requirement 2.5 (previously 2.4) now includes a footnote to add an exception for IBR response during a frequency excursion. Language was also changed to voltage/frequency excursions throughout to add clarity on this point. **Permissive Opertion Region:** The team added new 2.3 to include performance requirements during the permissive operation region. **R2 – use of reactive power**: Language was clarified in 2.1.1 and new 2.1.2 to address apparent vs reactive power limits per above. **General operation expectations**: Any additional operation for specific conditions such as the negative sequence overvoltage conditions, should be directed by the TOP as needed. **R2 General operation expectations**: Requirement 2.2. was clarified to allow for operating instructions from the TOP/PC/RC/TP to be followed but only if specified. Further usage of AVR was removed from the requirement. **R2 overvoltage clarification**: Revisions were made to R2.4 (previously 2.3) to specify exceedances above the high voltage thresholds. **R2.5:** The team has removed the previous 2.5. **Attachment 1 - corrections**: Attachment 1 tables and figures have been adjusted to correct some values and to include clear references to the operation regions. **Attachment 1 clarification on 500kv:** Attachment 1 sets the minimum expectation for operation regardless of voltage class. Expanding the no trip zone for 500kV may still be done based on the system need. **Attachment 1 clarification of accumulation Note**: The 10-second window is not used to define the thresholds within a particular operating region but it's the reset of the accumulation of the excursions into the mandatory and permissive operating regions. **Attachment 1 revision to Previous Note 10:** The team agrees on the details of note 10 in attachment 1 and have made this a new requirement in R2.3. **Attachment 1 - corrections**: The figures have been adjusted and now starts as zero.

In 2.1.1 the "apparent power limit" is what is capable during the System disturbance correct? What is the "applicable voltage" to determine 95% in 2.1.2 (and why is per unit not used)? Where are the "requirements specified" by the TP/PC/RC/TOP and how does a GO or TO determine which one to use? If in the Planning world, the requirements should be specified in the TPL Standards. It is unclear what actions a TO/GO will take and be consistently applied. Since this is an event driven compliance review in the Operations Assessment time horizon, why would a TP or PC provide preference for active or reactive power in that timeframe? In a response study by the TP/PC, perhaps guidance on preference could be provided but it is unclear and NOT required in TPL Standards to this point. Clarity between the Tables and Figures in Attachment one needs provided to avoid confusion.	

Just to be clear, It appears that any new units after the effective date of this Standard have to meet all the criteria. Do the existing units with limitations have six months after the effective date of Standard to submit equipment limitations. With PRC-024-3 and PRC-024-2 already having a Requirement in place that requires limitations to be provided to the TP/PC and the industry already leaning on IRO-010 and TOP-003 for notifications, why is there a need to add an additional 6 months for Requirement R6? The RC already has communication capability with GOs.

Response	
Thank you for your comments. **R2 – use of reactive power**: The team agrees and has clarified the language in 2.1. to use reactive power limit instead of “apparent power”. Also, the reference to “applicable voltage” was changed to “voltage”. The parent requirement states which voltage already. The team has also changed the 95% to per unit values to be consistent throughout the standard. **R2 – dynamic switching** The language of 2.1 and 2.2 was changed to clarify default preferences unless preference for active/reactive power support was established by the TP/PC/RC/TOP and based on system needs. Requirements do not require dynamic switching between these two modes of operation. A footnote was added that clarified that if a operation mode was specified by the TP/PC/RC/TOP, then that operation mode shall be followed instead. **Attachment 1 – corrections**: Attachment 1 tables and figures have been revised to clarify the operating regions and no-trip zones. **Implementation Plan**: The additional six month time frame is provided during the implementation plan for R4 (previous R6) to allow entities to verify documentation and cross check with the criteria within the new Standard. The required data to provide to qualify for an exemption must provide documentation stating which aspect of the voltage ride-through requirements cannot be met. Additionally, the criteria within PRC-029 is not one-to-one with criteria within PRC-024-4.

R1:

R1 should be revised to directly clarify, or include a footnote to clarify, the statement “that each IBR remains electrically connected and continues to exchange current” with “electrically connected, i.e., shall not trip, and continue to exchange current, i.e., shall not enter momentary cessation” that was provided in the Technical Rationale.

Attachment 1:

There is a discrepancy between the definition of the Term “Mandatory Operating Region” which states “≤ 1.2 per unit” and Table 1/Figure 1 or Table 2/Figure 2 which state “≥1.200” per unit “N/A”. Please clarify if Table 1/Figure 1 and Table 2/Figure 2 should state “>1200” or if the definition of the Term “Mandatory Operating Region” should state “<1.2 per unit”.

Please clarify Figure 1 and Figure 2 to clearly show the “Continuous Operating Region”, “Mandatory Operating Region”, and “Permissive Operating Region”, along with requirements beyond 10 seconds.

Please Clarify “9. The IBR may trip for more than four deviations of the applicable voltage….” In attachment 1.

R2.5:

This requirement is beyond the purpose of the standard, which is to establish Frequency and Voltage Ride-through Requirements for Inverter - Based Generating Resources and should be removed.

Comment	
On behalf of the SERC Generator Working Group: R2.4 does not take into consideration other dynamic system conditions as a result of the fault and the effects they can have on the PPC during a fault recovery. An example of this is Primary Frequency Response due to system frequency excursions during fault recovery. The active power recovery may be reduced or frozen during an over-frequency event while an IBR Resource is in recovery, thereby extending the time of the full recovery. R2.5: It is not practical for the GO to determine where every individual piece of equipment would be damaged, nor should the GO be required to subject equipment to failure by trying to identify that point, run to it, and risk damaging it.

EEI agrees with most of the proposed language in Requirements R1, R2 and R6; however, the phrase "of an applicable IBR" should be removed. Applicability is defined in the Applicability Section of the standard and anything more is unnecessary and redundant. EEI also does not support Requirement R2, subpart 2.5 because it contains unneeded language, which adds confusion and implies that GOs can only trip outside of the trip zone if their equipment might become damaged. This has never been an obligation for synchronous generators, and we do not agree that this should be an obligation for IBRs. If NERC or the SDT believe that the no-trip zone needs to be expanded, they should justify such a change and present it for industry review and comment, otherwise, Requirement R2, subpart 2.5 should be deleted. And while we support Requirement R6 and the provisions to notify PCs, TPs and RC about equipment limitations that would prevent an applicable IBR from meeting ride-through requirements as detailed in Requirements R1 and R2, the Requirement does not go far enough because there may be technical reasons why an applicable IBR is unable to meet Requirement R3 through R5, as well. To address this concern, R6 should be expanded to include Requirement R1 through R5.

Minnesota Power (MP) agrees with the MRO NSRF's comments on R1, R2, and R6, and the associated graphics from Attachment 1.

Additionally, MP notes that language from the Technical Rationale document specifies that R2.1, R2.3, and R2.4 are intended to apply when system conditions return to the Continuous Operation Region from the Mandatory or Permissive Operation regions. This should be specified in the standard.

Finally, MP proposes the following language changes to eliminate any possible uncertainty:

Section 2.1: "current or apparent power limit" to "current limit or apparent power limit"

Section 2.4: “pre-disturbance or available level” to “pre-disturbance level or available level, whichever is lesser”

EEI agrees with most of the proposed language in Requirements R1, R2 and R6; however, the phrase "of an applicable IBR" should be removed. Applicability is defined in the Applicability Section of the standard and anything more is unnecessary and redundant. EEI also does not support Requirement R2, subpart 2.5 because it contains unneeded language, which adds confusion and implies that GOs can only trip outside of the trip zone if their equipment might become damaged. This has never been an obligation for synchronous generators, and we do not agree that this should be an obligation for IBRs. If NERC or the SDT believe that the no-trip zone needs to be expanded, they should justify such a change and present it for industry review and comment, otherwise, Requirement R2, subpart 2.5 should be deleted. And while we support Requirement R6 and the provisions to notify PCs, TPs and RC about equipment limitations that would prevent an applicable IBR from meeting ride-through requirements as detailed in Requirements R1 and R2, the Requirement does not go far enough because there may be technical reasons why an applicable IBR is unable to meet Requirement R3 through R5, as well. To address this concern, R6 should be expanded to include Requirement R1 through R5.

Response	
Thank you for your comments. **Terminology:** The team has removed the word "applicable" and include a reference to the applicability section of the Standard. Any IBR that cannot meet voltage ride-through requirements, and may need to trip within the no-trip zone to protect equipment, would be covered under the documented equipment limitations as covered within Requirement R4 (previous R6).	

Equipment protection: Any IBR that cannot meet voltage ride-through requirements, and may need to trip within the no-trip zone to protect equipment, would be covered under the documented equipment limitations as covered within Requirement R4.
Previous R2.5: The team agrees with removing requirements on operation outside the no-trip zone and has removed R2.5.
Excemptions: The scope of allowable exemptions within Requirement R4 Previous R6 is consistent with the regulatory directives of Order No. 901. Requirement R3 (Previous R4) cannot apply. Previous Requirement R3 and R5 has also been removed.
Previous R5: Previous Requirement R5 has been removed and added as an exemption to Requirement R1.

R1/R2: Recommend that Attachment 1 have a chart to include the Continuous Operation Region, Mandatory Operation Region, and Permissive Operation Region or have those regions specified on existing Voltage Ride -through Requirements Figure 1 and Figure 2.

Requests the SDT review and align the data in **Attachment 1** so the data in Tables 1 and 2 aligns with what is shown in Figures 1 and 2. Currently, the graphs in Figures 1 and 2 do not match what is indicated in the Tables.

Comment	

Duke Energy recommends the implementation of EEI and NAGF comments.

Duke Energy does not agree that the language is clear. The language seems close to but not completely in alignment with IEEE 2800-2022. It is not clear that the -029 requirements align with the IEEE 2800 requirements, especially given that most would want to comply with both. Many times the Continuous Operation Region is associated with the voltage regulation function and the Mandatory Operation Region is associated with LVRT. This separation is not maintained in various statements within 2.1 and 2.2. It is not clear how the plant or inverters can be configured to operate as specified in R2. Overall the language seems overly prescriptive and the DT may consider less specificity and possibly even a reference to IEEE 2800 rather than trying to restate it. Voltage regulation functions are typically based on POI voltage while LVRT functions are based on inverter terminal voltage. It is not clear that the requirements recognize this difference. Also, there are multiple references in R1 and R2 to Attachment 1 containing or representing the various Regions, but they are not graphically represented. The DT may consider revising the Att. 1 Figures (and moving the vertical axis crossing to 0.1 sec). tt seems the industry has often misinterpreted the area outside of the No-trip Zone as an area where the plant must trip. The DT may consider specifically addressing and emphasizing in the text and on the Figure that the plant is not required to trip in this area. For example, it may be labeled May Trip Zone. To that end, it would also be helpful for the GO to submit equipment ride through limits. That is the actual equipment limits, not the various voltage protection settings. With that information, plants would have the bases to provide the maximum ride-through beyond the No-Trip Zone and still not exceed plant main and BOP equipment limits.

Response	
Thank you for your comments. **Outside references:** Requirements within the NERC PRC-029 address the scope of the SAR and draw from IEEE2800 but are mandatory and enforceable requirements; in contrast to IEEE2800. NERC Standards cannot refer to outside sources for the purposes of requirement language, per the Rules of Procedure. **R2:** Language was clarified in 2.1.1 and new 2.1.2 to address apparent vs reactive power limits per above and other comments. **Attachment 1:** Figures and tables in attachment 1 have been updated to include the operation regions. The figures have been updated to cross at 0 seconds. The area outside of the no-trip zone is now labeled “may trip or may ride-through zone”.	
Christine Kane - WEC Energy Group, Inc. - 3, Group Name WEC Energy Group	
Answer	No
Document Name	
Comment	

WEC Energy Group does not agree that the language in R1, R2, and R6 is clear for the following reasons:

R1.:

WEC disagrees with text "… shall ensure that each IBR remains connected…". How else can an entity "ensure" to remain connected other than to set voltage protection outside the no-trip zone? The requirement must state what must be done. Based on Attachment 1, this is clearly voltage protection settings function so R1 should try and match PRC-024 R1. Otherwise, this requirement is open-ended as IBR could potentially be disconnected due to other reasons and the entity will be deemed non-compliant.

The "main power transformer" should be defined in a footnote, similar to what's proposed in PRC-028. It's unclear if main power transformer represents individual IBR step-up transformer or the site step-up transformer.

The phrase "exchange current" should be listed and defined in Terms section. Confusion exists in understanding if "exchange current" applies to BESS while charging, real/reactive current components, or something else. An exception should be added to exclude BESS from the PRC-029 requirements while charging.

WEC also disagrees with M1. The only means for an entity to "ensure IBR remains connected" is to set voltage protection and voltage ride-through protection according to Attachment 1. Making sure that the settings are applied should be the measure. The "recorded data" is an inconclusive statement. If the entity applied settings outside the no-trip zone and it still tripped, which could be for various other reasons, does that mean then entity is non-compliant? What needs to be recorded and where? Does this measure now mandate additional recording capabilities in addition to PRC-030? (Same comment applies to M2, M3, and M4).

R2.:

WEC disagrees with text "…. shall ensure that each IBR remains connected…". The requirement must state what TO and GO must do. Otherwise, this requirement is open-ended without a measurable statement.

2.1: Term "Continuous Operating Region" as defined conflicts with equipment design limitations. Power transformers may not be designed for continuous operations from 0.9 and 1.1 pu. Please refer to IEEE C57.12.00, sections 4.1.6.1, 4.1.6.2 and 5.5, and ANSI C84.1. Without some specific maximum time applied, the continuous operating region will conflict with equipment limitations. Due to this wide range, entities will simply take exception to R2 and R2 will not have any positive benefit for BES reliability. There is a reason PRC-024-3 has a 4 second limit. This limitation should clearly be introduced in PRC-029. Finally, the proposed "Continuous Operating Region" range conflicts with acceptable continuous operating ranges by Transmission Operators. Many Transmission Operators classify continuous operating range from 0.95 and 1.05 pu, and consider voltage ranges from 0.9 to 0.95 pu and 1.05 to 1.1 pu as abnormal voltage ranges.

2.1.2: There is nothing that governs a TP, PC, RC or TO to specify active/reactive power prioritization.

2.3: This requirement is inconclusive. The requirement must state what TO and GO must do. Otherwise, this requirement is open-ended without a measurable statement. Something regarding "IBR gain" was briefly mentioned during the PRC-029 webinar. A wide spectrum of gains and tuning parameters exist within the IBR controls. The requirement must state what parameters are to be addressed and how to set them. Gains and tuning parameters are covered in MOD-026 and MOD-027 standards and shall not be introduced here. Another potential issue could be with AVR function within the power plant controller. AVR/PPC failure could potentially cause higher voltage outputs. AVR failure, or any equipment failure, should not be the criteria to violate the standard. WEC recommends this requirement be removed.

2.4: WEC owns and operates multiple IBR sites and it is in our experience that the limitation to the 1 second requirement will come from the power plant controller. The ramp rate capabilities of the power plant controllers are far slower than inverter ramp rates and are typically in minutes range. WEC also had an instance where the power plant controller ramp rate increase was denied by the Transmission Operator/Planner.

2.5: This requirement contradicts the meaning of established No-Trip zone. If the No-Trip zone is inadequate, then SDT should evaluate and adjust it accordingly. In addition, having protection settings applied right at the equipment damage curve is not a standard protection practice, especially if events such as voltage excursions have a cumulative effect on insulation degradation that could lead to premature failures. WEC recommends this requirement be removed.

R6.: This requirement should include and cover equipment limitations associated with R3, R4, and R5.

Response

Thank you for your comments.
Performance and capability: Assigned regulatory directives from Order 901 to this team necessitate the inclusion of performance-based requirements that an entity would be required to demonstrate using actual measured data. Additional language has been added to require entities to demonstrate their capability to meet the requirements; including the protection and controller settings. Additional clarity on what recorded data has been included in the measures to align with new disturbance monitoring data requirements in PRC-028. There are many causes of ride-through failure beyond just over- and undervoltage protection settings that are encompassed within PRC-029.
MPT: The team has added a footnote as suggested.
Terminology: BESS are applicable to ride-through if they are electrically connected at the time of a fault. The phrase "continue to exchange current" is consistent if a BESS is charging prior to a fault and providing voltage support after the fault. However, the team agrees that a definition for Ride-through is preferable and has replaced usage of "continue to exchange current".

R2: R2 wording is consistent with expectations for performance-based requirements and how a GO or TO plant/facilities must performance during a voltage excursion.
Attachment 1: Tables and Figures in Attachment 1 have been revised to add clarity on the operation regions. The range of values in row #4 of Tables 1 and 2 to clarify the continuous operation region. Language has been added to R2 to clarify that if such specification has provided to the GO/TO that the GO/TO shall follow those specifications.
Measurement: PRC-029 is not an equipment setting standard. Both the SAR and the assigned Order 901 direct the team to include capability and performance-based requirements for ride-through. The criteria does not cover any equipment failure during a disturbance.
R2.5 (previously 2.4): R2.5 requires that a GO/TO follow any RC/PC/TOP/TP specified operation in response to a voltage excursion, including a specified ramping time. For legacy equipment, R6 covers any known regulatory or hardware-based limation.
Previous Requirement R2.5 has been removed.
Exemptions: The scope of allowable exemptions within R4 (previously R6) is consistent with the regulatory directives of Order No. 901. Frequency or phase-jump requirements cannot apply for exemption. New IBR cannot apply for exemption. This is consistent with the ordered directives.
Previous R3: Previous requirement R3 has been removed.
Previous R5: Previous Requirement R5 has been removed and added as an exemption to Requirement R1.

Comment

The NAGF provides the following comments:

a. Requirement R1 - the NAGF request clarification on the term "exchange" being used in the proposed language for Requirement R1.

b. Requirement R2 – the Terms section identified the terms: Continuous Operating Region, Mandatory Operating Region, and Permissive Operating Region but these terms are not specifically referenced in the tables for Attachment 1. The NAGF believes that the regions should be included in Attachment 1 for clarity.

c. The PRC-029-1 draft remains silent on the network condition, so it is unclear how to model the transmission system to test compliance with these requirements. One option is to assume that the transmission grid at the point of interconnection may be modeled as an ideal voltage source. Another option is to model the transmission grid as a voltage with a Thevenin impedance based on a short circuit ratio (minimum and maximum), which would consider the network condition at the point of interconnection. The NAGF requests clarity on this topic regarding testing compliance.

d. The requirement stated in R2.4 for IBRs to restore active power to the pre-disturbance or available level within 1.0 second when voltage at high-side of the main power transformer returns to Continuous Operation Region. Based on the TO studies or requirements, it is recommended that flexibility be allowed in the recovery time requirement. For example, if studies indicate that a slower ramp-rate and/or pause in the power ramp-up is beneficial then that should be allowed. The NAGF also recommends an active power recovery threshold of 90% of pre-disturbance level to account for measurement and IBR unit control uncertainties and tolerances.

e. The requirement stated in R2.1.1 must allow IBRs apparent power to be limited if the voltage is outside the normal operating range and the IBR units have reached their maximum current limit.

Terminology: The phrase "continue to exchange current" is consistent if a BESS is charging prior to a fault and providing voltage support after the fault. However, the team agrees that a definition for Ride-through is preferable and has replaced usage of "continue to exchange current".
Attachment 1: Tables and Figures in Attachment 1 have been revised to add clarity on the operation regions. The range of values in row #4 of Tables 1 and 2 to clarify the continuous operation region.
Testing Conditions: The drafting team declines to address testing system conditions used to evaluate capability.
R2.5 (previous R2.4): R2.5 requires that a GO/TO follow any RC/PC/TOP/TP specified operation in response to a voltage excursion, including a specified ramping time. For legacy equipment, R6 covers any known regulatory or hardware-based limation.
R2 – use of reactive power: The team agrees that changes to clarify reaction power support in 2.1 was needed and made some adjustments to specify reactive power. This was broken into 2.1.1 and 2.1.2.
R2- -dynamic switching: Requirement 2.1.3 (previously 2.1.2) does not require dynamic switching between these two modes of operation. However, if that capability already exists, the operating mode would need to be specified by the TP, PC, RC, or TOP.

Sean Bodkin - Dominion - Dominion Resources, Inc. - 6, Group Name Dominion

Answer	No
Document Name	

Comment

Dominion Energy supports EEI comments. In addition, Dominion Enetgy has the following comments:

R2, Section 2.1 refers to the Continuous Opera**tion** Region as specified in Attachment 1; however the definition of Continuous Opera**ting** Region at the beginning of the standard is only applicable to voltages, measured at the high-side of the MPT that are between 0.9 PU and 1.1 PU. Does this mean that the definition of Continuous Operation Region is different from Continuous Operating Region? Or is the intent the same as the definition at the front of the standard and the “tion” should be changed to “ting”? Please clarify. This disconnect also exists in R2 and in R2.2.

R2, Section 2.1.2 and R2.4 both allude to a requirement for either the Transmission Planner, Planning Coordinator, Reliability Coordinator or Transmission Operator to provide a preference of active or reactive power if an IBR cannot deliver both due to a current or apparent power limit. The standard is not applicable to any of these listed entities and thus puts an administrative burden on the Generator Owner to contact each to determine a preference. Four entities determining the preference is three too many. A new requirement should be written directing one of the four entities to be the lead point of contact for the GO. Additionally, the standard should specify that the lead entity charged with determining the preference of active of reactive power should communicate the preference a minimum of 6 months prior to the effective date for the GO. The GO cannot put controls in place and ensure compliance until the TP, PC, RC or TOP has documented the compliance requirement.

R6, Section 6.2 is confusing since the Technical Rationale and FERC Order 901 Directives, Paragraph 193 states that “when the existing equipment is replaced, the exemption would no longer apply, and the new equipment must comply with the appropriate IBR performance requirements”. Further, FAC-002-5 considers replacement of inverters / converters or Power Plant Controllers to be “qualified changes” and would require a study

before implementation. This section seems to be an unnecessary administrative step, since the FAC-002 process would require submittal of "as-built settings" for the qualified change study.

Response	
Thank you for your comment. **Attachment 1:** The definitions for the operation regions have been removed. Additionally, the tables and figures in Attachment 1 have been updated for consistency. Also the continuous operation region have been labeled within the tables and figures. **Requirement R2:** R2 subparts require the GO/TO to follow provided TP/PC/RC/TOP restoration time or active power recovery threshold requirements – if different than default values in the sub-requirement. R2 does not intend that values other than the default values must be specified, only that performance for the plant/facility will be evaluated in accordance with those values if provided. Language has been added to M2 to clarify what evidence is expected if the TP/PC/RC/TOP provide other performance requirements. **Limitations:** Language has been added in R4 (previously R6) has been clarified that such a replacement would remove the limitation; consistent with the FERC Order 901. This is retained in PRC-029 to be consistent with new performance based requirements established in PRC-029 and the Order.

1 The language "continues to exchange current" in R1 is not clear, please explain. 2 OEMs have not been forthcoming with operating limit data/equipment trip capabilities. Due to the lack of information from OEMs, we are concerned that the following language in R2.5 will be difficult to comply with: "Each IBR shall only trip *to prevent equipment damage*, when the voltage at the high-side of the main power transformer is outside of the no-trip zone as specified in Attachment 1". 3 The SDT should consider equipment where the manufacturer is not able to provide the limits where equipment damage can occur. For legacy equipment, this information may not be available or may be available at a very high cost to the GO. These scenarios should be included as limitations. 4· Charts in Attachment 1 should be updated to graphically show the performance regions

Rhonda Jones - Invenergy LLC - 5	
Answer	No
Document Name	
Comment	
No, Invenergy disagrees that the language within PRC-029-1 requirements R1, R2, and R6 is clear. Specifically, we offer the below comments regarding these requirements: **R2.1.1.**: As currently drafted, R2.1.1. seems to ignore the changes to apparent power limits that could occur during a System disturbance. We recommended the following language: "R2.1.1. Continue to deliver the pre-disturbance level of active power or available active power, whichever is less, and continue to deliver active power and reactive power up to *the total aggregated current rating of the IBR Units in the plant*." **R2.1.2.**: Invenergy is concerned that the language in R2.1.2. regarding the active power or reactive power preferences of TPs, PCs, RCs, or TOPs may lead to increased confusion and unintended consequences. In its place, we recommend adopting something similar to the p/q/v capability curve demonstrated in Figure 8 of IEEE 2800-2022. **R2.3.**: It is unclear to us what R2.3. is requiring. Please clarify or remove. **R2.4.**: The ramp rate should be based on System needs; in weaker grid conditions such rapid ramping of active power could lead to power-oscillations or small-signal instability.	

R2.5.: This requirement is not auditable and is beyond the scope of the standard, which is to establish certain minimum ride-through requirements. As written, R2.5. suggests GOs should push their equipment as near to its breaking point as possible, even after the minimum ride-through requirements have been met. Thus, we ask R2.5. and similar statements throughout the draft standard be removed.

R6.: Given the technical limitations of many legacy IBRs, R6 must be thoroughly amended to allow exemptions for limitations related to frequency, rate-of-change-of-frequency, and phase angle change ride-through requirements. Consider that there are a range of possible concerns with legacy equipment and equipment already in commercial operation. At one end of the spectrum there exists legacy equipment where the manufacturer is no longer in business, or no longer produces the given IBR unit technology. In these cases, it is often infeasible to either truly document all aspects of the equipment limitations or to attempt to make any software or hardware modifications. At the other end of the spectrum there exists equipment that has been installed in recent years where software modifications may be enough to bring the units into compliance with the proposed requirements, after proper due-diligence and analyses have been performed. In between these two ends of the spectrum there is a range of possibilities.

Where available, software-only modifications are the most likely to yield meaningful reliability improvements where they are most needed while being technically and financially feasible for legacy IBRs to deploy. Indeed, the vast majority of performance issues identified with solar PV resources involved in the 2021 and 2022 Odessa disturbances (and other solar PV resources with the same inverter make/model that were not involved in the Odessa events) are being addressed in ERCOT with software-based modifications (see https://www.ercot.com/files/docs/2024/03/06/Odessa%20Update_03082024.pptx).

Thus, R6 needs a thorough rewrite to give due consideration, and acknowledgement, to these various nuances. Invenergy proposes the below modifications:

R6. Each Generator Owner and Transmission Owner with an applicable IBR that is in commercial operation prior to the effective date of this standard that is unable to meet the ride-through performance requirements detailed in Requirements R1 through R5 shall document the limitation, communicate each equipment limitation to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s), and provide a plan for making reasonable software and settings modifications that reduce or remove the limitation, if available and feasible.

6.1. Each Generator Owner and Transmission Owner shall include in its documentation, in each case as is available or can be reasonably obtained:

6.1.1. Identifying information of the IBR (name, facility #, other)

6.1.2. Current ride-through capability

6.1.3. Known ride-through limitations and documentation of such limitations

6.1.4. Reasonable software and settings modifications

6.1.5. Expected post-modification ride-through capability and documentation of any expected remaining limitations following implementation of such modifications

6.1.6. A schedule for implementing the modifications

6.2. Each Generator Owner and Transmission Owner with a previously communicated equipment limitation that makes a modification that reduces or removes such limitation shall document and communicate such modification to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s) within 30 days of the modification.

To supplement the language regarding reasonable software and settings modifications, the following language could be added to the Technical Rationale: Reasonable software and settings modifications are any available technically feasible modifications involving only software, firmware, settings, or parameterization changes that do not require physical modification of the IBR equipment and are reasonably priced.

Response

Thank you for your comments.
R2.1.1: Language was clarified in 2.1.2 (previously 2.1.1) to address apparent vs reactive power limits per above and other comments.
R2.1.2: R2.1.3 (previously R2.1.2) has been clarified that the GO/TO shall follow provided TP/PC/RC/TOP requirements if those are provided. The team has clarified that the GO/TO shall follow provided TP/PC/RC/TOP requirements only if those are provided.
R2.3: Language has been added to 2.4 (previously 2.3) to specify response as voltage recovers to the continuous operation region.
R2.4: R2.5 (previously R2.4) does not intend that values other than the default values must be specified, only that performance for the plant/facility will be evaluated in accordance with those values if provided. Language has been added to M2 to clarify what evidence is expected if the TP/PC/RC/TOP provide other performance requirements.
R2.5: What was previously R2.5 has been removed.
R4 (previously R6): The scope of allowable exemptions within R4 is consistent with the regulatory directives of Order No. 901. Frequency or phase-jump requirements cannot apply for exemption. Software-limitation also cannot apply for exemption. This is consistent with the ordered directives.

Colin Chilcoat - Invenergy LLC - 6	
Answer	No
Document Name	
Comment	

No, Invenergy disagrees that the language within PRC-029-1 requirements R1, R2, and R6 is clear. Specifically, we offer the below comments regarding these requirements:

R2.1.1.: As currently drafted, R2.1.1. seems to ignore the changes to apparent power limits that could occur during a System disturbance. We recommended the following language:

"R2.1.1. Continue to deliver the pre-disturbance level of active power or available active power, whichever is less, and continue to deliver active power and reactive power up to *the total aggregated current rating of the IBR Units in the plant*."

R2.1.2.: Invenergy is concerned that the language in R2.1.2. regarding the active power or reactive power preferences of TPs, PCs, RCs, or TOPs may lead to increased confusion and unintended consequences. In its place, we recommend adopting something similar to the p/q/v capability curve demonstrated in Figure 8 of IEEE 2800-2022.

R2.3.: It is unclear to us what R2.3. is requiring. Please clarify or remove.

R2.4.: The ramp rate should be based on System needs; in weaker grid conditions such rapid ramping of active power could lead to power-oscillations or small-signal instability.

R2.5.: This requirement is not auditable and is beyond the scope of the standard, which is to establish certain minimum ride-through requirements. As written, R2.5. suggests GOs should push their equipment as near to its breaking point as possible, even after the minimum ride-through requirements have been met. Thus, we ask R2.5. and similar statements throughout the draft standard be removed.

R6.: Given the technical limitations of many legacy IBRs, R6 must be thoroughly amended to allow exemptions for limitations related to frequency, rate-of-change-of-frequency, and phase angle change ride-through requirements. Consider that there are a range of possible concerns with legacy equipment and equipment already in commercial operation. At one end of the spectrum there exists legacy equipment where the manufacturer is no longer in business, or no longer produces the given IBR unit technology. In these cases, it is often infeasible to either truly document all aspects of the equipment limitations or to attempt to make any software or hardware modifications. At the other end of the spectrum there exists equipment that has been installed in recent years where software modifications may be enough to bring the units into compliance with the proposed requirements, after proper due-diligence and analyses have been performed. In between these two ends of the spectrum there is a range of possibilities.

Where available, software-only modifications are the most likely to yield meaningful reliability improvements where they are most needed while being technically and financially feasible for legacy IBRs to deploy. Indeed, the vast majority of performance issues identified with solar PV resources involved in the 2021 and 2022 Odessa disturbances (and other solar PV resources with the same inverter make/model that were not involved in the Odessa events) are being addressed in ERCOT with software-based modifications (see https://www.ercot.com/files/docs/2024/03/06/Odessa%20Update_03082024.pptx).

Thus, R6 needs a thorough rewrite to give due consideration, and acknowledgement, to these various nuances. Invenergy proposes the below modifications:

R6. Each Generator Owner and Transmission Owner with an applicable IBR that is in commercial operation prior to the effective date of this standard that is unable to meet the ride-through performance requirements detailed in Requirements R1 through R5 shall document the limitation, communicate each equipment limitation to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s), and provide a plan for making reasonable software and settings modifications that reduce or remove the limitation, if available and feasible.

6.1. Each Generator Owner and Transmission Owner shall include in its documentation, in each case as is available or can be reasonably obtained:

6.1.1. Identifying information of the IBR (name, facility #, other)

6.1.2. Current ride-through capability

6.1.3. Known ride-through limitations and documentation of such limitations

6.1.4. Reasonable software and settings modifications

6.1.5. Expected post-modification ride-through capability and documentation of any expected remaining limitations following implementation of such modifications

6.1.6. A schedule for implementing the modifications

6.2. Each Generator Owner and Transmission Owner with a previously communicated equipment limitation that makes a modification that reduces or removes such limitation shall document and communicate such modification to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s) within 30 days of the modification.

To supplement the language regarding reasonable software and settings modifications, the following language could be added to the Technical Rationale: Reasonable software and settings modifications are any available technically feasible modifications involving only software, firmware, settings, or parameterization changes that do not require physical modification of the IBR equipment and are reasonably priced.

Response

Thank you for your comments.
R2.1.1: Language was clarified in 2.1.2 (previously 2.1.1) to address apparent vs reactive power limits per above and other comments.
R2.1.2: R2.1.3 (previously R2.1.2) has been clarified that the GO/TO shall follow provided TP/PC/RC/TOP requirements if those are provided. The team has clarified that the GO/TO shall follow provided TP/PC/RC/TOP requirements only if those are provided.
R2.3: Language has been added to 2.4 (previously 2.3) to specify response as voltage recovers to the continuous operation region.
R2.4: R2.5 (previously R2.4) does not intend that values other than the default values must be specified, only that performance for the plant/facility will be evaluated in accordance with those values if provided. Language has been added to M2 to clarify what evidence is expected if the TP/PC/RC/TOP provide other performance requirements.
R2.5: What was previously R2.5 has been removed.
R4 (previously R6): The scope of allowable exemptions within R5 is consistent with the regulatory directives of Order No. 901. Frequency or phase-jump requirements cannot apply for exemption. Software-limitation also cannot apply for exemption. This is consistent with the ordered directives.

Comment	
A review of the data in Attachment 1 and Tables 1 and 2 should be performed so that they align. Currently, the graphs in Figures 1 and 2 do not match what is indicated in the Tables. We would recommend a part be added to the standard to directly address the Permissive Operating Region, similar to what is done in Part 2.1 (for Continuous Operation Region) and Part 2.2 (for Mandatory Operation Region) as, if left unaddressed, is unclear. For example, there should be some linkage between the body of the standard and Attachment 1, item 10. The following language is provided for consideration (*new* Part 2.3): **2.3** While voltage at the high-side of the main power transformer is within the Permissive Operation Region as specified in Attachment 1, an IBR may operate in current block mode only if necessary to protect the equipment. Otherwise, each IBR shall follow the requirements for the Mandatory Operation Region in Requirement R2.2.

Thank you for your comment. The tables and figures in Attachment 1 have been updated for consistency. The team agrees and has added a new requirement R2.3 for the permissive operation region.	
Ben Hammer - Western Area Power Administration - 1	
Answer	No
Document Name	
Comment	
Plese review and align the data in Attachement 1 so that data in Tables 1 & 2 align with Figures 1 & 2. Also, it is recommended a part be added to the standard to directly address the Permissive Operating Region, similar to what is done in Part 2.1 (for Continuous Operation Region) and Part 2.2 (for Mandatory Operation Region) as, if left unaddressed, is unclear. For example, there should be some linkage between the body of the standard and Attachment 1, item 10. See the following proposed language for consideration (*new* Part 2.3):	

2.3 While voltage at the high-side of the main power transformer is within the Permissive Operation Region as specified in Attachment 1, an IBR may operate in current block mode only if necessary to protect the equipment. Otherwise, each IBR shall follow the requirements for the Mandatory Operation Region in Requirement R2.2.

OPTION A.

Requirement R6 provides an overly broad exemption as written as the standard is silent as to what criteria must be met. Only notification to other reliability entities is required with no requirement to develop and implement a Corrective Action Plan. The SDT should consider:

- Develop more specific criteria as to what qualifies as an equipment limitation[1], OR
- Require exemptions be submitted to NERC and/or the Regional Entities for approval in order to qualify for the exemption.

OPTION B.

Leave R6 as written, apply R6 to R1 through R5.

it is recommended that there be no requirement to document limitations on legacy equipment and that this standard focuses on equipment brought into service after the implementation date.

R2: We agree with the present flexibility that some of the IBR VRT performance could be modified to meet the individual system needs by the applicable Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator. However, some clarity may be required on how this process is initiated and what type is evidence is required to demonstrate request is received and implemented. This may be an additional requirement assigned to the Transmission Planner. Each Transmission Planner, Planning Coordinator, and Transmission Operator that jointly specifies the following voltage ride-through performance requirements within their area(s) different than those specified under R2, shall make those requirements available to each associated applicable IBR Generator Owner and Transmission Owner

[1] *See Implementation Plan (page 4), i.e. "only those IBR that are unable to meet voltage ride-through requirements due to their inability to modify their coordinated protection and control settings may be considered for potential exemption." See Technical Rationale (page 9); i.e. specify which voltage band(s) and associated duration(s) cannot be satisfied or specific as to the number of cumulative voltage deviations within a ten-second time period that the equipment can ride-through if less than four… identify the specific equipment and explain the characteristic(s) of that equipment that prevent ride-through.*

Thank you for your comment. **Attachment 1:** Tables and Figures in Attachment 1 have been revised to add clarity on the operation regions. The range of values in row #4 of Tables 1 and 2 to clarify the continuous operation region. **R2.3 (permissive region):** The team agrees and has added a new requirement R2.3 for the permissive operation region. **R4 (previously R4):** The scope of allowable exemptions within R4 is consistent with the regulatory directives of Order No. 901. Frequency or phase-jump requirements cannot apply for exemption. New IBR cannot apply for exemption. This is consistent with the ordered directives. **Requirement R2** subparts require the GO/TO to follow provided TP/PC/RC/TOP restoration time or active power recovery threshold requirements – if different than default values in the sub-requirement. R2 does not intend that values other than the default values must be specified, only that performance for the plant/facility will be evaluated in accordance with those values if provided. Language has been added to M2 to clarify what evidence is expected if the TP/PC/RC/TOP provide other performance requirements.

Thank you for your comment. Coordination between PRC-029 and PRC-030 drafting teams have implemented changes to those drafts that triggers within PRC-030 to initiate an analysis will be evaluated against PRC-029 ride through criteria. PRC-029 established the criteria and PRC-030 includes requirements for conducting the analysis of performance after a disturbance. The compliance measures were revised from “actual recorded data” to “actual disturbance monitoring (i.e. Sequence of Event Recorder, Dynamic Disturbance Recorder, and Fault Recorder) data”. Additions were made to the requirements to require demonstration of IBR capability and the measures were updated to include capability-based evidence.

Comment	
Black Hills Corporation supports EEI's and NAGF's comments. Additionally, Black Hills Corporation has concerns regarding event-based "Measures" for Requirement R2, R3, R4 and R5 as GO will likely not have immediate knowledge of "System disturbance" or other transmission system events (transient overvoltage due to switching, frequency excursion, instantaneous positive sequence voltage phase angle changes) when they occur and data collection systems have a limited amount of storage capacity (i.e. data overwrite happens over time, in our case, data is retained for a rolling 12 months). If available data remains the "Measure" for demonstrating compliance, then consideration needs to be given to when and how GO are notified of an event, so data can be reviewed and archived for future demonstration of compliance.

- 2.1.2 refers to requirements specified by the TP, TOP, PC, RC. It is unclear what the expectation is if those requirements have not been defined.
- Is 2.2.2 is stating that the IBR shall maintain reactive power per default setpoints unless a new reactive setpoint has been requested or it's been requested to maintain a certain active power? Why wouldn't this be worded similarly to the sub-bullets in 2.1?
- 2.3: if the IBR is already responding to Mandatory or Permissive Operation regions (exceedances of Attachment 1 Table 1 or Table 2), how could it then cause an exceedance?
- R2.4   There is concern that the controls will be either unable to respond within the 1 second timeframe, or that the historical records to prove the response would not have the resolution to be meaningful.

- R 2.5: How would someone prove that an IBR tripped only to prevent equipment damage? This sub-bullet cannot be enforced.

Answer	No
Document Name	Proposed change to table Q2.PNG

Comment

The IESO recommends the following modifications to the text improve clarity or to better convey intent.

With regards to R1:

"…as specified in Attachment 1 unless **not doing so is** needed to clear a fault or a documented **and communicated** equipment limitation exists in accordance with **Requirement R6."**

With regards to M1:

"…demonstrating adherence to ride-through requirements, as specified in Requirement R1**, or shall have evidence of a documented and communicated equipment limitation, as specified in Requirement R6**."

With regards to R2:

"…each IBR's voltage performance adheres to the following, unless a documented **and communicated** equipment limitation exists…"

With regards to 2.1: (and Tables 1 & 2, Figures 1 & 2):

There appears to be inconsistency between the definition of 'Continuous Operation Region', the Minimum Ride-Through Time values stated in Tables 1 & 2, and the plots in Figures 1 & 2.

It seems the intent is to have 'continuous' operation between 95% and 105% voltage, and a minimum ride-through time of at least 1800 seconds (half an hour) when voltage is above 105% and not exceeding 110%. If it is really required that equipment must be able to operate ***continuously*** at voltages up to 110%, then the tables and plots should be labelled with a descriptor that implies indefinite operation is required (i.e., continuous) rather than a minimum time (1800 seconds). For example, a version of Table 2 that achieves what seems to be intent could look like the following:

See file attached - Proposed change to table Q2

With regards to 2.5:

The IESO believes the principle of tripping only when necessary (i.e., to clear faults and to prevent equipment damage during disturbances) is important enough that it warrants a dedicated requirement. With regards to tripping during over-voltages, this principle of only tripping for equipment protection purposes may apply equally to system disturbances discussed in R2 and to switching transients as discussed in R3 (tripping for equipment protection is not presently addressed in R3, though is acknowledged in the Technical Rationale document).

With regards to R6:

The IESO suggests there should be explicit requirements to both 'document equipment limitations' and to 'communicate' those documented limitations to the appropriate parties. The following modifications are proposed:

"Each Generator Owner and Transmission Owner with a **known** equipment limitation that would prevent an applicable IBR that is in-service by the effective date of this standard from meeting voltage ride-through requirements as detailed in Requirements R1 and R2 shall **document** each equipment limitation **and communicate it** to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s).

With regards to M6:

Each Generator Owner and Transmission Owner shall have evidence of **known** equipment limitations, as specified in Requirement R6, **having been** documented **and communicated** to each associated Planning Coordinator, Transmission Planner, and Reliability Coordinator prior to the effective date of PRC-029-1.

Each Generator Owner and Transmission Owner with changes to equipment shall have evidence of communication to each associated Planning Coordinator, Transmission Planner, and Reliability Coordinator.

Thank you for your comment.
R1: Modifications have been made to R1 and M1 for clarity – please see the new draft for those changes.
Attachment 1: The tables and figures in Attachment 1 have been updated for consistency. The operation regions have been included on the figures.
R2: Previous requirement R2.5 has been removed.
R5: Previously R6 has been updated to include “known”, “regulatory”, and “communicated”.

Jennie Wike - Jennie Wike On Behalf of: John Merrell, Tacoma Public Utilities (Tacoma, WA), 1, 4, 5, 6, 3; - Jennie Wike, Group Name Tacoma Power

Answer	No
Document Name	

Comment

Tacoma Power does not agree that the language in the applicability section of PRC-029-1 is clear. The applicable facilities language in Section 4 is vague and difficult for entities to understand what is in scope of the Standard. Specifically, the term "BPS IBR" is broad and would encompass all transmission connected IBRs, regardless of size or interconnection voltage. Additionally, the language and formatting of the applicability sections in PRC-028, PRC-029 and PRC-030 are not consistent. These three Standards apply to the same facilities, and therefore, should use the same language. Tacoma Power recommends that Section 4 of PRC-029 and PRC-030 should be revised to align with the language proposed in Section 4 of PRC-028, as follows:

4.1. Functional Entities:

4.1.1. Transmission Owner that owns equipment as identified in section 4.2

4.1.2. Generator Owner that owns equipment as identified in section 4.2

4.2. Facilities: The Elements associated with (1) BES Inverter-Based Resources; and (2) Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

Comment	
BC Hydro appreciates the drafting team's efforts and the opportunity to comment, and offers the following: 1. Requirement R2 Part 2.1.2 appears to set an additional Requirement for TP, PC, RC, or TOP to specify requirements for scenarios where an IBR cannot deliver both active and reactive power when the voltage is within the Continuous Operating Region and below 95%. BC Hydro recommends that if these are intended as mandatory or deemed as a necessary input for the IBR Owner/Operator, then these should be codified as standalone Requirement(s) against the appropriate functional entities (TP, PC, RC, or TOP suggested by the current draft). 2. The VSL Table for Requirement R1 does not reflect the allowance of a documented limitation. As drafted, it implies that a Severe VSL will be assessed in spite of a preexisting and documented equipment limitation. BC Hydro recommends that the wording be revised to clarify the compliance expectations when evaluating IBR performance.	
Likes 0	
Dislikes 0	
Response	

Thank you for your comment:
R2 does not intend that values other than the default values must be specified, only that performance for the plant/facility will be evaluated in accordance with those values if provided. If the TP, PC, RC, or TOP require different criteria for system reliability then the flexibility to require GO/TOs to follow those criteria is allowable. Requring planner/operators to provide values when different criteria are not needed was determined to be unnecessary.
VSL: The VSL tables were adjusted to clarify if there is an exemption in place.

3. Do you agree with the drafting team's proposals for including IBR transient overvoltage, frequency, ROCOF, and instantaneous voltage phase-angle jump ride-through performance criteria in PRC-029-1 Requirements R3, R4, and R5?	
Thomas Foltz - AEP - 5	
Answer	No
Document Name	
Comment	

Designing an IBR plant for transient over-voltage ride-through compliance is complicated by separation of the IBR Units from MPT high side by the non-aggregated collector system including the MPT itself, frequency dependence of the collector system, GSU (i.e., pad mount transformers) and MPT transformer saturation, and surge arrestors on the collector system. DFRs triggered on TOV are essential for monitoring compliance.

Assessing IBR plant phase jump ride-through is dependent on being able to trigger DFR records on non-fault line switching events. Also, as the standard is now written, phase angle jump of any magnitude during a fault must be ridden through and it does not seem possible to determine if a ride-through failure is caused by a fault-caused phase jump exceeding 25 degrees (in which case the IBR could be compliant), or if instead there is a true non-conformity with R1. AEP is not aware if anything can be done about this, but it may be a minor point in most practical situations.

Regarding R4, the technical rationale supporting the standard seems to neglect the possibility of torsional interaction between the wind facilities where sub-synchronous control interaction could exist that can result in possible damage to the wind turbine generator shaft. Therefore, a blanket statement that an inverter-based resource is not affected by off-nominal frequencies may be an assumption that should warrant further considerations when establishing inverter-based resource, frequency ride through requirements. We believe this is supported by page 6 of the technical rationale which states *"In the case of the non-hydraulic turbine synchronous resources, the turbine is usually considered to be more restrictive than generator in limiting IBR frequency ride-through because of possible mechanical resonances in the many stages of turbine blades. Off-nominal frequencies may bring blade vibrational frequencies closer to a mechanical resonate frequency and cause damage due to the vibration stresses. However, inverter- interfaced-IBR does not share this vibrational failure mode."* Furthermore, how should phase jump be considered in R5 where synch check relay settings are greater than 25 degrees?

Response	

Thank you for your comments. **Previous R3:** The team has removed Requirement R3. **Assessing phase jump:** Previous Requirement R5 has been removed and added as an exemption to Requirement R1. There is no exemption to trip within the no-trip zone for a fault. If there is a trip during non-fault initiated switching events, measurement data taken from the high-side of the MPT would include this information. The measure for R1 has been modified to reflect this change. The analysis is triggered by the plant tripping which is an event included within an analysis required by PRC-030. At a minimum, the DFR should be configured to trigger when a trip or a reduction in active power occurs for PRC-030. **R3 (Previous R4):** R3 requires ride-through only during frequency deviations of the fundamental waveform as described in Attachment 2 (previously Attachment 3) and is, as you correctly observe, the intent of the standard is currently only for the fundamental frequency and does not address other superimposed frequencies including those resulting from sub-synchronous resonances. We expect that the actual phase jump seen at an IBR POI or high side of MPT in the case of a sync-check supervised line reclosing would be substantially less than the pre-reclose angle across the open breaker.“ In most cases and for most sync-check settings, we don’t believe the actual phase jump would be greater than 25 degrees.”

- R3:
  - Technical Rationale “High Voltage Ride Through and Low Voltage Ride Through” modes were not clearly defined. “Mode” implies a specific, programmed, set of actions within controls which may not be real for solar sites.
  - A GO may not know if a switching event occurs. In that case, how would a GO be expected to determine if the event in question is a switching event or not? While R6 addresses exemptions for R1 and R2 in the case that equipment or the ability to record doesn’t exist in an existing site, the same may be of concern for the sub-second requirements listed in R3, 4 and 5. The same exclusions should be for the entire standard, if applicable.
- R4:
  - If the Rate of Change of Frequency is 5 Hz/second, there’s concern that the level of calculation needed on parameters that may not have more than a 1/second resolution would net little reaction.
- R5:
  - While R6 addresses exemptions for R1 and R2 in the case that equipment or the ability to record doesn’t exist in an existing site, the same may be of concern for the sub-second requirements listed in R3, 4 and 5. The same exclusions should be for the entire standard, if applicable.

Thank you for your comment.	

Previous R3: Requirement R3 has been removed.
R3 (previous R4): The team is drafting PRC-029 to align with the proposed requirements for measurements within PRC-028. Additional information on calculating ROCOF has been provided in the technical rationale.
R4 (previous R6): The scope of allowable exemptions within R5 is consistent with the regulatory directives of Order No. 901. Frequency or phase-jump requirements cannot apply for exemption. New IBR cannot apply for exemption.

Comment	

No, Invenergy disagrees with the proposals for including IBR transient overvoltage, frequency, ROCOF, and instantaneous voltage phase-angle jump ride-through performance criteria in Requirements R3, R4, and R5. We offer the below comments regarding these Requirements:

R3: Can the drafting team provide data that demonstrates observed overvoltages during recent System events were of the TOV magnitudes and durations defined in Attachment 2 Table 3? TOVs of such scale are primarily due to the following three scenarios: 1) a lightning strike on the nearby transmission system, 2) transmission line switching transients, and 3) resonant phenomena like voltage magnification due to shunt capacitor switching on the transmission system. Measures are already in place to mitigate such events, including but not limited to proper insulation coordination and substation design, metal oxide varistors, and proper capacitor bank switching of transmission level shunt capacitors (e.g. synchronous switching or use of pre-insertion resistors to mitigate voltage magnification to the extent possible).

To support our statement above, consider an often-quoted document to support these TOV requirements in the NERC Odessa Disturbance Texas Events: May 9, 2021 and June 26, 2021 Joint NERC and Texas RE Staff Report, Dated September 2021. A detailed read of the section that is entitled Inverter Transient AC Overvoltage Tripping Persists identifies poor coordination of controls and protection as the primary driver of these events, rather than TOV conditions at the point of measurement due to switching transients or any type of resonance. What the report explains is that in some cases the IBR units force maximum reactive power output during a fault to push the network voltages up, then once the fault clears they do not pull back on the reactive power injection quickly enough, which leads to an RMS over-voltage (not switching event TOV) at the terminals of the IBR unit, and thus the IBR units tripped. This is solved by 1) proper controls and protection coordination, 2) proper IBR plant design, and 3) proper evaluation of the LVRT and HVRT ride-through capabilities of the IBR plant during the design phase of the plant.

R3 should be removed, and the focus placed on low voltage ride-through and high voltage ride-through, with an emphasis that both LVRT and HVRT performance should be tested during the design phase of a facility using validated IBR unit models based on type-testing.

R4: In the Technical Rationale, the drafting team explains that due to lower system inertia “a wider frequency ride-through capability for IBR **may** be required to avoid the risk of widespread tripping.” Can the drafting team cite more specific reasoning or data to support the expansion of the frequency ride-through capability requirement to the range of 64Hz to 56Hz, well beyond the IEEE 2800-2022 standard frequency ride-through requirement and the capabilities of many legacy IBRs?

The proposed 6-second frequency ride-through capability requirement for the ranges of 61.8Hz to 64Hz and 57Hz to 56Hz does not align with the requirements on the rest of the BES. For the foreseeable future, synchronous generators will continue to be a significant part of the grid. It is a

well-established fact that such large electric machinery, which are directly connected to the grid, cannot be exposed to such large variations in frequency. Therefore, it does not seem reasonable to ask IBRs to go to such extremes. **R5**: We fail to see the value of requirement R5 given the other ride-through requirements, and it's unclear to us how an entity is to determine if the subject switching event is initiated by a fault or not. Additionally, we don't believe the language in R5.1. regarding equipment tripping to prevent equipment damage is reasonable or auditable. We recommend Requirement R5 is removed.

1 AES CE agrees that such performance criteria in R3, R4, and R5 needs to be included, but requests modifications and clarifications as requested below:

2· The language in R3 and R5 relating to "switching events" is difficult to track from the GO perspective. If such an event occurs at the Transmission Operator (TOP), we may not be aware of the need to track and assess our IBR performance as applicable to PRC-029 unless notified by the TOP. If a performance issue with an IBR is identified we would need to be informed by the TOP that a switching event occurred to assess applicability to PRC-029.

3 Please update the technical rationale to clearly state that the 5 Hz/second criteria in R4 aligns with IEEE2800.

R5 , First time seeing this type of protective setting, unsure as to whether or not any documentation exists or protective settings currently exist in our fleet for this. M5 , Will the PC's be communicating in writing to the Generator Owner every time there is a disturbance with the request for this data. How long will the data need to be held? The values for ride through are different from PRC-24. All current generation sites have targeted to comply with the curve given in PRC-24. The basis of moving these protective curves are unclear.	
Likes 0	
Dislikes 0	

Response	
Thank you for your comment. **R5**: The requirements in PRC-029 are not protection or controller setting requirements. Revisions have been to made to include capability based requirements along with performance based requirements. Phase jump protection would typically only be located within the inverter controller and would not be part of requirements for evaluating performance of the full plant/facility; per PRC-030. The documentation could include protection and control settings, manufacturer guidance, engineering analysis, or other guidance on why the trip settings were selected. **M5**: PRC-030 dictates the requirements for entities to send/receive requests for disturbance monitoring data and specifies the retention rate for compliance. The PRC-028 draft specifies data retention requirements for disturbance monitoring data outside of those requests. Ride-through curves: The team identifies that there is reliability need to address IBR technologies with these wider range or ride-through capability, which have demonstrated through multiple reports of wide-area disturbances.

Comment	
Yes, they are needed but the understanding of what those criteria should be is not evolved sufficiently at this time. Also, large scale EMT network models are not of sufficient quality to assess the criteria in the design phase. For example, if RoCoF is for a time period of greater than or equal to 0.1 second, it leaves the choice of sample time to the user. The plant can take the 100ms for calculations and meet the criteria. The System Operator criteria may calculate RoCoF over 500ms (as we do) and would see the plant as not meeting criteria for the same event. The proposed RoCoF of 5Hz/s is higher than IEEE1547 Category I, II and III. Transmission Wind turbines and their capabilities are often the same as DER plants. A transmission facility just has a lot more of them. That said, we are looking to introduce higher RoCoF for DER as they may be vulnerable as we transition to a very high IBR grid. RoCoF is not calculated during the fault occurrence and clearance? The standard would only apply for loss of a source of generation without a fault? For loss of our tieline for a fault it would not apply but loss of tieline for neighbouring RAS action it would? It is most needed when there is a fault. For a fault, we are also losing the older wind MW as they go into momentary cessation during the fault making the generation loss greater. For simple loss of supply, a high IBR grid is stronger than for a loss of supply due to fault. We apply RoCoF criteria during a fault. Our current criteria for transmission design is 2.4 Hz/s calculated over 500ms. Our current design criteria for generation facilities ride through is	

4Hz/s. But it is under review in EMT studies. We do not use rolling average at this time as it is difficult to accurately calculate in PSSE. We hope to be able to move to rolling average as we increase our use of PSCAD study results for operational studies.

How does it align with the RoCoF criteria for synchronous plants? We are surveying our existing thermal plants and it is still a bit of an unknown in some areas. Our current criteria of 4Hz/s applies to all generating facilities.

Response

Thank you for your comment.
Models: PRC-029 is one part of many standard revisions that are being made to address poor performance. Modeling issues, inclusive of EMT, will be addressed as part Milestone 3 projects (due to be filed Nov 2025).
RoCoF: The requirements within PRC-029 only state the calculation will be of at least 0.1s. Please refer to the Technical Rationale for more information.
Measures - data: The compliance measures for demonstration of performance were revised from "actual recorded data" to "actual disturbance monitoring (i.e. Sequence of Event Recorder, Dynamic Disturbance Recorder, and Fault Recorder) data".
Clarification: The requirements to demonstrate ride-through performance are in relation to the response to a fault and include no-trip zones and operation regions to require specific performance during the recovery period, immediately following a fault.
PRC-024 -RoCoF: PRC-024 does include criteria for calculating RoCoF for synchronous machines.

Comment

The NAGF provides the following comments:

a. Requirement R3 – the NAGF notes that GOs do not have knowledge of BPS/BES "switching events" and requests that the Drafting Team (DT) consider adding a requirement for the TO/TOP to notify the GOs of such events.

b. Requirement R4:

i. The term "applicable IBR" needs clarification.

ii. Request additional clarification/justification regarding the proposed 5 Hz/second threshold.

iii. The NAGF requests clarity on how to test compliance with the TOV Ride-Through requirement during study or plant IBR design phase.

c. Requirement R5:

i. Same concern as identified for R3

ii. The requirements for phase angle shift of 25 degrees should allow IBR tripping if the post-fault system condition is drastically changed and the device protection is activated.

Likes 0	
Dislikes 0	

Response

Thank you for your comments.
TOV (previous R3): Previous requirement R3 has been removed.
R3 (previous R4): the term "applicable IBR" has been replaced to refer the applicability section. Additionally, the team has aligned the usage of the 5hz/second criterion with IEEE 2800 and additional clarity has been added to the TR.
R4 (**previous R5**): The evidence of compliance for disturbance monitoring that are associated with voltage and frequency excursions that were System disturbances and would be identified for analysis or another trigger by an applicable entity within draft PRC-030. Evidence of disturbance monitoring of IBR associated with those disturbances would be triggered by compliance under the requirements for PRC-030.

Christine Kane - WEC Energy Group, Inc. - 3, Group Name WEC Energy Group

Answer	No
Document Name	

Comment

- WEC Energy Group disagrees with R3. FERC Order 901 calls for addressing system disturbances. A switching event does not qualify as a system disturbance. In addition, disturbance events summarized this as an anti-islanding protection issue and therefore it should be stated in R3 to reduce confusion. If the SDT decides to keep R3, then R3 should include following text, "unless a documented equipment limitation exists in accordance with Requirement R6."
- WEC Energy Group agrees with inclusion of R4 with following exception: R4 should include following text, "unless a documented equipment limitation exists in accordance with Requirement R6."
- WEC Energy Group agrees with inclusion of R5 with following exceptions:

- R5 should include following text, “unless a documented equipment limitation exists in accordance with Requirement R6.”
- The industry term is known as PLL Loss of Synchronism and is identified as such in disturbance reports. Therefore, R5 should adopt the same to reduce the confusion.

Previous R3: Previous requirement R3 has been removed.
Previous R5: Previous Requirement R5 has been removed and added as an exemption to Requirement R1. There is no exemption to trip within the no-trip zone for a fault. If there is a trip during non-fault initiated switching events, measurement data taken from the high-side of the MPT would include this information. The measure for R1 has been modified to reflect this change**.**
Exemptions: The scope of allowable exemptions within R4 (previously R6) is consistent with the regulatory directives of Order No. 901. Frequency or phase-jump requirements cannot apply for exemption. New IBR cannot apply for exemption. This is consistent with the ordered directives.
PLL loss of synchronism: A footnote has been added to R1 to clarify PLL loss of synchronism.

Andy Thomas - Duke Energy - 1,3,5,6 - SERC,RF

Answer	No
Document Name	

Comment

Duke Energy recommends the implementation of EEI and NAGF comments.

Duke Energy also recommends, if not already considered, to verify with OEMs that the inverters can satisfy Att 2. Figure 3 does not align with IEEE 2800 Figure 14; again, making compliance with both requirements more complicated.

The controls only respond to voltage and therefore will have no context of the initiating event as could be implied by the statements in R3 and R5. Recommend adding an exception to R3 worded in a similar format to the exception stated in 5.1.

Comment	

There are several concerns with the equipment limitation exemption language in the draft of R6, and such exemptions not being allowed for R3 and R5. To justify R6 only allowing an equipment limitation exemption for existing resources to R1 and R2, and not the other requirements of PRC-029, the NERC drafting team's technical rationale document points to FERC Order 901:

The objective of Requirement R5 [sic] is to ensure legacy IBR may need to obtain an exemption to the voltage ride-through requirements if hardware replacements or other costly upgrades would be necessary to comply with Requirements R1 or Requirement R2… FERC Order No. 901 states that this provision would be limited to exempting "certain registered IBRs from voltage ride-through performance requirements." This is the reason that no similar provisions are included for exemptions for frequency, rate-of-change-of-frequency (ROCOF), phase angle change ride-through requirements.

First, the R6 equipment limitation exemption should also apply to R3, which requires ride-through for "a transient overvoltage as a result of a switching event whereby instantaneous voltage at the high-side of the main power transformer exceeds 1.2 per unit." As NERC notes, FERC Order 901 directed NERC that existing resources can have equipment limitation exemptions from voltage ride-through requirements, and remaining online during transient over-voltage is clearly a voltage ride-through requirement. Transient over-voltage can damage equipment, so allowing IBRs to protect against this damage is consistent with FERC's intent in Order 901 to only allow tripping that is necessary to protect equipment. Moreover, in many cases making existing equipment better able to withstand transient overvoltages would require replacing or modifying hardware.

For similar reasons, an equipment limitation exemption for existing resources should also apply to R5, which requires ride-through for voltage phase angle changes of less than 25 degrees. FERC Order 901 directed NERC that existing resources can have equipment limitation exemptions from voltage ride-through requirements, and remaining online during voltage phase angle changes should be interpreted as part of voltage ride-through requirements. Remaining online during phase angle changes of less than 25 degrees could be a problem for existing generators, particularly wind generators as phase angle changes can impose mechanical stresses on the wind turbine's rotating equipment. Not allowing an

equipment limitation exemption for existing generators under R5 is particularly problematic as it is not typically feasible to retrofit existing wind turbines to increase their ability to withstand mechanical stresses due to phase angle changes. In such cases, making existing equipment better able to withstand voltage phase angle changes would require replacing or modifying hardware. Phase angle changes can damage equipment, so allowing IBRs to protect against this damage is consistent with FERC's intent in Order 901 to only allow tripping that is necessary to protect equipment. Moreover, a contextual reading of Order 901 indicates FERC was mostly focused on limiting equipment limitation exemptions to existing generators that would have to physically replace or modify hardware, and not strictly limiting such exemptions to a narrow reading of what constitutes voltage ride-through requirements. Paragraph 193 in its entirety, and particularly the first sentence, explain that FERC's intent was focused on exempting existing resources that would have to physically replace or modify hardware: "we agree that a subset of existing registered IBRs –typically older IBR technology with hardware that needs to be physically replaced and whose settings and configurations cannot be modified using software updates – may be unable to implement the voltage ride though performance requirements directed herein." FERC continued by directing that "Any such exemption should be only for voltage ride-through performance for those existing IBRs that are unable to modify their coordinated protection and control settings to meet the requirements without physical modification of the IBRs' equipment."{C}[1] As explained above, equipment limitation exemptions for R3 and R5 are likely necessary to ensure some existing generators do not have to physically replace or modify hardware, and thus such exemptions are consistent with FERC's directive in Order 901. Finally, R6 equipment limitation exemptions should be allowed for resources with signed interconnection agreements as of the effective date of the Standard, instead of resources that are in-service as of that date. Resource equipment decisions are typically locked down at the time the interconnection agreement is signed, and a change in requirements after that point can require a costly change in equipment or settings that may also trigger a material modification and resulting interconnection restudies. The implementation plan for PRC-029 indicates that the effective date for the Standard will be the first day of the first quarter six months after FERC approval. Many resources take significantly longer than that to move from a signed interconnection agreement to being placed in service, so it makes more sense to allow R6 equipment limitation exemptions for resources that have a signed interconnection agreement as of the effective date of the Standard. {C}[1]{C} Order 901, https://www.ferc.gov/media/e-1-rm22-12-000, at paragraph 193

Thank you for your comments. **Previous R3:** The team agrees and previous requirement R3 has been removed. **Previous R5:** Previous Requirement R5 has been removed and added as an exemption to Requirement R1. There is no exemption to trip within	

the no-trip zone for a fault. If there is a trip during non-fault initiated switching events, measurement data taken from the high-side of the MPT would include this information. The measure for R1 has been modified to reflect this change. **Exemptions**: The scope of allowable exemptions within R4 (previously R6) is consistent with the regulatory directives of Order No. 901. Frequency. Newly interconnecting IBR cannot apply for exemption and "legacy IBR" is generally understood to include those IBR that are "in-service". This is consistent with the ordered directives.

A premise of R3 is knowing of a transient OV, due to a switching event on the transmission system.   The Generator Owner is not going to have the intelligence to know if a transient OV is due to a switching event. So, is the GO expected to treat all OV events as non-switching events?

1. Requirement R3: The Transient Overvoltage Ride-Through requirement is just not ready to be included in a regulatory standard. The measure for this requirement is based on actual recorded data. The existing facilities may not even have recording equipment in place to measure switching transients. The IEEE P2800.2 WG has also struggled to come up with a Design Evaluation procedure to show that the plant would be able to ride-through the specified TOV ride-through requirements.
2. Requirement R4:
    - The intent of "continue to exchange current" is understood, however, the requirement is vague. During frequency excursion events, it is necessary that IBR adjusts active power output in response to frequency deviation. But these details are not necessary in NERC standards, currently. The IBR that "continues to exchange current" but not based on frequency deviation, would comply with the standard requirements, which is not ideal. The TP/PC is expected to specify IBR performance during abnormal system frequency. Hence, the requirement should read as following: Each GO or TO of an applicable IBR shall ensure each IBR remains electrically connected and continues to exchange current **as specified by TP or PC** during a frequency excursion event……
    - Why is there no exception for Volts/Hz limit? This could be an issue for type III WTG and transformer within the plant. The frequency ride-through requirement in the IEEE Std 2800 recognizes Volts/Hz limitation.
3. Requirement R5:
    - Consider revising to read as follows: Each GO or TO of an applicable IBR facility shall ensure that each IBR remains electrically connected and continues to exchange current during non-fault switching events where the instantaneous change in positive sequence voltage phase angle is less than or equal to 25 electrical degrees at the high-side of the main power transformer.
    - Has the SDT discussed how to measure "instantaneous" phase angle jump based on recorded data?

- Part 5.1 is not necessary. The IBR may not trip because it measured phase angle jump of greater than 25 electrical degrees but may trip due to affects of such a jump in phase angle. Not sure how to even prove that equipment was at risk or not.
- For R5, the GO will not know if a phase jump is the result of a non-fault switching event, so is the GO expected to treat all phase jump events as non-fault switching events?
- In R5, what happens if an IBR trips due to phase angle jump while the frequency and voltage remain in the continue to operate range? IBRs will not know whether the system has experienced a fault or not.

4. Attachment 3:
    - Why does the SDT require more stringent ride-through capability compared to the IEEE Std 2800? If a certain interconnection requires stringent ride-through requirement then it should only be required for that interconnection. There is no need to extend the stringent requirements of one interconnection to all interconnections. Such an approach is implemented in the PRC-024, PRC-006, etc. Additionally, the PRC-006 specifies boundaries between which the frequency needs to remain while simulating and designing UFLS scheme. The IBR frequency ride-through coordinated with boundaries in PRC-006 should be enough.
    - Table 4:
        - Not sure what is implied by “average system frequency”. The term “average” makes sense when associated with ROCOF but not with frequency.
        - ≥64 should be >64
        - ≥61.8 should be >61.8
    - Note 1 is not necessary. Which measurement is taken on each phase?
    - Note 2: Consider replacing with following: Frequency is measured over a period of time, typically 3-6 cycles.
    - Note 3: not sure which “control settings” are referred here. Consider the following from PRC-024: Instantaneous trip settings based on instantaneously calculated frequency measurement is not permissible.
    - Note 5: Why did the SDT specify 15-min time period instead of 10-min time period in the IEEE Std 2800.

ROCOF and phase angle jumps:

- Some legacy IBRs have technical limitations that will prevent them from riding through ROCOF less than or equal to 5 hz / second or phase angle jumps less than 25 electrical degrees. Such IBRs need the ability to seek an exemption for these requirements.Note: ERCOT has questioned the validity of how ROCOF and phase angle jumps are measured, and whether the 5 hz / second and 25 electric degree values are accurate.
- R5 specifies that IBRs must ride through phase angle jumps initiated by **non-fault** switching events and are changes of less than 25 electrical degrees. There is an issue Southern Company has encountered on NOGRR245. ERCOT has proposed that IBRs not trip for any ROCOF or phase angle jumps during **fault** conditions. It is an understanding that IBRs should ignore ROCOF and phase angle jump values during fault conditions. Southern Company would support similar fault language in PRC-029-1, but a technical exemption would be required because some legacy IBRs are unable to distinguish between a fault and non-fault condition.

R6.1.2 discusses *"aspects of VRT requirements that the IBR would be unable to meet"*. This language could be clearer by requesting the IBR to identify actual VRT capabilities.[A1] M6 requires evidence of equipment limitations prior to the effective date of the standard. This could be extremely challenging to meet. Finally, Southern Company supports NAGF comments.

Response	
Thank you for your comment. **Previously R3:** Previous requirement R3 has been removed. Previous R5 does not require to track all switching events. However, Previous R5 has been removed and the non-fault exclusionary language has been added to R1. A requirement to notify the Generator Owner or Transmission Owner and to evaluate performance when the plant/facility tripped because of a switching event is in the current draft PRC-030. **Terminology:** The phrase "continue to exchange current" is consistent if a BESS is charging prior to a fault and providing voltage support after the fault. However, the team agrees that a definition for Ride-through is preferable and has replaced usage of "continue to exchange current". **R3 (Previously R4):** Previous requirement R4 does not require additional performance requirements beyond ride-through capability. Other 901 related Standards Projects are expected to address. The scope of allowable exemptions within R4 (previously R6) permits a Volts/Hz-related exemption but in general the IBR should regulate voltage to avoid exceeding Volts/Hz limitations during an underfrequency event. **Previous R5:** Previous Requirement R5 has been removed and added as an exemption to Requirement R1. There is no exemption to trip within the no-trip zone for a fault. If there is a trip during non-fault initiated switching events, measurement data taken from the high-side of the MPT would include this information. The measure for R1 has been modified to reflect this change. Previous R5 does not require to track all switching events. Previous R5 has been removed and the non-fault exclusionary language has been added to R1. A requirement to notify the Generator Owner or Transmission Owner and to evaluate performance when the plant/facility tripped because of a switching event is in the current draft PRC-030. **Attachment 3:** Please refer to the technical rationale for why the approach was taken for Regional variants. Other Regional variants are able to be pursued by each Region as needed. **Table 4:** The word "averaged" has been removed from the title of Table 4. **Note 1:** The team agrees and has removed the "each phase" language. **Note 2**: The language was modified as suggested. **Note 3**: PRC-029 is a performance-based Standard and does not require specific equipment settings. **Note 4:** The 15 minutes was included to coincide with Table 4 as the maximum defined time intervals is 11 minutes (660 seconds). **Phase Jump:** The phase jump requirement (previously R5) has been removed and moved into the scope of R1. The scope of allowable exemptions within R4 (previously R6) is consistent with the regulatory directives of Order No. 901. This is consistent with the ordered directives.	

ROCOF: Please refer to the Technical Rationale for more details on the team's decisions for RoCoF and phase jump criteria. Similarly, this has been brought into the scope of R1.
R4 (Previously R6): Requirement R4 has been revised to include additional clarity on equipment capability as requested information. Additionally, the scope of allowable exemptions must be for known equipment limitations. The implementation plan for R4 does include an additional 6 month window to communicate those known limitations.

Rwquirement 3

PG&E believes specific requirements for the inverter capabilities should be removed from the NERC standard and left to the IEEE 2800-22 standard for inverter specifications. The utility relies on RMS measurements and does not have a means to accurately measure transient over-voltage conditions for protective relays; therefore, it would be extremely difficult for the entity to prove its compliance.

Requirement 4

Frequency ride-through limits have been raised considering that IBRs can continue to generate. For synchronous machines, it is not possible to have such a wide frequency range (as per attachment 3 copied below). When the system has majority of IBRs, the effect on synchronous machines with such wide frequency variations is unknown. Also, it would affect the underfrequency load shedding schemes.

PG&E has the following questions for the SDT to consider: Should there be separate ride through limits for Grid Forming inverters and Grid Following inverters? Would higher penetration of IBRs affect the allowable frequency ranges?

Requirement 5

PG&E believes specific requirements for the inverter capabilities should be removed from the NERC standard and left to the IEEE 2800-22 standard for inverter specifications.

PG&E has the following question for the SDT: how do we set relays or trigger a DFR for a switching/non-fault event to show compliance with the requirement?

The IESO recommends the following modifications to the text improve clarity or to better convey intent. **With regards to R4:** "…continues to exchange current during a frequency excursion event whereby the **system** frequency remains within the "no trip zone" according to…"	

This suggestion would differentiate the actual system frequency from, say, the frequency measurement as 'seen' by the PLL or other parts of the controls.

With regards to 5.1

As commented above, IESO believes 'not tripping except to provide equipment protection' warrants a dedicated Requirement, which may be referred to the context of other requirements, such as performance during phase angle jumps.

PGE supports EEI's comments but in addition would add clarification: For the requirement to say "may trip, but shall only trip to prevent equipment damage" does not provide clear direction. If the IBR can stand a 30 electrical degree change, is it acceptable to trip at 25.0 to prevent equipment damage? It would be preferrable to provide a safety margin before reaching the damage point. Or, is this stating that the IBR wait until 30.0 electrical degrees is reached before taking action? What is the measure for making sure an IBR does not trip at 25.0 or above except to protect the equipment? If there is nothing particularly harmful about tripping an IBR above 25.0, why not indicate that above 25.0 is not a "Must Trip Zone/Criteria"?

However, please verify the ROCOF with regards to how FR data at the IBR Unit level (per the definitions proposed by 2020-06) is required to be captured (Per proposed PRC-028-1). Note that PRC-002-4 and -5 have ROCOF triggers for recording that are significantly different than 5 Hz/second. Measure 4 of PRC-029-1 has a reference to a Planning Coordinator's area but Requirement 4 has no such limitation or uses Planning Coordinator within the language. It appears that the stated ROCOF is high based on IRPT reports (https://www.nerc.com/comm/PC/InverterBased%20Resource%20Performance%20Task%20Force%20IRPT/Fast_Frequency_Response_Concepts_and_BPS_Reliability_Needs_White_Paper.pdf). And the ROCOF definition is different from said report by the IRPTF.	
Likes 0

ERCOT joins the comments of the IRC SRC and adopts them as its own in addition to the following comments, except to the extent of any specific differences between the SRC comments and the following comments from ERCOT. Footnote 2 is not clear as to whether RoCoF measurement should begin immediately or upon fault clearing. IEEE 2800.2 discussions are heading in a direction that would indicate that during fault occurrence, clearance, and recovery back to a steady-state operating point, failure to ride through should only be allowed if the voltage is beyond the requirement (i.e., the unit should not trip due to any perceived RoCoF during the entire disturbance and recovery period). This is similar for phase angle jump. Requirement R4 may need to include language similar to that found in Requirement R5, Part 5.1 to ensure RoCoF is set to the equipment capability and is not arbitrarily set at 5 Hz/s. ERCOT also notes that the IEEE 2800-2 drafting team is identifying that there should be agreement between unit owners and planners/operators on how to measure RoCoF (at what time points, greater than or equal to .1 second) to ensure consistency in testing, model validation, application, and performance evaluation. Otherwise, such a requirement may create confusion or	

otherwise be unenforceable. IEEE 2800-2 also identifies the potential need for higher RoCoF requirements, which may be appropriate in smaller Interconnections.

The current language in Requirement R5 excludes voltage phase angle change of exactly 25 degrees, which is included in IEEE2800 requirements:

SDT's proposed language:

"Each Generator Owner or Transmission Owner of an applicable IBR shall ensure each IBR remains electrically connected and continues to exchange current during instantaneous positive sequence voltage phase angle changes **that are initiated by non-fault switching events on the transmission system and are changes of less than 25 electrical degrees at the high-side of the main power transformer.**"

ERCOT's proposed language:

Each Generator Owner or Transmission Owner of an applicable IBR shall ensure each IBR remains electrically connected and continues to exchange current during instantaneous positive sequence voltage phase angle **changes of 25 electrical degrees or less at the high-side of the main power transformer that are initiated by non-fault switching events on the transmission system**.

Finally, ERCOT believes that under the Violation Risk Factor guidelines, Requirements R3, R4, and R5 should have a VRF of High as they are requirements "**that, if violated, could directly cause or contribute to Bulk-Power System instability, separation, or a cascading sequence of failures, or could place the Bulk-Power System at an unacceptable risk of instability, separation, or cascading failures** . . . ."

Response

Thank you for your comment.
ROCOF: Footnote 7 clarifies that ROCOF should not be measured during the fault or fault clearnce. The R3 (previous R4) requirement is only applicable to frequency excursions. Ride-through during a voltage excursion would be covered under requirements R1 and R2. Ride-through expectations within R1 and R2 are independent of ROCOF.
The technical rationale has been adjusted to include additional language on setting ROCOF trigger points appropriately and not arbitrarily. The reference to prevent equipment damage (previous R2.5) has been removed from the Standard based on previous comments.
Previous R3: Previous requirement R3 has been removed. Information on the TOV calculation has been added to Attachment 1.
Severity Level: R3 (Previous R4) has been adjusted to a High as suggested.
Previous R5: This requirement has been removed and added as an exemption to Requirement R1.

Overall, we at ACES support Requirements R3 through R5; however, we have a minor concern with the wording of Requirement R3, Option 2. Specifically, we have concerns with the requirement to "restart current exchange within 5 cycles of the instantaneous voltage falling below (and remaining below) 1.2 per unit." For how long of a duration should the instantaneous voltage remain below 1.2 p.u. to trigger the 5 cycles wherein the IBR must resume current exchange? We recommend that the SDT consider adding a time component to the return from the transient overvoltage condition.

Initial review indicates the proposed requirements R3, R4, and R5 align with IEEE 2800, which the SRC supports. The SRC recommends the following modifications to the text to improve clarity and to better convey the intent of the standard. Recommended changes to R4: "…continues to exchange current during a frequency excursion event whereby the **system** frequency remains within the "no trip zone" according to…" This revision would clarify that the actual system frequency is the relevant measurement instead of the frequency measurement as 'seen' by the PLL or other parts of the IBR control system. Recommended changes to R5.1 As noted above, the SRC believes 'not tripping except to provide equipment protection' warrants a dedicated Requirement, which may be referred to in the context of other requirements, such as performance during phase angle jumps.

Yes. The SDT should consider citing IEEE 2800-2022 directly in the standard and consider using the IEEE 2800-2022 ride-through requirements as a means to comply with Requirements R1-R5 instead of using Attachment 1 of the standard.

Thank you for your comment. Requirements within the NERC PRC-029 address the scope of the SAR and draw from IEEE2800 but are mandatory and enforceable requirements; in contrast to IEEE2800. NERC Standards cannot refer to outside sources for the purposes of requirement language, per the Rules of Procedure.

Attachment 1 needs a few corrections.

- Figures 1 and 2 use a logarithmic time scale for the Time x-axis. This should be updated to be a regular non-logarithmic time scale.
- There are numerous inconsistencies in this standard language and Attachment 1 when compared to IEEE 2800. These should be considered and reviewed for clarity and completeness in the standard. The option to cite IEEE 2800-2022 and use the requirements in the IEEE 2800-2022 directly should be allowed over just the use of Attachment 1 (give each GO/TO the ability to use either of these guides to base their performance off of).

- IEEE 2800 identifies the following items, but the standard does not support. Clarification/review should occur for each of these items:
  - Exceptions for Negative-sequence voltage exceeding thresholds
  - IEEE 2800 recognizes Volts/Hz limitations, but the standard does not.
  - IEEE 2800 recognizes 500kV system voltages are actually operated in the range of 525kV and therefore has equipment rated to 550kV. These 500kV operating conditions should be considered in the standard.
  - In IEEE 2800 the frequency ride-through criteria defines 10-minute time periods whereas the standard defines them in a 15 minute time period (Table 4 of Attachment 3). This should be clarified and identified.

The standard is quite vague in terms of technical limitations and documentation exemptions to the requirements. Experience has shown that this is a highly nuanced and difficult consideration. There is no language focused on software versus hardware limitations and what is allowed/expected. This could lead to inconsistent, subjective auditing practices rather than clear objective requirements and auditing.

Response

Thank you for your comment.
Attachment 1: The figures have been updated/corrected. The logarithmic scale has been removed.
IEEE 2800 – negative sequence: The PC/TOP/RC/TP are able to provide specific operational criteria beyond the requirements within R2.
Attachment 1 clarification on 500kv: Attachment 1 sets the minimum expectation for operation regardless of voltage class. Expanding the no trip zone for 500kV may still be done based on the system need.
Attachment 1: The tables and figures in Attachment 1 have been updated for consistency. The continuous operating region applies for beyond 10 seconds. Note 9 in Attachment 1 is an exception of the overall requirement.
Attachment 3: Note 4: The 15 minutes was included to coincide with Table 4 as the maximum defined time intervals is 11 minutes (660 seconds); which 10 minute does not sufficiently cover.
Exemptions: Language has modified within the Requirement R4 (previous R6), Implementation Plan, as well as the Technical Rationale. Software-based limitations are not subject to potential exemption.

Comment

The SRC requests several enhancements to **PRC-029**.

1. **Clarify and emphasize that documented equipment limitations under Requirement R6 must not be construed to be complete exemptions from the Requirements of PRC-029.** If entities are unable to ride-through portions of the ride-through curve, this should not automatically exempt them from complying with the balance of the ride-through curve as described in the Technical Rationale. While this is clearly expressed in the Technical Rationale for Requirement R6 (page 9), this point needs to be brought out more clearly in the PRC-029 standard itself.
2. **Expand PRC-029 to require that Corrective Action Plans be developed and implemented to remove equipment limitations within a specified timeline or require a** technical justification that addresses why corrective actions will not be applied nor implemented.
3. PRC-029 will need to explicitly require any new inverter/controller replacing older equipment to be compliant with PRC-029 rather than set to original equipment specification.
4. Applicability:In Introduction, Section 4.2.2, it is not obvious what aspect of 'IBR Registration Criteria' makes an IBR an 'applicable' IBR – is it simply that an IBR meets NERC Registration Criteria? This bullet point should be elaborated upon to ensure clarity.
5. Event-Based Standard: The SRC has concerns that this standard is an event-based standard that does not necessarily provide an assurance of reliability before events occur, such as would be provided by having an engineering analysis or results from bench-testing and real-time simulations of control equipment that indicate that successful ride through of prescribed disturbances is expected.
6. Without disturbance events that show whether IBRs perform properly, there is no way to determine if an IBR is compliant with the standard. At a minimum, the measures (e.g, M2-M5) should be extended to indicate that a statement that no such events are known to have occurred will qualify as evidence of compliance.
7. Presentation of Ride-Through Ranges: The intended ride-through requirements would be made more clear if the 'minimum ride-through times' were associated with precisely stated, *non-overlapping ranges* of voltages or frequencies, such as in the example 'Table 2' provided by the SRC in its comments above.
8. Nominal Voltages: Note #4 of Attachment 1 would be clearer if the 'nominal' system voltage values were listed as they are in Attachment 2 of PRC-024-3, i.e., "(e.g., 100 kV, 115 kV, 138 kV, 161 kV, 230 kV, 345 kV, 400 kV, 500 kV, 765 kV, etc.)"
9. Harmonize Tables, Figures, Requirements: The voltage/frequency excursion levels and the associated minimum ride-through times for all tables, figures, and any associated performance requirements that modify the requirements should be carefully reviewed and harmonized. There are presently some conflicting entries in the tables/figures.
10. PRC-029 introduces new terms. The drafting team should consider using these new terms in PRC-024 for consistency. The ranges in these definitions may be specific to IBRs due to their unique performance characteristics, but these regions serve the same purpose for synchronous generators.
    i. Term(s):
    ii. Continuous Operating Region – The range of voltages, measured at the high-side of the main power transformer, that are ≥ 0.9 per unit and ≤ 1.1 per unit.

iii. Mandatory Operating Region – The range of voltages, measured at the high-side of the main power transformer, that are > 0.1 per unit and < 0.9 per unit – or – > 1.1 and ≤ 1.2 per unit.
iv. Permissive Operating Region – The range of voltages, measured at the high-side of the main power transformer, that is ≤ 0.1 per unit.

11. There does not seem to be a direct explanation of how these new terms used in the Requirements are applied in Attachment 1, where the ranges for “No-Trip” and “Must-trip” are shown. the only mention of these terms in Attachment 1 appears to be in bullets 8, 9, and 10 where one or two Regions are mentioned and assumed to be understood. Additionally, these terms are not used consistently throughout the standard, as these terms are defined as “Operating Regions,” but frequently appear in the standard as “Operation Regions.” The SRC recommends that the SDT standardize on a consistent format for these terms.

R1. Each Generator Owner or Transmission Owner of an applicable IBR shall ensure that each IBR remains electrically connected and continues to exchange current in accordance with the no-trip zones and operation regions as specified in Attachment 1

Attachment 1

8. The specified duration of the Mandatory Operation Regions and the Permissive Operation Regions in Tables 1 and 2 is cumulative over one or more disturbances within a 10 second time period.

Response

Thank you for your comments.
Exemption: The team agrees that only specific ride-through limitations would be applied and there is no global exemption intended. Language has modified within the Requirement R4 (previous R6) as well as the Technical Rationale to clarify this.
Removing Limitations: The team agrees that replacing equipment associated with the limitation also remove any exemption. This has been clarified in Requirement R4 (previous R6).
Capability and Performance Measures: The team agrees and the measures for R1 through R3 have been adjusted to include design/capability based requirements as well as the demonstration of performance during disturbances.
Applicability: The applicability section has been modified to include more specific details on currently applicable facilities. The IBR that will be included as part of registration changes (Category 2 assets) will be added following the approval of pending changes to the NERC Rules of Procedure. These are currently excluded from this draft.
Measures - data: The compliance measures for demonstration of performance were revised from “actual recorded data” to “actual disturbance monitoring (i.e. Sequence of Event Recorder, Dynamic Disturbance Recorder, and Fault Recorder) data”.

Measures (events): The evidence of compliance for disturbance monitoring that are associated with voltage and frequency excursions that were System disturbances and would be identified for analysis or another trigger by an applicable entity within draft PRC-030. Evidence of disturbance monitoring of IBR associated with those disturbances would be triggered by compliance under the requirements for PRC-030**.**
CAPs: The analysis of voltage/frequency excursions as well as the development of CAPs are conducted within the PRC-030 draft (project 2023-02).
Ride-through Ranges: The tables in the Attachments have been adjusted to reflect this.
Nominal Voltage: The attachments apply to all system voltages as established by the TOP.
Attachment 1: Tables and Figures in Attachment 1 have been revised to add clarity on the operation regions. The range of values in row #4 of Tables 1 and 2 to clarify the continuous operation region.
Terminology – operating regions: These operating regions have been removed as defined terms. The language of the requirements has been modified to reflect these changes.
Terminology- Ride-through: The team agrees and has defined a new term for Ride-through and replaced language the requirements with this new term. Attachments have also been updated to utilize this term as the "Must Ride-through Zone".
Attachment 1 – corrections: Attachment 1 tables and figures have been revised to clarify the operating regions and no-trip zones.

Comment

Requirements R1, R2, R3, R4, and R5 and associated Measures do not make it clear whether equipment settings or configurations that render a facility unable to meet the performance requirements constitute a non-compliance prior to the occurrence of an event where the facility fails to meet the performance requirements. An understanding of these requirements as event-based (as described in the current draft of the PRC-029-1 Technical Rationale) would only partially accomplish the risk objectives described in the SAR and in FERC order 901 as many events would not be prevented. This is particularly concerning for frequency excursion events (R4) as these events are relatively infrequent and yet widespread, potentially resulting in the failure of a multitude of IBRs to meet the performance requirements if frequency trip settings are not evaluated preemptively. As such, these requirements should make it clear that facilities are to be configured to meet performance requirements and that the relevant equipment settings should be available as evidence to show compliance.

If there are portions of the performance criteria in this standard that equipment owners cannot be expected to meet through assessment of equipment settings in the absence of an event, those portions should be addressed in separate requirements that specify corrective actions to be performed following an event rather than identify non-compliance at the time of the event.

Attachment 1, Part 2b. I assume that "ESS" means Energy Storage System? Please document or clarify.

Part 7 " … trip …" again. Same question as in comment 2 above. The second sentence is also unclear. What is "the 10-second time period"? Is this phrase identified in Parts 8 and 9? If so, please define it before first use and use the same phrase subsequently.

Attachment 2 Part 3 " … trip …" again. Same question as in comment 2 and Attachment 1 Part 2b above.

Attachment 3, Table 4 Part 2. I agree with averaging frequency over a set time period. But 3 cycles seems rather short to assure a reasonable frequency value, especially during fault conditions. IEEE 2800 says "… at least 0.1 sec" [6 cycles] for ROCOF, and that is probably a good target for frequency also.

Table 4 and Part 4 " … trip …" again. Same question as in comment 2 and Attachment 1 Part 2b and 3 above.

The new or modified terms should define what the "voltage" is, RMS, Positive Sequence? Instantaneous? Etc. for Continuous Operating Region, Mandatory Operating Region and Permissive Operating Region.

In Attachment 1, bullet 3 is problematic, basing the applicable table based on direction by the Transmission Planner needs to have a specific requirement describing how that would be done. Bullet 4 is also problematic for the same reason. Bullet 8 – Mandatory Operation Regions should conform with IEEE 2800 7.2.2.4 for consecutive disturbances, and differentiate from dynamic voltage oscillations. Bullet 9 should also conform to IEEE 2899 7.2.2.4.

- It is the opinion of ACES that Section 4.2 should be modified to utilize the registration criteria as defined in the latest revision of the NERC Rules of Procedure.

Thus, we recommend the following revisions to Section 4.2:

4. Applicability:

4.1 Functional Entities:

4.1.1 Generator Owner that owns an applicable facility in Section 4.2.1.

4.1.2 Transmission Owner that owns an applicable facility in Section 4.2.3.

4.2 Facilities:

4.2.1 Either of the following Inverter-Based Resource (IBR)1 types:

4.2.1.1 BES IBR

4.2.1.2 non-BES IBR that is:

4.2.1.2.1 Connected to the Bulk Power System, and

4.2.1.2.2 Meets the criteria for a Category 2 GO facility.

4.2.2 High-voltage Direct Current (VSC-HVDC) Transmission facilities that serve as a dedicated connection for an Inverter-Based Resource meeting the criteria of 4.2.1.1 • Transmission is a defined term in the NERC Glossary of Terms. As it is currently defined, this term does not specify a voltage threshold for its applicability; therefore, we recommend capitalizing all uses of the word "transmission" within PRC-029-1 for the sake of clarity.

ERCOT joins the comments of the IRC SRC and adopts them as its own in addition to the following comments, except to the extent of any specific differences between the SRC comments and the following comments from ERCOT.

The proposed changes to PRC-024 create a reliability gap, as Type 1 and Type 2 wind turbines are not synchronous machines and would therefore no longer be required to comply with PRC-024 but are not included in PRC-029 because they are not IBRs. The SDT should consider including a specific requirement in PRC-024 or PRC-029 that addresses this technology and requires these types of units to try to meet requirements up to their equipment limitations, to notify their PC/TP/RC/TOP of such limitations, and to reflect any such limitations in their dynamic models. This will ensure that the PC/TP/RC/TOP can incorporate the expected performance of these units in their studies.

ERCOT agrees with the SDT’s overall approach of ensuring that PRC-029 is clearly a performance-based standard. However, the standard is not entirely clear on this point, as the Time Horizon is “operations assessment” instead of “Real-time Operations.” Additionally, the standard generally uses a structure of ‘owners…shall… ensure that’ instead of an ‘owners….shall.. perform’ structure. Structures found in other standards, such as BAL-001’s ‘entity…shall.. operate such that…’ structure or BAL-001-TRE’s ‘entity….shall….meet (or exceed)’ structure may also work well for PRC-029.

ERCOT notes that FERC Order 901 states, “we adopt the NOPR proposal and direct NERC to develop new or modified Reliability Standards that require registered IBR generator owners and operators to use appropriate settings (i.e., inverter, plant controller, and protection) to ride through frequency and voltage system disturbances and that permit IBR tripping **only to protect the IBR equipment** in scenarios similar to when synchronous generation resources use tripping as protection from internal faults. The new or modified Reliability Standards must require registered IBRs to continue to inject current and perform frequency support during a Bulk-Power System disturbance” (emphasis added). To meet this directive, it may be important to clearly specify that partial failures (individual IBR unit trips or abnormal responses) also fall under PRC-029.

ERCOT therefore recommends modifying the Purpose statement for PRC-029 as follows: “To ensure that Inverter-Based Resources**, and their IBR Units,** remain connected and perform operationally as expected to support the Bulk-Power System during and after defined frequency and voltage excursions.”

The figures in Attachments 1, 2, and 3 appear to be intended to be graphical representations of the tables. To that extent, they are redundant (and potentially contradict what is in the tables). They may be valuable in visualizing the requirements, but they are also ambiguous in that the lines are not precisely defined, and it is not clear if ride-through is required on the lines themselves. ERCOT recommends that these figures be moved to the Technical Rationale or that Attachments 1, 2, and 3 include a clarification that the plots are for visualization purposes only and that the tables define what is actually enforceable

Item 7 in Attachment 1 should not imply that the IBR shall trip beyond the minimum duration. While the inclusion of the term "minimum" helps clarify item 7, the "shall not trip until…" language implies that the IBR shall trip once the minimum ride-through time duration has elapsed.

SDT's proposed language:

"At any given voltage value, each IBR shall not trip until the time duration at that voltage exceeds the specified minimum ride-through time duration. If the voltage is continuously varying over time, it is necessary to add the duration within each band of Tables 1 and 2 over the 10-second time period to determine compliance."

ERCOT's proposed language:

"The IBR shall ride through voltage conditions beyond those specified in Tables 1 and 2 above to the maximum extent the equipment allows. If the voltage is continuously varying over time, it is necessary to add the duration within each band of Tables 1 and 2 over the 10-second time period to determine compliance."

Similar wording should also be applied in item 3 of Attachment 2 and item 4 of Attachment 3.

ERCOT is concerned that item 10 in Attachment 1 ("If the positive sequence voltage at the high-side of the main power transformer enters the Permissive Operation Region, an IBR may operate in current block mode if necessary to protect the equipment") is inconsistent with the following directive from paragraph 190 of FERC Order 901 (as cited in the technical rationale): "Any new or modified Reliability Standard must also require registered IBR generator owners and operators to prohibit momentary cessation in the no-trip zone during disturbances."

The proposed defined terms do not seem to be appropriate for the NERC glossary, especially if they are intended to be used exclusively for IBRs. If the SDT keeps these proposed terms, the definitions should be improved to include durations in addition to voltage ranges and to note that they are only valid for application to IBRs. Furthermore, there are inconstancies between these terms and Tables 1 and 2 in Attachment 1. For example, the Continuous Operating Region is defined as 0.9-1.1 pu (inclusive), but the tables specify only a one second ride-through time for 1.1pu voltage and an 1800 second ride-through time for voltages greater than or equal to 1.05pu, which is not consistent with the concept of continuous operations. Additionally, the terms are used inconsistently in PRC-029, as the terms are defined as "Operating Regions," but frequently appear in PRC-029 as "Operation Regions."

The Technical Rationale includes the following language:

"The proposed PRC-029 must be understood as an event-based standard. Compliance with PRC-029 is determined from IBR ride-through performance during transmission system events in the field and not from interconnection studies, transmission planning studies, operational planning studies, or from IBR models."

ERCOT recommends that the SDT add basic expectations to the Technical Rationale instead of simply stating that compliance is not determined by studies. For example, GOs should design and/or test their facilities to help ensure they won't be non-compliant during an actual event. Furthermore, it would be helpful to offer advice or SDT opinions on how ride-through should be evaluated during design, interconnection, planning, and operational studies. Even though deficient performance in such studies may not be a violation of PRC-029, it makes little sense to proceed with or allow an interconnection of a plant whose simulation models indicate that it will be unable to comply with PRC-029. Such guidance in the Technical Rationale would be beneficial for industry even if the Requirements in the standard do not contain a corresponding mandate.

The Technical Rationale should describe the basis for the "6-second frequency ride-through capability requirement for frequencies in the ranges of 61.8Hz to 64Hz or 57.0Hz to 56.0Hz range," as it is unclear why this approach was chosen instead of an approach that goes all the way up to 65 Hz and down to 55 Hz for 10 seconds or only up to 63.5 Hz and down to 56.5 Hz for 5 seconds.

It is also unclear how the SDT addressed the phase lock loop (PLL) loss of synchronism concerns discussed in FERC Order 901. While there is certainly an interrelationship, certain protection systems like PLL loss of synch may not need to be enabled. Even if enabled, these systems may, if not correctly configured, require additional tuning to ensure the PLL circuit properly controls and prevents some of the other parameters from tripping the unit offline (e.g. phase angle, RoCoF, and overvoltage). The SDT should consider adding additional language to PRC-029 to clarify that phase lock loss of synchronism trips (whether directly or indirectly involved) are not allowed.

The SDT should also consider adding the following items to Attachment 1 for clarity:

11. To the extent possible, IBRs should not use these curves as the absolute voltage or frequency protection set points but should strive to exceed them up to their equipment capabilities while still ensuring adequate equipment protection.

12. IBRs are not required to trip when voltage and frequency are in the may-trip or permissive operation regions.

Additionally, ERCOT has overall concerns with the work plan pushing the planner and operator requirement changes to the final phases. FERC Order 901 states, "To the extent NERC determines that a limited and documented exemption for those registered IBRs currently in operation and unable to meet voltage ride-through requirements is appropriate due to their inability to modify their coordinated protection and control settings, we direct NERC to develop new or modified Reliability Standards to mitigate the reliability impacts to the Bulk-Power System of such an exemption. As NERC will consider the reliability impacts to the Bulk-Power System caused by an such [sic] exemption, we believe that the concerns raised by NYSRC and Indicated Trade Associations on the appropriate registered entity responsible for implementing the mitigation activities, and the nature of such mitigation, should be addressed in the NERC standards development process."

Due to the interrelationship between these factors, the allowance for limited exemptions should be linked to the need to mitigate the impact of such exemptions, which will take time in and of itself. In addition, Order 901 directs NERC to consider the reliability impacts of such an exemption. If the SDT does not have identified quantities or models of likely exemptions to assess the impact of allowing exemptions, it is unclear how NERC is considering the reliability impacts of allowing exemptions. There must be guardrails in place to ensure that exemptions are truly limited, not open-ended, and there should be verification by means of accurate models and studies that the system can withstand the impacts of exemptions. If such studies demonstrate unreliable operations (i.e. Instability, Cascading Outages, and uncontrolled separation) would result from granting exemptions, then the exemptions should not be accepted. While ERCOT understands the impacts to generator owners, such assessment and determination should be made under FERC's direction to ensure that the limited exemptions and risk posed by such exemptions are balanced in such a way that the system maintains Reliable Operation.

Finally, regarding the implementation plan, ERCOT does not agree with how the FERC Order 901 excerpt quoted under "Equipment Limitations and Process for Requirement R6" has been applied. The FERC Order 901 excerpt refers to "typically older IBR technology," which would exclude a majority of IBRs that are in operation today. Aligning eligibility for PRC-029-1 exemptions based on documented equipment limitations under Requirement R6 with the effective date of PRC-029-1 would allow potentially hundreds of GWs of newer IBRs to qualify for exemptions. Such an allowance could result in a failure to realize the reliability benefits FERC intended to capture, as it would allow legacy IBRs to claim exemptions even if they are ultimately capable of complying with the requirements of PRC-029. Unless there is assurance, based on validated and accurate models, that planners and operators can verify that the System can withstand the impact of allowing these exemptions, this allowing this level of potential exemptions may not allow for Reliable Operations. In such instances where exemptions may not allow for Reliable Operations, there should be additional evaluation of available physical modifications (e.g. upgrade kits, new power plant controllers, new controller cards/circuits, control communication networks, component upgrades) for IBR technology that is not approaching its end of life and or an upcoming replacement/refurbishment cycle like "typically older IBR technology" is. Additionally, IBRs that make physical modifications to achieve compliance or that have to make software changes at multiple sites may need additional implementation time when such changes require changes at each individual inverter or turbine.

ERCOT expresses appreciation for all of the SDT's hard work in meeting an expedited timeline for developing a technically complex set of Requirements that attempts to balance elements from IEEE 2800, FERC Orders, NERC recommendations, and vast amounts of stakeholder input. The SDT is to be commended for its progress thus far on this critical standard.

Response

Thank you for your comments

Type 1 and Type 2 Wind: The team agrees and has added these resources into PRC-024-4 applicability. Language throughout the Standard was adjusted to reflect this change.

Capability and Performance Measures: The team agrees and the measures for R1 through R3 have been adjusted to include design/capability based requirements as well as the demonstration of performance during disturbances.

Time Horizon: The team finds that the Operational Assessment selection is appropriate. Real-time Operations is defined as “actions required within one hour or less to preserve the reliability of the bulk electric system”. In the event of Ride-through, no actions are taken by an operator in requirement language.

Note 5 (previous Note 4): The team finds that the per unit value should be left to the PC/TP. That approach is consistent with PRC-024-4.

Partial Failures and “IBR Unit”: The team would point to the PRC-030 draft that would analyze voltage/frequency excursions and identify if partial plant performance would necessitate a Corrective Action Plan. PRC-029 is only applicable to the overall plant/facility.

Attachment 1: Tables and Figures in Attachment 1 have been revised to add clarity on the operation regions. The range of values in row #4 of Tables 1 and 2 to clarify the continuous operation region. The team believes the figures provide additional clarity and complement the tables.

Shall not trip until…: The team agrees and has modified the notes in Attachment 1 and Attachment 2 (previous attachment 3) to “shall Ride-through unless… has been exceeded…”.

R2: The team added requirement subpart 2.3 to provide clarity on the operation within the Permissive Operation Region.

Terminology: The team has removed the definitions for operating regions. Language within the requirements and the attachments have been revised to reflect this.

Evaluation of Studies: clarity on capability expectations as well as performance have been added to the requirements and measures.

Previous R5: Previous Requirement R5 has been removed and added as an exemption to Requirement R1.

Frequency Values: The team selected these values to reflect the system need and to align with IEEE 2800 -when possible- and to accommodate ride-through frequency requirements in PRC-024 for synchronous machines and Type 1 and 2 wind.

PLL loss of synchronism: A footnote has been added to R1 to clarify PLL loss of synchronism

Attachment 1 – Clarification: Note 12 has been added to clarify the zones.

Regarding Exemptions: The team has modified Requirement R4 (previous R6) to include clarity on allowable exemptions and requires identification of such limitations to be documented and submitted.

For PRC-029-1 PG&E asks the SDT the following question: Does Table 1 or 2 apply to Type 4 Wind IBRs? It is unclear which table it would apply to and should be clarified since Table 1 specifies “Wind IBR” but not which types of Wind IBRs. PG&E suggests reconsidering the use of the term “trip” or “no-trip.” Per IEEE 2800-22, “trip” for IBRs may not mean the same as has been traditionally used for synchronous machines and other electric elements. For PRC-024-4 PG&E has the following question for the SDT to clarify: For Transmission Owners, does new language in sections 4.1.2 & 4.2.2 only apply to Synchronous Condensers?

Response	
Thank you for your comments.	

Attachment 1 – Type 1 and Type 2 wind: Additional language was added to a new footnote 10 and adjustments were made to Note 1 to clarify.
Terminology- Ride-through: The team agrees and has defined a new term for Ride-through and replaced language the requirements with this new term. Attachments have also been updated to utilize this term as the "Must Ride-through Zone".
Synchronous Condensers: The applicability section has been modified to apply to synchronous condensers, their step-up transformers, and auxiliary transformers.

NextEra aligns with EEI's comments:

PRC-029-1 (Applicability Section) Comments: EEI does not support the Applicability Section of PRC-029-1 for the following reasons:

{C}1. Applicability details should not be contained in footnotes. Please remove footnote 1 from the Applicability Section.

{C}2. Voltage Source Converter – High-voltage Direct Current (VSC-HVDC) are not defined or justified within the Technical Rationale as to why these resources need to be added PRC-029.

{C}3. Without a justification of a need to include VSC-HVDC systems, TOs should be removed from PRC-029-1.

{C}4. EEI does not support the use of the term "BPS IBRs" because no such term exists in the NERC Glossary of Terms that might provide entities with the knowledge to know definitively which IBRs are applicable.

{C}5. EEI also does not support language that points to the registration criteria.

To address our concerns, we suggest the following changes to the Applicability Section of PRC-029-1, noting the Facilities portion of our comments utilize the recommendations from the Project 2020-06 SDT (see boldface changes below):

{C}**4. Applicability:**

{C}4.1 Functional Entities:

{C}4.1.1 Generator Owner

{C}**4.1.2** {C}**Transmission Owner (and footnote 1)**

{C}4.2 Facilities: **(1) BES Inverter-Based Resources; and (2) Non-BES Inverter Based Resources (IBRs) that that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV. For purposes of this standard, the term "applicable Inverter-Based Resource" or "applicable Inverter-Based Resources" refers to the following:**

{C}**4.2.1** {C}**BPS IBRs**

{C}**4.2.2** {C}**IBR Registration Criteria**

PRC-024 Comments: While there were no questions related to the proposed modifications to PRC-024-4, EEI does not support all of the proposed changes made to PRC-024-4. Note the following:

Applicability Section of PRC-024-4

EEI does not support changing the intent of 4.2.1.4 (Previously 4.2.1.5) to include multiple synchronous generators connecting to a common bus under the BES Definition, Inclusion I4. Since the development of the BES definition, Inclusion I4 did not include or intend to include synchronous generators. Had that been the intent, the SDT could have included synchronous generator resources in I4. Furthermore, the BES Reference Document states in Chapter I4: BES Inclusion the following:

Dispersed power producing resources are small-scale power generation technologies that use a system designed primarily for aggregating capacity providing an alternative to, or an enhancement of, the traditional electric power system. Examples could include, but are not limited to: solar, geothermal, energy storage, flywheels, wind, microturbines, and fuel cells.

While EEI is open to making modifications to the BES Definition, trying to provide interpretations within individual Applicability Sections of proposed NERC Reliability Guidelines is not the proper method to make such a change. For this reason, and since 4.2.1.4 (previously 4.2.1.5) was intended to address IBRs; this part of the Applicability Section of PRC-024-4 should be deleted.

Comments on the proposed New Definitions

EEI has no concerns with the proposed new definitions, but we do have some non-substantive comments on their usage throughout PRC-029, Implementation Plan and Technical Rationale. (See below)

{C}· Usage of the newly defined terms deviated from the defined term within PRC-029 and the Technical Rational. (i.e., Operating vs. Operations)

{C}· Incorrectly stating in the Implementation Plan that there were no newly defined terms. Please correct this error.

Continuous Operating Region – Only used once in Requirement 2.3.

{C}· Continuous Operation Region used in Requirements 2.1, 2.1.2, 2.4, & once in Attachment 1 (i.e., suggest changing the defined term to Continuous **Operation** Region or correct to Continuous **Operating** Region throughout)

{C}· Continuous Operation Region used twice in the Technical Rationale; Continuous Operating Region never used in the Technical Rationale.

Mandatory Operating Region – Never used in PRC-029

{C}· Mandatory Operation Region used in PRC-029 in Requirements 2.2, 2.3, 2.4 & once in Attachment 1 (i.e., suggest changing the defined term to Mandatory **Operation** Region or correct to Mandatory **Operating** Region throughout)

{C}· Mandatory Operation Region was used twice in Technical Rationale; Mandatory Operating Region was never used in the Technical Rational.

Permissive Operating Region – Never used in PRC-029

{C}· Permissive Operation Region used in PRC-029 in Requirements 2.3, 2.4, & used twice in Attachment 1 (i.e., suggest changing the defined term to Permissive **Operation** Region or correct to Permissive **Operating** Region throughout)

{C}· Permissive Operation Region used once in the Technical Rationale; Permissive Operating Region never used in the Technical Rationale.

Response

Thank you for your comments.
Applicability footnotes: The usage of footnotes in the applicability section is often used to provide clarity and is consistent with usage in PRC-024-4.
VSC-HVDC: Modifications have been made to include these elements within PRC-029.
Applicability: The applicability section has been modified to include more specific details on currently applicable facilities. The IBR that will be included as part of registration changes (Category 2 assets) will be added following the approval of pending changes to the NERC Rules of Procedure. These are currently excluded from this draft.

Operation Region: The team agrees and has removed the operation regions as defined terms.
Attachment 1: Tables and Figures in Attachment 1 have been revised to add clarity on the operation regions.

Has the MPT Volts/Hz capability been considered when considering the high voltage/low frequency curves?

For R6, the use of "repair" seems inappropriate - an equipment limitation is not equivalent to a broken part in need of repair. We suggest that "repair(s) or replace the limiting element" in R6.1.4 and R6.2 be changed to "remedy the equipment limitation".

The standard requires IBR to ride-through regardless of operating condition of the transmission system. The IBR is typically designed to ride-through for planning events, most likely defined in TPL-001 standard. Considering 24 hour/365 day operation, the transmission system may be experiencing outages beyond planning events. During such an abnormal operating condition, the IBR may not be able ride-through system disturbances as specified. The same could also be true as the transmission system changes over time, as new transmission lines are added to the transmission system and generating plants are added to or removed from the transmission system. The IBR which is designed to ride-through certain transmission network and operating conditions at the time of entering commercial operation may not be able to do so if transmission network and operating conditions change significantly over time. The standard needs to recognize such issues and grant an exception if IBR fails to ride-through.

The SDT proposes to add continuous operating region, mandatory operating region, and permissive operating region terms to the Glossary of Terms. However, these terms are specific to voltage ride-through requirements. There is no reason to limit those terms to voltage ride-through capability only. The continuous and mandatory operation region terms could be applied to frequency ride-through capability as well. Refer to IEEE 2800 to see how these terms are used for both voltage and frequency ride-through capabilities.

Continuous/mandatory/permissive operating region terms:

1. The SDT uses continuous/mandatory/permissive “operating” region as well as continuous/mandatory/permissive “operation” region. Be consistent with either “operating” or “operation” throughout the standard.
2. Following comments to align voltage ranges in Attachment 1, Tables 1 & 2:
    - Mandatory Operating Region term should read like following: The range of voltages, measured at the high-side of main power transformer, that are ≥ 0.1 per unit and < 0.9 per unit OR > 1.1 per unit and ≤ 1.2 per unit.

- Permissive Operating Region term should read like the following: The range of voltages, measured at the high-side of main power transformer, that is ≤< 0.1 per unit.

3. These terms specify voltage threshold, but which voltage is used in these terms is in the Attachment 1. Per attachment 1, the continuous and mandatory operating regions are based on phase-to-ground or phase-to-phase voltages. But the permissive operating region is based on positive-sequence voltage. The defined terms should also make it clear which voltage thresholds are defined.

Consider revising the purpose statement as following: To ensure that Inverter-Based Resources (IBRs) remain connected and support the Bulk Power System (BPS) during and after frequency and voltage excursions events.

Transmission Owner is included as a Functional Entity in section 4. However, footnote 1 makes it confusing. Would standard only apply to Transmission Owner when it owns the VSC-HVDC transmission facility connecting isolated IBR with BPS?

Currently, PRC-029-1 allows for a GO or TO to seek an exemption from meeting voltage-ride through requirements in R1 and R2.

Southern Company believes that GOs and TOs should be able to seek exemptions from meeting frequency and voltage ride-through requirements in R1 – R5.

The proposed standard only provides for VRT exemptions. Any consideration for FRT, ROCOF, phase angle?

Comment to PRC-024-4:

Facilities section 4.2.1.1 should include I2 of the BES definition and section 4.2.1.4 be removed or reference I2 in place of I4. I4 of the BES definition was intended to point to IBRs at the time of the latest BES definition adoption in 2018 as dispersed power resources and was not intended to point to synchronous generation resources.

Opportunity to clarify that legacy IBRs must maximize capabilities:

1. For NOGRR245, it has been advocated that legacy IBRs should make software / settings changes to maximize capabilities to meet or approach the new ride-through requirements, unless such changes are unreasonably priced.
2. Southern's experience is that software / settings changes are commercially reasonable. The "unreasonably priced" language is intended to protect against price gauging from OEMs.
3. The current PRC-029-1 draft requires legacy IBRs to meet the new voltage ride-through requirements unless a documented technical limitation exists. So a legacy IBR can document an exemption and have performance capabilities less than new VRT standard. But what happens if that legacy IBR owner later learns there is an available software / setting change that would reduce or remove the limitation? The current draft need clarity to address this.

4. Southern Company supports such a software / setting deployment requirement and believes it would (1) be commercially reasonable and (2) more clearly require ride-through capability maximization.

Finally, Southern Company supports EEI and NAGF comments.

Response

Thank you for your comments.
Voltz/Hz Capability: The team agrees this capability needed clarity and have included this as a potential exemption to voltage Ride-through requirement R1.
Removing Limitations: The team agrees that replacing equipment associated with the limitation also remove any exemption. This has been clarified in Requirement R4 (previous R6).
Scope of legacy IBR and approach by the team: The scope of PRC-029 is consistent with the SAR assigned to this team and the regulatory directives from FERC Order No. 901 that were assigned to this team. There is some potential for documented limitations within Requirement R4 and the Implementation Plan for legacy equipment that cannot meet any voltage ride-through requirements (R1 and R2). Some revisions were made to clarify design capabilities would still be required.
Terminology and Attachment 1: The team agrees and has removed the terms for operating regions from the list of defined terms and the requirements. Attachment 1 has been modified to add clarity for the operating conditions for each of the regions referenced in the tables.
Purpose statement: The team agrees and has modified the purpose statement.
Transmission Owner: Correct, the current version of the draft would apply to VSC-HVDCs with a dedicated IBR connection that is owned by the TO.
Exemptions: The scope of allowable exemptions within R4 (previously R6) is consistent with the regulatory directives of Order No. 901. Frequency or phase-jump requirements cannot apply for exemption. New IBR cannot apply for exemption. This is consistent with the ordered directives.
Regarding Excemptions: The team has modified Requirement R4 (previous R6) to include clarity on allowable exemptions and requires identification of such limitations to be documented and submitted.
PRC-024 and PRC-029 applicability: The applicability sections have been modified to include more specific details on currently applicable facilities. The IBR that will be included as part of registration changes (Category 2 assets) will be added following the approval of pending changes to the NERC Rules of Procedure. These are currently excluded from these draft.

While inclusive, is PRC-024-4 Facility Section Part 4.2.1.4 applicable to synchronous generators? Inclusion 4, when written, was designed to catch the wind/solar aspects of the generation fleet. Inclusion 2 seems to be more appropriate (if not already covered in 4.2.1.1). The MPT footnote appears to be limited to Quebec TO synchronous generators and does not include a reference to synchronous condensers (4.2.2 synchronous condenser applicable facilities simply says “step-up transformer(s)”). In PRC-024-4 Requirement 2 there is a reference to “MPT” and the introduction of Transmission Owner within Requirement. It is not clear if applicable to TOs outside of Quebec based on the language provided (from Requirement R2---“…a voltage excursion at the high-side of the GSU or MPT…” which the GSU/MPT is not mentioned in applicable Facilities for synchronous condensers Section 4.2.2). In Attachment 1 there is a similar issue in that footnote 8 on page 21 mentions the high-side of the GSU or MPT—Also should be noted that Footnote 8 does not appear to have an anchor (location within document to reference the footnote). On page 22 of Attachment 2A there are references to the GSU/MPT as well. Just seeking clarification to avoid an entity having a synchronous condenser indicating no applicability because of the language. This inconsistency in language does not appear to follow items 8 (“Clear Language”) and 10 (“Consistent Terminology”) of the Ten Benchmarks of an Excellent Reliability Standard as referenced in the Guideline for Quality Review of NERC Reliability Standards Project Documents.

PRC-029-1- SDTs need to use the same IBR terms and not add additional descriptors. Even the title of the Standard is not consistent. Should use the proposed definitions in 2020-06 Verifications of Models and Data for Generators for clarity and consistency. There is no such Facility as “IBR Registration Criteria”. Footnote 1 contains undefined terms which should be defined within this Standard if used. Because of the inconsistency in definition use, it is not clear whether this applies to the IBR or IBR Unit locations (even when stated that it does not apply to “individual inverter units or measurements takes at individual inverter unit terminals.” If looking at Project 2020-06, the inverters in a “common IBR Unit configuration’ as shown in Figure 2.2 and 2.3 of the Technical Rational are exactly at the individual IBR Units (see link 2020-06_IBR_Definitions_Technical_Rationale_02222024.pdf (nerc.com)). Is “exchange current” considered the same as “inject current” which is used (various ways) in other Standards being proposed? The new terms introduced address range of voltages that may not correlate to the Tables effectively. The Continuous Operating Region definition shows to **include** 1.1 per unit and should reflect the 1800 seconds in Table 1 and Table 2 but the 1.1 voltage per unit in the Tables show only a 1 second capability (Mathemataical expression includes 1.1 per unit in the Table which it should not). Furthermore the 1.2 voltage per unit is shown to be included in the Mandatory Operating Region but NOT in the Tables. Please clarify the expectations as entities had an issue in PRC-024 setting protection on the curves when initially mandatory. With conflicting information, and Figures that are not as explicit or appear to match the Tables, WECC is concerned there may be confusion. This language does not appear to follow Item 8 (“Clear Language”) and 10 of the Ten Benchmarks of an Excellent Reliability Standard as referenced in the Guideline for Quality Review of NERC Reliability Standards Project Documents.

At a minimum, bullet 2 under Attachment 1 Table 2 should mention all the types of IBR as listed in other Standards (Type 3 and type 4 of wind is covered in bullet 1, “Isolated IBR” is undefined, and 2.b. simply says “Other IBR plants” and limits hybrid to PV and “ESS” (possible typo that

should be "BESS"?). The "not limited to" should remain and the SDT may say all are covered with said language but clarity could be provided by adding consistent language as used in other Standards. This inconsistency in language does not appear to follow items 10 ("Consistent Terminology") of the Ten Benchmarks of an Excellent Reliability Standard as referenced in the Guideline for Quality Review of NERC Reliability Standards Project Documents. Attachment 1 Table 2 Bullet 3 leaves the applicability to the TP but the TP is not called out as an applicable entity and this is an Operations Assessment time horizon. In the Technical Rationale it clearly states "*Compliance with PRC-029 is determined from IBR ride-through performance during transmission system events in the field and not from* ***interconnection studies, transmission planning studies****, operational planning studies, or from IBR models*." So, if IBRs in a hybrid plant have issues, the TP is to blame for calling out the incorrect Table? TPs may very well have the studies to determine how long a ride-through should be sustained by IBRs, but there is no compliance responsibility (not saying there should be—should be responsibility properly assigned through the Standards process). Bullet 4 allows the PC or TP to change the Requirement criteria but there is no accountability if done (furthermore no notifications for awareness to those entities in the Operations side of business). The apparent responsibility does not appear to follow items 1 ("Applicability") of the Ten Benchmarks of an Excellent Reliability Standard as referenced in the Guideline for Quality Review of NERC Reliability Standards Project Documents. "MPT" is not defined in the Standard yet used repeatedly. Clarity can be provided with a footnote or addition of a definition (not that synchronous condenser use in PRC-024-4 was unclear for MPT). There are only Severe VSLs for Requirements R1 through R5. Clarity on where the inverter is (based on the 2020-06 drawings provided and language in this Standards Technical Rational) will be important to understand. Failure of individual IBR units (as defined in 2020-06) appears to not be addressed9unless it is intended to be addressed by the Sever VSL) and will have an impact on being complaint at the IBR level.

Thank you for your comment. **PRC-024 applicability and MPTs:** The applicability section has been modified to include more specific details on currently applicable facilities. The IBR that will be included as part of registration changes (Category 2 assets) will be added following the approval of pending changes to the NERC Rules of Procedure. These are currently excluded from this draft. Additionally, the footnotes have been modified to add clarity regarding the MPT. **PRC-029 applicability:** The applicability section has been modified to include more specific details on currently applicable facilities. The IBR that will be included as part of registration changes (Category 2 assets) will be added following the approval of pending changes to the NERC Rules of Procedure. These are currently excluded from this draft.	

Terminology and Attachment 1: The team agrees and has removed the terms for operating regions from the list of defined terms and the requirements. Attachment 1 has been modified to add clarity for the operating conditions for each of the regions referenced in the tables. Further, the notes have been revised to resolve issues identified above. **VSL tables:** The tables have been revised to include additional levels per the capability-based requirement language.

For each of the measures M1-M5, what “other evidence” can demonstrate compliance with R1-R5 other than recorded data? How does the drafting team believe that generator owners can assure this performance expectation can be achieved prior to an actual event? There is no test verification that can be performed to confirm the expected performance that considers every type of system disturbance that can occur.

Many references in the requirements point toward Continuous Operating Region, Mandatory Operating Region, and Permissive Operating Region "as specified in **Attachment 1**", yet Attachment 1 does not specify any of these regions. Operating Regions should be added to Attachment 1 tables and figures. No-trip zone Figures 1 & 2 don't match the tables. Is there a point or distinction being made by using capitalized "Systen" instead of undefined "system" in requirements?

Comment	

On behalf of the SERC Generator Working Group:

Consider allowing for some period of time beyond the effective date of PRC-029 to document limitations per (R6) – contemplate the real impact to BES reliability of limitation documentation.

Consider synchronizing the phase in of PRC-028 with the measures such as M1 stating "*shall have evidence of actual recorded data*...".

For each of the measures M1-M5, what "other evidence" can demonstrate compliance with R1-R5 other than recorded data? How does the drafting team believe that generator owners can assure this performance expectation can be achieved prior to an actual event? There is no test verification that can be performed to confirm the expected performance that considers every type of system disturbance that can occur.

MP agrees with the NSRF's suggestions to enhance PRC-029, especially regarding limiting the power of equipment limitations from exempting applicable entities from compliance, expanding the applicable facilities to include IBRs of 20MVA and above, and more precisely defining applicable entities and facilities within the text of the standard. MP also suggests that a formal definition of "Inverter-Based Resources" precede the adoption of the standard.

Comment	
We are concerned that the standard refers to a defined term for IBR which has yet to be adopted in project 2020-06. We suggest that the drafting team ensure consistent language is used in the section 4.2 "Facilities" section with the other projects such as 2021-04 (PRC-028) and 2023-02(PRC-030). Section 4.2.2 refers to IBR Registration criteria, however it is our understanding that section 4.2.1 would refer to GOs and TOs "that own equipment as identified in section 4.2" and where section 4.2 would indicate "the Elements associated with (1) BES Inverter-Based Resources; and (2) Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV." . We question why "attachment 1" and "Requirement R6" are written in bold. Attachment 1: should the "including, but not limited to" in table 2 include the same list (or minimally the same wording) that is found in the technical rationale of the IBR definition in project 2020-0?. For example, the IBR list in 2020-06 refers to "solar photovoltaic" whereas table 2 refers to "photovoltaic (PV)".	

In what standard does the PC/TP define the applicable table in point 3 of section 2 in attachment 1? Same question for the voltage base for per unit calculation in both Attachment 1 and 2. Is there a corresponding requirement in another standard that requires the PC/TP to do this?

· Terms : Mandatory and permissive operation should be defined based on the attachment figures allowing for interconnections to use different requirements

· A-4.2.2 What is the IBR registration criteria? Add a clear reference and make sur the user understands what the IBR registration criteria is.

· B-R2-2.1 Attachment 1 only uses "no-trip zone". Define continuous operating region more clearly in the table (similar to what is done in PRC-024-4)

· B-R2-2.1.2 Can the TP ask for a mix of active/reactive power based on a predetermined ratio (currently only indicated as active or reactive).

· B-R2-2.2 Attachment 1 only uses "no-trip zone". Define "mandatory operation region" in Attachment 1.

· B-R2-2.4 Permissive operation region is not used or defined in attachment 1.

· B-R3. The document refers to an overvoltage value of 1.2pu. It should refer to a voltage exceeding the mandatory operating region in order for Interconnections to set their own overvoltage table.

· B-R3. Since R6 does not apply to this requirement, what will be done with existing IBR that cannot ride through these overvoltages ? An exemption clause is required for existing IBR that cannot be modified or upgraded.

· B-R4. The 5Hz/s value should be moved to Attachment 3 and B-R4 should only refer to the value in the Attachment.

· B-R4. Since R6 does not apply to this requirement, what will be done with existing IBR that cannot ride through these frequencies and ROCOF ? (for instance, for all the HQ connected projects, the ROCOF requirement was 4Hz/s) An exemption clause is required for existing IBR that cannot be modified or upgraded.

· B-R5. Since R6 does not apply to this requirement, what will be done with existing IBR that cannot ride through this phase angle jump ? An exemption clause is required for existing IBR that cannot be modified or upgraded.

· Attachment 1. Tables 1 and 2: Indicate what is considered as “continuous operation”, “mandatory operation” and “permissive operation” in an additional column.

· Attachment 1. HQ needs a Quebec regional variance since the Québec Interconnection has its own requirements in this regard.

· Attachment 2. Bullet 3: This sentence is hard to read. Proposed replacement: "Each IBR shall not trip unless the cumulative time of one or more instances in which the instantaneous voltage exceeds the respective voltage threshold over a 1-minute time window exceeds the minimum ride-through time" · Attachment 2. HQ needs a Quebec regional variance since the Québec Interconnection has its own requirements in this regard. · Attachment 3. This attachment should also include the maximum absolute ROCOF value. · Attachment 3. HQ needs a Quebec regional variance (or the equivalent through the “regie de l’energie” approval process). · B-R2-2.1.2 Which entity between Transmission Planner, Planning Coordinator, Reliability Coordinator and Transmission Operator has priority to specify those requirements? · B-R2-2.4 Which entity between Transmission Planner, Planning Coordinator, Reliability Coordinator and Transmission Operator has priority to specify those requirements?

Response
Thank you for your comment. **IBR:** The team agrees and will include IBR defined terms once those are approved. **Applicability section:** The team agrees and has collaborated with PRC-028 and PRC-030 teams for consistent language in the applicability section. **Attachment 1:** These notes have been modified to clarify usage of the tables. **Attachment 1**: Tables and Figures in Attachment 1 have been revised to add clarity on the operation regions and the “must Ride-through zone”. The range of values in row #4 of Tables 1 and 2 to clarify the continuous operation region. **Applicability**: The applicability section has been modified to include more specific details on currently applicable facilities. The IBR that will be included as part of registration changes (Category 2 assets) will be added following the approval of pending changes to the NERC Rules of Procedure. These are currently excluded from this draft. **Transient Overvoltage**: Previous requirement R3 and Previous Attachment 2 have been removed. **Frequency 5hz clarification**: The team has made modifications to the requirement language and the attachment to address this. **Regarding Excemptions**: The scope of allowable exemptions within R4 (previously R6) is consistent with the regulatory directives of Order No. 901. Frequency or phase-jump requirements cannot apply for exemption. New IBR cannot apply for exemption. This is consistent with the

ordered directives.The team has modified Requirement R4 (previous R6) to include clarity on allowable exemptions and requires identification of such limitations to be documented and submitted. **Quebec variant**: The team will coordinate with Hydro Quebec to include their variant as identified by Hydro Quebec. Priority: This issue is out of scope for the team. The language in the requirement is to make allowance for established operational instructions.

Comment	
Overall comments: 1. Implementation date: 6 months is not sufficient for IBR manufacturers to meet the new standard. Instead we propose 2yrs to accommodate product development/adequacy and appropriate validation. 2. For R6, R3,R4,R5 should be included as well for the documented limitation communication (see R6 comments below).	

3. For Attachment 1, for VSC-HVDC connected IBRs, it is not clear if Table 2 is applicable at the MPT on grid side or on the IBR side of HVDC (see Attachment 1 comments below)

4. For MFRT, GEV suggests to align to IEEE2800-2022 7.2.2.4 for consistency (see Attachment 1 comments below).

GEV comments to R6: The language in R6 only allows documented limitations for Requirements R1 and R2. The standard must allow for documentation of limitations for Requirements R3, R4, and R5, as some existing site equipment was not designed to these requirements originally.

GEV comments to Table 2 in Attachment 1: For VSC-HVDC connected IBRs, please clarify if Table 2 is applicable at the MPT on grid side or on the IBR side.

GEV comments to MFRT: For MFRT requirements, GE Vernova strongly suggests that this language should align to IEEE2800-2022 7.2.2.4. Exceptions from the IEEE standard that are relevant were not included, making these requirements inconsistent with 2800-2022.

EEI offers the following additional comments on both PRC-024 & PRC-029:

PRC-029-1 (Applicability Section) Comments: EEI does not support the Applicability Section of PRC-029-1 for the following reasons:

1. Applicability details should not be contained in footnotes. Please remove footnote 1 from the Applicability Section.
2. Voltage Source Converter – High-voltage Direct Current (VSC-HVDC) are not defined or justified within the Technical Rationale as to why these resources need to be added PRC-029.
3. Without a justification of a need to include VSC-HVDC systems, TOs should be removed from PRC-029-1.
4. EEI does not support the use of the term “BPS IBRs” because no such term exists in the NERC Glossary of Terms that might provide entities with the knowledge to know definitively which IBRs are applicable.
5. EEI also does not support language that points to the registration criteria.

To address our concerns, we suggest the following changes to the Applicability Section of PRC-029-1, noting the Facilities portion of our comments utilize the recommendations from the Project 2020-06 SDT (see removals (i.e., TOs, registration criteria, etc. and other text) and boldface changes below:

4. Applicability:

4.1 Functional Entities:

4.1.1 Generator Owner

Facilities:

(1) BES Inverter-Based Resources; and (2) Non-BES Inverter Based Resources (IBRs) that that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

PRC-024 Comments: While there were no questions related to the proposed modifications to PRC-024-4, EEI does not support all of the proposed changes made to PRC-024-4. Note the following:

Applicability Section of PRC-024-4

EEI does not support changing the intent of 4.2.1.4 (Previously 4.2.1.5) to include multiple synchronous generators connecting to a common bus under the BES Definition, Inclusion I4. Since the development of the BES definition, Inclusion I4 did not include or intend to include synchronous generators. Had that been the intent, the SDT could have included synchronous generator resources in I4. Furthermore, the BES Reference Document states in Chapter I4: BES Inclusion the following:

Dispersed power producing resources are small-scale power generation technologies that use a system designed primarily for aggregating capacity providing an alternative to, or an enhancement of, the traditional electric power system. Examples could include, but are not limited to: solar, geothermal, energy storage, flywheels, wind, microturbines, and fuel cells.

While EEI is open to making modifications to the BES Definition, trying to provide interpretations within individual Applicability Sections of proposed NERC Reliability Guidelines is not the proper method to make such a change. For this reason, and since 4.2.1.4 (previously 4.2.1.5) was intended to address IBRs; this part of the Applicability Section of PRC-024-4 should be deleted.

Comments on the proposed New Definitions

EEI has no concerns with the proposed new definitions, but we do have some non-substantive comments on their usage throughout PRC-029, Implementation Plan and Technical Rationale. (See below)

- Usage of the newly defined terms deviated from the defined term within PRC-029 and the Technical Rational. (i.e., Operating vs. Operations)
- Incorrectly stating in the Implementation Plan that there were no newly defined terms. Please correct this error.

Continuous Operating Region – Only used once in Requirement 2.3.

- Continuous Operation Region used in Requirements 2.1, 2.1.2, 2.4, & once in Attachment 1 (i.e., suggest changing the defined term to Continuous **Operation** Region or correct to Continuous **Operating** Region throughout)
- Continuous Operation Region used twice in the Technical Rationale; Continuous Operating Region never used in the Technical Rationale.

Mandatory Operating Region – Never used in PRC-029

- Mandatory Operation Region used in PRC-029 in Requirements 2.2, 2.3, 2.4 & once in Attachment 1 (i.e., suggest changing the defined term to Mandatory **Operation** Region or correct to Mandatory **Operating** Region throughout)
- Mandatory Operation Region was used twice in Technical Rationale; Mandatory Operating Region was never used in the Technical Rational.

Permissive Operating Region – Never used in PRC-029

- Permissive Operation Region used in PRC-029 in Requirements 2.3, 2.4, & used twice in Attachment 1 (i.e., suggest changing the defined term to Permissive **Operation** Region or correct to Permissive **Operating** Region throughout)

- Permissive Operation Region used once in the Technical Rationale; Permissive Operating Region never used in the Technical Rationale.

Comment

1. Implementation should align with PRC-028-1 proposed implementation to ensure data collecting information is available to adhere to PRC-029-1.

2. PRC-024-4 Applicability and Purpose should include asynchronous type 1 and type 2 wind since these are not IBRs and therefore not applicable to PRC-029:

4.2.1.4 Elements that are designed primarily for the delivery of capacity from the multiple synchronous generators ***or asynchronous type 1 or type 2 wind generators,*** connecting to a common bus identified in the BES Definition, Inclusion I4, to the point where those resources aggregate to greater than 75 MVA.

4.2.1.6 Type I and type II asynchronous wind generation identified in the BES Definition, Inclusion I4.

3. Suggest that the drafting team ensure consistent language is used in the section 4.2 “Facilities” section with the other projects such as Project 2021-04 (PRC-028) and 2023-02(PRC-030). We suggested the following language be included in the applicability section. Facilities: The Elements associated with (1) BES Inverter-Based Resources; and (2) Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

Comment	
The NAGF provides the following additional comments for consideration: *PRC-024:* *a. Section 4.2.1.2 – Consider adding the language "Main Power Transformer (MPT)".*	

b. Section 4.2.1.4 and 4.2.1.5 - Recommend that the proposed language be modified to reference BES Definition – Inclusion I2 instead of Inclusion I4 – Dispersed Power Producing Resources. The proposed new PRC-029 standard's focus is on Frequency and Voltage Ride-through Requirements for Inverter-Based Generating Resources and therefore should include a reference BES I4 resources.

PRC-029:

a. Terms – the NAGF requests additional clarification on how the proposed defined terms work with the proposed PRC-030. Will analysis be required for an event under the proposed PRC-029 and under PRC-030? Potential double jeopardy issue. Alternatively, if tripping is allowed under PRC-029, would an analysis still be required under PR-030?

b. Section 4.2 - Facilities:

i. Use of the capitalized term "Bulk Power System (BPS) Inverter-Based Resources (IBR)" should be reviewed as it is not a defined term in the NERC Glossary of Terms. In addition, it is very likely that not all Bulk Power System Inverter-Based Resources will be registered even under NERC's modified Rules of Procedure. Until the definition of Inverter-Based Resources is approved, the SDT should only use the term "inverter-based resource" if needed.

ii. The NAGF requests clarification if IBR plants that include synchronous condensers should meet the PRC-029 requirements.

c. Comments Related to Attachments:

i. Attachment 1 – Recommend adding to the table a column that species what area is the Continuous Operating Region, Mandatory Operating Region and Permissive Operating Region. As currently structured, it is not clear where the different regions begin or end. If possible, the NAGF recommends a graph showing the different areas for clarity.

ii. The abbreviations "MPT" and "ESS" are not defined within the standard/attachment. Please ensure all acronyms/initializations are fully defined for use.

iii. If the term ESS is intended to mean Energy Storage Systems, does this also apply to water storage systems, or only Battery Energy Storage Systems? If the intent is to refer to Battery Energy Storage Systems, please modify the term used.

iv. Attachment 1, note 3 – There does not appear to be a requirement proposed for the Transmission Planner (TP) to provide direction as stated in note 3. Request clarification on how the TP will provide such guidance/direction on the applicable table to be used.

v. Attachment 1, Note 7 – These notes appear to state that no unit should trip in a 10 second period if voltage is fluctuating, but the summation of time interval does not appear to be 10 seconds in most instances. As an example, assuming that the SDT intends for a generator to follow the voltage for 10 seconds when it is fluctuating between .7 and .5, the unit should be allowed to trip when voltage is below the .5 level

for 1.2 seconds. However, note 7 appears to state that there is a 10 second limit if voltage were to be below .7 for 1 second, then goes below .5 for 3 seconds, then returns to the .7 for 6 seconds. Please verify this interpretation is correct, or how this language should be understood. *vi. Attachment 1, Notes 7 and 8 – Both of these items discuss cumulative numbers in Tables 1 and 2. As worded, it is unclear if the intent is to add the numbers in Table 1 to the numbers in Table 2, or if the intent is to add the numbers in the second column of Table 1 for those resources that are considered Table 1 entities, and similar for Table 2 entities. Please clarify the wording so the intent of the standard is clear.*	
Likes 0	
Dislikes 0	
Response	
Thank you for your comments. **MPT**: The team agrees and has modified PRC-024 and PRC-029 to clarify language for the MPT. Thank you for your comment**.** **Applicability**: The applicability section has been modified to include more specific details on currently applicable facilities. The IBR that will be included as part of registration changes (Category 2 assets) will be added following the approval of pending changes to the NERC Rules of Procedure. These are currently excluded from this draft. **Measures (events**): The evidence of compliance for disturbance monitoring that are associated with voltage and frequency excursions that were System disturbances and would be identified for analysis or another trigger by an applicable entity within draft PRC-030. Evidence of disturbance monitoring of IBR associated with those disturbances would be triggered by compliance under the requirements for PRC-030. A GO/TO who provides the data per the requirements in PRC-030 would fulfill the obligations of those requirements. **Operation Region:** The team agrees and has removed the operation regions as defined terms. **Attachment 1**: Tables and Figures in Attachment 1 have been revised to add clarity on the operation regions. **ESS:** This has been revised to BESS **Attachment 1 Notes**: The team has modified notes to address which table should be used. **10 second accumulation:** The team has added clarity to the requirements and TR on how to determine the 10-second window and changing voltages.

AZPS supports the following comments that were submitted by EEI on behalf of its members:

PRC-029-1 (Applicability Section) Comments: EEI does not support the Applicability Section of PRC-029-1 for the following reasons:

1. Applicability details should not be contained in footnotes. Please remove footnote 1 from the Applicability Section.

2. Voltage Source Converter – High-voltage Direct Current (VSC-HVDC) are not defined or justified within the Technical Rationale as to why these resources need to be added PRC-029.

3. Without a justification of a need to include VSC-HVDC systems, TOs should be removed from PRC-029-1.

4. EEI does not support the use of the term “BPS IBRs” because no such term exists in the NERC Glossary of Terms that might provide entities with the knowledge to know definitively which IBRs are applicable.

5. EEI also does not support language that points to the registration criteria.

To address our concerns, we suggest the following language in the Applicability Section of PRC-029-1, noting the Facilities portion of our comments utilize the recommendations from the Project 2020-06 SDT):

4. Applicability:

4.1 Functional Entities:

4.1.1 Generator Owner

4.2 Facilities: (1) BES Inverter-Based Resources; and (2) Non-BES Inverter Based Resources (IBRs) that that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

PRC-024 Comments: While there were no questions related to the proposed modifications to PRC-024-4, EEI does not support all of the proposed changes made to PRC-024-4. Note the following:

Applicability Section of PRC-024-4

EEI does not support changing the intent of 4.2.1.4 (Previously 4.2.1.5) to include multiple synchronous generators connecting to a common bus under the BES Definition, Inclusion I4. Since the development of the BES definition, Inclusion I4 did not include or intend to include synchronous generators. Had that been the intent, the SDT could have included synchronous generator resources in I4. Furthermore, the BES Reference Document states in Chapter I4: BES Inclusion the following:

Dispersed power producing resources are small-scale power generation technologies that use a system designed primarily for aggregating capacity providing an alternative to, or an enhancement of, the traditional electric power system. Examples could include, but are not limited to: solar, geothermal, energy storage, flywheels, wind, microturbines, and fuel cells.

While EEI is open to making modifications to the BES Definition, trying to provide interpretations within individual Applicability Sections of proposed NERC Reliability Guidelines is not the proper method to make such a change. For this reason, and since 4.2.1.4 (previously 4.2.1.5) was intended to address IBRs; this part of the Applicability Section of PRC-024-4 should be deleted.

Comments on the proposed New Definitions

EEI has no concerns with the proposed new definitions, but we do have some non-substantive comments on their usage throughout PRC-029, Implementation Plan and Technical Rationale. (See below)

- Usage of the newly defined terms deviated from the defined term within PRC-029 and the Technical Rational. (i.e., Operating vs. Operations)
  - Incorrectly stating in the Implementation Plan that there were no newly defined terms. Please correct this error.

Continuous Operating Region – Only used once in Requirement 2.3.

- Continuous Operation Region used in Requirements 2.1, 2.1.2, 2.4, & once in Attachment 1 (i.e., suggest changing the defined term to Continuous Operation Region or correct to Continuous Operating Region throughout)
- Continuous Operation Region used twice in the Technical Rationale; Continuous Operating Region never used in the Technical Rationale.

Mandatory Operating Region – Never used in PRC-029

- Mandatory Operation Region used in PRC-029 in Requirements 2.2, 2.3, 2.4 & once in Attachment 1 (i.e., suggest changing the defined term to Mandatory Operation Region or correct to Mandatory Operating Region throughout)
- Mandatory Operation Region was used twice in Technical Rationale; Mandatory Operating Region was never used in the Technical Rational.

Permissive Operating Region – Never used in PRC-029

- Permissive Operation Region used in PRC-029 in Requirements 2.3, 2.4, & used twice in Attachment 1 (i.e., suggest changing the defined term to Permissive Operation Region or correct to Permissive Operating Region throughout)
- Permissive Operation Region used once in the Technical Rationale; Permissive Operating Region never used in the Technical Rationale.

Comment

If using ALL CAPS, consider RCF as the acronym. It is not that significant a metric to require capitalization of “of”.

RoCoF is also used in many other jurisdictions.

FERC order:

“In other words, under certain conditions some IBRs cease to provide power to the Bulk-Power System due to how they are configured and programmed. ” Yes, but PRC-024 now prohibits this. In some cases, settings in the older plants can be tweaked to improve performance but we are having trouble getting good models from the GOs. To address NERC concerns we need requirements for better models.

“some models and simulations incorrectly predict that some IBRs will ride through disturbances, i.e., maintain real power output at pre-disturbance levels and provide voltage and frequency support consistent with Reliability Standard PRC-024-3”. Only if incorrectly modelled.

Require better modelling to identify issues and determine mitigations. PRC-029 will not stop the problem of simulating a system that works great in the virtual world but will not perform when called upon.	
Likes 0

Texas RE has the following additional comments for PRC-029-1:	

1. Texas RE recommends the new terms included in PRC-029-1 clearly state the voltage measurements included are at the high-side of the main transformer connecting to the BPS transmission system. Texas RE suggests the following changes (in bold):

Term(s): Continuous Operating Region – The range of voltages, measured at the high-side of the **BPS** main power transformer, that are ≥ 0.9 per unit and ≤ 1.1 per unit.

Mandatory Operating Region – The range of voltages, measured at the high-side of the **BPS** main power transformer, that are > 0.1 per unit and < 0.9 per unit – or – > 1.1 and ≤ 1.2 per unit.

Permissive Operating Region – The range of voltages, measured at the high-side of the **BPS** main power transformer, that is ≤ 0.1 per unit.

2. Consider changing 'each IBR' to 'each IBR Facility' for all the requirements.

3. For consistency, consider modifying the title of the standard to (in bold):

Title: Frequency and Voltage Ride-through Requirements for Inverter-Based **Generating** Resources

4. Consider changing 4.2.1 to **BES** IBRs (instead of BPS IBRs) to be consistent with other PRC standards such as proposed reliability standards PRC-028-1 and PRC-024-4.

5. Consider changing voltage (per unit) in Attachment 1 (third row) to greater than 1.05 pu only (i.e. remove the equal 1.05 criterion). Typical BES and BPS systems are expected to operate continuously for voltage levels 0.95 – 1.05 pu.

Attachment 1 - changes

In Table 1 & Table 2 change > 1.05 to >1.05

Add the following to Table 1 and 2:

Voltage (per unit): > 0.9 Minimum Ride-Through: Continuous

Voltage (per unit): < 1.05 Minimum Ride-Through: Continuous

Response	

Thank you for your comment. **Operation Region:** The team agrees and has removed the operation regions as defined terms and added clarity on the point of measurement. **Attachment 1:** Tables and Figures in Attachment 1 have been revised to add clarity on the operation region. Additionally, values were corrected. **Applicability**: The applicability section has been modified to include more specific details on currently applicable facilities. The IBR that will be included as part of registration changes (Category 2 assets) will be added following the approval of pending changes to the NERC Rules of Procedure. These are currently excluded from this draft.

• GTC recommends increasing the implementation timeline to be 12 to 18 months after the effective date of the applicable governmental authority's order approving for both the PRC-024-4 and PRC-029-1 standards. • There were no balloting questions provided for the language changes in the PRC-024-4 standard. GTC recommends providing balloting questions for the industry to respond to the changes in the PRC-024-4 standard.

NERC should remain consistent with their revised Rules of Procedure by avoiding the use of “BPS IBR” terminology in the applicable facilities. This is overly broad and can lead to misinterpretation for Generator Owners who own IBRs that do and do not fit the 60 kV and 20 MVA thresholds. The third question in the Project 2020-06 comment form, copied below, is a clearer definition of IBR which NERC has determined has a material impact to the BPS. NERC should consider adopting this terminology in PRC-029

Section 4. Applicability:

4.1 Functional Entities: Generator Owner, Generator Operator

4.2 Facilities: (1) BES Inverter-Based Resources; and (2) Non-BES Inverter Based Resources (IBRs) that that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

Dominion Energy supports EEI comments. In addition, we have the following coments: The term BPS IBRs and IBR Registration Criteria are not clear-cut Facilities. The standard should reference terms available for use in the NERC Glossary of Terms to determine applicability, such as the BES defintion. As stated in the EEI comments, the BES defintion would be the appropriate place to address defintions of this type. The Effective Date of 6 months following approval by FERC is too short for Generator Owners and Transmission Owners that own numerous IBR generating sites, to develop internal controls and processes; and perform the necessary compliance evaluations and possible settings changes to meet the ride-through criteria. Conversely, 6 months after the effective date is too long for documenting Limitations per Requirement R6. The documentation of limitations is typically done during the compliance analysis and study. A staggered implementation plan, that takes into account the registration and requirements for Level 2 GO registrations should be designed and implemented. The Implementation Plan should also consider those IBRs that are approved to be built and have had their Interconnection Studies approved. The contracts for building these sites are signed years in advance with the inverters ordered. A staggered applicability for R6 should be considered that allow for projects in service prior to 2027 or 2028 to be eligible for equipment limitations and those in service after to meet the performance criteria without limitations.

The SDT explains in the draft PRC-029-1 Technical Rationale that "An IBR becomes noncompliant with PRC-029 only when an event in the field occurs that shows that one or more requirements were not satisfied." This, coupled with the removal of IBRs from PRC-024 applicability, would result in a lack of accountability until actual harm (i.e., failure to adequately support the reliability of the BES during a system event) occurs for IBRs not prepared to meet the performance requirements. There would not be auditable and enforceable requirements for owners of IBRs to proactively take action to reasonably ensure the performance requirements will be met. Reliability standards exist to prevent potential harm, which minimizes actual harm.

While RF acknowledges the observed limitations of the existing PRC-024 standard in preventing the undesirable responses of IBRs to the system disturbance events cited in the SAR, RF does not support the whole-sale elimination of frequency and voltage protection settings verification requirements for IBRs. Generator frequency protection settings verification is critical in ensuring UFLS programs are adequately coordinated with generator capabilities, and RF does not wish to rely on self-revealing events to determine where miscoordination exists between IBR frequency protection and UFLS. Unless additional verification requirements are added to PRC-029, RF believes PRC-024 should remain applicable to IBRs.

RF notes that the range of system conditions in which PRC-029 would require IBRs to remain online appear to be significantly larger than those established in PRC-024 (which would remain applicable to synchronous generators). Although the unique capabilities of IBRs may support such a large expansion for only IBR resource types, additional discussion of the technical justification for this expansion would be useful.

Regarding implementation, RF finds a 12-month implementation period acceptable.

- The new performance-based approach opens us up to a lot of issues with other tripping/cessation besides basic overvoltage/under voltage/frequency that our operations team has seen during events.
    - This protection is not modeled in basic models right now and will require substantial effort to ensure we can perform as required. AES CE requests that the Implementation Plan be modified to use a phased-in approach for existing sites to allow adequate time to prepare for these performance requirements.

    Additionally, the standard and rationale is absent of language on studies/assessments that should be performed. AESCE believes that providing examples of the types of studies and assessments that should be run to ensure that resources would perform as expected is necessary for reliability and adequate implementation of this standard by GOs.

- Please provide additional clarification on acceptable limitations under R6. Language such as "hardware replacements or other costly upgrades" from the Technical rationale document is vague and open to interpretation.
- AESCE would like the SDT to consider the challenges with ensuring plants, particularly legacy operational plants, can ride through per the requirements. To ensure this or identify equipment limitations, studies and equipment information is necessary and is not available for most legacy equipment.
- First, EMT studies and RMS model studies are necessary to study plant ride-through capabilities specified in the standard. However, there are significant challenges with these models today that should be considered in the implementation and equipment limitations. Quality EMT models including all equipment information needed are not available for legacy equipment (inverters, PPCs). Many legacy inverters do not have an EMT model, and those that do have models that are not adequately validated against equipment performance. Creation of models is either not supported or can be developed at a very high cost. Models created after the inverters were initially released are of inadequate quality because the equipment is no longer able to be in a lab environment.
    - To consider this, AESCE suggests that the SDT include exceptions for legacy equipment where the performance may not be predictable due to a lack of modeling or inverter information.
- Second, not all current models are of the level of quality that they can be used to ensure that the plant will ride-through as specified in the standard. The implementation of this standard should consider the significant resources and cost to implement.

- Third, manufacturer support for GOs to ensure that IBRs only trip to prevent equipment damage as noted in R2.5 is limited for existing equipment and is unavailable for some legacy equipment. Additionally, this support has been very costly for us to obtain and will strain manufacturer resources to provide.

Considering these limitations, AESCE suggests that the SDT include exceptions for legacy equipment where 1. The performance may not be predictable due to a lack of accurate models at a reasonable cost, 2. Equipment limits may not be known or where the cost may be egregious to provide.

- Expectations for demonstrating and checking performance are unclear, please add language or examples to illustrate how the SDT believes this will happen.

Response

Thank you for your comment.
Implementation Plan: The Implementation Plan has been revised to follow the effective date of PRC-028. All revisions to Reliability Standards directed by Order 901 must be fully implemented by 2030.
Models: The team agrees the model improvements are needed however those will not be addressed within PRC-029. Modifications to model requirements will be covered by other projects addressing Order 901.
Regarding Exemptions: The team has modified Requirement R4 (previous R6) to include clarity on allowable exemptions and requires identification of such limitations to be documented and submitted.
Scope: The team acknowledges challenges with some plants meeting Ride-through requirements per PRC-029. The scope of these performance requirements and allowable exemptions is consistent with the regulatory directives of Order No. 901 and cannot be modified as suggested.

Rhonda Jones - Invenergy LLC - 5

Answer	
Document Name	

Comment

Invenergy thanks the drafting team for their work and the opportunity to provide comments.

Regarding the proposed Implementation Plan for R6, six months may not be enough time to gather all applicable documentation regarding equipment limitations. There are a limited number of vendors of IBR technology that have serviced the industry, and they will be inundated with requests for documentation once the standard becomes effective.

On a final note, NERC appears to have borrowed from some of the requirements within IEEE 2800-2022 and brought them into this standard (e.g. the phase-angle jump requirement, etc.). Invenergy believes it would be incorrect to adopt such requirements until the work of IEEE Working Group p2800.2 has been completed and their recommended practice standard published. Without such an approved recommended practice standard, there is no industry-wide accepted set of procedures for verifying conformity to the borrowed requirements in PRC-029-1.

The Implementation Plan has been modified to 12 months following the effective date of PRC-028.
Requirements within the NERC PRC-029 address the scope of the SAR and draw from IEEE2800 but are mandatory and enforceable requirements.

David Jendras Sr - Ameren - Ameren Services - 1,3,6

Answer	
Document Name	

Comment

Ameren agrees with EEI's comments.

In addition, Ameren believes that ride-through requirements should be in a MOD standard instead of a PRC standard. Protection relay engineers do not have access to the necessary IBR equipment and do not have the expertise to determine the root cause of why an IBR behaved in an unexpected manner. Thus, evaluating and establishing a CAP to correct a reduction in power following a disturbance will not be performed by a relay engineer.

With regards to PRC-029 we woulkd ask: **1. Clarify and emphasize that limitations must not be construed as complete exemptions.** If entities are unable to ride-through portions of the ride-through curve, this does not automatically exempt them from complying with the balance of the ride-through curve as described in the Technical Rationale. While this is clear in the Technical Rationale for Requirement R6 (page 9), this point needs to be brought out more clearly in the PRC-029 standard itself. **2. Expand PRC-029 to require Corrective Action Plans be implemented to remove equipment limitations within a specified timeline**. **3. we recommend modifying Section 4 of PRC-029-1 as follows:** 4. Applicability: 4.1 Functional Entities: 4.1.1 Generator Owner that owns equipment identified in section 4.2, 4.1.2 Transmission Owner that owns equipment as identified in section 4.2 Generator Owner that owns equipment identified in section 4.2. 4.2 Facilities: to include 4.2.3 Shunt static or dynamic reactive device(s) associated with IBR that either have or contribute to meeting the performance requirements. **4. The standard is event-based compliance that requires installing recorded equipment data with higher sampling rates at all applicable legacy IBR Facilities. Therefore, we suggest that the implementation plan for PRC-029 should be aligned with Project 2021-04 (PRC-028-1) for the legacy IBR. Also, we suggest having a different implementation plan for the legacy IBR from IBR connected after the approval date of PRC-029.** **5. Some clarity on how these requirements would be enforced in the location where no data recording is available at the IBR facility during system events.** **6. M1-M5 required GO to maintain the evidence of actual recorded data or other evidence for each applicable IBR demonstrating adherence to ride-through requirements, as specified in Requirement R1-R5. What are the criteria for selecting the event(s) that should be analyzed to demonstrate compliance with the VRT, FRT, and VRT performance requirement(s)? If the performance does not meet the requirement(s), do Generator Owner needs to present a correction action plan and provide it to each applicable Reliability Coordinator. We suggest coordinate this project 2020-02 (PRC-029) with project 2023-02(PRC-030) regarding the IBR ride-through performance analysis.**

7. We suggest that the drafting team ensure consistent language is used in the section 4.2 “Facilities” section with the other projects such as Project 2021-04 (PRC-028) and 2023-02(PRC-030). We suggested the following language be included in the applicability section. Facilities: The Elements associated with (1) BES Inverter-Based Resources; and (2) Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

8. The title of the standard calls out “Inverter-Based Generating Resources”, should “Generating” be removed to be consistent?

Likes 0	
Dislikes 0	

Response

Thank you for your comment.
Exemption: The team agrees that only specific ride-through limitations would be applied and there is no global exemption intended. Language has modified within the Requirement R4 (previous R6) as well as the Technical Rationale to clarify this.
CAPs: The scope for some documented exemptions is consistent with the Order.
Applicability: Language within the applicability section has been modified per other suggestions.
Implementation Plan: The Implementation Plan has been modified to 12 months following the effective date of PRC-028.
PRC-029 compliance: The team agrees that the ability to validate the capability of each applicable IBR was not clear from the initial draft. Changes have been made to ensure the design/capability of each IBR can be validated prior to an event – in addition to retaining the event and performance-based requirements. PRC-028 compliance will be established within PRC-028 and the associated Implementation Plan.
Applicability: The applicability section has been modified to include more specific details on currently applicable facilities. The IBR that will be included as part of registration changes (Category 2 assets) will be added following the approval of pending changes to the NERC Rules of Procedure. These are currently excluded from this draft.
Title: The title has been modified as suggested.

New terms are introduced on page 2 (Continuous **Operating** Region, Mandatory **Operating** Region, Permissive **Operating** Region). Requirement R1 includes the words "**operation** regions" and R2 includes the terms "Continuous **Operation** Region" (Part 2.1) and "Mandatory **Operation** Region" (Part 2.2). We recommend the drafting team review all instances of "**operation** region" within the standard and determine if it should be changed to "**operating** region" to align with the proposed terms. Or conversely, consider if the word "Operating" within the defined terms should be changed to "Operation". For Requirement R2: How will the Generator Owner or Transmission Owner of an applicable IBR be made aware that a PRC-029-1 applicable "System disturbance" has occurred within their associated Planning Coordinator(s) area(s)? Part 2.1.2 refers to "requirements [for active or reactive power preference] specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator".	

Part 2.2.2 refers to a "certain magnitude of reactive power response to voltage changes" or a preference for "active power priority instead of reactive power priority" that can be specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

Part 2.4 refers to a "lower post-disturbance active power level requirement" or "different post-disturbance active power restoration time" specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

With up to four registered entity types being able to provide these preferences (spanning the operations and planning time horizons), is there a chance the Generator Owner or Transmission Owner of an applicable IBR will receive conflicting requirements? Is there a corresponding standard(s) that includes a requirement(s) for the TP, PC, RC or TOP to specify these preferences?

For Requirement R3, how will the Generator Owner or Transmission Owner of an applicable IBR know that a PRC-029-1 applicable transient overvoltage period has occurred within their associated Planning Coordinator(s) area(s)?

For Requirement R4, how will the Generator Owner or Transmission Owner of an applicable IBR know that a PRC-029-1 applicable frequency excursion event has occurred within their associated Planning Coordinator(s) area(s)?

Requirement R6 requires that a Generator Owner or Transmission Owner of an applicable IBR that has a documented equipment limitation, that prevents it from meeting voltage ride-through requirements as detailed in Requirements R1 and R2, communicate each equipment limitation to their associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s). Since the Transmission Operator is also identified in R2, it seems strange to omit the TOP from R6.

With regard to the Implementation Plan, having PRC-024-4 becoming effective six months after approval is reasonable, since this Standard's changes are primarily to limit its applicability to synchronous generators / condensers, and they should already be compliant with the existing version.

However, having PRC-029-1 become effective six months after approval is not reasonable. The technical rationale doesn't provide guidance on how to provide evidence of compliance. It can take considerable time to develop and perform the required analyses, generate potential design changes to make the required setting changes, and implement them.

We recommend providing implementation guidance or technical data showing how to demonstrate performance.

We also recommend allowing at least 24 months to achieve full compliance with the proposed requirements in PRC-029-1.

Dislikes 0	

Response	
Thank you for your comments. **Operation Region**: The team agrees and has removed the operation regions as defined terms. **Measures (events)**: The evidence of compliance for disturbance monitoring that are associated with voltage and frequency excursions that were System disturbances and would be identified for analysis or another trigger by an applicable entity within draft PRC-030. Evidence of disturbance monitoring of IBR associated with those disturbances would be triggered by compliance under the requirements for PRC-030. **R2 General operation expectations**: Requirement 2.2. was clarified to allow for operating instructions from the TOP/PC/RC/TP to be followed but only <u>if</u> specified. Further usage of AVR was removed from the requirement. **Previous Requirement R3:** This requirement and attachment 2 have been removed. **TOP**: This was an error. The TOP has been added to Requirement R4 (previous r6). **Implementation Plan**: The Implementation Plan has been modified to 12 months following the effective date of PRC-028. All revisions to Reliability Standards directed by Order 901 must be fully implemented by 2030. **Capability and Performance Measures**: The team agrees that the ability to validate the capability of each applicable IBR was not clear from the initial draft. Changes have been made to ensure the design/capability of each IBR can be validated prior to an event – in addition to retaining the event and performance-based requirements.

The language proposed in the Applicability section of PRC-029-1 is inadequate to define what IBR Facilities this Standard would apply to. The terms “BPS IBRs” and “IBR Registration Criteria” are too broad, vague, and undefined, and could include all IBRs interconnected to the Bulk Power System at any voltage level. SMUD recommends the Standards Drafting Team use similar language to that proposed in NERC Standards Project 2021-04 Modifications to PRC-002 - Phase II, PRC-028-1 draft #2. If modified accordingly, the Applicability section would state: “4.1. Functional Entities: 4.1.1. Generator Owner that owns equipment as identified in section 4.2 4.1.2. Transmission Owner that owns equipment as identified in section 4.2 4.2. Facilities: The Elements associated with (1) BES Inverter-Based Resources; and (2) Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.”

1. Clarify and emphasize that limitations must not be construed as complete exemptions. If entities are unable to ride-through portions of the ride-through curve, this does not automatically exempt them from complying with the balance of the ride-through curve as described in the	

Technical Rationale. While this is clear in the Technical Rationale for Requirement R6 (page 9), this point needs to be brought out more clearly in the PRC-029 standard itself. **2. Expand PRC-029 to require Corrective Action Plans be implemented to remove equipment limitations within a specified timeline**. 3.**. we recommend modifying Section 4 of PRC-029-1 as follows:** 4. Applicability: 4.1 Functional Entities: 4.1.1 Generator Owner that owns equipment identified in section 4.2, 4.1.2 Transmission Owner that owns equipment as identified in section 4.2 Generator Owner that owns equipment identified in section 4.2. 4.2 Facilities: to include 4.2.3 Shunt static or dynamic reactive device(s) associated with IBR that either have or contribute to meeting the performance requirements. 4**. The standard is event-based compliance that requires installing recorded equipment data with higher sampling rates at all applicable legacy IBR Facilities. Therefore, we suggest that the implementation plan for PRC-029 should be aligned with Project 2021-04 (PRC-028-1) for the legacy IBR. Also, we suggest having a different implementation plan for the legacy IBR from IBR connected after the approval date of PRC-029.** 5**. Some clarity on how these requirements would be enforced in the location where no data recording is available at the IBR facility during system events.** **6. M1-M5 required GO to maintain the evidence of actual recorded data or other evidence for each applicable IBR demonstrating adherence to ride-through requirements, as specified in Requirement R1-R5. What are the criteria for selecting the event(s) that should be analyzed to demonstrate compliance with the VRT, FRT, and VRT performance requirement(s)? If the performance does not meet the requirement(s), do Generator Owner needs to present a correction action plan and provide it to each applicable Reliability Coordinator. We suggest coordinate this project 2020-02 (PRC-029) with project 2023-02(PRC-030) regarding the IBR ride-through performance analysis.** **7.** We suggest that the drafting team ensure consistent language is used in the section 4.2 "Facilities" section with the other projects such as Project 2021-04 (PRC-028) and 2023-02(PRC-030). We suggested the following language be included in the applicability section. Facilities: The Elements associated with (1) BES Inverter-Based Resources; and (2) Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

Response

Thank you for your comment.
Exemption: The team agrees that only specific ride-through limitations would be applied and there is no global exemption intended. Language has modified within the Requirement R4 (previous R6) as well as the Technical Rationale to clarify this.
CAPs: The scope for some documented exemptions is consistent with the Order.
Applicability: Language within the applicability section has been modified per other suggestions.
Implementation Plan: The Implementation Plan has been modified to 12 months following the effective date of PRC-028.
PRC-029 compliance: The team agrees that the ability to validate the capability of each applicable IBR was not clear from the initial draft. Changes have been made to ensure the design/capability of each IBR can be validated prior to an event – in addition to retaining the event and performance-based requirements. PRC-028 compliance will be established within PRC-028 and the associated Implementation Plan.
Applicability: The applicability section has been modified to include more specific details on currently applicable facilities. The IBR that will be included as part of registration changes (Category 2 assets) will be added following the approval of pending changes to the NERC Rules of Procedure. These are currently excluded from this draft.

Comment

BC Hydro appreciates the drafting team's efforts and the opportunity to comment, and offers the following:

1. The Applicability section (A.4.2 Facilities) of PRC-029-1 references BPS IBR and IBR Registration Criteria. BC Hydro suggests that the Facilities section instead use wording reflective of the proposed Category 2 GO as included in the recent revisions to the NERC Rules of Procedure.
2. BC Hydro suggests that the use of "shall" in the language of the Measures may not be appropriate as it could imply a new Requirement or expansion on the existing Requirement. The obligation of having evidence is adequately established and enforceable via the CMEP.
3. The Measure M3 of PRC-029-1 references "the associated Planning Coordinator". The associated Requirement R3 does not. BC Hydro suggests that this is not needed as there may be switching events within a PC's area that do not create overvoltage conditions to trigger R3 for certain IBRs within the PC area.

Applicability: In Introduction, Section 4.2.2, it is not obvious what aspect of ‘IBR Registration Criteria’ makes an IBR an ‘applicable’ IBR – is it simply that an IBR meets NERC Registration Criteria? This bullet point should be elaborated to ensure clarity. **Event-Based Standard:** The IESO has concerns with this standard being an event-based standard, in that it does not necessarily provide an assurance of reliability before events occur, such as would be provided by having an engineering analysis, or bench-testing/real-time simulations of controls equipment that indicates successful ride through of prescribed disturbances is expected. Without disturbance events that challenge the IBRs to perform properly it would be unknown if the IBR is compliant. At a minimum, the measures (e.g, M2-M5) should be extended to allow a statement that no such events are known to have occurred to ‘count’ as evidence of compliance. **Presentation of Ride Through Ranges:** The intended ride through requirements could be made more clear if the ‘minimum ride through times’ were associated with precisely stated, *non-overlapping ranges* of voltages or frequencies, such as in the example ‘Table 2’ provided by the IESO in the comments above, for Section 2.1.	

Nominal Voltages:

To ensure clarity of intent in note #4 of Attachment 1, the 'nominal' system voltage values should be listed as they are in the existing PRC-024, i.e., “(e.g., 100 kV, 115 kV, 138 kV, 161 kV, 230 kV, 345 kV, 400 kV, 500 kV, 765 kV, etc.)”

Harmonize Tables, Figures, Requirements:

The levels of voltage/frequency excursion and the minimum ride through times for all tables, figures, and any associated performance requirements that modify the requirements at given times should be carefully reviewed and harmonized. There are presently some conflicting entries in the tables/figures.

Applicability: The applicability section has been modified to include more specific details on currently applicable facilities. The IBR that will be included as part of registration changes (Category 2 assets) will be added following the approval of pending changes to the NERC Rules of Procedure. These are currently excluded from this draft.
Capability and Performance Measures: The team agrees that the ability to validate the capability of each applicable IBR was not clear from the initial draft. Changes have been made to ensure the design/capability of each IBR can be validated prior to an event – in addition to retaining the event and performance-based requirements.
Attachment 1: Tables and Figures in Attachment 1 have been revised to add clarity on the operation regions and the values in the tables. This should address issues with identifying more than one row.
Attachment 1 clarification on 500kv: Attachment 1 sets the minimum expectation for operation regardless of voltage class. Expanding the no trip zone for 500kV may still be done based on the system need.

Comment

We are concerned that the standard refers to a defined term for IBR which has yet to be adopted in project 2020-06.

We suggest that the drafting team ensure consistent language is used in the section 4.2 “Facilities” section with the other projects such as 2021-04 (PRC-028) and 2023-02(PRC-030). Section 4.2.2 refers to IBR Registration criteria, however it is our understanding that section 4.2.1 would refer to GOs and TOs “that own equipment as identified in section 4.2” and where section 4.2 would indicate “the Elements associated with (1) BES Inverter-Based Resources; and (2) Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.” .

We question why “attachment 1” and “Requirement R6” are written in bold.

Attachment 1: should the “including, but not limited to” in table 2 include the same list (or minimally the same wording) that is found in the technical rationale of the IBR definition in project 2020-0?. For example, the IBR list in 2020-06 refers to “solar photovoltaic” whereas table 2 refers to “photovoltaic (PV)”.

In what standard does the PC/TP define the applicable table in point 3 of section 2 in attachment 1? Same question for the voltage base for per unit calculation in both Attachment 1 and 2. Is there a corresponding requirement in another standard that requires the PC/TP to do this?

· Terms : Mandatory and permissive operation should be defined based on the attachment figures allowing for interconnections to use different requirements

· A-4.2.2 What is the IBR registration criteria? Add a clear reference and make sur the user understands what the IBR registration criteria is.

· B-R2-2.1 Attachment 1 only uses "no-trip zone". Define continuous operating region more clearly in the table (similar to what is done in PRC-024-4)

· B-R2-2.1.2 Can the TP ask for a mix of active/reactive power based on a predetermined ratio (currently only indicated as active or reactive).

· B-R2-2.2 Attachment 1 only uses "no-trip zone". Define "mandatory operation region" in Attachment 1.

· B-R2-2.4 Permissive operation region is not used or defined in attachment 1.

· B-R3. The document refers to an overvoltage value of 1.2pu. It should refer to a voltage exceeding the mandatory operating region in order for Interconnections to set their own overvoltage table.

· B-R3. Since R6 does not apply to this requirement, what will be done with existing IBR that cannot ride through these overvoltages ? An exemption clause is required for existing IBR that cannot be modified or upgraded.

· B-R4. The 5Hz/s value should be moved to Attachment 3 and B-R4 should only refer to the value in the Attachment. · B-R4. Since R6 does not apply to this requirement, what will be done with existing IBR that cannot ride through these frequencies and ROCOF ? (for instance, for all the HQ connected projects, the ROCOF requirement was 4Hz/s) An exemption clause is required for existing IBR that cannot be modified or upgraded. · B-R5. Since R6 does not apply to this requirement, what will be done with existing IBR that cannot ride through this phase angle jump ? An exemption clause is required for existing IBR that cannot be modified or upgraded. · Attachment 1. Tables 1 and 2: Indicate what is considered as “continuous operation”, “mandatory operation” and “permissive operation” in an additional column. · Attachment 1. HQ needs a Quebec regional variance since the Québec Interconnection has its own requirements in this regard. · Attachment 2. Bullet 3: This sentence is hard to read. Proposed replacement: "Each IBR shall not trip unless the cumulative time of one or more instances in which the instantaneous voltage exceeds the respective voltage threshold over a 1-minute time window exceeds the minimum ride-through time" · Attachment 2. HQ needs a Quebec regional variance since the Québec Interconnection has its own requirements in this regard. · Attachment 3. This attachment should also include the maximum absolute ROCOF value. · Attachment 3. HQ needs a Quebec regional variance · B-R2-2.1.2 Which entity between Transmission Planner, Planning Coordinator, Reliability Coordinator and Transmission Operator has priority to specify those requirements? · B-R2-2.4 Which entity between Transmission Planner, Planning Coordinator, Reliability Coordinator and Transmission Operator has priority to specify those requirements?

Response
Thank you for your comment. **IBR**: The team has removed the currently undefined term IBR and will include the term once it has been approved.

Applicability: The applicability section has been modified to include more specific details on currently applicable facilities. The IBR that will be included as part of registration changes (Category 2 assets) will be added following the approval of pending changes to the NERC Rules of Procedure. These are currently excluded from this draft.
Attachment 1: Tables and Figures in Attachment 1 have been revised to add clarity on the operation regions. The range of values in row #4 of Tables 1 and 2 to clarify the continuous operation region. Changes were made to align terms used throughout.
R2.1.2 (previous R2.1.1) and R2.1.3 (previous 2.1.2): Language was clarified in R2.1.2 and R2.1.3 to address apparent vs reactive power limits per above and other comments. R2.1.3 has been clarified that the GO/TO shall follow provided TP/PC/RC/TOP requirements if those are provided. Requirement R2 subparts require the GO/TO to follow provided TP/PC/RC/TOP restoration time or active power recovery threshold requirements – if different than default values in the sub-requirement. R2 does not intend that values other than the default values must be specified, only that performance for the plant/facility will be evaluated in accordance with those values if provided. Language has been added to M2 to clarify what evidence is expected if the TP/PC/RC/TOP provide other performance requirements.
Previous Requirement R3: This requirement has been removed.
Exemptions: The scope of allowable exemptions within R4 (previously R6) is consistent with the regulatory directives of Order No. 901. Frequency cannot apply for exemption. New IBR cannot apply for exemption. This is consistent with the ordered directives.
Previous Requirement R5: This requirement has been removed and the non-fault exclusionary language has been added to R1. A requirement to notify the Generator Owner or Transmisson Owner and to evaluate performance when the plant/facility tripped because of a switching event is in the current draft PRC-030.
Quebec variant: The team will coordinate with Hydro Quebec to include their variant as identified by Hydro Quebec.
Priority: This issue is out of scope for the team. The language in the requirement is to make allowance for established operational instructions

Duane Franke - Manitoba Hydro - 1,3,5,6 - MRO

- Evidence Retention: We would suggest that the evidence retention period for both Standards should be changed from five years to three years, to be consistent with other NERC Standards.

- The standard is event-based compliance that required installing recorded equipment data with higher sampling rates at all applicable legacy IBR Facilities. Therefore, we recommend that the implementation plan for PRC-029 should be aligned with Project 2021-04 (PRC-028-1) for the legacy IBR. Also, we suggest have different implementation plan for the legacy IBR from IBR connected after the approval date of PRC-029.

- Some clarity how these requirements would be enforced in a location where no data recording is available at an IBR facility during system events.

- M1-M5 required the GO to maintain the evidence of actual recorded data or other evidence for each applicable IBR demonstrating adherence to ride-through requirements, as specified in Requirement R1-R5. What are the criteria for selecting the event(s) that should be analyzed to demonstrate compliance with the VRT, FRT and VRT performance requirement(s)? If the performance does not meet the requirement(s), do Generator Owner need to present a corrective action plan and provide it to each applicable Reliability Coordinator. We suggest coordinating this project 2020-02 (PRC-029) with project 2023-02(PRC-030) regarding the IBR ride-through performance analysis.

- R2: We agree with the present flexibility that some of the IBR VRT performance could be modified to meet the individual system needs by the applicable Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator. However, some clarity may be required on how this process is initiated and what type of evidence is required to demonstrate the request is received and implemented. This may be an additional requirement assigned to the Transmission Planner. Each Transmission Planner, Planning Coordinator, and Transmission Operator that jointly specifies the following voltage ride-through performance requirements within their area(s) different than those specified under R2, shall make those requirements available to each associated applicable IBR Generator Owner and Transmission Owner.

- We suggest that the drafting team ensures consistent language is used in the section 4.2 "Facilities" section with the other projects such as Project 2021-04 (PRC-028) and 2023-02(PRC-030). We suggest the following language be included in the applicability section. Facilities: The Elements associated with (1) BES Inverter-Based Resources; and (2) Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

- R3: we suggest adding to the attachment 2 how the instantaneous transient overvoltage should be calculated (such as what is the pu based on? and the minimum sampling rate?)

Response

Thank you for your comment.
Retention: The compliance retention period was modified to align with PRC-030.
Implementation Plan: The Implementation Plan has been modified to 12 months following the effective date of PRC-028. All revisions to Reliability Standards directed by Order 901 must be fully implemented by 2030.

Capability and Performance Measures: . The team agrees that the ability to validate the capability of each applicable IBR was not clear from the initial draft. Changes have been made to ensure the design/capability of each IBR can be validated prior to an event – in addition to retaining the event and performance-based requirements.
Measures - data: The compliance measures for demonstration of performance were revised from "actual recorded data" to "actual disturbance monitoring (i.e. Sequence of Event Recorder, Dynamic Disturbance Recorder, and Fault Recorder) data".
R2.1.2 (previous R2.1.1) and R2.1.3 (previous 2.1.2): Language was clarified in R2.1.2 and R2.1.3 to address apparent vs reactive power limits per above and other comments. R2.1.3 has been clarified that the GO/TO shall follow provided TP/PC/RC/TOP requirements if those are provided. Requirement R2 subparts require the GO/TO to follow provided TP/PC/RC/TOP restoration time or active power recovery threshold requirements – if different than default values in the sub-requirement. R2 does not intend that values other than the default values must be specified, only that performance for the plant/facility will be evaluated in accordance with those values if provided. Language has been added to M2 to clarify what evidence is expected if the TP/PC/RC/TOP provide other performance requirements.
Applicability: The applicability section has been modified to include more specific details on currently applicable facilities. The IBR that will be included as part of registration changes (Category 2 assets) will be added following the approval of pending changes to the NERC Rules of Procedure. These are currently excluded from this draft.
Previous Requirement R3: This requirement has been removed.

Comment

1. The proposed Standard refers to four different operating regions (no-trip zone, Continuous Operation Region, Mandatory Operation Region, and Permissive Operating Region). The different zones require Generator Owners to take different actions based on the number of disturbances and deviations that occur within in a 10 second period as well as the positive sequence voltage on the high side of the MPT. The ability of plant operators or inverter controls to identify, track, and respond effectively to all these variables is unrealistic. Why are these requirements not applied to non-IBR owners?
2. In R1, GOs are required to ensure that IBRs continue to "exchange current in accordance with the no-trip zones and operation regions as specified in Attachment 1." The Standard does not define the term "exchange current". Please define this term.
3. Measure 1 requires the Generator Owner and Transmission Owner to have actual recorded data for each applicable IBR demonstrating ridethrough adherence. This measure needs a timeframe for retention of the data.
4. The second half of the sentence in 2.1.1 doesn't appear to add any value to the sub-requirement. Please clarify what added operational requirement is meant by, "…and continue to deliver active power and reactive power up to its apparent power limit."

5. Requirement R2.1.2 allows four different entities to dictate each IBR's operating mode. This contradicts the requirements of VAR-001 which states that GOs must operate in voltage control mode unless exempted by the TOP. Recommend selecting one of these entities to determine the preference.
6. For overvoltage conditions greater than 140% Attachment 2 requires Generator Owners to distinguish and respond with different time delays, all less than or equal to 3 ms. Recommend requiring IBRs to delay their response to voltage excursions and program their IBRs to match the responses of synchronous machines.
7. Clarify Requirement 2.2.1 to address the expected operational response to close-in faults. Recommend the Standard specify separate performance requirements for close-in faults and more distant faults.
8. Requirement 2.2 appears to mandate that IBRs who operate in active power priority mode in the continuous operating region would be required to switch to the reactive power mode if a voltage disturbance occurs. What criteria are IBRs expected to use to determine when this switch should occur? What are IBRs expected to do if their inverters cannot be switched without software modifications?
9. The ride through requirements should all be specified in the same units of time.
10. Couldn't the voltage overshoot concerns addressed by Requirement 2.3 be addressed more reliably by slowing the response time of the IBR plant controllers to match that of synchronous generation?
11. Measure 2 requires the GO and TO to have actual recorded data during each system disturbance. Recommend establishing a timeframe for the retention of this data.
12. Measure 3 requires the GO and TO to have actual recorded data during each transient voltage event. Recommend establishing a timeframe for the retention of this data.
13. Measure 4 requires the GO and TO to have actual recorded data during each frequency excursion event. Recommend establishing a timeframe for the retention of this data.
14. Measure 5 requires the GO and TO to have actual recorded data during each positive sequence voltage phase angle changes that are less than 25 electrical degrees at the high side of the main transformer. Recommend establishing a timeframe for the retention of this data.
15. Requirement 6 has more specific requirements for an equipment limitation than is being proposed for the synchronous generators. Recommend PRC-029 reflect the wording proposed for PRC-024-4.
16. PRC-029 frequency ride-through is a single graph for all regions. The graph no trip zone is larger than the existing PRC-024 frequency no-trip zone for Eastern, Western, and ERCOT zones. The wording in the rationale is very soft (may be required). The change will cause the LFRT and HFRT settings to be updated as well as collector and transformer frequency settings. Recommend the frequency settings remain consistent with PRC-024 until the time that it is justified from grid events.

Response	

Thank you for your comments. **Ride-through expectations:** PRC-029 is not an equipment setting standard and sets minimum performance thresholds for determining Ride-through. Both the SAR and the assigned Order 901 direct the team to include capability and performance-based requirements for ride-through. The criteria does not cover any equipment failure during a disturbance. **Terminology "exchange current":** Also the team agrees for more clarity and has defined a new term for Ride-through and replaced language the requirements with this new term. Attachments have also been updated to utilize this term as the "Must Ride-through Zone". The operating regions have been removed as defined terms as well. **Measures (events)**: The evidence of compliance for disturbance monitoring that are associated with voltage and frequency excursions that were System disturbances and would be identified for analysis or another trigger by an applicable entity within draft PRC-030. Evidence of disturbance monitoring of IBR associated with those disturbances would be triggered by compliance under the requirements for PRC-030. **R2 – use of reactive power**: The team agrees that changes to clarify reaction power support in 2.1 was needed and made some adjustments to specify reactive power. This was broken into 2.1.1 and 2.1.2. **R2.1.2 (previous R2.1.1) and R2.1.3 (previous 2.1.2**): Language was clarified in R2.1.2 and R2.1.3 to address apparent vs reactive power limits per above and other comments. R2.1.3 has been clarified that the GO/TO shall follow provided TP/PC/RC/TOP requirements if those are provided. Requirement R2 subparts require the GO/TO to follow provided TP/PC/RC/TOP restoration time or active power recovery threshold requirements – if different than default values in the sub-requirement. R2 does not intend that values other than the default values must be specified, only that performance for the plant/facility will be evaluated in accordance with those values if provided. Language has been added to M2 to clarify what evidence is expected if the TP/PC/RC/TOP provide other performance requirements. **Previous R3**: Previous requirement R3 has been removed. Information on the TOV calculation has been added to Attachment 1. **R2- -dynamic switching**: Requirement 2.1.3 (previously 2.1.2) does not require dynamic switching between these two modes of operation. However, if that capability already exists, the operating mode would need to be specified by the TP, PC, RC, or TOP. **Previous R5**: Previous Requirement R5 has been removed and added as an exemption to Requirement R1. There is no exemption to trip within the no-trip zone for a fault. If there is a trip during non-fault initiated switching events, measurement data taken from the high-side of the MPT would include this information. The measure for R1 has been modified to reflect this change. **Exemptions**: The scope of allowable exemptions within R4 (previously R6) is consistent with the regulatory directives of Order No. 901. **Regional Variants**: Additional regional variants; such as by Interconnection may be pursued as needed.

In some cases, the initial 6-month implementation period to develop a technical rationale for an exemption may be too short. This is attributable to the necessary input from the original OEM and in some cases due to the complexity associated with facilities comprised of new and old equipment. One example where this may exist are plants where a repower project may have taken place that does not replace all inverters. In a case such as this, the new equipment may meet the requirements, but the remaining existing equipment may not. This may require a detailed study to verify compliance, or perhaps instead, require some form of hybrid exemption for the site. Unlike the stated technical goal of the standard where this is a "performance based" standard, the justification for a technical exemption will require some form of a study to justify that exemption. This could lead to a greater than 6-month period in developing the exemption request. To accommodate these situations, AEP recommends an implementation period of 18 months. PRC-029 requires that IBR's shall ride through 110%-120% overvoltage from 0-1 seconds as seen at the high side of the main power step-up transformer. Due to voltage drop, the voltage seen at the equipment terminals can be another 5% higher leading to potential equipment damage from overvoltage. AEP suggests that the SDT consider lowering the ride through to 110% at the high side of the main step-up transformer.

Thank you for your comment. **Regarding Exemptions**: The team has modified Requirement R4 (previous R6) to include clarity on allowable exemptions and requires identification of such limitations to be documented and submitted. The Implementation Plan has been modified to 12 months following the effective date of PRC-028. All revisions to Reliability Standards directed by Order 901 must be fully implemented by 2030. **Previous R3**: Previous requirement R3 has been removed. Information on the TOV calculation has been added to Attachment 1.

Standards Announcement

Project 2020-02 Modifications to PRC-024 (Generator Ride-through) | PRC-024-4 and PRC-029-1

Initial Ballots and Non-binding Polls Open through April 22, 2024

Now Available

Initial ballots for **Project 2020-02 Modifications to PRC-024 (Generator Ride-through)** and non-binding polls of the associated Violation Risk Factors and Violation Severity Levels are open through **8 p.m. Eastern, Monday, 22, 2024**.

The Standards Committee approved waivers to the Standard Processes Manual at their December 2023 meeting. These waivers were sought by NERC Standards staff for reduced formal comment and ballot periods. This will assist the drafting teams in expediting the standards development process due to firm timeline expectations set by FERC Order 901. *FERC Order 901 was issued under* Docket No. RM22-12-000 *on October 19, 2023*.

Reminder Regarding Corporate RBB Memberships

Under the NERC Rules of Procedure, each entity and its affiliates is collectively permitted one voting membership per Registered Ballot Body Segment. Each entity that undergoes a change in corporate structure (such as a merger or acquisition) that results in the entity or affiliated entities having more than the one permitted representative in a particular Segment must withdraw the duplicate membership(s) prior to joining new ballot pools or voting on anything as part of an existing ballot pool. Contact ballotadmin@nerc.net to assist with the removal of any duplicate registrations.

Balloting

Members of the ballot pools associated with this project can log in and submit their votes by accessing the Standards Balloting and Commenting System (SBS) here.

- *Contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern) for problems regarding accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out.*
- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*
- *Please be mindful of ballot and comment period closing dates. We ask to **allow at least 48 hours** for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts **prior to the last day** of a comment/ballot period.*

Next Steps
The ballot results will be announced and posted on the project page. The drafting team will review all responses received during the comment period and determine the next steps of the project.

For information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Manager of Standards Development, Jamie Calderon (via email) or at 404-960-0568 Subscribe to this project's observer mailing list by selecting "NERC Email Distribution Lists" from the "Service" drop-down menu and specify “Project 2020-02 Modifications to PRC-024 (Generator Ride-through) observer list” in the Titla and Description Box.

Contact ballotadmin@nerc.net to assist with the removal of any duplicate registrations.

Commenting

Use the Standards Balloting and Commenting System (SBS) to submit comments. An unofficial Word version of the comment form is posted on the project page.

Ballot Pools

Ballot pools are being formed through **8 p.m. Eastern, Friday, April 5, 2024.** Registered Ballot Body members can join the ballot pools here.

- *Contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern) for problems regarding accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out.*
- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*

- *Please be mindful of ballot and comment period closing dates. We ask to* ***allow at least 48 hours*** *for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts* ***prior to the last day*** *of a comment/ballot period.*

Next Steps

Initial ballots for the standards and implementation plan, as well as non-binding polls of the associated Violation Risk Factors and Violation Severity Levels will be conducted **April 12 - 22, 2024**.

For information on the Standards Development Process, refer to the Standard Processes Manual.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

Draft 2 of PRC-024-4 is posted for a 15-day formal comment period with additional ballot.

Completed Actions	Date
Standards Committee accepted revised Standard Authorization Request (SAR) for posting	April 19, 2023
Standards Committee approved waivers to the Standards Process Manual	December 13, 2023
25-day formal comment period with initial ballot	March 27 - April 22, 2024

Anticipated Actions	Date
15-day formal comment period and additional ballot	June 18 – July 8, 2024
Final Ballot	July 15 – July 19, 2024
Board Adoption	August 14, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

None

A. Introduction

1. **Title:** **Frequency and Voltage Protection Settings for Synchronous Generators, Type 1 and Type 2 Wind Resources, and Synchronous Condensers**

2. **Number:** **PRC-024-4**

3. **Purpose:** To assure that protection of synchronous generators, type 1 and type 2 wind resources, and synchronous condensers do not cause tripping during defined frequency and voltage excursions in support of the Bulk Power System (BPS).

4. **Applicability:**

4.1. Functional Entities:

4.1.1. Generator Owners that apply protection listed in Sections 4.2.1 or 4.2.2.

4.1.2. Transmission Owners that apply protection listed in Section 4.2.2.

4.1.3. Transmission Owners (in the Quebec Interconnection only) that own a BES generator step-up (GSU) transformer or main power transformer (MPT)[1] and apply protection listed in Section 4.2.1.

4.1.4. Planning Coordinators (in the Quebec Interconnection only)

4.2. Facilities[2]:

4.2.1 Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip the generating resource(s); or (ii) provide signals to the generating resource(s) to trip; and are applied to the following:

4.2.1.1 Bulk Electric System (BES) synchronous generators.

4.2.1.2 BES GSU transformer(s) for synchronous generators.

4.2.1.3 High-side of the synchronous generator-connected unit auxiliary transformer[3] (UAT) installed on BES generating resource(s).

4.2.1.4 Individual dispersed power producing type 1 or type 2 wind resource(s) identified in the BES Definition, Inclusion I4.

---

[1] For the purpose of this standard, the MPT is the power transformer that steps up voltage from multiple small synchronous generators (e.g. multiple small hydro generators connecting to a common bus) or from a type 1 or type 2 wind resource collector station to transmission voltage .

[2] It is not required to install or activate the protections described in Facilities Section 4.2.

[3] These transformers are variously referred to as station power UAT, or station service transformer(s) used to provide overall auxiliary power to the synchronous generators. This UAT is the transformer connected on the generator bus between the low side of the GSU and the generator terminal.

4.2.1.5 Elements that are designed primarily for the delivery of capacity from multiple synchronous generators connecting to a common bus or individual dispersed power producing type 1 or type 2 wind resources identified in the BES Definition, Inclusion I4, to the point where those resources aggregate to greater than 75 MVA.

4.2.1.6 MPT of multiple synchronous generators connecting to a common bus or MPT of individual dispersed power producing type 1 or type 2 wind resources as identified in the BES Definition, Inclusion I4.

4.2.2 Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip transmission connected synchronous condensers; or (ii) provide signals to trip transmission connected synchronous condenser and are applied to the following:

4.2.2.1 BES synchronous condensers

4.2.2.2 BES step-up transformer(s) for synchronous condensers.

4.2.2.3 High-side of the synchronous condenser-connected unit auxiliary transformer (UAT).

4.2.3 **Exemptions:** Protection on all auxiliary equipment within the synchronous generator, type 1 or type 2 wind resource, or synchronous condenser Facility.

5. **Effective Date:** See Implementation Plan for PRC-024-4

B. Requirements and Measures

R1. Each Generator Owner and Transmission Owner shall set applicable frequency protection[4] in accordance with PRC-024-4 Attachment 1 such that the applicable protection does not cause the Facility to which it is applied to trip within the "no trip zone" during a frequency excursion with the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- Applicable frequency protection may be set to trip within a portion of the "no trip zone" for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.

M1. Each Generator Owner and Transmission Owner shall have evidence that the applicable frequency protection has been set in accordance with Requirement R1, such as dated setting sheets, calibration sheets, calculations, or other documentation.

R2. Each Generator Owner and Transmission Owner shall set applicable voltage protection[5] in accordance with PRC-024-4 Attachment 2, such that the applicable protection does not cause the Facility to which it is applied trip within the "no trip zone" during a voltage excursion at the high-side of the GSU or MPT, subject to the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- If the Transmission Planner allows less stringent voltage protection settings than those required to meet PRC-024-4 Attachment 2, then the Generator Owner or Transmission Owner may set its protection within the voltage recovery characteristics of a location-specific Transmission Planner's study.
- Applicable voltage protection may be set to trip during a voltage excursion within a portion of the "no trip zone" for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.

M2. Each Generator Owner and Transmission Owner shall have evidence that applicable voltage protection has been set in accordance with Requirement R2, such as dated setting sheets, voltage-time boundaries, calibration sheets, coordination plots, dynamic simulation studies, calculations, or other documentation.

R3. Each Generator Owner and Transmission Owner shall document each known regulatory or equipment limitation[6] that prevents an its synchronous generator, type 1 or type 2 wind resource, or synchronous condenser, with applicable frequency or voltage protection from meeting the protection setting criteria in Requirements R1 or R2, including (but not limited to) study results, experience from an actual event, or

[4] Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip the synchronous generator(s), type 1 or type 2 wind resource(s), or synchronous condenser(s); or (ii) provide signals to same to trip.
[5] Ibid.
[6] Excludes limitations caused by the setting capability of the frequency, voltage, and volts per hertz protective relays applied to the synchronous generator(s), type 1 and type 2 wind resource(s), and condenser(s). This does not exclude limitations originating in the equipment protected by the relay(s).

manufacturer's advice. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

3.1. The Generator Owner and Transmission Owner shall communicate the documented regulatory or equipment limitation, or the removal of a previously documented regulatory or equipment limitation, to its Planning Coordinator and Transmission Planner within 30 calendar days of any of the following:

- Identification of a regulatory or equipment limitation.
- Repair of the equipment causing the limitation that removes the limitation.
- Replacement of the equipment causing the limitation with equipment that removes the limitation.
- Creation or adjustment of an equipment limitation caused by consumption of the cumulative turbine life-time frequency excursion allowance.

M3. Each Generator Owner and Transmission Owner shall have evidence that it has documented and communicated any known regulatory or equipment limitations that resulted in an exception to Requirements R1 or R2 in accordance with Requirement R3, such as a dated email or letter that contains such documentation as study results, experience from an actual event, or manufacturer's advice.

R4. Each Generator Owner and Transmission Owner shall provide its applicable protection settings associated with Requirements R1 and R2 to the Planning Coordinator or Transmission Planner that models the associated Facility within 60 calendar days of receipt of a written request for the data and within 60 calendar days of any change to those previously requested settings unless directed by the requesting Planning Coordinator or Transmission Planner that the reporting of protection setting changes is not required. *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

M4. Each Generator Owner and Transmission Owner shall have evidence that it communicated applicable protection settings in accordance with Requirement R4, such as dated e-mails, correspondence or other evidence and copies of any requests it has received for that information.

C. Compliance

1. **Compliance Monitoring Process**

   1.1. **Compliance Enforcement Authority:** "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

   1.2. **Evidence Retention:** The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

   The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

   - The Generator Owner and Transmission Owner shall keep data or evidence of Requirements R1 through R4 for five years or until the next audit, whichever is longer.
   - If a Generator Owner or Transmission Owner is found non-compliant, the Generator Owner or Transmission Owner shall keep information related to the non-compliance until mitigation is complete and approved for the time period specified above, whichever is longer.

   1.3. **Compliance Monitoring and Enforcement Program:** As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable frequency protection so that it does not trip according to Requirement R1.
R2.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable voltage protection so that it does not trip according to Requirement R2.
R3.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 30 calendar days but less than or equal to 60 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 60 calendar days but less than or equal to 90 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 90 calendar days but less than or equal to 120 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner failed to document any known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2. OR The Generator Owner or Transmission Owner failed to communicate the documented limitation to its Planning Coordinator and Transmission Planner within 120 calendar

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
				days of identifying the limitation.
R4.	The Generator Owner or Transmission Owner provided its protection settings more than 60 calendar days but less than or equal to 90 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner provided protection settings more than 60 calendar days but less than or equal to 90 calendar days of a written request.	The Generator Owner or Transmission Owner provided its protection settings more than 90 calendar days but less than or equal to 120 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner provided protection settings more than 90 calendar days but less than or equal to 120 calendar days of a written request.	The Generator Owner or Transmission Owner provided its protection settings more than 120 calendar days but less than or equal to 150 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner or provided protection settings more than 120 calendar days but less than or equal to 150 calendar days of a written request.	The Generator Owner or Transmission Owner failed to provide its protection settings within 150 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner failed to provide protection settings within 150 calendar days of a written request.

D. Regional Variances

D.A. Variance for the Quebec Interconnection

This Variance replaces Requirement R2 of the continent-wide standard in its entirety and adds a new requirement, Requirement D.A.5., applicable to Planning Coordinators in the Quebec Interconnection.

This Variance replaces continent-wide Requirement R2 in its entirety with the following:

D.A.2. Each Generator Owner and Transmission Owner shall set applicable voltage protection[7] in accordance with PRC-024 Attachment 2B, such that the applicable protection does not cause the Facility to which it is applied to trip within the “no trip zone” during a voltage excursion at the high-side of the GSU or MPT, subject to the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- For newly designated strategic power plants, applicable protections must comply with the high voltage durations for such plants within 48 calendar months of the notification made pursuant to Requirement D.A.5. During this transition period, voltage protections must at least comply with the high voltage durations for “all power plants”.
- Applicable voltage protection may be set to trip during a voltage excursion within a portion of the “no trip zone” of PRC-024 Attachment 2B for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.
- If the Transmission Planner allows less stringent voltage protection settings than those required to meet PRC-024 Attachment 2B, then the Generator Owner or Transmission Owner may set its protection within the voltage recovery characteristics of a location-specific Transmission Planner’s study.

M.D.A.2. Each Generator Owner and Transmission Owner shall have evidence that applicable voltage protection has been set in accordance with Requirement R2, such as dated setting sheets, voltage-time boundaries, calibration sheets, coordination plots, dynamic simulation studies, calculations, or other documentation.

This Variance adds the following Requirement:

D.A.5 Each Planning Coordinator shall designate, at least once every five calendar years, the strategic power plants that must comply with Attachment 2B and notify, within 30 calendar days of its designation,

[7] Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip the synchronous generator(s), type 1 or type 2 wind resource(s), or synchronous condenser(s); or (ii) provide signals to same to trip.

each Generator Owner or Transmission Owner that owns facilities[8] in the strategic power plants. *[Violation Risk Factor: Medium] [Time Horizon: Long-term planning]*

M.D.A.5 Each Planning Coordinator shall have evidence that it designated, at least once every five calendar years, strategic power plants in accordance with Requirement D.A.5, Part 5 and shall have dated evidence that each Generator Owner or Transmission Owner has been notified in accordance with Requirement D.A.5, part 5.2. Evidence may include, but is not limited to letters, emails, electronic files, or hard copy records demonstrating transmittal of information.

[8] Facilities in the strategic power plants include facilities with synchronous generator(s) from the generator up to and including the MPT or GSU.

Violation Severity Levels

This Variance adds a VSL for D.A.5 and modifies the VSL for R2 as follows:

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
D.A.2.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable voltage protection so that it does not trip in accordance with Requirement D.A.2. OR The Generator Owner or Transmission Owner set its applicable voltage protection in accordance with Requirement D.A.2 but, for strategic power plants, failed to do so within 48 months of notification.
D.A.5.	N/A	The Planning Coordinator designated strategic power plants at least once every five calendar years but notified each Generator Owner or Transmission Owner that owns facilities in the strategic power plants between 31 days and 45 days after its designation.	The Planning Coordinator designated strategic power plants at least once every five calendar years but notified each Generator Owner or Transmission Owner that owns facilities in the strategic power plants between 46 days and 60 days after its designation.	The Planning Coordinator failed to designate, at least once every five years, the strategic power plants that must comply with Attachment 2B. OR The Planning Coordinator failed to notify, each Generator Owner or Transmission Owner that owns facilities in the strategic power plants or notified them more than 60 days after its designation.

Attachment 1

(Frequency No Trip Boundaries by Interconnection[9])

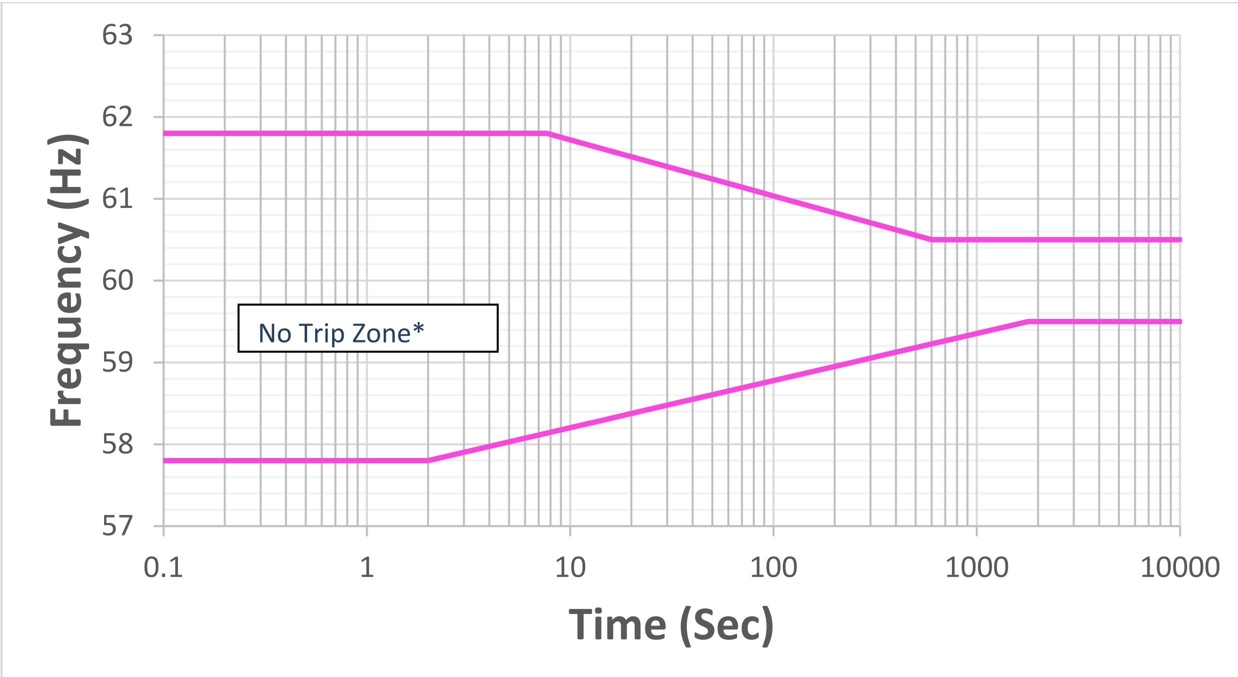

Figure 1: Eastern Interconnection Boundaries

**** The area outside the "No Trip Zone" is not a "Must Trip Zone."***

Table 1: Frequency Boundary Data Points - Eastern Interconnection

High Frequency Duration		Low Frequency Duration	
Frequency (Hz)	Minimum Time (Sec)	Frequency (Hz)	Minimum Time (sec)
≥61.8	Instantaneous[10]	≤57.8	Instantaneous[11]
≥60.5	$10^{(90.935-1.45713*f)}$	≤59.5	$10^{(1.7373*f-100.116)}$
<60.5	Continuous operation	> 59.5	Continuous operation

[9] The figures do not visually represent the "no trip zone" boundaries before 0.1 seconds and after 10,000 seconds. The Frequency Boundary Data Points Table defines the entirety of the "no trip zone" boundaries.

[10] Frequency is calculated over a window of time. While the frequency boundaries include the option to trip instantaneously for frequencies outside the specified range, this calculation should occur over a time window. Typical window/filtering lengths are three to six cycles (50 – 100 milliseconds). Instantaneous trip settings based on instantaneously calculated frequency measurement is not permissible.

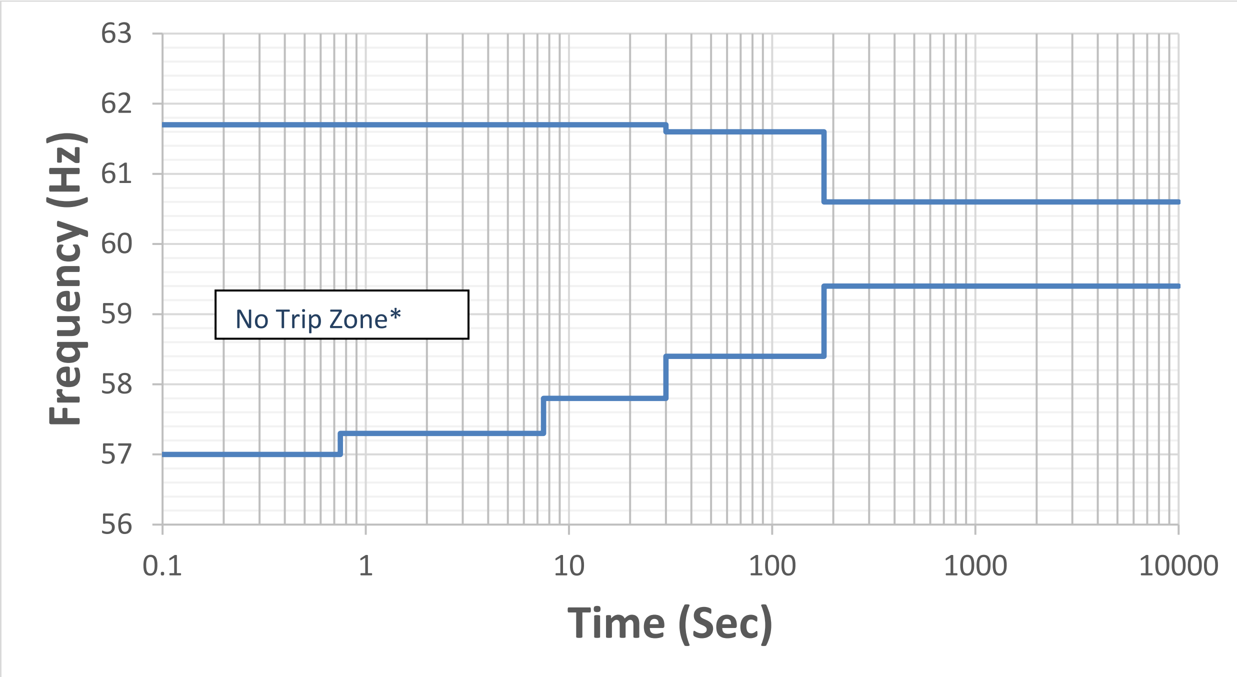

Figure 2: Western Interconnection Boundaries

**** The area outside the "No Trip Zone" is not a "Must Trip Zone."***

Table 2: Frequency Boundary Data Points – Western Interconnection

High Frequency Duration		Low Frequency Duration	
Frequency (Hz)	**Minimum Time (Sec)**	**Frequency (Hz)**	**Minimum Time (sec)**
≥61.7	Instantaneous[11]	≤57.0	Instantaneous[11]

≥1.200	0.00	<0.45	0.15
≥1.175	0.20	<0.65	0.30
≥1.15	0.50	<0.75	2.00
≥1.10	1.00	<0.90	3.00
<1.10	4.00	≥ 0.90	4.00

Attachment 2A: Voltage Boundary Clarifications – Eastern, Western, and ERCOT Interconnections

Boundary Details:

1. Unless otherwise specified by the Transmission Planner, the per unit voltage base for these boundaries is the nominal transmission system voltage (e.g., 100 kV, 115 kV, 138 kV, 161 kV, 230 kV, 345 kV, 400 kV, 500 kV, 765 kV, etc.).
2. The values in the table represent the minimum time durations allowed for specified voltage excursion thresholds.
3. When evaluating volts per hertz protection, either assume a system frequency of 60 Hertz or the magnitude of the high voltage boundary can be adjusted in proportion to deviations of frequency below 60 Hertz.
4. Voltages in the boundaries assume RMS fundamental frequency phase-to-ground or phase-to-phase per unit voltage.
5. For applicability to PRC-024, the “no trip zone” ends at 4 seconds.

Evaluating Protection Settings:

The voltage values in the Attachment 2 voltage boundaries are voltages at the high-side of the GSU/MPT. For resources with multiple stages of step up to reach interconnecting voltage, this is the high-side of the transformer with a low side below 100kV and a high-side 100kV or above**.** When evaluating protection settings, consider the voltage differences between where the protection is measuring voltage and the high-side of the GSU/MPT. A steady state calculation or dynamic simulation may be used.

If using a steady state calculation or dynamic simulation, use the following conditions when evaluating protection settings:

a. The most probable real and reactive loading conditions for the unit under study.
b. All installed generating plant reactive support (e.g., static VAR compensators, synchronous condensers, capacitors) equipment is available and operating normally.
c. Account for the actual tap settings of transformers between the generator terminals and the high-side of the GSU/MPT.
d. For dynamic simulations, the automatic voltage regulator is in automatic voltage control mode with associated limiters in service.

PRC-024— Attachment 2B

<0.75	1.00
<0.85	2.00
<0.90	30
≥0.90	continuous

Attachment 2C: Voltage Boundary Clarifications – Quebec Interconnection

Boundary Details:

1. The per unit voltage base for these boundaries is the nominal operating voltage (e.g., 120 kV, 161 kV, 230 kV, 315 kV, 735 kV, etc.).
2. The values in the table represent the minimum time durations allowed for specified voltage excursion thresholds.
3. When evaluating volts per hertz protection, either assume a system frequency of 60 Hertz or the magnitude of the high voltage boundary can be adjusted in proportion to deviations of frequency below 60 Hertz.
4. Voltages in the Quebec Interconnection boundaries assume positive-sequence values.

Evaluating Protection Settings:

The voltage values in the Attachment 2B voltage boundaries are voltages at the high-side of the GSU/MPT. For resources with multiple stages of step up to reach interconnecting voltage, this is the high-side of the transformer that connects to the interconnecting voltage. When evaluating protection settings, consider the voltage differences between where the protection is measuring voltage and the high-side of the GSU/MPT. A steady state calculation or dynamic simulation may be used.

If using a steady state calculation or dynamic simulation, use the following conditions when evaluating protection settings:

a. The most probable real and reactive loading conditions for the unit under study.
b. All installed generating plant reactive support (e.g., static VAR compensators, synchronous condensers, capacitors) equipment is available and operating normally.
c. Account for the actual tap settings of transformers between the generator terminals and the high-side of the GSU/MPT.
d. For dynamic simulations, the automatic voltage regulator is in automatic voltage control mode with associated limiters in service.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

Draft 2 of PRC-024-4 is posted for a 15-day formal comment period with additional ballot.

Completed Actions	Date
Standards Committee accepted revised Standard Authorization Request (SAR) for posting	April 19, 2023
Standards Committee approved waivers to the Standards Process Manual	December 13, 2023
25-day formal comment period with initial ballot	March 27 - April 22, 2024

Anticipated Actions	Date
15-day formal comment period and additional ballot	June 18 – July 8, 2024
Final Ballot	July 15 – July 19, 2024
Board Adoption	August 14, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

None

A. Introduction

1. **Title:** **Frequency and Voltage Protection Settings for Synchronous Generators, Type 1 and Type 2 Wind Resources, and Synchronous Condensers**

2. **Number:** **PRC-024-4**

3. **Purpose:** To assure that protection of synchronous generators, type 1 and type 2 wind resources, and synchronous condensers do not cause tripping during defined frequency and voltage excursions in support of the Bulk Power System (BPS).

4. **Applicability:**

4.1. Functional Entities:

4.1.1. Generator Owners that apply protection listed in Sections 4.2.1 or 4.2.2.

4.1.2. Transmission Owners that apply protection listed in Section 4.2.2.

4.1.3. Transmission Owners (in the Quebec Interconnection only) that own a BES generator step-up (GSU) transformer or main power transformer (MPT)[1] and apply protection listed in Section 4.2.1.

4.1.4. Planning Coordinators (in the Quebec Interconnection only)

4.2. Facilities[2]:

4.2.1 Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip the generating resource(s); or (ii) provide signals to the generating resource(s) to -trip; and are applied to the following:

4.2.1.1 Bulk Electric System (BES) synchronous generators.

4.2.1.2 BES GSU transformer(s) for synchronous generators.

4.2.1.3 High-side of the synchronous generator-connected unit auxiliary transformer[3] (UAT) installed on BES generating resource(s).

4.2.1.4 Individual dispersed power producing type 1 or type 2 wind resource(s) identified in the BES Definition, Inclusion I4.

[1] For the purpose of this standard, the MPT is the power transformer that steps up voltage from multiple small synchronous generators~~,~~ (e.g. multiple small hydro generators connecting to a common bus) or from a type 1 or type 2 wind resource collector station to transmission voltage .

[2] It is not required to install or activate the protections described in Facilities Section 4.2.

[3] These transformers are variously- referred to as station power UAT, or station service transformer(s) used to provide overall auxiliary power to the synchronous generators. This UAT is the transformer connected on the generator bus between the low side of the GSU and the generator terminal.

~~4.2.1.4~~4.2.1.5 Elements that are designed primarily for the delivery of capacity from multiple synchronous generators connecting to a common bus or individual dispersed power producing type 1 or type 2 wind resources identified in the BES Definition, Inclusion I4, to the point where those resources aggregate to greater than 75 MVA.

~~4.2.1.5~~4.2.1.6 MPT of multiple synchronous generators connecting to a common bus or MPT of individual dispersed power producing type 1 or type 2 wind resources as identified in the BES Definition, Inclusion I4.

4.2.2 Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip transmission connected synchronous condensers; or (ii) provide signals to trip transmission connected synchronous condenser and are applied to the following:

4.2.2.1 BES synchronous condensers

4.2.2.2 BES step-up transformer(s) for synchronous condensers.

4.2.2.3 High-side of the synchronous condenser-connected unit auxiliary transformer (UAT).

4.2.3 **Exemptions:** Protection on all auxiliary equipment within the synchronous generator, type 1 or type 2 wind resource, or synchronous condenser Facility.

5. **Effective Date:** See Implementation Plan for PRC-024-4

B. Requirements and Measures

R1. Each Generator Owner and Transmission Owner shall set applicable frequency protection[4] in accordance with PRC-024-4 Attachment 1 such that the applicable protection does not cause the ~~synchronous generator(s) or condenser(s)~~Facility to which it is applied to trip within the "no trip zone" during a frequency excursion with the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- Applicable frequency protection may be set to trip within a portion of the "no trip zone" for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.

M1. Each Generator Owner and Transmission Owner shall have evidence that the applicable frequency protection has been set in accordance with Requirement R1, such as dated setting sheets, calibration sheets, calculations, or other documentation.

R2. Each Generator Owner and Transmission Owner shall set applicable voltage protection[5] in accordance with PRC-024-4 Attachment 2, such that the applicable protection does not cause the ~~synchronous generator(s) or condenser(s)~~Facility to which it is applied trip within the "no trip zone" during a voltage excursion at the high-side of the GSU or MPT, subject to the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- If the Transmission Planner allows less stringent voltage protection settings than those required to meet PRC-024-4 Attachment 2, then the Generator Owner or Transmission Owner may set its protection within the voltage recovery characteristics of a location-specific Transmission Planner's study.
- Applicable voltage protection may be set to trip during a voltage excursion within a portion of the "no trip zone" for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.

M2. Each Generator Owner and Transmission Owner shall have evidence that applicable voltage protection has been set in accordance with Requirement R2, such as dated setting sheets, voltage-time boundaries, calibration sheets, coordination plots, dynamic simulation studies, calculations, or other documentation.

R3. Each Generator Owner and Transmission Owner shall document each known regulatory or equipment limitation[6] that prevents an ~~applicable~~its synchronous generator~~(s)~~, type 1 or type 2 wind resource, or synchronous condenser~~(s)~~, with applicable frequency or voltage protection from meeting the protection setting criteria in Requirements R1 or R2, including (but not limited to) study results,

---

[4] Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip the synchronous generator(s~~)~~), type 1 or type 2 wind resource(s), or synchronous condenser(s); or (ii) provide signals to ~~the synchronous generator(s) or condenser(s)~~same to trip.

[5] Ibid.

[6] Excludes limitations caused by the setting capability of the frequency, voltage, and volts per hertz protective relays ~~for~~applied to the synchronous generator(s~~) or~~), type 1 and type 2 wind resource(s), and condenser(s). This does not exclude limitations originating in the equipment protected by the relay~~.~~(s).

experience from an actual event, or manufacturer's advice. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

3.1. The Generator Owner and Transmission Owner shall communicate the documented regulatory or equipment limitation, or the removal of a previously documented regulatory or equipment limitation, to its Planning Coordinator and Transmission Planner within 30 calendar days of any of the following:

- Identification of a regulatory or equipment limitation.
- Repair of the equipment causing the limitation that removes the limitation.
- Replacement of the equipment causing the limitation with equipment that removes the limitation.
- Creation or adjustment of an equipment limitation caused by consumption of the cumulative turbine life-time frequency excursion allowance.

M3. Each Generator Owner and Transmission Owner shall have evidence that it has documented and communicated any known regulatory or equipment limitations that resulted in an exception to Requirements R1 or R2 in accordance with Requirement R3, such as a dated email or letter that contains such documentation as study results, experience from an actual event, or manufacturer's advice.

R4. Each Generator Owner and Transmission Owner shall provide its applicable protection settings associated with Requirements R1 and R2 to the Planning Coordinator or Transmission Planner that models the associated ~~synchronous generator(s) or condenser(s)~~Facility within 60 calendar days of receipt of a written request for the data and within 60 calendar days of any change to those previously requested settings unless directed by the requesting Planning Coordinator or Transmission Planner that the reporting of protection setting changes is not required. *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

M4. Each Generator Owner and Transmission Owner shall have evidence that it communicated applicable protection settings in accordance with Requirement R4, such as dated e-mails, correspondence or other evidence and copies of any requests it has received for that information.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- The Generator Owner and Transmission Owner shall keep data or evidence of Requirements R1 through R4 for five years or until the next audit, whichever is longer.
- If a Generator Owner or Transmission Owner is found non-compliant, the Generator Owner or Transmission Owner shall keep information related to the non-compliance until mitigation is complete and approved for the time period specified above, whichever is longer.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable frequency protection so that it does not trip according to Requirement R1.
R2.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable voltage protection so that it does not trip according to Requirement R2.
R3.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 30 calendar days but less than or equal to 60 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 60 calendar days but less than or equal to 90 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner documented the known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2 and communicated the documented limitation to its Planning Coordinator and Transmission Planner more than 90 calendar days but less than or equal to 120 calendar days of identifying the limitation.	The Generator Owner or Transmission Owner failed to document any known non-protection system equipment limitation that prevented it from meeting the criteria in Requirement R1 or R2. OR The Generator Owner or Transmission Owner failed to communicate the documented limitation to its Planning Coordinator and Transmission Planner within 120 calendar

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
				days of identifying the limitation.
R4.	The Generator Owner or Transmission Owner- provided its protection settings more than 60 calendar days but less than or equal to 90 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner provided protection settings more than 60 calendar days but less than or equal to 90 calendar days of a written request.	The Generator Owner or Transmission Owner provided its protection settings more than 90 calendar days but less than or equal to 120 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner provided protection settings more than 90 calendar days but less than or equal to 120 calendar days of a written request.	The Generator Owner or Transmission Owner- provided its protection settings more than 120 calendar days but less than or equal to 150 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner or provided protection settings more than 120 calendar days but less than or equal to 150 calendar days of a written request.	The Generator Owner or Transmission Owner- failed to provide its protection settings within 150 calendar days of any change to those settings. OR The Generator Owner or Transmission Owner failed to provide protection settings within 150 calendar days of a written request.

D. Regional Variances

D.A. Variance for the Quebec Interconnection

This Variance replaces Requirement R2 of the continent-wide standard in its entirety and adds a new requirement, Requirement D.A.5., applicable to Planning Coordinators in the Quebec Interconnection.

This Variance replaces continent-wide Requirement R2 in its entirety with the following:

D.A.2. Each Generator Owner and Transmission Owner shall set applicable voltage protection[~~6~~7] in accordance with PRC-024 Attachment 2B, such that the applicable protection does not cause the ~~synchronous generator(s) or condenser(s)~~Facility to which it is applied to trip ~~-~~within the "no trip zone" during a voltage excursion at the high-~~-~~side of the GSU or MPT, subject to the following exceptions: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

- For newly designated strategic power plants, applicable protections must comply with the high voltage durations for such plants within 48 calendar months of the notification made pursuant to Requirement D.A.5. ~~-~~During this transition period, voltage protections must at least comply with the high voltage durations for "all power plants".
- ~~Synchronous generator(s) are permitted to~~Applicable voltage protection may be set to trip during a voltage excursion ~~bounded by~~within a portion of the "no trip zone" of PRC-024 Attachment 2B for documented and communicated regulatory or equipment limitations in accordance with Requirement R3.
- If the Transmission Planner allows less stringent voltage protection settings than those required to meet PRC-024 Attachment 2B, then the Generator Owner or Transmission Owner may set its protection within the voltage recovery characteristics of a location-specific Transmission Planner's study.

M.D.A.2. Each Generator Owner and Transmission Owner shall have evidence that applicable voltage protection has been set in accordance with Requirement R2, such as dated setting sheets, voltage-time boundaries, calibration sheets, coordination plots, dynamic simulation studies, calculations, or other documentation.

This Variance adds the following Requirement:

D.A.5 Each Planning Coordinator shall designate, at least once every five calendar years, the strategic power plants that must comply with

[7] Frequency, voltage, and volts per hertz protection (whether provided by relaying or functions within associated control systems) that respond to electrical signals and: (i) directly trip the synchronous generator(s), type 1 or type 2 wind resource(s), or synchronous condenser(s); or (ii) provide signals to same to trip.

Attachment 2B and notify, within 30 calendar days of its designation, each Generator Owner or Transmission Owner that owns facilities[8] in the strategic power plants. *[Violation Risk Factor: Medium] [Time Horizon: Long-term planning]*

M.D.A.5 Each Planning Coordinator shall have evidence that it designated, at least once every five calendar years, strategic power plants in accordance with Requirement D.A.5, Part 5 and shall have dated evidence that each Generator Owner or Transmission Owner has been notified in accordance with Requirement D.A.5, part 5.2. Evidence may include, but is not limited to letters, emails, electronic files, or hard copy records demonstrating transmittal of information.

[8] Facilities in the strategic power plants include facilities with synchronous generator(s) from the generator up to and including the MPT or GSU.

Violation Severity Levels

This Variance adds a VSL for D.A.5 and modifies the VSL for R2 as follows:

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
D.A.2.	N/A	N/A	N/A	The Generator Owner or Transmission Owner failed to set its applicable voltage protection so that it does not trip in accordance with Requirement D.A.2. OR The Generator Owner or Transmission Owner set its applicable voltage protection in accordance with Requirement D.A.2 but, for strategic power plants, failed to do so within 48 months of notification.
D.A.5.	N/A	The Planning Coordinator designated strategic power plants at least once every five calendar years but notified each Generator Owner or Transmission Owner that owns facilities in the strategic power plants between 31 days and 45 days after its designation.	The Planning Coordinator designated strategic power plants at least once every five calendar years but notified each Generator Owner or Transmission Owner that owns facilities in the strategic power plants between 46 days and 60 days after its designation.	The Planning Coordinator failed to designate, at least once every five years, the strategic power plants that must comply with Attachment 2B. OR The Planning Coordinator failed to notify, each Generator Owner or Transmission Owner that owns facilities in the strategic power plants or notified them more than 60 days after its designation.

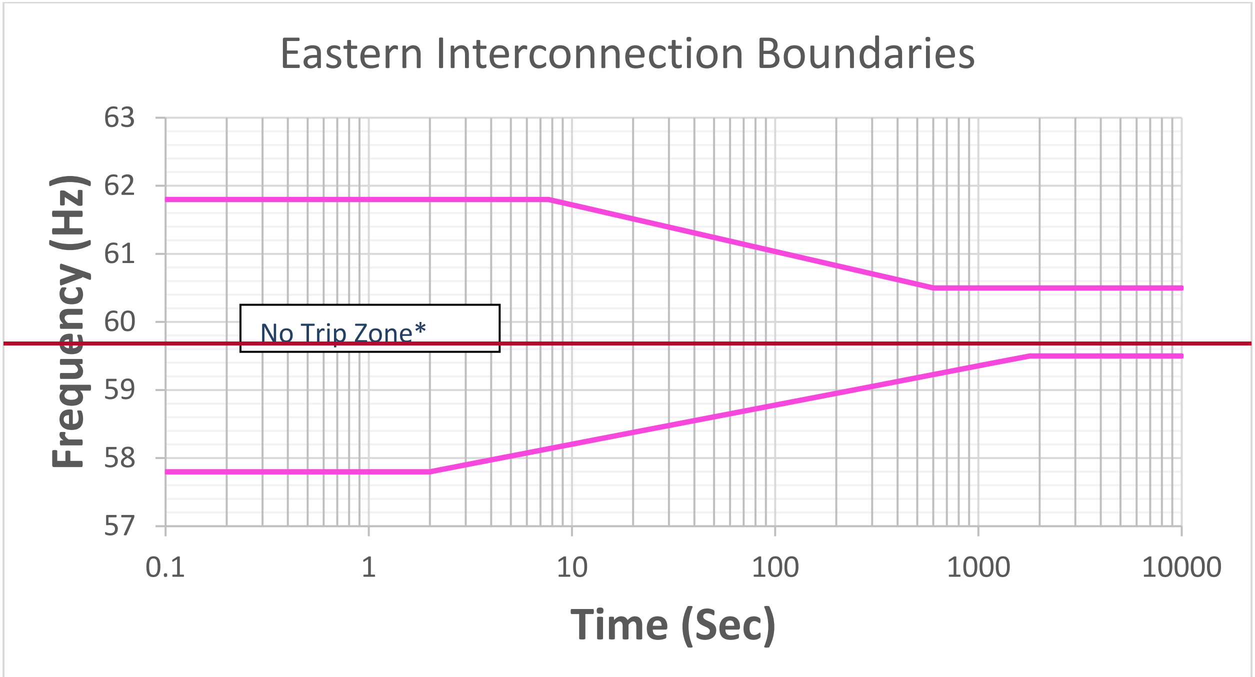
Attachment 1

(Frequency No Trip Boundaries by Interconnection[9])



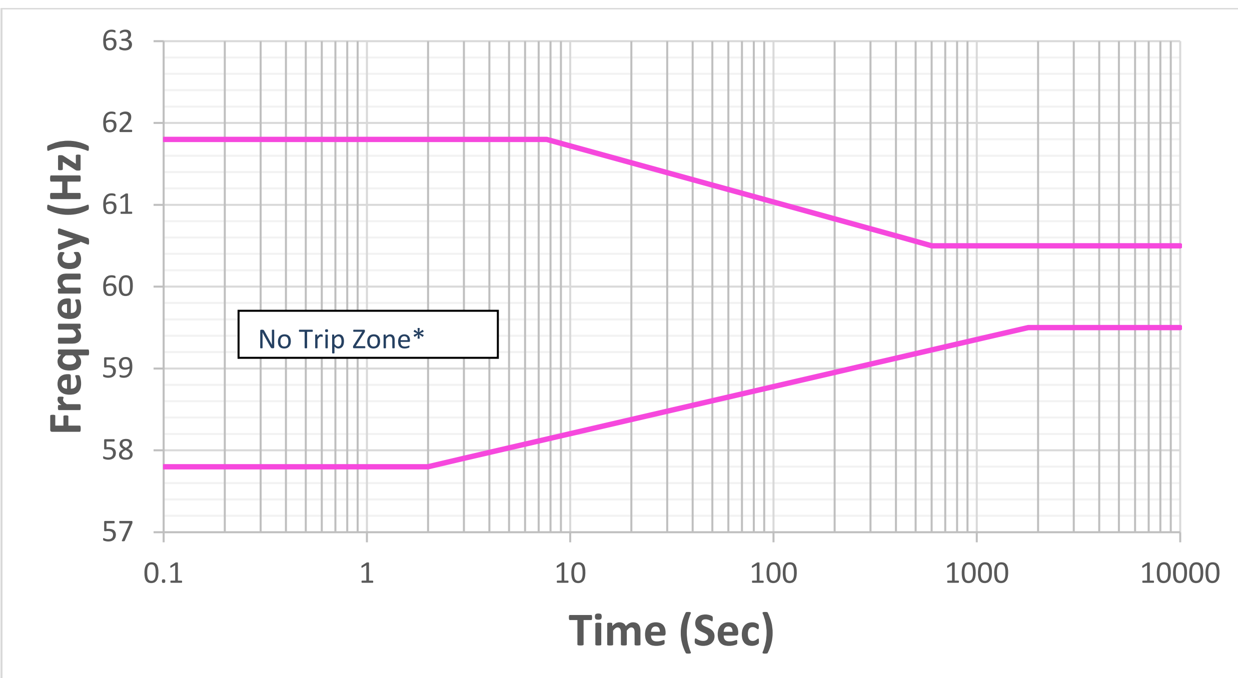


Figure 1~~1.1~~

: Eastern Interconnection Boundaries

[9] The figures do not visually represent the "no trip zone" boundaries before 0.1 seconds and after 10,000 seconds. The Frequency Boundary Data Points Table defines the entirety of the "no trip zone" boundaries.

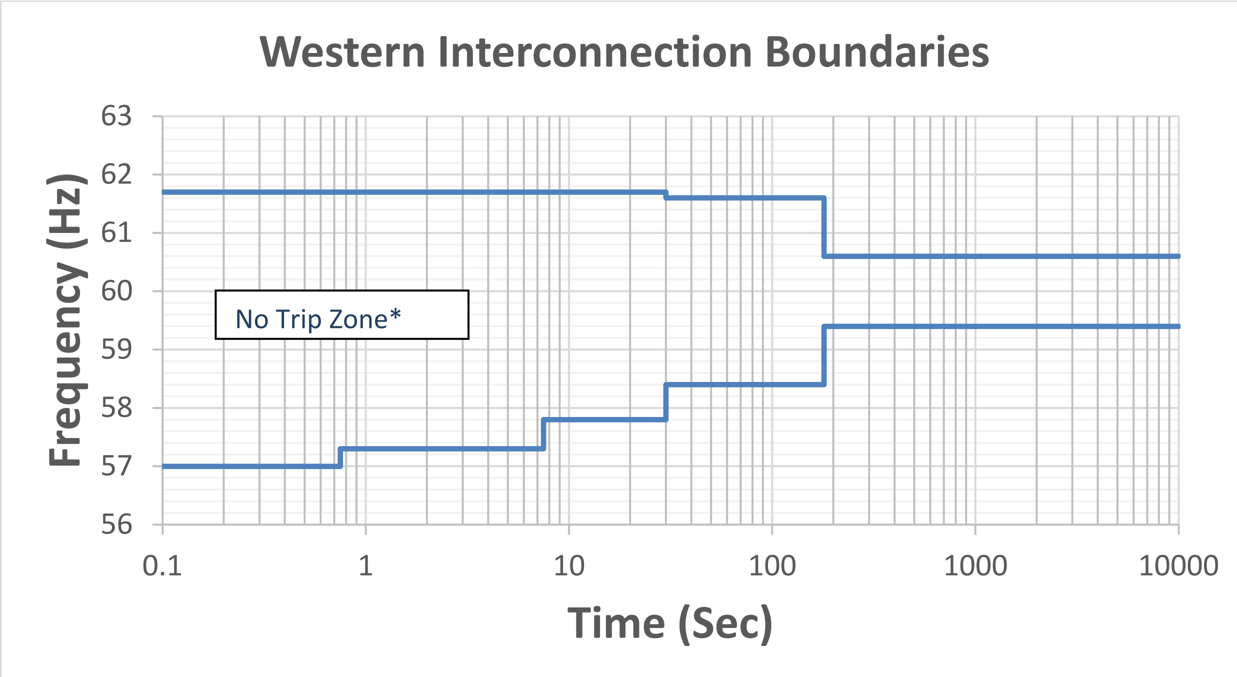
***** The area outside the "No Trip Zone" is not a "Must Trip Zone."***

Table 1: Frequency Boundary Data Points — Eastern Interconnection

High Frequency Duration		Low Frequency Duration	
Frequency (Hz)	Minimum Time (Sec)	Frequency (Hz)	Minimum Time (sec)
≥61.8	Instantaneous[10]	≤57.8	Instantaneous[11]
≥60.5	$10^{(90.935-1.45713*f)}$	≤59.5	$10^{(1.7373*f-100.116)}$
<60.5	Continuous operation	> 59.5	Continuous operation

~~Table 1.2~~

[10] Frequency is calculated over a window of time. While the frequency boundaries include the option to trip instantaneously for frequencies outside the specified range, this calculation should occur over a time window. Typical window/filtering lengths are three to six cycles (50 – 100 milliseconds). Instantaneous trip settings based on instantaneously calculated frequency measurement is not permissible.



~~Figure1.3~~ Figure 2: Western Interconnection Boundaries

** The area outside the "No Trip Zone" is not a "Must Trip Zone."*

Table 2: Frequency Boundary Data Points – Western Interconnection

High Frequency Duration		Low Frequency Duration	
Frequency (Hz)	Minimum Time (Sec)	Frequency (Hz)	Minimum Time (sec)
≥61.7	Instantaneous[11]	≤57.0	Instantaneous[11]
≥61.6	30	≤57.3	0.75
≥60.6	180	≤57.8	7.5
<60.6	Continuous operation	≤58.4	30
		≤59.4	180
		>59.4	Continuous operation

<1.10	4.00	≥ 0.90	4.00

~~Table 2.2~~

[8] ~~Voltage at the high-side of the GSU or MPT.~~

Attachment 2A: Voltage Boundary Clarifications ~~(~~ – Eastern, Western, and ERCOT Interconnections~~)~~

Boundary Details:

1. Unless otherwise specified by the Transmission Planner, the per unit voltage base for these boundaries is the nominal transmission system voltage (e.g., 100 kV, 115 kV, 138 kV, 161 kV, 230 kV, 345 kV, 400 kV, 500 kV, 765 kV, etc.).
2. The values in the table represent the minimum time durations allowed for specified voltage excursion thresholds.
3. When evaluating volts per hertz protection, either assume a system frequency of 60 Hertz or the magnitude of the high voltage boundary can be adjusted in proportion to deviations of frequency below 60 Hertz.
4. Voltages in the boundaries assume RMS fundamental frequency phase-to-ground or phase-to-phase per unit voltage.
5. For applicability to PRC-024, the "no trip zone" ends at 4 seconds.

Evaluating Protection Settings:

The voltage values in the Attachment 2 voltage boundaries are voltages at the high-side of the GSU/MPT. For resources with multiple stages of step up to reach interconnecting voltage, this is the high-side of the transformer with a low side below 100kV and a high-side 100kV or above**.** When evaluating protection settings, consider the voltage differences between where the protection is measuring voltage and the high-side of the GSU/MPT. A steady state calculation or dynamic simulation may be used.

If using a steady state calculation or dynamic simulation, use the following conditions when evaluating protection settings:

a. The most probable real and reactive loading conditions for the unit under study.
b. All installed generating plant reactive support (e.g., static VAR compensators, synchronous condensers, capacitors) equipment is available and operating normally.
c. Account for the actual tap settings of transformers between the generator terminals and the high-side of the GSU/MPT.
d. For dynamic simulations, the automatic voltage regulator is in automatic voltage control mode with associated limiters in service.

<0.85	2.00
<0.90	30
≥0.90	continuous

~~Table 2~~

Attachment 2C
~~(~~: Voltage Boundary Clarifications – Quebec Interconnection~~)~~

Boundary Details:

1. The per unit voltage base for these boundaries is the nominal operating voltage (e.g., 120 kV, 161 kV, 230 kV, 315 kV, 735 kV, etc.).
2. The values in the table represent the minimum time durations allowed for specified voltage excursion thresholds.
3. When evaluating volts per hertz protection, either assume a system frequency of 60 Hertz or the magnitude of the high voltage boundary can be adjusted in proportion to deviations of frequency below 60 Hertz.
4. Voltages in the Quebec Interconnection boundaries assume positive-sequence values.

Evaluating Protection Settings:

The voltage values in the Attachment 2B voltage boundaries are voltages at the high-side of the GSU/MPT. For resources with multiple stages of step up to reach interconnecting voltage, this is the high-side of the transformer that connects to the interconnecting voltage. When evaluating protection settings, consider the voltage differences between where the protection is measuring voltage and the high-side of the GSU/MPT. A steady state calculation or dynamic simulation may be used.

If using a steady state calculation or dynamic simulation, use the following conditions when evaluating protection settings:

a. The most probable real and reactive loading conditions for the unit under study.
b. All installed generating plant reactive support (e.g., static VAR compensators, synchronous condensers, capacitors) equipment is available and operating normally.
c. Account for the actual tap settings of transformers between the generator terminals and the high-side of the GSU/MPT.
d. For dynamic simulations, the automatic voltage regulator is in automatic voltage control mode with associated limiters in service.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

Completed Actions	Date
Standards Committee accepted revised Standard Authorization Request (SAR) for posting	April 19, 2023
Standards Committee approved waivers to the Standards Process Manual	December 13, 2023
Initial 25-day formal comment period and additional ballot	March 27 – April 21, 2024

Anticipated Actions	Date
15-day formal comment period and additional ballot	June 18 – July 8, 2024
Final Ballot	July 16 - 20, 2024
Board adoption	August 14, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

Ride-through: Remaining connected, synchronized with the Transmission System, and continuing to operate in response to System conditions through the time-frame of a System Disturbance.

A. Introduction

1. **Title:** **Frequency and Voltage Ride-through Requirements for Inverter-Based Resources**
2. **Number:** **PRC-029-1**
3. **Purpose:** To ensure that Inverter-Based Resources (IBRs) adhere to Ride-through requirements as expected to support the Bulk Power System (BPS) during and after defined frequency and voltage excursions.
4. **Applicability:**

    4.1 Functional Entities:

    4.1.1. Generator Owner

    4.1.2. Transmission Owner[1]

    4.2 Facilities:

    4.2.1. BES inverter-based resources[2]

    4.2.2. IBR Registration Criteria

Effective Date: See Implementation Plan for Project 2020-02 – PRC-029-1

Standard-Only Definition: None

[1] For owners of Voltage Source Converter – High-voltage Direct Current (VSC-HVDC) transmission facilities that are dedicated connections for IBR to the BPS

[2] For the purpose of this standard, "inverter-based resources" refers to a collection of individual solar photovoltaic (PV), Type 3 and Type 4 wind turbines, battery energy storage system (BESS), or fuel cells that operate as a single plant/resource. In case of offshore wind plants connecting via a dedicated VSC-HVDC, the inverter-based resource includes the VSC-HVDC system.

B. Requirements and Measures

R1. Each Generator Owner or Transmission Owner shall ensure the design and operation is such that each facility adheres to Ride-through requirements, in accordance with the “must Ride-through[3] zone” as specified in Attachment 1, except for the following: *[Violation Risk Factor: High] [Time Horizon: Operations Assessment]*

- The facility needed to electrically disconnect in order to clear a fault;
- A documented equipment limitation exists in accordance with Requirement R4; or
- The instantaneous positive sequence voltage phase angle change is more than 25 electrical degrees at the high-side of the main power transformer and is initiated by a non-fault switching event on the transmission system; or
- The Volts per Hz (V/Hz) at the high-side of the main power transformer exceed 1.1 per unit for longer than 45 seconds or exceed 1.18 per unit for longer than 2 seconds.

M1. Each Generator Owner and Transmission Owner have evidence of dynamic simulations, studies, or other evidence to demonstrate the design of each facility will adhere to Ride-through requirements, as specified in Requirement R1. Each Generator Owner and Transmission Owner have evidence of actual disturbance monitoring (i.e. Sequence of Event Recorder, Dynamic Disturbance Recorder, and Fault Recorder) to demonstrate that the operation of each facility did adhere to Ride-through requirements, as specified in Requirement R1. If the Generator Owner and Transmission Owner choose to utilize Ride-through exemptions that occur within the “must Ride-through zone” and are caused by non-fault initiated phase jumps of greater than 25 electrical degrees, then each Generator Owner and Transmission Owner also have evidence of actual disturbance monitoring (i.e. Sequence of Event Recorder, Dynamic Disturbance Recorder, and Fault Recorder) data to demonstrate that the facility failed to Ride-through during a phase jump of greater than or equal to 25 electrical degrees, and documentation from their Transmission Planner, Reliability Coordinator, Planning Coordinator, or Transmission Operator that a non-fault initiated switching event occurred.

R2. Each Generator Owner or Transmission Owner shall ensure the design and operation is such that the voltage performance for each facility adheres to the following during a voltage excursion, unless a documented equipment limitation exists in accordance with Requirement R4. *[Violation Risk Factor: High] [Time Horizon: Operations Assessment]*

[3] Includes no tripping associated with phase lock loop loss of synchronism

2.1. While the voltage at the high-side of the main power transformer[4] remains within the continuous operation region as specified in Attachment 1, each facility shall:

2.1.1 Continue to deliver the pre-disturbance level of active power or available active power, whichever is less.[5]

2.1.2 Continue to deliver reactive power up to its reactive power limit and according to its controller settings.

2.1.3 If the facility cannot deliver both active and reactive power due to a current limit or reactive power limit, when the voltage is below 95 per unit and still within the continuous operation region, then preference shall be given to active or reactive power according to requirements if required by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

2.2. While voltage at the high-side of the main power transformer is within the mandatory operation region as specified in Attachment 1, each IBR shall exchange current, up to the maximum capability to provide voltage support, on the affected phases during both symmetrical and asymmetrical voltage disturbances, either under[6]:

- Reactive power priority by default; or
- Active power priority if required by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

2.3. While voltage at the high-side of the main power transformer is within the permissive operation region, as specified in Attachment 1, each facility may operate in current block mode if necessary to avoid tripping. Otherwise, each facility shall follow the requirements for the mandatory operation region in Requirement R2.2.

2.3.1 If a facility enters current block mode, it shall restart current exchange in less than or equal to five cycles of positive sequence voltage returning to a continuous operation region or mandatory operation region.

2.4. Each facility shall not itself cause voltage at the high-side of the main power transformer to exceed the applicable high voltage thresholds and time

[4] For the purpose of this standard, the main power transformer is the power transformer that steps up voltage from the collection system voltage to the nominal transmission/interconnecting system voltage for inverter-based resources. In case of offshore wind plants connecting via a dedicated VSC-HVDC, the main power transformer is the onshore main power transformer.

[5] Except if this would occur during a frequency excursion. The active power response should recover in accordance with the primary frequency controller.

[6] In either case and if required, the magnitude of active power and reactive current shall be as specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

durations in its response as voltage recovers from the mandatory or permissive operation regions to the continuous operation region.

2.5. Each facility shall restore active power output to the pre-disturbance or available level (whichever is lesser) within 1.0 second when the voltage at the high-side of the main power transformer returns from the mandatory operation region or permissive operation region (including operating in current block mode), as specified in Attachment 1, unless the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator requires a lower post-disturbance active power level requirement or requires a different post-disturbance active power restoration time.[7]

M2. Each Generator Owner and Transmission Owner have evidence of dynamic simulations, studies, or other evidence to demonstrate the design of each facility will adhere to requirements, as specified in Requirement R2. Each Generator Owner and Transmission Owner also have evidence of actual disturbance monitoring (i.e. Sequence of Event Recorder, Dynamic Disturbance Recorder, and Fault Recorder) data to demonstrating that the operation of each facility did adhere to performance requirements, as specified in Requirement R2, during each voltage excursion measured at the high-side of the main power transformer. The Generator Owner or Transmission Owner have evidence of receiving such performance requirements, (e.g. email exchange, contract information) if the Transmission Planner, Transmission Operator, Reliability Coordinator, or Planning Coordinator has required the Generator Owner or Transmission Owner to follow performance requirements other than those in Requirement R2 (e.g. ramp rates, reactive power prioritization).

R3. Each Generator Owner or Transmission Owner shall ensure the design and operation is such that each facility adheres to Ride-through requirements during a frequency excursion event whereby the System frequency remains within the "must Ride-through zone" according to Attachment 2 and the absolute rate of change of frequency (RoCoF)[8] magnitude is less than or equal to 5 Hz/second. *[Violation Risk Factor: High] [Time Horizon: Operations Assessment]*

M3. Each Generator Owner and Transmission Owner have evidence of dynamic simulations, studies, or other evidence to demonstrate the design of each facility will adhere to Ride-through requirements, as specified in Requirement R3. Each Generator Owner and Transmission Owner also have evidence of actual disturbance monitoring (i.e. Sequence of Event Recorder, Dynamic Disturbance Recorder, and Fault Recorder) data to demonstrate the operation of each facility did adhere to Ride-through requirements, as specified in Requirement R3, during each frequency excursion event measured at the high-side of the main power transformer.

R4. Each Generator Owner and Transmission Owner identifying a facility that is in-service by the effective date of PRC-029-1, has known hardware limitations that prevent the

[7] Except if this would occur during a frequency excursion. The active power response should recover in accordance with the primary frequency controller.

[8] Rate of change of frequency (ROCOF) is calculated as the average rate of change for multiple calculated system frequencies for a time period of greater than or equal to 0.1 second. ROCOF is not calculated during the fault occurrence and clearance.

facility from meeting voltage Ride-through criteria as detailed in Requirements R1 and R2, and requires an exemption from specific voltage Ride-through criteria shall*:*[9] *Lower] [Time Horizon: Long-term Planning]*

4.1. Document information supporting the identified hardware limitation no later than 12 months following the effective date of PRC-029-1. This documentation shall include:

4.1.1 Identifying information of the IBR (name, facility #, other);

4.1.2 Which aspects of voltage ride-through requirements that the IBR would be unable to meet and the capability of the equipment due to the limitation;

4.1.3 Identify the specific piece(s) of equipment causing the limitation;

4.1.4 Supporting technical documentation verifying the limitation is due to hardware that needs to be physically replaced or that the limitation cannot be removed by software updates or setting changes, and;

4.1.5 Information regarding any plans to remedy the equipment limitation (such as an estimated date).

4.2. Provide a copy of the information detailed in Requirement R4.1 to the applicable Planning Coordinator(s), Transmission Planner(s), Transmission Operator(s), Reliability Coordinator(s), and to the Regional Entity no later than 12 months following the effective date of PRC-029-1.

4.2.1 Any response to additional information requested by the applicable Planning Coordinator(s), Transmission Planner(s), Transmission Operator(s), Reliability Coordinator(s), and to the Regional Entity shall be provided back to the requestor within 90 days of the request.

4.3. Each Generator Owner and Transmission Owner with a previously submitted request for exemption that replace the equipment causing the limitation shall document and communicate such an equipment change to the associated Planning Coordinator(s), Transmission Planner(s), Transmission Operator(s), and Reliability Coordinator(s) within 90 days of the equipment change.

4.3.1 When existing equipment is replaced, the exemption for that Ride-through criteria no longer applies.

M4. Each Generator Owner and Transmission Owner seeking an exemption for facilities that are in-service by the effective date of PRC-029-1 have evidence of submission to the Regional Entity consistent with the information listed in Requirement R4.1. Each Generator Owner and Transmission Owner have evidence of communicated copies of each submission in accordance with Requirement R4.2 and to the applicable entities described in Requirement R4.2. Acceptable type of evidence for submittals include but

[9] The exemption requests for a non-US Registered Entity should be implemented in a manner that is consistent with, or under the direction of, the applicable governmental authority or its agency in the non-US jurisdiction

are not limited to, meeting minutes, agreements, copies of procedures or protocols in effect, or email correspondence. Acceptable types of evidence for an equipment limitation may include but is not limited to, documentation that contains study results, experience from an actual event, or manufacturer's advice. Each Generator Owner and Transmission Owner that replace equipment at a facility that is directly associated with an approved exemption and that equipment is the cause for the limitation, have evidence of communicating the equipment change to the applicable entities described in Requirement R4.3 within 30 calendar days of the equipment replacement.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- Each Generator Owner and Transmission Owner shall retain evidence with Requirements R1, R2, and R3 in this standard for 36 calendar months.
- Each Generator Owner and Transmission Owner shall retain evidence with Requirement R4 in this standard for five calendar years.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.	The Generator Owner or Transmission Owner failed to demonstrate the capability of each applicable facility to Ride-through in accordance with Attachment 1, except for those conditions identified in Requirement R1. < 0.10	Permissive Operation Region	0.32

[10] Type 3 and type 4 wind resources directly connected to the AC Transmission System
[11] Refer to bullet #5 below.
[12] These conditions are referred to as the "may Ride-through zone".
[13] Refer to bullet #5 below.
[14] These conditions are referred to as the "may Ride-through zone".

1. Table 1 applies to type 3 and type 4 wind facilities unless connected via a dedicated VSC-HVDC transmission facility.
2. Table 2 applies to all other inverter-based resource facility types not covered in Table 1; including, but not limited to, the following facilities:
   a. Inverter-based resources, regardless of their energy resource, interconnecting via a dedicated VSC-HVDC transmission facility.
   b. Other inverter-based resource plants or hybrid plants consisting of photovoltaic (PV) and BESS.
3. The applicable voltage for Voltage Source Converter High Voltage Direct Current (VSC HVDC) system with a dedicated connection to an inverter-based resource is on the AC side of the transformer(s) that is (are) used to connect the VSC HVDC system to the interconnected transmission system
4. Table 1 applies to hybrid facilities consisting of wind (type 3 or type 4) and various other IBR technologies. Otherwise, Table 2 applies to hybrid facilities with no wind (type 3 or type 4).
5. The voltage base for per unit calculation is the nominal phase-to-ground or phase-to-phase transmission system voltage unless otherwise defined by the Planning Coordinator or Transmission Planner.
6. The applicable voltage for Tables 1 and 2 is identified as the voltage max/min of phase to neutral or phase to phase fundamental root mean square (RMS) voltage at the high side of the main power transformer.
7. Tables 1 and 2 are only applicable when the frequency is within the “must Ride-through zone” as specified in Table 3 of Attachment 2.
8. At any given voltage value, each facility shall Ride-through unless the time duration at that voltage has exceeded the specified minimum Ride-through time duration. If the voltage is continuously varying over time, it is necessary to add the duration within each band of Tables 1 and 2 over any 10 second time period.
9. The specified duration of the mandatory operation regions and the permissive operation regions in Tables 1 and 2 is cumulative over one or more disturbances within any 10 second time period.
10. The facility may trip for more than four deviations of the applicable voltage at the high-side of the main power transformer outside of the continuous operation region within any 10 second time period.
11. Instantaneous trip settings based on instantaneously calculated voltage measurements with less than filtering lengths of one cycle (16.6 msec) are not permissible.
12. The “must Ride-through zone” is the combined area of the mandatory operating regions, the continuous operating regions, and the permissive operating region. All

area outside of these operating regions is referred to as the “may Ride-through zone”.

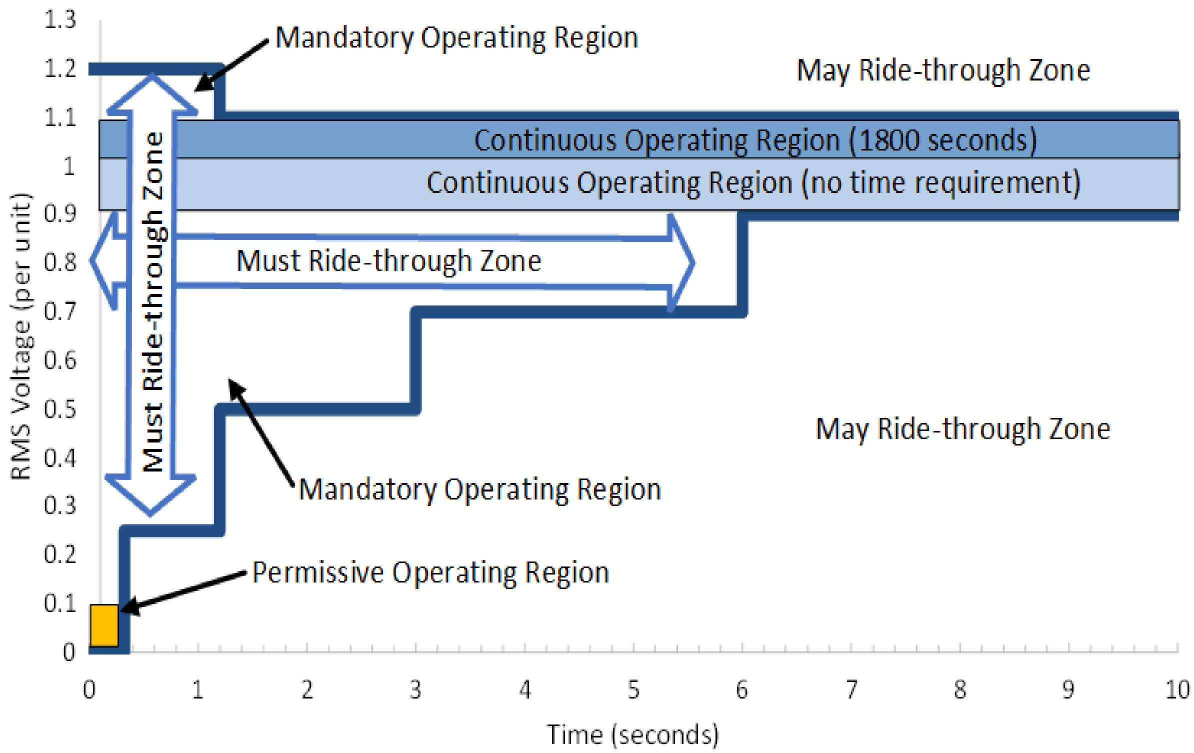

Figure 2: Voltage Ride-Through Requirements for All Other IBR

Attachment 2: Frequency Ride-Through Criteria

Table 3: Frequency Ride-Through Capability Requirements

System Frequency (Hz)	Minimum Ride-Through Time (sec)
≥64	May trip
< 64 and ≥61.8	6
< 61.8 and ≥ 61.5	299
< 61.5 and > 61.2	660
≤ 61.2 and < 58.8	Continuous
≤ 58.8 and < 58.8	660
< 58.5 and ≥ 57	299
< 57.0 and ≥ 56	6
< 56	May trip

1. Frequency measurements are taken at the high-side of the main power transformer.
2. Frequency is measured over a period of time (typically 3-6 cycles) to calculate system frequency at the high-side of the main power transformer.
3. Instantaneous or single points of measurement may not be used in the determination of control settings.
4. At any given frequency value, each facility shall Ride-through unless the time duration at that frequency has exceeded the specified minimum ride-through time duration.
5. The specified durations of Table 3 are cumulative over one or more disturbances within a 15-minute time period.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

Completed Actions	Date
Standards Committee accepted revised Standard Authorization Request (SAR) for posting	April 19, 2023
Standards Committee approved waivers to the Standards Process Manual	December 13, 2023
Standards Committee approved waivers to the Standards Process Manual	December 13, 2023

Anticipated Actions	Date
15-day formal comment period and additional ballot	June 18 – July 8, 2024
Final Ballot	July 16 - 20, 2024
Board adoption	August 14, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

Ride-through: Remaining connected, synchronized with the Transmission System, and continuing to operate in response to System conditions through the time-frame of a System Disturbance.

~~**Continuous Operating Region** – The range of voltages, measured at the high-side of the main power transformer, that are ≥ 0.9 per unit and ≤ 1.1 per unit.~~

~~**Mandatory Operating Region** – The range of voltages, measured at the high-side of the main power transformer, that are > 0.1 per unit and < 0.9 per unit – or – > 1.1 and ≤ 1.2 per unit.~~

~~**Permissive Operating Region** – The range of voltages, measured at the high-side of the main power transformer, that is ≤ 0.1 per unit.~~

A. Introduction

1. **Title:** **Frequency and Voltage Ride-through Requirements for Inverter-Based ~~Generating~~ Resources**
2. **Number:** **PRC-029-1**
3. **Purpose:** To ensure that Inverter-Based Resources (IBRs) adhere to Ride-through requirements ~~remain connected and perform operationally~~ as expected to support ~~of~~ the Bulk Power System (BPS) during and after defined frequency and voltage excursions.
4. **Applicability:**

   4.1 Functional Entities:

   4.1.1. Generator Owner

   4.1.2. Transmission Owner[1]

   4.2 Facilities: ~~**For purposes of this standard, the term "applicable Inverter-Based Resource" or "applicable Inverter-Based Resources" refers to the following:**~~

   4.2.1. BE~~P~~S inverter-based resources[2] ~~IBRs~~

   4.2.2. IBR Registration Criteria

~~5.~~ **Effective Date:** See Implementation Plan for Project 2020-02 – PRC-029-1

Standard-Only Definition: None

[1] For owners of Voltage Source Converter – High-voltage Direct Current (VSC-HVDC) transmission facilities that are dedicated connections for IBR to the BPS

[2] For the purpose of this standard, "inverter-based resources" refers to a collection of individual solar photovoltaic (PV), Type 3 and Type 4 wind turbines, battery energy storage system (BESS), or fuel cells that operate as a single plant/resource. In case of offshore wind plants connecting via a dedicated VSC-HVDC, the inverter-based resource includes the VSC-HVDC system.

B. Requirements and Measures

R1. Each Generator Owner or Transmission Owner ~~of an applicable IBR~~ shall ensure the~~at~~ design and operation is such that each facility~~IBR~~ adheres to Ride-through requirements,~~remains electrically connected and continues to exchange current~~ in accordance with the “must Ride-through[3]~~no-trip~~ zone~~s~~” ~~and operation regions~~ as specified in Attachment 1, except for the following:~~unless needed to clear a fault or a documented equipment limitation exists in accordance with Requirement R6.~~ *[Violation Risk Factor: High] [Time Horizon: Operations Assessment]*

- The facility needed to electrically disconnect in order to clear a fault;
- A documented equipment limitation exists in accordance with Requirement R4; or
- The instantaneous positive sequence voltage phase angle change is more than 25 electrical degrees at the high-side of the main power transformer and is initiated by a non-fault switching event on the transmission system; or
- The Volts per Hz (V/Hz) at the high-side of the main power transformer exceed 1.1 per unit for longer than 45 seconds or exceed 1.18 per unit for longer than 2 seconds.

M1. Each Generator Owner and Transmission Owner ~~shall~~ have evidence of dynamic simulations, studies, or other evidence to demonstrate the design of each facility will adhere to Ride-through requirements, as specified in Requirement R1. Each Generator Owner and Transmission Owner have evidence of actual disturbance monitoring (i.e. Sequence of Event Recorder, Dynamic Disturbance Recorder, and Fault Recorder) ~~recorded~~ to demonstrate that the operation of each facility did adhere to Ride-through requirements, as specified in Requirement R1. If the Generator Owner and Transmission Owner choose to utilize Ride-through exemptions that occur within the “must Ride-through zone” and are caused by non-fault initiated phase jumps of greater than 25 electrical degrees, then each Generator Owner and Transmission Owner also have evidence of actual disturbance monitoring (i.e. Sequence of Event Recorder, Dynamic Disturbance Recorder, and Fault Recorder) data to demonstrate that the facility failed to Ride-through during a phase jump of greater than or equal to 25 electrical degrees, and documentation from their Transmission Planner, Reliability Coordinator, Planning Coordinator, or Transmission Operator that a non-fault initiated switching event occurred.~~data or other evidence for each applicable IBR demonstrating adherence to ride-through requirements, as specified in **Requirement R1**~~.

R2. Each Generator Owner or Transmission Owner ~~of an applicable IBR~~ shall ensure the design and operation is such that ~~at during a System disturbance, each IBR's~~ the voltage performance for each facility adheres to the following during a voltage excursion, unless a documented equipment limitation exists in accordance with Requirement R4~~6~~. *[Violation Risk Factor: High] [Time Horizon: Operations Assessment]*

[3] Includes no tripping associated with phase lock loop loss of synchronism

2.1. While the voltage at the high-side of the main power transformer[4] remains within the ~~C~~continuous ~~O~~operation ~~R~~region as specified in Attachment 1, each ~~IBR~~ facility shall:

2.1.1 Continue to deliver the pre-disturbance level of active power or available active power, whichever is less.[5] ~~,~~

~~**2.1.1**~~**2.1.2** ~~and c~~Continue to deliver reactive power ~~and reactive power~~ up to its ~~apparent~~ reactive power limit and according to its controller settings.

~~**2.1.2**~~**2.1.3** If the facility~~IBR~~ cannot deliver both active and reactive power due to a current ~~or apparent power~~ limit or reactive power limit, when the ~~applicable~~ voltage is below 95~~%~~ per unit and still within the ~~C~~continuous o~~O~~peration ~~R~~region, then preference shall be given to active or reactive power according to requirements if required ~~specified~~ by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

2.2. While voltage at the high-side of the main power transformer is within the ~~M~~mandatory o~~O~~peration ~~R~~region as specified in Attachment 1, each IBR shall exchange current, up to the maximum capability to provide voltage support, on the affected phases during both symmetrical and asymmetrical voltage disturbances, either under[6]:

~~**2.2.1**~~ • Reactive power priority by default; or~~Exchange current, up to the maximum capability while maintaining automatic voltage regulation, on the affected phases during both symmetrical and asymmetrical voltage disturbances.~~

~~**2.2.2**~~ • Active ~~djust reactive current injection at the high-side of the main~~ power priority ~~transformer so that the magnitude of the reactive current responds to changes in voltage at the high-side of the main power transformer in accordance with default reactive prioritization unless the~~ if required by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator. ~~specifies a certain magnitude of reactive power response to voltage changes or specifies active power priority instead of reactive power priority.~~

---

[4] For the purpose of this standard, the main power transformer is the power transformer that steps up voltage from the collection system voltage to the nominal transmission/interconnecting system voltage for inverter-based resources. In case of offshore wind plants connecting via a dedicated VSC-HVDC, the main power transformer is the onshore main power transformer.

[5] Except if this would occur during a frequency excursion. The active power response should recover in accordance with the primary frequency controller.

[6] In either case and if required, the magnitude of active power and reactive current shall be as specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

2.3. While ~~The IBR shall not itself cause~~ voltage at the high-side of the main power transformer is within the permissive operation region~~to exceed the applicable~~, as specified in Attachment 1, each facility ~~Table 1 or Table~~ may operate in current block mode if necessary to avoid tripping. Otherwise, each facility shall follow the requirements for the ~~2 no-trip zone voltage thresholds and time durations in its response from M~~mandatory ~~or Permissive O~~operation ~~R~~region in Requirement R2.2~~s to the Continuous Operating Region~~.

~~2.3.~~2.3.1 If a facility enters current block mode, it shall restart current exchange in less than or equal to five cycles of positive sequence voltage returning to a continuous operation region or mandatory operation region.

2.4. Each ~~IBR~~ facility shall not itself cause ~~restore active power output to the pre-disturbance or available level within 1.0 second when the~~ voltage at the high-side of the main power transformer ~~returns~~ to exceed the applicable high voltage thresholds and time durations in its response as voltage recovers from the mandatory or permissive operation regions to the ~~C~~continuous ~~O~~operation ~~R~~region ~~from the Mandatory Operation Region or Permissive Operation Region (including operation in current block mode) as specified in **Attachment 1**, unless the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator specifies a lower post-disturbance active power level requirement or specifies a different post-disturbance active power restoration time~~.

2.5. Each ~~IBR~~ facility shall restore active power output to the pre-disturbance or available level (whichever is lesser) within 1.0 second~~only trip to prevent equipment damage,~~ when the voltage at the high-side of the main power transformer returns from the mandatory operation region or permissive operation region (including operating in current block mode), ~~is outside of the no-trip zone~~ as specified in Attachment 1, unless the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator requires a lower post-disturbance active power level requirement or requires a different post-disturbance active power restoration time.[7]

M2. Each Generator Owner and Transmission Owner ~~shall~~ have evidence of dynamic simulations, studies, or other evidence to demonstrate the design of each facility will adhere to requirements, as specified in Requirement R2. Each Generator Owner and Transmission Owner also have evidence of actual disturbance monitoring (i.e. Sequence of Event Recorder, Dynamic Disturbance Recorder, and Fault Recorder)~~recorded~~ data ~~or other evidence for each applicable IBR~~to ~~demonstrating~~demonstrating that the operation of each facility did adhere~~nce~~ to performance requirements, as specified in Requirement R2, during each ~~System~~ voltage excursion measured at the high-side of the main power transformer. The Generator Owner or Transmission Owner have evidence of receiving such

[7] Except if this would occur during a frequency excursion. The active power response should recover in accordance with the primary frequency controller.

performance requirements, (e.g. email exchange, contract information) if the Transmission Planner, Transmission Operator, Reliability Coordinator, or ~~disturbance which has occurred within the associated~~ Planning Coordinator~~(s) area(s)~~ has required the Generator Owner or Transmission Owner to follow performance requirements other than those in Requirement R2 (e.g. ramp rates, reactive power prioritization).

~~**R3.** Each Generator Owner or Transmission Owner of an applicable IBR shall ensure that during a transient overvoltage as a result of a switching event whereby instantaneous voltage at the high-side of the main power transformer exceeds 1.2 per unit, each IBR shall either: *[Violation Risk Factor: Lower] [Time Horizon: Operations Assessment]*~~

- ~~Remain electrically connected and continue to exchange current in accordance with instantaneous transient overvoltage levels and durations specified in Attachment 2; or~~
- ~~Remain electrically connected in current block mode in accordance with instantaneous transient overvoltage levels and durations specified in **Attachment 2**, and restart current exchange within 5 cycles of the instantaneous voltage falling below (and remaining below) 1.2 per unit.~~

~~**M3.** Each Generator Owner and Transmission Owner shall have evidence of actual recorded data or other evidence for each applicable IBR demonstrating adherence to performance requirements, as specified in Requirement R3, during each transient overvoltage period which has occurred within the associated Planning Coordinator(s) area(s).~~

~~R4.~~R3. Each Generator Owner or Transmission Owner ~~of an applicable IBR~~ shall ensure the design and operation is such that each ~~IBR~~ facility~~remains electrically connected and continues to exchange current~~ adheres to Ride-through requirements during a frequency excursion event whereby the System frequency remains within the "~~no trip~~must Ride-through zone" according to Attachment 2~~3~~ and the absolute rate of change of frequency (R~~O~~oC~~O~~oF)[8] magnitude is less than or equal to 5 Hz/second. *[Violation Risk Factor: ~~Lower~~High] [Time Horizon: Operations Assessment]*

M~~4~~3. Each Generator Owner and Transmission Owner ~~shall~~ have evidence of dynamic simulations, studies, or other evidence to demonstrate the design of each facility will adhere to Ride-through requirements, as specified in Requirement R3. Each Generator Owner and Transmission Owner also have evidence of actual disturbance monitoring (i.e. Sequence of Event Recorder, Dynamic Disturbance Recorder, and Fault Recorder) ~~recorded~~ data ~~or other evidence~~ to demonstrate the operation of~~for~~ each ~~applicable IBR~~facility did ~~demonstrating~~ adheren~~ce~~ to ~~r~~Ride-through requirements, as specified in Requirement R~~4~~3, during each frequency excursion event measured ~~which has occurred within the associated Planning Coordinator(s) area(s)~~ at the high-side of the main power transformer.

[8] Rate of change of frequency (ROCOF) is calculated as the average rate of change for multiple calculated system frequencies for a time period of greater than or equal to 0.1 second. ROCOF is not calculated during the fault occurrence and clearance.

~~**R5.** Each Generator Owner or Transmission Owner of an applicable IBR shall ensure each IBR remains electrically connected and continues to exchange current during instantaneous positive sequence voltage phase angle changes that are initiated by non-fault switching events on the transmission system and are changes of less than 25 electrical degrees at the high-side of the main power transformer. *[Violation Risk Factor: Lower] [Time Horizon: Operations Assessment]*~~

~~**5.1.** When the instantaneous positive sequence voltage phase angle change is more than 25 electrical degrees at the high-side of the main power transformer and is initiated by a non-fault switching event on the transmission system, the IBR may trip, but shall only trip to prevent equipment damage.~~

~~**M5.** Each Generator Owner and Transmission Owner shall have evidence of actual recorded data or other evidence for each applicable IBR demonstrating adherence to ride-through requirements, as specified in Requirement R5, during instantaneous positive sequence voltage phase angle changes that are changes of less than 25 electrical degrees at the high-side of the main power transformer and that such changes are not initiated by non-fault switching events.~~

~~R6.~~R4. Each Generator Owner and Transmission Owner identifying a facility that is in-service by the effective date of PRC-029-1, has known hardware~~with a documented equipment~~ limitations that ~~would~~ prevent the facility~~an applicable IBR that is in-service by the effective date of this standard~~ from meeting voltage ~~r~~Ride-through ~~requirements~~ criteria as detailed in Requirements R1 and R2, and requires an exemption from specific voltage Ride-through criteria shall~~communicate each equipment limitation to the associated Planning Coordinator(s), Transmission Planner(s), and Reliability Coordinator(s). *[Violation Risk Factor*~~*:*[9] *Lower] [Time Horizon: Long-term Planning]*

~~6.1.~~4.1. ~~Each Generator Owner and Transmission Owner shall include in its d~~Document information supporting the identified hardware limitation no later than 12 months following the effective date of PRC-029-1. This documentation shall include~~ation~~:

~~6.1.1~~4.1.1 Identifying information of the IBR (name, facility #, other);

~~6.1.2~~4.1.2 Which aspects of voltage ride-through requirements that the IBR would be unable to meet and the capability of the equipment due to the limitation;

~~6.1.3~~4.1.3 Identify the specific piece(s) of equipment causing the limitation;

4.1.4 Supporting technical documentation verifying the limitation is due to hardware that needs to be physically replaced or that the limitation cannot be removed by software updates or setting changes, and;

[9] The exemption requests for a non-US Registered Entity should be implemented in a manner that is consistent with, or under the direction of, the applicable governmental authority or its agency in the non-US jurisdiction

~~6.1.4~~4.1.5 Information regarding any plans to ~~repair or~~ remedy~~place~~ the ~~limiting~~ equipment ~~that would remove the~~ limitation (such as an estimated date ~~of repair/replacement~~).

4.2. Provide a copy of the information detailed in Requirement R4.1 to the applicable Planning Coordinator(s), Transmission Planner(s), Transmission Operator(s), Reliability Coordinator(s), and to the Regional Entity no later than 12 months following the effective date of PRC-029-1.

4.2.1 Any response to additional information requested by the applicable Planning Coordinator(s), Transmission Planner(s), Transmission Operator(s), Reliability Coordinator(s), and to the Regional Entity shall be provided back to the requestor within 90 days of the request.

4.3. Each Generator Owner and Transmission Owner with a previously ~~communicated~~ submitted request for exemption~~equipment limitation~~ that ~~repairs or~~ replace~~s~~ the equipment causing the limitation shall document and communicate such an equipment change to the associated Planning Coordinator(s), Transmission Planner(s), Transmission Operator(s), and Reliability Coordinator(s) within ~~3~~90 days of the equipment change.

~~6.2.~~4.3.1 When existing equipment is replaced, the exemption for that Ride-through criteria no longer applies.

M~~6~~4. Each Generator Owner and Transmission Owner seeking an exemption for facilities that are in-service by the effective date of PRC-029-1 ~~shall~~ have evidence of submission to the Regional Entity consistent with the information listed ~~equipment limitations, as specified~~ in Requirement R~~6~~4.1~~, documented prior to the effective date of PRC-029-1~~. Each Generator Owner and Transmission Owner have evidence of communicated copies of each submission in accordance with Requirement R4.2 and to the applicable entities described in Requirement R4.2. Acceptable type of evidence for submittals include but are not limited to, meeting minutes, agreements, copies of procedures or protocols in effect, or email correspondence. Acceptable types of evidence for an equipment limitation may include but is not limited to, documentation that contains study results, experience from an actual event, or manufacturer's advice. Each Generator Owner and Transmission Owner that replace ~~with changes to~~ equipment at a facility that is directly associated with an approved exemption and that equipment is the cause for the limitation, ~~shall~~ have evidence of communicating the equipment change to the applicable entities described in Requirement R4.3 within 30 calendar days of the equipment replacement~~communication to each associated Planning Coordinator, Transmission Planner, and Reliability Coordinator. Acceptable types of evidence may include, but are not limited to, meeting minutes, agreements, copies of procedures or protocols in effect between entities or between departments of a vertically integrated system, or email correspondence~~.

C. Compliance

1. **Compliance Monitoring Process**

   1.1. **Compliance Enforcement Authority:** “Compliance Enforcement Authority” means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

   1.2. **Evidence Retention:** The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

   The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

   - Each Generator Owner and Transmission Owner shall retain evidence with Requirements R1, R2, and R3 in this standard for 36 calendar months.
   - Each Generator Owner and Transmission Owner shall retain evidence with Requirement R4 ~~each requirement~~ in this standard for five calendar years.

   1.3. **Compliance Monitoring and Enforcement Program:** As defined in the NERC Rules of Procedure, “Compliance Monitoring and Enforcement Program” refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

[10] Type 3 and type 4 wind resources directly connected to the AC Transmission System

[11] Refer to bullet #5 below.

[12] These conditions are referred to as the “may Ride-through zone”.

[13] Refer to bullet #5 below.

[14] These conditions are referred to as the “may Ride-through zone”.

1. Table 1 applies to type 3 and type 4 wind facilities ~~applicable wind IBR~~ unless connected via a dedicated VSC-HVDC transmission facility.
2. Table 2 applies to all other inverter-based resource facility ~~IBR~~ types not covered in Table 1; including, but not limited to, the following ~~IBR~~facilities:
   a. ~~Isolated~~ Inverter-based resources~~IBR~~, regardless of their energy resource, interconnecting via a dedicated VSC-HVDC transmission facility.
   b. Other ~~IBR~~ inverter-based resource plants or hybrid plants consisting of photovoltaic (PV) and BESS.
3. The applicable voltage for Voltage Source Converter High Voltage Direct Current (VSC HVDC) system with a dedicated connection to an inverter-based resource is on the AC side of the transformer(s) that is (are) used to connect the VSC HVDC system to the interconnected transmission system

~~3.~~4. Table 1 applies to hybrid facilities consisting of wind (type 3 or type 4) ~~In the case of hybrid IBR consisting of wind~~ and various other IBR technologies~~, the applicable table shall be based on direction by the Transmission Planner~~. Otherwise, Table 2 applies to hybrid facilities with no wind (type 3 or type 4).

~~4.~~5. The voltage base for per unit calculation is the nominal phase-to-ground or phase-to-phase transmission system voltage unless otherwise defined by the Planning Coordinator or Transmission Planner.

~~5.~~6. The applicable voltage for Tables 1 and 2 is identified as the voltage max/min of phase to neutral or phase to phase fundamental root mean square (RMS) voltage at the high side of the ~~MPT~~main power transformer.

~~6.~~7. Tables 1 and 2 are only applicable when the frequency is within the "must Ride-through~~no trip~~ zone" as specified in Table 3 of Attachment ~~3~~2.

~~7.~~8. At any given voltage value, each ~~IBR~~ facility shall Ride-through ~~not trip until~~ unless the time duration at that voltage has exceed~~s~~ed the specified minimum R~~r~~ide-through time duration. If the voltage is continuously varying over time, it is necessary to add the duration within each band of Tables 1 and 2 over ~~the~~ any 10~~-~~second time period ~~to determine compliance~~.

~~8.~~9. The specified duration of the ~~M~~mandatory ~~O~~operation ~~R~~regions and the ~~P~~permissive ~~O~~operation ~~R~~regions in Tables 1 and 2 is cumulative over one or more disturbances within any 10 second time period.

~~9.~~10. The ~~IBR~~ facility may trip for more than four deviations of the applicable voltage at the high-side of the main power transformer outside of the ~~C~~continuous ~~O~~operation ~~R~~region within any 10 second time period.

11. Instantaneous trip settings based on instantaneously calculated voltage measurements with less than filtering lengths of one cycle (16.6 msec) are not permissible.

12. The “must Ride-through zone” is the combined area of the mandatory operating regions, the continuous operating regions, and the permissive operating region. All area outside of these operating regions is referred to as the “may Ride-through zone”.

~~10. If the positive sequence voltage at the high-side of the main power transformer enters the Permissive Operation Region, an IBR may operate in current block mode if necessary to protect the equipment.~~

Implementation Plan

Project 2020-02 Modifications to PRC-024 (Generator Ride-through) Reliability Standards PRC-024-4 and PRC-029-1

Applicable Standard(s)

- PRC-024-4 Frequency and Voltage Protection Settings for Synchronous Generators, Type 1 and Type 2 Wind Resources, and Synchronous Condensers
- PRC-029-1 Frequency and Voltage Ride Through Requirements for Inverter-Based Generating Resources

Requested Retirement(s)

- PRC-024-3 Frequency and Voltage Protection Settings for Generating Resources

Prerequisite Standard(s)

- PRC-028-1 Disturbance Monitoring and Reporting Requirements for Inverter-Based Resources

Proposed Definition(s)

- None

Applicable Entities

- See subject Reliability Standards.

Background

The purpose of Project 2020-02 is to modify Reliability Standard PRC-024-3 or replace it with a performance-based ride-through standard that ensures generators remain connected to the Bulk-Power System (BPS) during system disturbances. Specifically, the project focuses on using disturbance monitoring data to substantiate inverter-based resource (IBR) ride-through performance during grid disturbances. The project also ensures associated generators that fail to ride-through system events are addressed with a corrective action plan (if possible) and reported to necessary entities for situational awareness.

The purpose for this project is based on the culmination of multiple analyses conducted by the ERO Enterprise regarding widespread inverter-based resource tripping events. Furthermore, the NERC Inverter-Based Resource Performance Subcommittee[1] has developed comprehensive recommendations

[1] See documents at the NERC IRPS website: https://www.nerc.com/comm/RSTC/Pages/IRPS.aspx and the previous Inverter-Based Resource Performance Working Group website https://www.nerc.com/comm/RSTC/Pages/IRPWG.aspx

for improved performance of inverter-based resources, including the recommendation to develop comprehensive ride-through requirements.

In October 2023, FERC issued Order No. 901[2] which directs the development of new or modified Reliability Standards that include new requirements for disturbance monitoring, data sharing, post-event performance validation, and correction of IBR performance. In January 2024, NERC submitted a filing to FERC outlining a comprehensive work plan to address the directives within Order No. 901.[3] Within the work plan, NERC identified three active Standards Development projects that would need to be filed for regulatory approval with FERC by November 4, 2024. These projects include **2020-02 Modifications to PRC-024 (Generator Ride-through)**[4], **2021-04 Modifications to PRC-002-2**[5], and **2023-02 Analysis and Mitigation of BES Inverter-Based Resource Performance Issues**[6].

Project 2020-02

Proposed Reliability Standard PRC-029-1 is a new Reliability Standard that includes ride-through requirements and performance requirements for IBRs. The scope of this project was adjusted to align with associated regulatory directives from FERC Order No. 901 and the scope of the other projects related to "Milestone 2" of the NERC work plan. The components of this project's Standard Authorization Request (SAR) that related to the inclusions of new data recording requirements are covered in Project 2021-04 and the proposed new PRC-028-1 Reliability Standard. Components of this project's SAR that relate to analytics and corrective actions plans are covered in Project 2023-02 and the proposed new PRC-030-1 Reliability Standard.

PRC-029-1 includes requirements for Generator Owner and Transmission Owner IBR to continue to inject current and perform frequency support during a BPS disturbance. The standard also specifically requires Generator Owner and Transmission Owner IBR to prohibit momentary cessation in the no-trip zone during disturbances.

PRC-024-4 includes modifications to revise applicable facility types to remove IBR and to include synchronous condensers.

General Considerations

The ERO Enterprise acknowledges that there are IBRs currently in operation and unable to meet voltage ride-through requirements due to their inability to modify their coordinated protection and control settings. Consistent with FERC Order No. 901, a limited and documented exemption process for those IBR is appropriate and included within this Implementation Plan. Other NERC Standards Development projects will be pursued to address ongoing identification and mitigation of any potential reliability impacts to the BPS for such exemptions.

Effective Date and Phased-in Compliance Dates

The effective dates for the proposed Reliability Standards are provided below. Where the standard drafting team identified the need for a longer implementation period for compliance with a particular section of a proposed Reliability Standard (i.e., an entire Requirement or a portion thereof), the additional time for compliance with that section is specified below. The phased-in compliance dates for those particular sections represent the date that entities must begin to comply with that particular section of the Reliability Standard, even where the Reliability Standard goes into effect at an earlier date.

PRC-024-4

Where approval by an applicable governmental authority is required, Reliability Standard PRC-024-4 shall become effective on the first day of the first calendar quarter that is 6 months after the effective date of the applicable governmental authority's order approving the PRC-028-1 standard, or as otherwise provided for by the applicable governmental authority.

Where approval by an applicable governmental authority is not required, the Reliability Standard PRC-024-4 shall become effective on the first day of the first calendar quarter that is 6 months after the date the standard is adopted by the NERC Board of Trustees, or as otherwise provided for in that jurisdiction.

PRC-029-1

Where approval by an applicable governmental authority is required, Reliability Standard PRC-029-1 shall become effective on the first day of the first calendar quarter that is six months after the effective date of the applicable governmental authority's order approving the PRC-028-1 standard, or as otherwise provided for by the applicable governmental authority.

Where approval by an applicable governmental authority is not required, the Reliability Standard PRC-029-1 shall become effective on the first day of the first calendar quarter that is six months after the date the standard is adopted by the NERC Board of Trustees, or as otherwise provided for in that jurisdiction.

Retirement Date

PRC-024-3

Reliability Standard PRC-024-3 shall be retired immediately prior to the effective date of Reliability Standards PRC-024-04 and PRC-029-1 in the particular jurisdiction in which the revised standard is becoming effective.

Equipment Limitations and Process for Requirement R4

Consistent with FERC Order No. 901, a limited and documented exemption for some legacy IBR with certain documented equipment limitations are acceptable. Per the Order, these IBRs are

> "…typically older IBR technology with hardware that needs to be physically replaced and whose settings and configurations cannot be modified using software updates – may be unable to implement the voltage ride though performance requirements."[7]

To ensure compliance with Requirement R4 and alignment with FERC Order No. 901, only those IBR that are in operation as of the effective date of PRC-029-1 may be considered for potential exemption. Further, only those IBR that are unable to meet voltage ride-through requirements due to their inability to modify their coordinated protection and control settings may be considered for potential exemption.

Background Information

The goal of Project 2020-02 is to mitigate the recent and ongoing disturbance ride through performance issues identified across multiple Interconnections and numbers of disturbances analyzed by NERC and the Regions. These issues have been associated with Inverter-Based Resources (IBR) with many causes of their tripping or cessation unrelated to voltage and frequency protection settings requirements in the currently effective version of PRC-024, PRC-024-3. Proposed Reliability Standard PRC-024-4 includes revisions to limit its applicability to synchronous generators and synchronous condensers only and remains as a protection-based standard. A new standard, PRC-029-1, is proposed as a true disturbance ride-through Reliability Standard with applicability to inverter-based resources.

In October 2023, FERC issued Order No. 901, which directed NERC to develop new or modified existing Reliability Standards that include new requirements for disturbance monitoring, data sharing, post-event performance validation, and correction of IBR performance. Project 2020-02 was one of three projects identified by NERC that must be completed and filed with FERC by November 4, 2024 to address Order No. 901 directives. At the December 2023 SC meeting, the SC approved waivers for Project 2020-02, allowing formal comment periods to be reduced from 45 days to 25 calendar days, and final ballot periods to be reduced from 10 days to as few as 5 calendar days.

The initial draft of the PRC-024-4 and PRC-029-1 drafts were posted for comment March 27, 2024- April 22, 2024. Comments have been reviewed and incorporated. Substantive changes were made to the PRC-029-1 draft based on comments received. Formal comment responses are available in the consideration of comments received document posted along with these additional drafts.

<u>Questions</u>

1. Provide any additional comments for the Drafting Team to consider, if desired.

   Comments:

Technical Rationale

Project 2020-02 Modifications to PRC-024 (Generator Ride-through)

PRC-024-4 – Frequency and Voltage Protection Settings for Synchronous Generators and Synchronous Condensers

General Rationale

The drafting team proposes to modify PRC-024-3 to retain the Reliability Standard as a protection-based standard with applicability to only synchronous generators and synchronous condensers. This proposal is a consequence of both the different natures of synchronous and inverter-based generation resources and several recent events exhibiting significant IBR ride-through deficiencies. The behavior of rotating synchronous generators during faults and other disturbances on the transmission system is well established and understood in comparison to IBR generation. The disturbance ride-through vulnerabilities of synchronous generators are pole slipping instability and undervoltage dropout of critical plant auxiliary equipment, leading to tripping of a generator. Pole slipping can be managed by active power dispatch and system condition constraints, and is outside the scope of PRC-024-3. Undervoltage dropout of critical auxiliary equipment is also outside the scope of PRC-024-3 because of complexities associated with auxiliary systems and how such equipment behaves under low voltage conditions.

The Project 2020-02 Standard Authorization Request (SAR) notes that auxiliary equipment has not posed a ride-through risk and the SAR specifically excludes modifications in PRC-024-3 for auxiliary equipment. Over-frequency protection, under-frequency protection, and voltage protection may or may not be applied to synchronous generating units. If applied however, settings should be coordinated between the needs of generating unit protection, reasonable expected excursions of system frequency and voltage in a straightforward fashion, e.g., as no-trip zones within PRC-024-3 attachments, as well as the coordination of generating unit capabilities, voltage regulating controls, and protection within PRC-019-2. Excitation and governing controls affect synchronous generator ride-through behavior to some degree but because of progressive improvement, standardization, and level of maturity of these controls, they are rarely if ever cause unnecessary tripping during disturbances.

In addition, there are other existing NERC standards to prevent unnecessary tripping of the generators during a system disturbance such as PRC-025-2 “Generator Relay Loadability”, and PRC-026-2 “Relay Performance During Stable Power Swings”. For these reasons, there is no need to impose actual disturbance ride-through requirements on synchronous units and only include restrictions for frequency and voltage protection setting ranges as maintained in PCR-024-4.

Rationale for Applicability Section (4.0)

Functional Entities (4.1)

The functional entity responsible for setting frequency, voltage, and volts per hertz protection for synchronous generators and synchronous condensers is the Generator Owner (GO) and Transmission

Owner (TO). Planning Coordinators (PC) are also retained as applicable entities but are only in the Quebec Interconnection. Modifications are proposed in PRC-024-4 to expand functional entity applicability to includes those Transmission Owners that apply protection, as listed in new Facility applicability section 4.2.2.

Facilities (4.2)

Applicability Facilities subparts in Section 4.1.1 were modified to restrict PRC-024-4 to synchronous generators. Section 4.2.2 was added as new subparts to identify which synchronous condensers and equipment.

Rationale for Requirements R1 through R4

Modifications were made to Requirements R1, R2, R3, and R4 to include the Transmission Owner as an functional entity applicable to each requirement.

Modifications were made to Requirements R1, R2, R3, and R4 to include language for synchronous condensers and to remove language that relates to inverter-based resource functionality (i.e., “cease injecting current”).

Technical Rationale

Project 2020-02 Modifications to PRC-024 (Generator Ride-through)

PRC-029-1 – Frequency and Voltage Ride-Through Requirements for Inverter-Based Generating Resources

General Rationale

The drafting team has created a new Reliability Standard (PRC-029-1) to address inverter-based resource (IBR) disturbance ride-through performance criteria. This proposal is a consequence of both the different natures of synchronous and inverter-based generation resources and several recent events exhibiting significant IBR ride-through deficiencies. The proposed PRC-029-1 coincides with certain ride-through requirements of IEEE 2800-2022 but is structured to follow language from FERC Order No. 901, which states that "NERC has the discretion to consider during its standards development process whether and how to reference IEEE standards in the new or modified Reliability Standards."[1]

The lack of standardization of IBR technology (equipment/controller behavior) has created reliability challenges associated with the interconnection of IBR facilities to the power grid. The nature of the fast switching of power electronics of IBR generation and the electronic interface to the transmission system is such that disturbance ride-through behavior is largely determined by manufacturer-specific equipment and controls system designs. These controls may be programmed but also have more restrictive limits on current, both in magnitude and duration. IBR responses to grid disturbances are highly controlled and managed by using fast switching of power electronics devices dependent upon manufacturer specific control system design that can be programmed in many ways and with various and concurrent ride-through performance objectives. Rather than attempting to restrict the myriad of control approaches, protections, and settings, it is more straightforward to require ride-through during defined frequency and voltage excursions.

In contrast to synchronous generation, the need for IBR ride-through requirements has been heightened by recent events during which IBRs have not met PRC-024-3 frequency and voltage ride-through expectations, often due to controls and protection only indirectly associated with the system voltage and frequency excursions. In addition to ride-through, there is the question of what IBRs should be doing as they ride-through. IBR responses to system disturbances can be beneficial or detrimental to both their own ride-through and system reliability, often depending on adjustable control settings. Thus, it is essential to set expectations on performance during ride-through as well as ride-through capability.

IBR do not provide inertia or short circuit contributions, unlike synchronous machines. The drafting team thinks that IBR should compensate for their lack of inertia and short circuit contributions with wider

[1] P 195, FERC Order No. 901; https://elibrary.ferc.gov/eLibrary/filelist?accession_number=20231019-3157&optimized=false; October 17, 2023

tolerances for frequency and voltage excursions. This is the reason for the differences in the frequency and voltage tables and graphs between the two standards.

The proposed PRC-029 must be understood as an event-based standard though it is also required to provide evidence of the ability to ride-through disturbance events by means of dynamic models and simulation results. Compliance with PRC-029 is determined chiefly though not exclusively from IBR ride-through performance during transmission system events in the field. An IBR becomes noncompliant with PRC-029 when an event in the field occurs that shows that one or more requirements were not satisfied. This intent is clarified by *Operations Assessment* as the Time Horizon designation of requirements R1-R5.

FERC Order No. 901 Directives

PRC-029-1 is proposed in consideration of directives from FERC Order No. 901 that were assigned to the Project 2020-02 drafting team. The following directives were assigned to this drafting team for inclusion in this Standards Project (paragraph numbers of the FERC Order are included for reference):

- Paragraph 190: "Pursuant to section 215(d)(5) of the FPA, we adopt the NOPR proposal and direct NERC to develop new or modified Reliability Standards that require registered IBR generator owners and operators to use appropriate settings (i.e., inverter, plant controller, and protection) to ride through frequency and voltage system disturbances and that permit IBR tripping only to protect the IBR equipment in scenarios similar to when synchronous generation resources use tripping as protection from internal faults."
- Paragraph 190: "The new or modified Reliability Standards must require registered IBRs to continue to inject current and perform frequency support during a Bulk-Power System disturbance."
- Paragraph 190: "Any new or modified Reliability Standard must also require registered IBR generator owners and operators to prohibit momentary cessation in the must ride-through zone during disturbances."
- Paragraph 190: "NERC must submit new or modified Reliability Standards that establish IBR performance requirements, including requirements addressing frequency and voltage ride through, post-disturbance ramp rates, phase lock loop synchronization, and other known causes of IBR tripping or momentary cessation."
- Paragraph 193: "Therefore, we direct NERC through its standard development process to determine whether the new or modified Reliability Standards should provide for a limited and documented exemption for certain registered IBRs from voltage ride through performance requirements."
- Paragraph 193: "Further, we direct NERC to ensure that any such exemption would be applicable for only existing equipment that is unable to meet voltage ride-through performance. When such existing equipment is replaced, the exemption would no longer apply, and the new equipment must comply with the appropriate IBR performance requirements specified in the Reliability Standards (e.g., voltage and frequency ride through, phase lock loop, ramp rates, etc.)."

- Paragraph 193: "Finally, we direct NERC, through its standard development process, to require the limited and documented exemption list (i.e., IBR generator owner and operator exemptions) to be communicated with their respective Bulk-Power System planners and operators (e.g., the IBR generator owner's or operator's planning coordinator, transmission planner, reliability coordinator, transmission operator, and balancing authority)."
- Paragraph 199: "Pursuant to section 215(d)(5) of the FPA, we modify the NOPR proposal. To the extent NERC determines that a limited and documented exemption for those registered IBRs currently in operation and unable to meet voltage ride-through requirements is appropriate due to their inability to modify their coordinated protection and control settings, we direct NERC to develop new or modified Reliability Standards to mitigate the reliability impacts to the Bulk-Power System of such an exemption."
- Paragraph 208: "Pursuant to section 215(d)(5) of the FPA, we adopt the NOPR proposal and direct NERC to develop and submit to the Commission for approval new or modified Reliability Standards that require post-disturbance ramp rates for registered IBRs to be unrestricted and not programmed to artificially interfere with the resource returning to a pre-disturbance output level in a quick and stable manner after a Bulk-Power System."
- Paragraph 209: "The proposed new or modified Reliability Standards must require registered IBRs to ride through momentary loss of synchronism during Bulk-Power System disturbances and require registered IBRs to continue to inject current into the Bulk-Power System at pre-disturbance levels during a disturbance, consistent with the IBR Interconnection Requirements Guideline and Canyon 2 Fire Event Report recommendations."
- Paragraph 209: "Related to ACP/SEIA's comment recommending to revise the directive to require generators to maintain synchronism where possible and continue to inject current to support system stability, we direct NERC, through its standard development process, to consider whether there are conditions that may limit generators to maintain synchronism."
- Paragraph 226: "Further, we believe that there is a need to have all of the directed Reliability Standards effective and enforceable well in advance of 2030 and direct NERC to ensure that the associated implementation plans sequentially stagger the effective and enforceable dates to ensure an orderly industry transition for complying with the IBR directives in this final rule prior to that date." (*pertains multiple projects*)

Rationale for Applicability Section (4.0)

Functional Entities (4.1)

The functional entity responsible for assuring acceptable ride-through performance of IBR is either the Generator Owner (GO) or, in the case of High-voltage Direct Current (VSC-HVDC) transmission facilities that are dedicated connections for IBR inverter-based resources to the BPS, the Transmission Owner (TO).

Facilities (4.2)

Applicability Facilities includes only those IBR that also meet NERC registration criteria. Language used within PRC-029-1 applicability only refers to IBR as a whole plant/facility. Consistent with FERC Order No. 901, IBR performance is based on the overall IBR plant and disturbance monitoring equipment requirements established under the proposed PRC-028-1. Requirements within PRC-029-1 do not apply to individual inverter units or measurements taken at individual inverter unit terminals.

Rationale for Requirement R1

The objective of Requirement R1 is to ensure that all applicable IBRs will ride through grid voltage disturbances consistent with the must ride-through zone and operation regions specified in **Attachment 1**. IBRs must be able to demonstrate ride-through performance, that they remain electrically connected, i.e., shall not trip, and continue to exchange current, i.e., shall not enter momentary cessation.

The drafting team determined that the definition of “must ride-through zones” and “operation regions” should be consistent with those terms as used within IEEE 2800-2022. Additionally, the team determined that the voltage thresholds of each operation region should be based on measurements taken on the high-side of the main power transformer in PRC-029-1, also consistent with IEEE 2800-2022.

Exceptions to **Attachment 1** performance criteria are allowable when 1) an IBR needs to trip to clear a fault within its zone of protection, and 2) a documented equipment limitation prevents an IBR from riding through the disturbance as permitted under Requirement R4.

When a grid disturbance occurs, such as a close-in fault or a relatively large switching event, the grid voltage may experience a rapid phase angle shift. In such cases, the phase displacement $\Delta\theta$ can be large enough to pose challenges for the PLL to track the terminal voltage, cause control instability within the inverter, such as the inner current control loop or the DC link control loop, and even lead to tripping of the inverter due to the malfunction of the controls.

Since phase angle jumps are common occurrences on the BPS, this standard requires the IBR to be designed and operated to ride-through a minimum phase angle jump of 25 electrical degrees. This is a typical value and aligns with the requirement in IEEE 2800 2022.

Some IBR equipment has PLL loss of synchronism protection, referring to a protective function that operates when the angle displacement $\Delta\theta$ exceeds a threshold for a predetermined period of time (on the order of a couple of milliseconds). Historically, this protection has been used by some inverter manufacturers, especially for inverters in distribution systems. For the IBR connected to the BPS, this protection function should be disabled. If it is enabled, the phase angle jump protection setting should be configured such that the IBR shall only trip to prevent equipment damage.

Rationale for Requirement R2

In addition to having minimum voltage ride-through capability specified in Requirement R1, all applicable IBRs are also required to adhere to certain voltage ride-through performance criteria during system disturbances. Acceptable performance criteria depend on the operation region that an IBR is presently in or when in transition from one operation region to another operation region. Requirement R2 includes specific performance criteria and is needed to assure consistent IBR performance within and each operation region in **Attachment 1** and when in transition between regions.

Rationale for Requirement R2.1

This subpart of Requirement 2 ensures, when the voltage at the high-side of the main power transformer (MPT) recovers to the Continuous Operation Region from either the Mandatory Operation Region or the Permissive Operation Region, an IBR is expected to deliver the pre-disturbance level of active power or available active power, whichever is less. This requires an IBR to exit the "High Voltage Ride Through (HVRT)" or "Low Voltage Ridge Through (LVRT)" modes properly such that it does not cause reduction in the active power when the system already recovers the voltage within the Continuous Operation Region.

When the voltage at the high-side of the MPT is greater than 0.9 per-unit and less than 0.95 per-unit, IBRs are expected to exit the LVRT mode and come back to "normal operating mode". If an IBR has a default total current limit of 1.0 per-unit, the apparent power production of an IBR will be limited to be below 1.0 per-unit (e.g., the per-unit value of IBR terminal voltage). In such case, IBR needs to configure a preference setting, either to maintain pre-disturbance active power or maximize the reactive power in order to further help with voltage recovery, according to requirements specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

Rationale for Requirement R2.2

This subpart of Requirement 2 ensures when the voltage at the high-side of the MPT is within the Mandatory Operation Region, IBRs are expected to enter the HVRT and LVRT mode such that it will inject or absorb reactive current proportional to the level of terminal voltage deviations it measures. IBR shall follow Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator specified certain magnitude of reactive power response to voltage changes, if available.

By default, reactive current prioritization shall be configured unless Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator requires active power priority.

Rationale for Requirement R2.3

This subpart of Requirement 2 ensures when the voltage at the high-side of the MPT is within the permissive operation region, IBRs are allowed to enter the current block mode to avoid tripping off from the grid. The drafting team takes into consideration the physical operational capability of the power electronics devices under such low voltage condition. However, the IBR facility shall restart current exchange in less than or equal to five cycles of positive sequence voltage retraining to a continuous operation region or mandatory operation region.

Rationale for Requirement R2.4

This subpart of Requirement 2 ensures when a fault is cleared on the transmission system, the voltage regulators of connected IBRs must adjust the reactive current injection to restore the transmission system voltage to the pre-disturbance voltage as defined by the automatic voltage regulator (AVR) setpoint. The drafting team acknowledges that tuning of the AVR requires a balance between multiple competing physical factors, e.g., rise time, overshoot, and transient stability. However, it is anticipated that IBR controls will be tuned to allow for a stable post-disturbance voltage recovery without causing excessive overshoot or undershoot of the setpoint. When such overshoots do occur, they must not exceed the magnitude and duration of the applicable table given in **Attachment 1**. Furthermore, this standard anticipates that control system tuning to prevent such over/under voltages will focus on the speed at which the controller responds to setpoint changes rather than on the magnitude of the reactive current response. For example, reductions in k-factor to prevent over/under voltages should only be considered as a last resort.

Rationale for Requirement R2.5

This subpart of Requirement 2 ensures that IBR returns to effective pre-disturbance operation unless otherwise specified or needed by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

Must Ride-through

Rationale for Requirement R3

The objective of Requirement R3 is to ensure that IBRs remain electrically connected, synchronized, and exchanging current, that is, continuing to operate during a frequency excursion event.

Grid frequency reflects the balance of system generation and load. A system event that causes a generation/load imbalance will cause system frequency to deviate from nominal. The system may experience an over-frequency event (in the case of more generation than load) or an under-frequency event (in the case of less generation than load). Inertia resists the deviation from nominal frequency, giving the operators additional time to rebalance generation and load. System inertia depends on the amount of rotating mass connected to the system (such as the synchronous generators or motors). The larger the system inertia, the slower the system frequency will deviate from the nominal value and the lower the grid Rate Of Change Of Frequency (ROCOF), giving more time to try to rebalance generation and load. Also, higher system inertia may minimize the risk of Cascading generation loss caused by the operation of generator frequency protection.

A reduction in system inertia is an inevitable consequence of a power system transiting toward more IBR and less synchronous generators. As discussed in the previous paragraph, less system inertia means the frequency will deviate from the nominal value more quickly during a generation/load imbalance event and will expose the system to a higher ROCOF. A wider frequency ride-through capability for IBR may be required to avoid the risk of widespread tripping. To reduce the risk of widespread IBR tripping during frequency disturbances, and more generally to ensure the reliability of future grids with high IBR penetration, the drafting team proposes a 6-second frequency ride-through capability requirement for frequencies in the ranges of 61.8Hz to 64Hz or 57.0Hz to 56.0Hz range. The proposed 6-second time frame of the frequency ride-through capability requirement is beyond the IEEE 2800 standard frequency ride-through requirement and beyond frequency ride-through requirements for synchronous machines under PRC-024.

IBRs lack the inertia and short circuit contributions of synchronous machines. To compensate for the lack of inertia and short circuit contributions, they should have wider tolerances for frequency and voltage excursions to meet the needs of future power systems with a higher percentage of IBR. Synchronous resources are more sensitive to frequency deviations than IBR resources. All IBR resources (except for type 3 wind turbines) interface to the grid through fast switching of power electronics devices. These power electronic devices are much less sensitive to the transmission system frequency excursion than non-hydraulic turbine synchronous resources (steam turbines and combustion turbines). In the case of the non-hydraulic turbine synchronous resources, the turbine is usually considered to be more restrictive than the generator in limiting IBR frequency ride-through because of possible mechanical resonances in the many stages of turbine blades. Off-nominal frequencies may bring blade vibrational frequencies closer to a mechanical resonate frequency and cause damage due to the vibration stresses. However, inverter-interfaced-IBR does not share this vibrational failure mode. Therefore, IBR should be capable of riding through the increased proposed 6-second frequency ride-through requirement without risk of equipment damage or need for frequency protection to operate.

Requirement R3 does not prescribe specific frequency protection settings for IBR equipment. IBR frequency protection settings should only be set to protect the IBR from damage caused by operation at off-nominal frequency. An IBR owner must ensure that the IBR frequency protection does not prevent an IBR from meeting the R3 ride-through requirement.

This standard requires that IBRs remain electrically connected and continue to exchange current during a frequency excursion event in which the frequency remains within the must ride-through zone according to **Attachment 3** and while the absolute ROCOF magnitude is less than or equal to 5 Hz/second. Some IBR controllers and their ability to remain electrically connected and continue to exchange current with the grid are sensitive to ROCOF during a frequency excursion event. If needed to maintain the stability of the IBR or prevent equipment damage, the R3 requirement allows the IBR to trip for an absolute ROCOF exceeding 5Hz/sec within the must ride-through zone as shown in **Attachment 2**. Failure to ride-through due to ROCOF exceeding 5Hz/sec shall only be allowed during a generator/load imbalance event that causes the frequency to deviate from nominal.

The ROCOF protection should not operate at the onset of a fault, during a fault, or at fault clearance, i.e., it should be disabled for faults. The IBR shall ride-through any system disturbance while the voltage at the high side of the main power transformer remains within the must ride-through zones as specified in **Attachment 1**. Furthermore, to reduce the risk of IBR tripping on ROCOF protection, ROCOF shall be calculated as the average rate of change for multiple calculated system frequencies for some time greater than or equal to 0.1 seconds.

Rationale for Requirement R4

The objective of Requirement R4 is to ensure legacy IBR are able to obtain an exemption to the voltage ride-through requirements if hardware replacements or other costly upgrades would be necessary to comply with Requirements R1 or Requirement R2. This provision allows such exemptions as long as such limitations are documented and communicated to the Planning Coordinator, Transmission Planner, and Reliability Coordinator of the respective footprints in which the IBR project is located. The Planning Coordinator, Transmission Planner, and Reliability Coordinator will then need to take the voltage ride-through limitations into account in planning and operations.

Limitations must not be construed as complete exemptions from the applicable **Attachment 1** table but must be specific as to which voltage band(s) and associated duration(s) cannot be satisfied or specific as to the number of cumulative voltage deviations within a ten-second time period that the equipment can ride-through if less than four. Limitation descriptions should identify the specific equipment and explain the characteristic(s) of that equipment that prevent ride-through. If any equipment limitation is removed or otherwise corrected, it is likewise necessary to communicate to the Planning Coordinator, Transmission Planner, and Reliability Coordinator of this.

FERC Order No. 901 states that this provision would be limited to exempting “certain registered IBRs from voltage ride-through performance requirements.” This is the reason that no similar provisions are included for exemptions for frequency or rate-of-change-of-frequency (ROCOF) ride-through requirements per R3.

Technical Rationale

Project 2020-02 Modifications to PRC-024 (Generator Ride-through)

PRC-029-1 – Frequency and Voltage Ride-Through Requirements for Inverter-Based Generating Resources

General Rationale

The drafting team has created a new Reliability Standard (PRC-029-1) to address inverter-based resource (IBR) disturbance ride-through performance criteria. This proposal is a consequence of both the different natures of synchronous and inverter-based generation resources and several recent events exhibiting significant IBR ride-through deficiencies. The proposed PRC-029-1 coincides with certain ride-through requirements of IEEE 2800-2022 but is structured to follow language from FERC Order No. 901, which states that "NERC has the discretion to consider during its standards development process whether and how to reference IEEE standards in the new or modified Reliability Standards."[1]

The lack of standardization of IBR technology (equipment/controller behavior) has created reliability challenges associated with the interconnection of IBR facilities to the power grid. The nature of the fast switching of power electronics of IBR generation and the electronic interface to the transmission system is such that disturbance ride-through behavior is largely determined by manufacturer-specific equipment and controls system designs. These controls may be programmed but also have more restrictive limits on current, both in magnitude and duration. IBR responses to grid disturbances are highly controlled and managed by using fast switching of power electronics devices dependent upon manufacturer specific control system design that can be programmed in many ways and with various and concurrent ride-through performance objectives. Rather than attempting to restrict the myriad of control approaches, protections, and settings, it is more straightforward to require ride-through during defined frequency and voltage excursions.

In contrast to synchronous generation, the need for IBR ride-through requirements has been heightened by recent events during which IBRs have not met PRC-024-3 frequency and voltage ride-through expectations, often due to controls and protection only indirectly associated with the system voltage and frequency excursions. In addition to ride-through, there is the question of what IBRs should be doing as they ride-through. IBR responses to system disturbances can be beneficial or detrimental to both their own ride-through and system reliability, often depending on adjustable control settings. Thus, it is essential to set expectations on performance during ride-through as well as ride-through capability.

IBR do not provide inertia or short circuit contributions, unlike synchronous machines. The drafting team thinks that IBR should compensate for their lack of inertia and short circuit contributions with wider

[1] P 195, FERC Order No. 901; https://elibrary.ferc.gov/eLibrary/filelist?accession_number=20231019-3157&optimized=false; October 17, 2023

tolerances for frequency and voltage excursions. This is the reason for the differences in the frequency and voltage tables and graphs between the two standards.

The proposed PRC-029 must be understood as an event-based standard~~.~~ though it is also required to provide evidence of the ability to ride-through disturbance events by means of dynamic models and simulation results. Compliance with PRC-029 is determined chiefly though not exclusively from IBR ride-through performance during transmission system events in the field~~ and not from interconnection studies, transmission planning studies, operational planning studies, or from IBR models.~~. An IBR becomes noncompliant with PRC-029~~ only~~ when an event in the field occurs that shows that one or more requirements were not satisfied. This intent is clarified by *Operations Assessment* as the Time Horizon designation of requirements R1-R5.

FERC Order No. 901 Directives

PRC-029-1 is proposed in consideration of directives from FERC Order No. 901 that were assigned to the Project 2020-02 drafting team. The following directives were assigned to this drafting team for inclusion in this Standards Project (paragraph numbers of the FERC Order are included for reference):

- Paragraph 190: "Pursuant to section 215(d)(5) of the FPA, we adopt the NOPR proposal and direct NERC to develop new or modified Reliability Standards that require registered IBR generator owners and operators to use appropriate settings (i.e., inverter, plant controller, and protection) to ride through frequency and voltage system disturbances and that permit IBR tripping only to protect the IBR equipment in scenarios similar to when synchronous generation resources use tripping as protection from internal faults."
- Paragraph 190: "The new or modified Reliability Standards must require registered IBRs to continue to inject current and perform frequency support during a Bulk-Power System disturbance."
- Paragraph 190: "Any new or modified Reliability Standard must also require registered IBR generator owners and operators to prohibit momentary cessation in the ~~no-trip~~must ride-through zone during disturbances."
- Paragraph 190: "NERC must submit new or modified Reliability Standards that establish IBR performance requirements, including requirements addressing frequency and voltage ride through, post-disturbance ramp rates, phase lock loop synchronization, and other known causes of IBR tripping or momentary cessation."
- Paragraph 193: "Therefore, we direct NERC through its standard development process to determine whether the new or modified Reliability Standards should provide for a limited and documented exemption for certain registered IBRs from voltage ride through performance requirements."
- Paragraph 193: "Further, we direct NERC to ensure that any such exemption would be applicable for only existing equipment that is unable to meet voltage ride-through performance. When such existing equipment is replaced, the exemption would no longer apply, and the new equipment

must comply with the appropriate IBR performance requirements specified in the Reliability Standards (e.g., voltage and frequency ride through, phase lock loop, ramp rates, etc.)."

- Paragraph 193: "Finally, we direct NERC, through its standard development process, to require the limited and documented exemption list (i.e., IBR generator owner and operator exemptions) to be communicated with their respective Bulk-Power System planners and operators (e.g., the IBR generator owner's or operator's planning coordinator, transmission planner, reliability coordinator, transmission operator, and balancing authority)."
- Paragraph 199: "Pursuant to section 215(d)(5) of the FPA, we modify the NOPR proposal. To the extent NERC determines that a limited and documented exemption for those registered IBRs currently in operation and unable to meet voltage ride-through requirements is appropriate due to their inability to modify their coordinated protection and control settings, we direct NERC to develop new or modified Reliability Standards to mitigate the reliability impacts to the Bulk-Power System of such an exemption."
- Paragraph 208: "Pursuant to section 215(d)(5) of the FPA, we adopt the NOPR proposal and direct NERC to develop and submit to the Commission for approval new or modified Reliability Standards that require post-disturbance ramp rates for registered IBRs to be unrestricted and not programmed to artificially interfere with the resource returning to a pre-disturbance output level in a quick and stable manner after a Bulk-Power System."
- Paragraph 209: "The proposed new or modified Reliability Standards must require registered IBRs to ride through momentary loss of synchronism during Bulk-Power System disturbances and require registered IBRs to continue to inject current into the Bulk-Power System at pre-disturbance levels during a disturbance, consistent with the IBR Interconnection Requirements Guideline and Canyon 2 Fire Event Report recommendations."
- Paragraph 209: "Related to ACP/SEIA's comment recommending to revise the directive to require generators to maintain synchronism where possible and continue to inject current to support system stability, we direct NERC, through its standard development process, to consider whether there are conditions that may limit generators to maintain synchronism."
- Paragraph 226: "Further, we believe that there is a need to have all of the directed Reliability Standards effective and enforceable well in advance of 2030 and direct NERC to ensure that the associated implementation plans sequentially stagger the effective and enforceable dates to ensure an orderly industry transition for complying with the IBR directives in this final rule prior to that date." (*pertains multiple projects*)

Rationale for Applicability Section (4.0)

Functional Entities (4.1)

The functional entity responsible for assuring acceptable ride-through performance of IBR is either the Generator Owner (GO) ~~and~~or, in the case of High-voltage Direct Current (VSC-HVDC) transmission facilities that are dedicated connections for IBR inverter-based resources to the BPS, the Transmission Owner (TO).

Facilities (4.2)

Applicability Facilities includes only those IBR that also meet NERC registration criteria. Language used within PRC-029-1 applicability only refers to IBR as a whole plant/facility. Consistent with FERC Order No. 901, IBR performance is based on the overall IBR plant and disturbance monitoring equipment requirements established under the proposed PRC-028-1. Requirements within PRC-029-1 do not apply to individual inverter units or measurements taken at individual inverter unit terminals.

Rationale for Requirement R1

The objective of Requirement R1 is to ensure ~~an~~that all applicable ~~IBR~~IBRs will ride~~-~~ through ~~a~~ grid voltage ~~disturbance~~disturbances consistent with the ~~no-trip~~must ride-through zone and ~~Operation Regions~~operation regions specified in Attachment 1. ~~IBR~~IBRs must be able to demonstrate ride-through performance, that they remain electrically connected, i.e., shall not trip, and continue to exchange current, i.e., shall not enter momentary cessation.

The drafting team determined that the definition of "~~no-trip~~must ride-through zones" and "~~Operation Regions~~operation regions" should be consistent with those terms as used within IEEE 2800-2022. Additionally, the team determined that the voltage thresholds of each ~~Operation Region are~~operation region should be based on measurements taken on the high-side of the main power transformer in PRC-029-1, also consistent with IEEE 2800-2022.

Exceptions to Attachment 1 performance criteria are allowable when 1) an IBR needs to trip to clear a fault within its zone of protection, and 2) a documented equipment limitation prevents an IBR from riding through the disturbance ~~in accordance with~~as permitted under Requirement ~~R6~~R4.

When a grid disturbance occurs, such as a close-in fault or a relatively large switching event, the grid voltage may experience a rapid phase angle shift. In such cases, the phase displacement $\Delta\theta$ can be large enough to pose challenges for the PLL to track the terminal voltage, cause control instability within the inverter, such as the inner current control loop or the DC link control loop, and even lead to tripping of the inverter due to the malfunction of the controls.

Since phase angle jumps are common occurrences on the BPS, this standard requires the IBR to be designed and operated to ride-through a minimum phase angle jump of 25 electrical degrees. This is a typical value and aligns with the requirement in IEEE 2800 2022.

Some IBR equipment has PLL loss of synchronism protection, referring to a protective function that operates when the angle displacement $\Delta\theta$ exceeds a threshold for a predetermined period of time (on the order of a couple of milliseconds). Historically, this protection has been used by some inverter manufacturers, especially for inverters in distribution systems. For the IBR connected to the BPS, this protection function should be disabled. If it is enabled, the phase angle jump protection setting should be configured such that the IBR shall only trip to prevent equipment damage.

Rationale for Requirement R2

In addition to having minimum voltage ride-through capability specified in Requirement R1, ~~an~~all applicable ~~IBR is~~IBRs are also required to adhere to certain voltage ride-through performance criteria during ~~a~~ system ~~disturbance~~disturbances. Acceptable performance criteria ~~is dependent~~depend on the ~~Operation Region~~operation region that an IBR is presently in~~,~~ or ~~it's change~~when in transition from one ~~Operation Region~~operation region to another ~~Operation Region~~operation region. Requirement R2 includes specific performance criteria and is needed to assure consistent IBR performance ~~during~~within and each ~~Operation Region~~operation region in Attachment 1 and when in transition between regions.

Rationale for Requirement R2.1

This subpart of Requirement 2 ensures, when the voltage at the high-side of the main power transformer (MPT) recovers to the Continuous Operation Region from either the Mandatory Operation Region or the Permissive Operation Region, an IBR is expected to deliver the pre-disturbance level of active power or available active power, whichever is less. This requires an IBR to exit the "High Voltage Ride Through (HVRT)" or "Low Voltage Ridge Through (LVRT)" modes properly such that it does not cause reduction in the active power when the system already recovers the voltage within the Continuous Operation Region.

When the voltage at the high-side of the MPT is greater than 0.9 per-unit and less than 0.95 per-unit, IBRs are expected to exit the LVRT mode and come back to "normal operating mode". If an IBR has a default total current limit of 1.0 per-unit, the apparent power production of an IBR will be limited to be below 1.0 per-unit (e.g., the per-unit value of IBR terminal voltage). In such case, IBR needs to configure a preference setting, either to maintain pre-disturbance active power or maximize the reactive power in order to further help with voltage recovery, according to requirements specified by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

Rationale for Requirement R2.2

This subpart of Requirement 2 ensures when the voltage at the high-side of the MPT is within the Mandatory Operation Region, IBRs are expected to enter the HVRT and LVRT mode such that it will inject or absorb reactive current proportional to the level of terminal voltage deviations it measures. IBR shall follow Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator specified certain magnitude of reactive power response to voltage changes, if available.

By default, reactive current prioritization shall be configured unless Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator requires active power priority.

Rationale for Requirement R2.3

This subpart of Requirement 2 ensures when the voltage at the high-side of the MPT is within the permissive operation region, IBRs are allowed to enter the current block mode to avoid tripping off from the grid. The drafting team takes into consideration the physical operational capability of the power electronics devices under such low voltage condition. However, the IBR facility shall restart current exchange in less than or equal to five cycles of positive sequence voltage retraining to a continuous operation region or mandatory operation region.

Rationale for Requirement R2.4

This subpart of Requirement 2 ensures when a fault is cleared on the transmission system, the voltage regulators of connected IBRs must adjust the reactive current injection to restore the transmission system voltage to the pre-disturbance voltage as defined by the automatic voltage regulator (AVR) setpoint. The drafting team acknowledges that tuning of the AVR requires a balance between multiple competing physical factors, e.g., rise time, overshoot, and transient stability. However, it is anticipated that IBR controls will be tuned to allow for a stable post-disturbance voltage recovery without causing excessive overshoot or undershoot of the setpoint. When such overshoots do occur, they must not exceed the magnitude and duration of the applicable table given in Attachment 1. Furthermore, this standard anticipates that control system tuning to prevent such over/under voltages will focus on the speed at which the controller responds to setpoint changes rather than on the magnitude of the reactive current response. For example, reductions in k-factor to prevent over/under voltages should only be considered as a last resort.

Rationale for Requirement R2.~~4~~5

This subpart of Requirement 2 ensures that IBR returns to effective pre-disturbance operation unless otherwise specified or needed by the Transmission Planner, Planning Coordinator, Reliability Coordinator, or Transmission Operator.

~~*Rationale for Requirement R2.5*~~

~~This subpart of Requirement 2 ensures that voltage protection settings of IBR are based on maximum equipment capabilities rather than settings based directly on, or just outside, of the no-trip zone.~~

Must Ride-through

Rationale for Requirement R3

The objective of Requirement R3 is to ~~provide transient overvoltage ride-through for IBR during the non-fault switching event. Voltage transients are commonly occurring on the BPS due to switching actions, fault clearing, lightning, etc. IBR shall ride-through the transient overvoltage condition specified in **Attachment 2** during the non-fault switching events in the transmission systems. During this transient overvoltage event, IBRs should continue to inject current, but it does not have to respond to transient overvoltage, i.e., enter reactive priority mode and/or change magnitude of current output.~~

~~If necessary, IBRs may operate in current blocking mode, when instantaneous voltage exceeds 1.2 p.u., to help~~ ensure ~~stable response~~ that ~~does not lead to tripping and to eliminate the IBR as a possible cause for the overvoltage. If IBRs operate in the current blocking mode, it shall restart current exchange in less than or equal to five cycles following instantaneous voltage falling below, and remaining below, 1.2 p.u. This is different than momentary cessation, which involves a resource returning over a longer time frame with a specified delay and ramp rate.~~

~~The drafting team notes that IBR should not be set to trip on an instantaneous, unfiltered voltage measurements, except due to known equipment limitations.~~

~~Rationale for Requirement R4~~

~~The objective of Requirement R4 is to ensure that IBR remains~~IBRs remain electrically connected, synchronized, and exchanging current~~-~~, that is, continuing to operate during a frequency excursion event.

Grid frequency reflects the balance of system generation and load. A system event that causes a generation/load imbalance will cause system frequency to deviate from nominal. The system may experience an over-frequency event (in the case of more generation than load) or an under-frequency event (in the case of less generation than load). Inertia resists the deviation from nominal frequency, giving the operators additional time to rebalance generation and load. System inertia depends on the amount of rotating mass connected to the system (such as the synchronous generators or motors). The larger the system inertia, the slower the system frequency will deviate from the nominal value and the lower the grid Rate Of Change Of Frequency (ROCOF), giving more time to try to rebalance generation and load. Also, higher system inertia may minimize the risk of Cascading generation loss caused by the operation of generator frequency protection.

A reduction in system inertia is an inevitable consequence of a power system transiting toward more IBR and less synchronous generators. As discussed in the previous paragraph, less system inertia means the frequency will deviate from the nominal value more quickly during a generation/load imbalance event and will expose the system to a higher ROCOF. A wider frequency ride-through capability for IBR may be required to avoid the risk of widespread tripping. To reduce the risk of widespread IBR tripping during frequency disturbances, and more generally to ensure the reliability of future grids with high IBR penetration, the drafting team proposes a 6-second frequency ride-through capability requirement for frequencies in the ranges of 61.8Hz to 64Hz or 57.0Hz to 56.0Hz range. The proposed 6-second time frame of the frequency ride-through capability requirement is beyond the IEEE 2800 standard frequency ride-through requirement and beyond frequency ride-through requirements for synchronous machines under ~~proposed~~ PRC-024~~-4~~.

~~IBR lacks~~IBRs lack the inertia and short circuit contributions of synchronous machines. To compensate for the lack of inertia and short circuit contributions, they should have wider tolerances for frequency and voltage excursions to meet the needs of future power ~~system~~systems with a higher percentage of IBR. Synchronous resources are more sensitive to frequency deviations than IBR resources. All IBR resources (except for type 3 wind turbines) interface to the grid through fast switching of power electronics devices. These power electronic devices are much less sensitive to the transmission system frequency excursion than non-hydraulic turbine synchronous resources (steam turbines and combustion turbines). In the case of the non-hydraulic turbine synchronous resources, the turbine is usually considered to be more restrictive than the generator in limiting IBR frequency ride-through because of possible mechanical resonances in the many stages of turbine blades. Off-nominal frequencies may bring blade vibrational frequencies closer to a mechanical resonate frequency and cause damage due to the vibration stresses. However, inverter-interfaced-IBR does not share this vibrational failure mode. Therefore, IBR should be capable of riding through the increased proposed 6-second frequency ride-through requirement without risk of equipment damage or need for frequency protection to operate.

Requirement ~~R4~~R3 does not prescribe specific frequency protection settings for IBR equipment. IBR frequency protection settings should only be set to protect the IBR from damage caused by operation at off-nominal frequency. An IBR owner must ensure that the IBR frequency protection does not prevent an IBR from meeting the ~~R4~~R3 ride-through requirement.

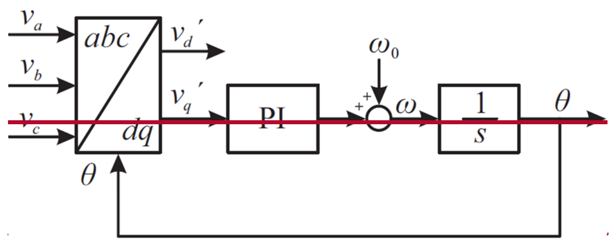
This standard requires that ~~IBR remains~~IBRs remain electrically connected and ~~continues~~continue to exchange current during a frequency excursion event in which the frequency remains within the ~~no-trip~~must ride-through zone~~\~~ according to Attachment 3 and while the absolute ROCOF magnitude is less than or equal to 5 Hz/second. Some IBR controllers and their ability to remain electrically connected and continue to exchange current ~~to~~with the grid are sensitive to ROCOF during a frequency excursion event. If needed to maintain the stability of the IBR or prevent equipment damage, the ~~R4~~R3 requirement allows the IBR to trip for an absolute ROCOF exceeding 5Hz/sec within the ~~no-trip~~must ride-through zone as shown in Attachment ~~3~~2. Failure to ride-through due to ROCOF exceeding 5Hz/sec shall only be allowed during a generator/load imbalance event that causes the frequency to deviate from nominal.

The ROCOF protection should not operate at the onset of a fault, during a fault, or at fault clearance, i.e., it should be disabled for faults. The IBR shall ride-through any system disturbance while the voltage at the high side of the main power transformer remains within the ~~no-trip~~must ride-through zones as specified in Attachment 1. Furthermore, to reduce the risk of IBR tripping on ROCOF protection, ROCOF shall be calculated as the average rate of change for multiple calculated system frequencies for some time greater than or equal to 0.1 seconds.

Rationale for Requirement ~~R5~~R4

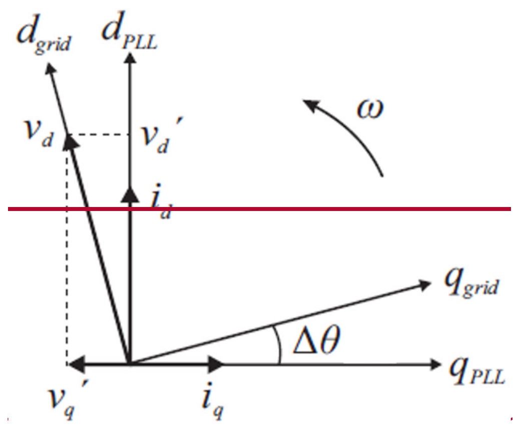
The objective of Requirement ~~R5 is to ensure IBR remains electrically connected and exchanging current during instantaneous positive sequence voltage phase angle changes initiated by certain non-fault switching events.~~

~~Unlike synchronous generators, for which the synchronization mechanism to the grid is naturally preserved by the inertia, the grid following voltage source inverters (VSI) used for the majority of existing IBR facilities are equipped with the Phase-lock loop (PLL) device for synchronization purposes. A typical synchronous reference frame PLL schematic is given in Fig. 1, where the three-phase voltages in the abc reference frame (v_a, v_b, and v_c) are transformed to the dq frame (v_d' and v_q') by the Park's transformation and the phase angle θ is controlled by a feedback loop that regulates the q component to zero.~~



~~**Figure 1: Schematic Diagram of a Synchronous Reference Frame PLL**~~

~~When the inverter operates in the steady state, it is locked to the grid voltage via the PLL, assuming the PI controller is well tuned. In this case the phase displacement between the grid voltage and that measured by the PLL, Δθ is zero, as shown in Fig. 2.~~



~~**Figure 2: Phasor Diagram of Grid Voltage and Current**~~

~~When a grid disturbance occurs, such as a close-in fault or a relatively large switching event, the grid voltage may experience a rapid phase angle shift. In such cases, the phase displacement Δθ can be large enough to pose challenges for the PLL to track the terminal voltage, cause control instability within the inverter, such as the inner current control loop or the DC link control loop, and even lead to tripping of the inverter due to the malfunction of the controls.~~

~~Since phase angle jumps are common occurrences on the BPS, this standard requires the IBR to be designed and operated to ride-through a minimum phase angle jump of 25 electrical degrees. This is a typical value and aligns with the requirement in IEEE 2800-2022. Furthermore, for a phase angle jump of 25 degrees or more, the IBR shall only trip to prevent equipment damage.~~

~~Some IBR equipment has PLL loss of synchronism protection, referring to a protective function that operates when the angle displacement Δθ exceeds a threshold for a predetermined period of time (on the order of a couple of milliseconds). Historically, this protection has been used by some inverter manufacturers, especially for inverters in distribution systems. For the IBR connected to the BPS, this protection function should be disabled. If it is enabled, the phase angle jump protection setting shall be configured such that the IBR shall only trip to prevent equipment damage.~~

~~**Rationale for Requirement R6**~~

~~The objective of Requirement R5~~R4 is to ensure legacy IBR ~~may need~~are able to obtain an exemption to the voltage ride-through requirements if hardware replacements or other costly upgrades would be necessary to comply with Requirements R1 or Requirement R2. This provision allows such exemptions as long as such limitations are documented and communicated to the Planning Coordinator, Transmission Planner, and Reliability Coordinator of the respective footprints in which the IBR project is located. The Planning Coordinator, Transmission Planner, and Reliability Coordinator will then need to take the voltage ride-through limitations into account in planning and operations.

Limitations must not be construed as complete exemptions from the applicable **Attachment 1** table but must be specific as to which voltage band(s) and associated duration(s) cannot be satisfied or specific as to the number of cumulative voltage deviations within a ten-second time period that the equipment can ride-through if less than four. Limitation descriptions should identify the specific equipment and explain the characteristic(s) of that equipment that prevent ride-through. If any equipment limitation is removed or otherwise corrected, it is likewise necessary to communicate to the Planning Coordinator, Transmission Planner, and Reliability Coordinator of this.

FERC Order No. 901 states that this provision would be limited to exempting “certain registered IBRs from voltage ride-through performance requirements.” This is the reason that no similar provisions are included for exemptions for frequency~~,~~, or rate-of-change-of-frequency (ROCOF) ~~,phase angle change~~ ride-through requirements per R3.

Violation Risk Factor and Violation Severity Level Justifications

Project 2020-02 Modifications to PRC-024 (Generator Ride-through)
PRC-024-4

This document provides the standard drafting team's (SDT's) justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-024-4. Each requirement is assigned a VRF and a VSL. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the Electric Reliability Organizations (ERO) Sanction Guidelines. The SDT applied the following NERC criteria and FERC Guidelines when developing the VRFs and VSLs for the requirements.

NERC Criteria for Violation Risk Factors

High Risk Requirement
A requirement that, if violated, could directly cause or contribute to BulkPower System instability, separation, or a cascading sequence of failures, or could place the Bulk-Power System at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to BulkPower System instability, separation, or a cascading sequence of failures, or could place the Bulk-Power System at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement
A requirement that, if violated, could directly affect the electrical state or the capability of the Bulk-Power System, or the ability to effectively monitor and control the Bulk-Power System. However, violation of a medium risk requirement is unlikely to lead to Bulk- Power System instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the BulkPower System, or the ability to effectively monitor, control, or restore the BulkPower System. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to Bulk Power System instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement
