Capital Power supports the comments submitted by NAGF. Capital Power notes that requiring data monitoring equipment at all IBR facilities is unnecessary and an excessive cost burden for existing IBR facility owners to bear which may lead to unintended adverse impacts to reliability. PRC-028-1 creates a more restrictive requirement on IBR facilities for data monitoring than for synchronous generation facilities. The requirement for data monitoring equipment should align between the two types of generating resources by requiring the TOP or applicable RE to indicate that monitoring equipment is necessary for the IBR facility. Additional clarification regarding the language “if capable of recording” used in Requirement 1.3 is requested to better understand the cost impacts of the proposed PRC-028-1.

PRC-028 should follow PRC-002 with criteria to filter the BES Elements required to provide SER and FR data, as well as DDR data. The cost of all IBR facilities providing this data seems excessive without some analysis first of which sites will provide the most benefit. Capturing all fault codes and all fault alarms under requirements R1.2 and R1.3 will also not provide much benefit vs. the cost.

The modifications include existing IBRs now and require monitoring specific elements that may be costly to implement especially for the units that are at a distance greater then or equal to 90% of the longest collector feeder. The proposed requirements for IBRs that will be installed are reasonable as new sites can be built to include that monitoring.

Comment	
Southern Company does not agree that the modifications are cost effective. For PRC-028-1, requiring DME equipment at all IBR facilities does not comport with the NERC risk-based approach. To incorporate an informed, risk-based approach to reliability, Southern would propose limiting the applicability through an engineering assessment to evaluate critical sites based on location, vendor susceptibility to trouble, or some other valid criterion. Southern agrees that the modifications made in PRC-002-5 are cost effective.

The modifications made in this PRC-028-1 draft are an improvement in cost expenditures from the initial version. However, the implementation costs for PRC-028-1 are still appreciably higher than PRC-002. With the additional data requirements and higher sampling rates, the costs are higher per facility for PRC-028 than PRC-002. With DME required to be implemented at all BES IBR facilities and many non-BES IBR facilities, the overall costs of PRC-028 exceeds PRC-002.

The level of data recording required and the amount of data that is to be collected is significantly greater than PRC-002. Also, requiring all applicable Facilities to have a DDR seems excessive. For PRC-002, the threshold for DDR is governed by a notification by the RC of applicable BES Elements however there is no comparable Requirement in PRC-028 resulting in all IBR generation being obligated to provide DDR data. There is a significant cost associated with the installation and maintenance of a DDR and expecting an IBR to have this level of recording when they do not meet the BES definition may be overreaching. Could this be better addressed by TOs having DDRs that could capture more information from multiple generation facilities during an event?

AEPC signed on to ACES comments: It is ACES' opinion that the proposed changes to PRC-002 are minimal and therefore should have little to no cost to implement. As for the proposed PRC-028-1, we agree with the approach taken by the SDT to create a new Standard to specifically address IBR facilities; however, we s**trongly disagree** with making this new standard inclusive of all applicable IBR facilities r**egardless of risk to the BES**. In the opinion of ACES, a blanket approach requiring every applicable IBR facility to install SER, FR, and/or DDR capabilities is overly gratuitous. We believe that the industry's finite resources would best be spent by first ascertaining which IBR facilities would provide the most benefit to the BES, before selectively adding such capabilities. In summary, it is our recommendation that PRC-028-1 take a similar risk-based approach as is done in PRC-002-5.

Thomas Foltz - AEP - 5

Answer	No
Document Name	

Comment

For the reasons expressed below, AEP is concerned by the cost versus perceived reliability benefit of the new Standard PRC-028-1.

AEP does not consider the inclusion of “at least one IBR Unit, per collector bus, on any of the collector feeders that is connected at a distance greater than or equal to 90% of the longest collector feeder” in PRC-028 1.2 and 1.3 as cost effective. AEP questions the reliability benefit of the data these BES Elements will provide when considering the proposed requirements of PRC-029 to a performance-based ride-through standard that ensures generators remain connected to the BPS during system disturbances and the proposed requirements of PRC-030, Unexpected Inverter-Based Resource Event Mitigation. Requirements proposed in PRC-030 clearly make the GO responsible for the performance of the Invertor-Based Resources and IBR units it owns. The proposed obligation to collect and provide FR and SER data beyond the MPT bus(es) in PRC-028 is unwarranted.

PRC-028 does not currently limit the applicability of required data, while PRC-002 provides criteria which limits the BES Elements that are required to have dynamic disturbance recording data.

AEP does not believe capturing all fault codes and fault alarms listed in R1.2 and R1.3 under this standard would be beneficial to the Transmission Planner, Planning Coordinator, Transmission Operator, Balancing Authority, Reliability Coordinator, Regional Entity, or NERC as there are several OEMs with thousands of differing fault codes and fault alarms. AEP is concerned with the ability of these entities to understand or utilize the data in an timely manner. For some entities, this data would be more akin to SCADA quality data and not delivered with the timing nor accuracy of typical SER data. In addition, under PRC-030, we are asking the GO to resolve those issues. AEP recommends the SDT for PRC-028, PRC-029 and PRC-030 review each proposed standard obligation to ensure there is an integrated plan across these standards to achieve the goal of correcting the past performance of Invertor-Based Resources and IBR units. Having a coherent strategy document that explains how these three standards complement each other (and not be duplicative) would be beneficial.

Comment	

No, simply from a value-add perspective. The standard requires IBR owners to have a robust compliance program implemented as well as event data collection process in place. However, for example, Requirement R1.2 only requires fault codes, fault alarms, mode status change, etc., from a single IBR Unit far down the feeder. This is common practice for this information to be stored on the IBR Unit inverter or logging device.

This will not help any event analysis process as it will not paint an adequate picture of the IBR facility's abnormal performance, if analyzed. At a minimum, fault codes should be available from every single IBR Unit within the facility. Lack of comprehensive data has significantly affected the ERO Enterprise's ability to conduct event analysis at many facilities over the past 7 years, as reported in numerous disturbance reports. The proposed standard would lead to inadequate data available at the inverter-level to do any useful event analysis and model validation, possibly leading to ongoing inconclusive root cause analyses. This would not be cost effective for industry.

Buckeye Power supports the comments made by ACES:

As writen, PRC-028-1 is applicable to both BES and non-BES IBRs; consequently, we recommend updating the Implementation Plan to use the term “IBR facility(ies)” in lieu of the term defined term “Facility(ies)”.
From the perspective of ACES, the special stipulations surrounding commercial operation are overly complex and unnecessary. For example, assume PRC-028-1 is approved by FERC and becomes effective 10/1/2024. Using the provided example, the end of the first calendar year that is 12 months following the effective date of the standard would be 12/31/2025. Thus any facilities entering commercial operation prior to 10/1/2025 would have until 12/31/2025 to be compliant while any facilities entering commercial operation on or after 10/1/2025 must be compliant immediately. We do not believe that a delay of only 1 day should move the compliance deadline forward by 3 calendar months.
We recommend removing these special stipulations and instead address this specific case using a strategy akin to that used for existing facilities. We suggest the following language:
“For facilities entering commercial operation a□er the effective date: Entities shall comply with Requirements R1 through R7 within three (3) calendar years of the effective date of PRC-028-1.”

Comment

Although the PRC-028 Implementation Plan mirrors PRC-002-2 Implementation Plan, PRC-028 requires all BES IBRs and many non-BES IBRs to have DME installed. If the GO has a large IBR fleet, numerous DME installations would be required with a demanding project schedule. With the large amount of DME required to be installed per PRC-028, OEMs might not be able to provide GOs with a timely supply of DME equipment.

The PRC-028-1 standard as written, requires 50% completion within (3) calendar years and 100% completion of R1-R7 by 1/1/2030, R9 by 1/1/2029 and R8 a maximum of 9 months after the effective date. The phased-in implementation plan needs to be given in a timeframe after the effective date for the standards. Specifying a fixed date may not provide adequate time for the wide scale installation of DME at all applicable IBR facilities. PRC-028, as written, will require much more DME than PRC-002 did, and the implementation plan needs to recognize this difference and provide adequate time to accomplish. Traditional language for implementation plans in other Standards have provided a certain period after implementation instead of a fixed date (e.g. within 6 calendar years of the effective date…).

As written, PRC-028-1 is applicable to both BES and non-BES IBRs; consequently, we recommend updating the Implementation Plan to use the term "IBR facility(ies)" in lieu of the term defined term "Facility(ies)".

From the perspective of ACES, the special stipulations surrounding commercial operation are overly complex and unnecessary. For example, assume PRC-028-1 is approved by FERC and becomes effective 10/1/2024. Using the provided example, the end of the first calendar year that is 12 months following the effective date of the standard would be 12/31/2025. Thus any facilities entering commercial operation prior to 10/1/2025 would have until 12/31/2025 to be compliant while any facilities entering commercial operation on or after 10/1/2025 must be compliant immediately. We do not believe that a delay of only 1 day should move the compliance deadline forward by 3 calendar months.

We recommend removing these special stipulations and instead address this specific case using a strategy akin to that used for existing facilities. We suggest the following language:

"For facilities entering commercial operation after the effective date:
Entities shall comply with Requirements R1 through R7 within three (3) calendar years of the effective date of PRC-028-1."

Implementation Plan Says:

R1-7: Current imp plan is 50% in 3 calendar years after effective date, 100% by 1/1/2030

R8: max 9 months after effective date

R9: no later than 1/1/2029

The phased in implementation plan needs to be given in a time frame after the effective date for the standard. Specifying a fixed date may not provide adequate time for the wide scale installation of DME at all IBR facilities. PRC-028, as written, will require much more DME than did PRC-002, and the implementation plan needs to recognize this difference and provide adequate time to accomplish.

Six years would be a sufficient amount of time to plan and budget for the procurement and installation of the DDR equipment barring any supply chain risk complications or any other delays. USV recognizes the FERC directive mandating completion by 1/1/2030, however, due to many of the IBR sites having strict language when dealing with manufacturers warranty and having to rely on third parties, it may result in additional complications that could delay the installation and setting up of this highly specialized equipment.

4. Do you agree with introduction of Requirement R9 in PRC-028-1 requiring Entities of an applicable facility that is in commercial operation before the effective date of this standard that is not able to install disturbance monitoring equipment in accordance with Requirements R1 through R7 in the time provided for compliance to develop, maintain, and implement a Corrective Action Plan?

Rhonda Jones - Invenergy LLC - 5,6

Answer	No
Document Name	

Comment

Invenergy **suggests the below language** for R9:

R9. Each Generator Owner and Transmission Owner with a documented equipment limitation that would prevent an applicable IBR that is in commercial operation prior to the effective date of this standard from installing disturbance monitoring equipment in accordance with Requirements R1 through R7 shall communicate each equipment limitation to the Regional Entity.

9.1. Each Generator Owner and Transmission Owner shall include in its documentation:

- 9.1.1. Identifying information of the applicable Element and cause of the limitation
- 9.1.2. Which aspect(s) of disturbance monitoring the Element would be unable to meet

9.2. Each Generator Owner and Transmission with a previously communicated equipment limitation that repairs or replaces the equipment causing the limitation shall document and communicate such equipment change to the Regional Entity within 30 days of the equipment change.

The idea of allowing a corrective action plan for compliance challenges at existing operations is a good one however the circumstance that would allow for use of the CAP is poorly defined.   What exactly is "not able to install" ? Does that mean within reason? cost effectively?   Not able to install regardless of time or money is a very high bar and essentially unhelpful.

Response

Kennedy Meier - Electric Reliability Council of Texas, Inc. - 2, Group Name ISO/RTO Council Standards Review Committee (SRC)

Answer	No
Document Name	

Comment

The SRC is concerned that the requirement as written may be overly broad. To address this, examples of legitimate reasons that an entity may be unable to “install disturbance monitoring equipment” should be provided in the Technical Rationale.

Alternatively, this concern could be addressed by revising the standard to require all installations to be completed within the parameters of the Implementation Plan for PRC-028.

Requiring comprehensive DME for SER, FR, and DDR at all "old" facilities is unnecessary.   The investigations performed into past grid disturbances have documented the trouble that legacy facilities have been experiencing.   Focusing on new equipment that has been designed and built to better ride-thru system disturbances will provide more benefit and value to system reliability.

R2.3 and R3.3 and their subparts are unnecessary as these devices have not been identified as causing any problems that suggest they need to be monitored.

Capital Power supports the comments submitted by NAGF. Capital Power does not support the proposed Requirement R9 due to the potential cost issues for existing IBR facilities. This can be a costly endeavor if equipment was recently replaced as per planned life cycle replacement strategies. There is also the potential reliability impacts due to existing IBR facilities ceasing operation due to economics.

PG&E does not agree with the language proposed. PG&E agrees with the following EEI comments: 1 - Given the voltage level identified in the Applicability section of PRC-028, DPs will likely own applicable equipment that will be impacted. For this reason, we suggest that DPs be added to R9. 2 - The use of "applicable facility" in R9 should be removed because this term has no defined meaning. To resolve this issue, we suggest replacing "of an applicable facility" with "that own equipment as identified in "Section 4.2 (Facilities)". 3 - Disturbance Monitoring Equipment is a NERC defined term and should be capitalized to ensure that responsible entities understand the scope of their responsibilities under this Reliability Standard.

Steven Rueckert - Western Electricity Coordinating Council - 10, Group Name WECC Entity Monitoring	

Answer	No
Document Name	

Comment

Conceptually, no, WECC believes there should not be a compliance loophole built into a Reliability Standard. General considerations mention three (3) calendar years to accommodate normal outage schedules.   As written the entity may only have to outage one (1) IBR unit per collector feeder (and in some cases maybe only (1) IBR Unit for the entire Inverter-Based Resource), to install equipment in Parts 1.2/2.2. (as an example as it is not clear where that data is being recorded). Granted, SER/FR on circuit breakers, if not already installed at Part 1.1 locations require a complete outage but is it not already industry standard to have that capability on breakers in that voltage class? Waiting until 2029 to create a CAP per the Implementation Plan does not support reliable operations (and at least two "normal outage schedule" periods will have passed since the official start of this Project to accommodate the SER/FR additions if not present.) Part 9.2 allows too broad of a scope to be considered reliable with no support (what is "beyond the control" and who defines that?). Submitting the CAP to the Regional Entity with a request to extend time provided for compliance does not support reliability. The Regional Entity does not necessarily have the authority to grant extensions for compliance. Timelines for compliance are dictated by Implementation Plans or the Requirement language itself. There are no required timelines for the CAP which could equate to a CAP that is never implemented. WECC appreciates the idea of striking a balance between cost and reliability (with compliance impacts) but as written the reliability aspect will suffer to support being compliant.

Eric Sutlief - CMS Energy - Consumers Energy Company - 3,4,5 - RF

Answer	No
Document Name	

Comment

Section R3.2 seems to specify that a Schweitzer level sampling rate of 64 samples per cycle needs to be implemented which it does not appear to be within the capabilities of the event recording generated by the turbine controllers. The minimum requirements appear to be the AC and Frequency values at that high of a resolution.

The GE documentation suggest the points and sampling rate of the trip files generated vary. Even if the resolution we need is possible, it may not have the correct setting dependent on the event that is recorded in the trip file. The fastest sampling rate in the GE trending software is at a 10 milli-seconds, which is significantly less than what would be required for 64 samples per 1 hz.

Colby Galloway - Southern Company - Alabama Power Company - 1,3,5,6 - SERC, Group Name Southern Company

Answer	No
Document Name	

Comment	
R9.5 requires Entities submit the CAP to the Regional Entity. Entities will require guidance on the process with input from each Regional Entity. This is an administrative process that could cause undue delay in the CAP process while managing time constraints. It would be more efficient for the Entity to create and maintain its own CAP similar to PRC-026 R3 and R4. The CAP can be made available during periodic audits. There is no demonstration of how "reporting" CAPs to Regional Entities adds to system Reliability. Requiring comprehensive DME for SER, FR, and DDR at all existing facilities is unnecessary. The investigations performed for past grid disturbances have documented the trouble that legacy facilities have been experiencing. Focusing on new equipment that has been designed and built to better ride-thru system disturbances will provide more benefit and value to system reliability. R2.3 and R3.3 and their subparts are not necessary as these devices have not been identified as causing any problems that suggest they need to be monitored. Southern Company agrees with EEI suggested modifications to the text: 1. The use of "applicable facility" in R9 should be removed because this term has no defined meaning. To resolve this issue, it is suggested replacing "of an applicable facility" with "that own equipment as identified in Section 4.2 (Facilities)". 2. Disturbance Monitoring Equipment is a NERC defined term and should be capitalized in order to ensure that responsible entities understand the scope of their responsibilities under this Reliability Standard.

EEI supports the language proposed in Requirement R9 but offers the following non substantive comments for consideration: 1. The use of “applicable facility” in R9 should be removed because this term has no defined meaning. To resolve this issue, we suggest replacing “of an applicable facility” with “that own equipment as identified in “Section 4.2 (Facilities)”. 2. Disturbance Monitoring Equipment is a NERC defined term and should be capitalized in order to ensure that responsible entities understand the scope of their responsibilities under this Reliability Standard.

SIGE supports the inclusion of Requirement R9; however, SIGE requests a clarification regarding disturbance monitoring equipment referenced in Requirement R9. Was the Standard Drafting team's use of the phrase "disturbance monitoring equipment" intended to reference the equipment covered by the NERC defined term "Disturbance Monitoring Equipment"? If so, SIGE recommends capitalizing the proposed language to clarify the intent.

Additionally, SIGE recommends two revisions to R9: 1) revise R9 to mirror the language in section 4.2 Functional Entities and 2) align the Applicability section reference with other NERC Standards. Recommended revisions are shown below:

R9. Each Transmission Owner and Generator Owner ***that owns equipment as identified*** in ***Applicability*** section ***4.2*** that is in commercial operation before the effective date of this standard that is not able to install disturbance monitoring equipment in accordance with Requirements R1 through R7 in the time provided for compliance shall develop, maintain, and implement a Corrective Action Plan to provide the required capability. For each Corrective Action Plan, the Transmission Owner and Generator Owner shall:

If the standard and implementation plan were to pass in its current form, we do not feel that 2030 would be a sufficient amount of time to implement DDR recording at all sites that meet the applicability section of PRC-028. The procurement and installation process is time-consuming due to the limited amount of vendors and having to do additional efforts for supply chain risk, etc.

1) In 4.3.2 of PRC-002-5, we need to clarify this trigger condition "Phase undervoltage or overcurrent". Does "phase undervoltage" refer to phase-phase or phase-to-neutral undervoltage"?

2) Under "Facilities" of 4.1 in PRC-028-1, how was this 60 kV threshold determined?

3) In section 3.1.3.2, section 3.2.3.1 and section 3.3.3.2 of PRC-028-1, we need to clarify this trigger condition "AC phase overvoltage and undervoltage". Does "phase undervoltage" refer to phase-phase or phase-to-neutral undervoltage"?

4) In R8 of PRC-028-1, "Submit a Corrective Action Plan (CAP) to the Regional Entity and implement it." should probably read "Submit a Corrective Action Plan (CAP) and a CAP implementing schedule to the Regional Entity"?

It is unclear why NERC is so adamant about not adopting IEEE standards within the NERC standards, and has stated this in multiple forums related to the adoption of IEEE 2800-2022. However, then now proposes to adopt IEEE C37.111 COMTRADE standard within the new PRC-028-1 proposed standard. Inconsistency regarding NERC's approach and opinion in this area leaves industry confused, uncertain, and concerned regarding whether NERC has a clear and effective standards improvement strategy.

BC Hydro appreciates the drafting team efforts and the opportunity to comment.

PRC-028-1 R1 requires an entity to record data “when triggered by ride-through operation”. BC Hydro requests that drafting provides additional clarity on or criteria to determine what would constitute “ride-through operation” as it pertains to an applicable entity’s compliance obligation to identify all events in scope of R1 Part 1.2.

Requirement R3 Footnote 3 on “main power transformer” should use IBR instead of the undefined term “dispersed power producing resources”. BC Hydro suggests that instead of this wording, which is indeed referenced in the inclusion I4 of the BES definition, the new IBR Glossary Term is preferrable.

Requirement R7 requires that all SER, DDR and FR data be provided upon request by an applicable entity. BC Hydro suggests that all data may not be feasible or even required and recommends instead that the provision of the SER, DDR and FR data be done in accordance with a qualified request and within the bounds set by Part 7.1 through Part 7.5 of Requirement R7.

PRC-028-1 Requirement R8 and PRC-002-5 R12 second bullet as written requires that a CAP will need to be implemented within 90 days. The VSL Table and the Technical Rationale provide clarity that it is only the CAP that requires submission within 90 days for the situations where an entity is unable to restore capability within 90 days. BC Hydro recommends that the drafting team revises the PRC-028-1 R8 and PRC-002-5 R12 wording to clarify that the 90-day timeline is only mandated for the CAP submission. Also important to clarify within the language of the Requirement is whether the 90-day timeline is based on business or calendar days.

BC Hydro recommends that the implementation plan for PRC-028-1 be coordinated with the approval of the approval of the IBR and IBR Unit definitions.

Comment	
This comment applies to PRC-028-1 R5.2. Idaho Power presently requires existing and future IBRs connecting to its transmission system to provide plant-level PMU data. This data is streamed to a central data concentrator in real time, where it is then stored in a central data historian. The message rate has been chosen to be 30 samples per second due to limitations of the communications systems. Moving this existing system to 60 samples per cycle to obtain this data may result in significant re-design and additional costs.

Comment	
AEP has concerns with several of the requirement differences between PRC-002 and PRC-028 such as ten day data retention vs. twenty day data retention, output recording rate of electrical quantities of at least 30 times per second versus 60 times per second, synchronized clock accuracy within +/- 2 milliseconds versus +/- 1 millisecond, etc.. The Technical Rational document is silent on the reason for these differences. These changes are not insignificant, and having differing requirements for synchronous vs IBR technologies, introduces a risk for human performance error. PRC-002 Attachment 1 limits the BES buses required to record SER and FR data. During the recent system disturbance events, were any IBR facility buses required to capture SER and FR data under PRC-002? What is the reliability-driven rationale behind requiring *all* IBR facility buses to capture SER and FR data in PRC-028 as opposed to a targeted set based on an engineering analysis as done for PRC-002? PRC-002 and PRC-028 should both be revised to make it clear that the ability to provide data in CSV format is for DDR or PMU data *only.*

Rachel Coyne - Texas Reliability Entity, Inc. - 10

Answer	
Document Name	
Comment	

Texas RE has the following additional comments:

- Texas RE suggests removing the terms “machine based” from PRC-002-5 Requirement Part 5.1.1 as simply stating “Synchronous generating resource” is sufficient.
- In PRC-028-1 Standard, Requirement Part 2.1.3 should specify Real and reactive power on a three-phase basis*:*
  - 2.1.3. Real and reactive power on a **three-phase basis.**
- In PRC-028-1 Standard, Requirement Part 2.3.3 should remove ‘Real’ from the requirement and specify the reactive power on a three-phase basis:
  - **2.3.3. Real and Reactive power on three-phase basis.**
- Remove the ending parathesis in Requirement Part 3.2.2.
- Texas RE recommends the SDT consider specifying the trigger settings for ‘overfrequency and underfrequency’ levels to be consistent with the PRC-024 requirements:
  - **3.2.3.2 Overfrequency level at minimum 60.6 Hz and underfrequency level at 59.4 Hz**
- Texas RE recommends the SDT consider including an option for existing registered entities that have IBR units that are incapable of recording data to provide technical justification for the IBR unit’s inability to record based on OEM specifications or based on an independent engineering assessment.

David Vickers - David Vickers On Behalf of: Daniel Roethemeyer, Vistra Energy, 5; - David Vickers

Answer	
Document Name	

Comment

Section 1.2 and 1.3: While IBR settings are important when analyzing events, the various settings and modes may not be recorded by the inverter data recorder. At a minimum 1.3.3 and 1.3.4 should be removed for IBR units that are in commercial operation since they would have not been designed to meet the requirement.

Section 2.1.3: PRC-002 does not require real and reactive power for FR data, the same should apply for PRC-028, Most fault recording equipment does not record power or frequency in FR records, this is a calculated value and is recorded in DDR/Continuous data. Software can be used to calculate power using FR data, power and frequency would not be in the comtrade file.

Section 2.3.3: Same comment as 2.1.3

Section 3.2..2 Existing IBRs may not be able to store 2 second event records at a 64 samples/cycle.

Section 3.2.3.2 Frequency triggers should not be required for FR data. They can be difficult to set and trigger erroneous events which can fill up storage. Frequency triggers should only be required for continuous/DDR recording.

Section 5.2 Not all existing install equipment may be able to meet the 60 samples/second recording rate. Requirement in PRC-002 is 30 samples/second.

Section 7.1 Existing IBRs may not be able to store FR or DDR data for 30 days.

For R8, it is not clear whether the CAP implementation referenced in the 2nd bullet item must be complete at the end of the 90 days specified in the R8 text. If so, what then is the difference in the first bullet (restoring the capability) and why might the Regional Entity need to know of a repair plan in progress that will be completed before the 90-day limit?

In R9.5 does the request to extend the time provided refer to any changes made to an original CAP timeline? (there are no other deadlines for completing any R9 CAP)

In R1.2 and R1.3 remove the unneeded brackets [ ] surrounding “the effective date of this standard”.

CAPS documentation specifications and submittals to the RE are purely administrative and should be removed from the requirement list. A simple requirement to fix any faulty equipment will accomplish the intent of R8 & R9. An audit can check to ensure that all broken equipment was handled properly.

What dictates a “ride-thru” event in R1?   The IBR mode status?

Why is R2.2.1 needed to be the IBR Unit transformer HV side versus the LV side?

Comments on cost:

Based on research for the last ballot on the costs of having this on each feeder at a wind farm. This doesn't include solar IBRS.

In addition, the contributing entity estimates that the cost of installing DFR equipment on the high side of a pad mounted transformer at the base of a wind turbine in the last 10% of an existing wind turbine feeder will be $300-450k or 2-3 times the cost of installing the same equipment in an existing substation. For example, one wind farm has 14 feeders so installing this equipment on every feeder there would cost an estimated $4.2-6.3 million dollars for that one facility.

EIA data shows that there are currently 604 wind farms with a size of 75 MW or greater with a total 975549 MW capacity. Assuming there is a feeder for every 10-20 MW worth of wind turbines and the estimate per installation, the range between $1.463-$2.195 billion dollars just to install these at the end of every feeder and does not include the substation installations that would be required. This estimate is only for feeders at wind turbines and does not include any estimates for solar farms or other IBRs so the total cost.

Wendy Kalidass - U.S. Bureau of Reclamation - 5

Answer	
Document Name	

Comment

Reclamation does not agree with the modifications to the wording of BES Elements in R6 and R7 in the “Violation Severity Levels” section. ‘Element’ is sufficiently defined in the NERC Glossary of terms and ‘BES Element’ encompasses the required equipment (elements) for Disturbance Monitoring. Reclamation recommends keeping the original wording “for all applicable BES Elements”.

Reclamation concurs that all IBR resources should have and maintain their own separate standards.

Rachel Schuldt - Black Hills Corporation - 6, Group Name Black Hills Corporation - All Segments

Answer

Document Name

Comment

Black Hills Corporation agrees with comments from NAGF and EEI, included here:

The NAGF notes that Project 2021-04 needs to be closely coordinated with other active NERC IBR related projects to ensure there is no conflict and/or duplication of efforts. The NAGF recommends that NERC publish a guideline/roadmap to demonstrate how all the on-going and pending IBR work activities fit together so that industry can understand how these efforts will enhance BPS/BES reliability. For example, why is it necessary for PRC-028 to be effective prior to other new IBR standards (i.e., PRC-029/PRC-030/PRC-031)?

EEI offers the following additional comments:

DDR Requirements for PRC-002 & PRC-028

EEI suggests that consideration should be given to modifying the requirements for dynamic Disturbance recording (DDR) equipment in both PRC-002 and PRC-028 in order to permit responsible entities to either install DDR equipment or Phasor Measurement Units (PMUs) since PMU equipment capture disturbance data at equal or better rates, and have the added benefit of synchronizing disturbance data from other locations utilizing existing network communications.

Data Retention Requirements for PRC-002 & PRC-028

EEI does not agree that the data retention requirements for PRC-002 (see Requirement R11 - 10 days) and PRC-028 (Requirement R7 – 20 days) should be different. Having two different data retention requirements for two Reliability Standards that have the exact same purpose is unjustified. Given the currently enforceable version of PRC-002 has a 10 day retention period, PRC-028 should have the same data retention period.

Reliability Coordinator Responsibilities for PRC-028

EEI suggests that the RC should be provided with oversight responsibilities for the placement of DDR equipment, even at IBR facilities. While EEI understands that the desire is to have DDR equipment at all IBR Facilities, as more of these facilities are added to the BPS, it is likely that there will be clusters of IBR facilities in some areas diminishing the need for this equipment at all of these facilities. We further note that the cost of this equipment is significant, and consideration should be given to the actual need and the RC would be the best judge to make this determination.

In R1.2 and R1.3 remove the unneeded brackets [ ] surrounding “the effective date of this standard”.

CAPS documentation specifications and submittals to the RE are purely administrative and should be removed from the requirement list. A simple requirement to fix any faulty equipment will accomplish the intent of R8 & R9. An audit can check to ensure that all broken equipment was handled properly.

What dictates a “ride-thru” event in R1? The IBR mode status?

Why is R2.2.1 needed to be the IBR Unit transformer HV side versus the LV side?

Based on research for the last ballot on the costs of having this on each feeder at a wind farm. This doesn't include solar IBRS. MRO NSRF estimates that the cost of installing DFR equipment on the high side of a pad mounted transformer at the base of a wind turbine in the last 10% of an existing wind turbine feeder will be $300-450k or 2-3 times the cost of installing the same equipment in an existing substation.

It is not understood what drives the 2 seconds length and the 64 samples/sec recording requirements. Existing FR equipment typically has a maximum recording time of 60 cycles and maximum of 16 or 32 samples/sec. Both of these are not consistent with similar requirements of PRC-002 (30 cycles & 16 samples/sec).

3.2 will be difficult to achieve for older IBRs. FR recording equipment will need to be added to meet this requirement. Meeting these requirements at the inverter/controller level will be challenging.

MRO NSRF recommends that the SDT reach out to various manufacturers to confirm the equipment capability and if any changes/updates that may be necessary for equipment can meet this requirement will become available.

MRO NSRF recommends that the SDT consider equipment limitation be introduced similar to PRC-024 where equipment limitation is allowed but adequately reported.

MRO NSRF recommends the SDT consider alternative methods/requirements be provided as an option for the equipment that are not capable of meeting the recording requirements. Refer to

PRC-025, Options 5a and 5b as an example, where 5b option was introduced to eliminate costly replacements.

RF appreciates the continued efforts of the SDT on this project.

RF recommends adding a justification for the addition of CSV file formats to PRC-002 R11 Part 11.4 to the Technical Rationale. RF also recommends considering whether the addition of CSV should be limited to Dynamic Disturbance Recording (DDR) data, with the use of COMTRADE remaining required for all Fault Recording (FR) data.

Comment

We recognize that IBR's pose a reliability risk and that being able to monitor the events and have in depth data for a trip is very important. However, the granularity of the information being required by PRC-028 does not seem to be in step with what PRC-002 is asking for. Could this data be captured by TOs who have a greater situational awareness?

The following comments are for the PRC-002-5 standard:

1) Replace "Hydro-Québec Interconnection" with "Québec Interconnection".

2) Correct VSL table for R1 Moderate and High since the examples don't cover exactly 70% et 80%. Suggest replacing with"more than 70%, but less than or equal to 80%" for the Moderate VSL and "more than 60%, but less than or equal to 70%" for the high VSL.

3) Severe VSL E11 : should read "…provided the requested data more than 60 days" instead of "…failed to provide the requested data more than 60 calendar days".

4) Attachment 1 step 3: "If the list has 11 or fewer buses, proceed to step 7" should be moved to step 2 with the following text "If the resulting list has 11 or fewer buses, proceed to Step 7".

The following comments are for the PRC-028-1 standard:

We are concerned that the standard refers to a defined term for IBR which has yet to be adopted in project 2020-06.

We suggest that the drafting team ensure consistent language is used in the section 4.2 "Facilities" section with the other projects such as 2020-02 (PRC-029) and 2023-02(PRC-030). Are we to understand that this is the recommended text for the facilities section in regards to the standards where IBRs are applicable and that the other projects will ensure consistent language use in line iwth the recent ROP and GO/GOP definition revisions?

For PRC-028, R8, it is not clear whether the CAP implementation in the 2nd bullet item must be complete at the end of the 90-days specified in the R8 text. If so, what then is the difference in the first bullet (restoring the capability) and why might the Regional Entity need to know of a repair plan in progress that will be completed before the 90-day limit?

In PRC-028, R9.5, does the request to extend the time provided refer to any changes made to an original CAP timeline? There are no other deadlines for completing any R9 CAP.

CAPs documentation specifications and submittals to the RE are purely administrative and should be removed from the requirements list. A simple requirement to fix any faulty equipment will accomplish the intent of PRC-028, R8 and R9. An audit can check to ensure that all broken equipment was handled properly.

What dictates a “ride-thru” event in PRC-028, R1, the IBR mode status? Clarity is recommended.

In PRC-028, R1.2 and R1.3 remove the unnecessary brackets “[]” surrounding the “effective date of this standard”.

PRC-028, R1.3 has an *“if capable of recording”* clause. If the inverter is incapable of recording certain data, does the SDT contemplate an “exemption process”?

Why does PRC-028, R2.2.1 need to be the IBR Unit transformer HV side versus the LV side?

Southern Company is in agreement with EEI, recommending that the IBR and IBR Unit definitions should be removed from PRC-002 and PRC-028 because the associated SAR does not provide this SDT with the authority to develop or adopt a definition that is currently unapproved. Moreover, once these definitions are approved and added to the Glossary of Terms there will be no need for inclusion of the definitions within these Reliability Standards.

The SDT needs to coordinate with other active IBR driven NERC Projects to avoid conflicts and duplications of requirements.

PRC-028 needs to align with PRC-002 in regards to synchronized clock accurracy within +/- 2 milliseconds vs. +/- 1 millisecond.

Also, data retention requirements in PRC-028 need to align with PRC-002 which has 10 days instead of 20 days.

The RC should have oversite of the placement of DDR equipment at IBR facilities as in PRC-002.

Comment	

Including post-approval references (i.e. “the effective date of this standard”) should not be considered as appropriate. Essentially this is grandfathering in the operational and reliability risk of not having appropriate data. The use of “if capable of recording” will be a pivotal point to consider when reviewing equipment for grandfathered IBR Units. Should be noted that “capable” does not equate to non-implementation of recording which could be a choice. With feeder lengths and determination of feeder length varying, the 90% criteria will possibly exclude feeders and significant numbers of IBR Units. If one feeder is 10 miles long and two others at same Inverter-Based Resource are 8.9 miles long only one IBR unit with SER (per Parts 1.2/1.3)/FR (per Part 2.2) data will be required to be compliant on the 10 mile feeder. If that one IBR unit is offline, where is the risk being mitigated? To ensure compliance, CMEP staff will have to ascertain applicability based on the criteria within the Requirement (i.e., entities will have to have documentation explaining their determination.) Non-BES Inverter-Based Resources will be even more difficult to apply the criteria.

The Technical Rationale picture/examples are good and clearly show that only one IBR Unit will need disturbance monitoring data to be compliant. One IBR unit’s data may still not allow for detailed analysis of events. Would reconsider Example 3’s use of BES definition references in light of the definitions proposed for Inverter-Based Resources and IBR Units.

Based on the Technical Rationale, to evaluate compliance for IBR units for SER, FR, and DDR data Regional Entities must access event analysis data.

In PRC-002 there is a need to capture DDR for stability SOLs and Elements included in an IROL. Please confirm that the RC can identify those situations for BES and non-BES IBRs (without considering any commercial operation date limitations) which would require DDR installation. Those situations exist and the risk needs mitigated.

IBR & Unit IBR Definitions:

The IBR and IBR Unit definitions should be removed from PRC-002 and PRC-028 because the associated SAR does not provide this SDT with the authority to develop or adopt a definition that is currently unapproved. Moreover, once these definitions are approved and added to the Glossary of Terms there will be no need for inclusion of the definitions within these Reliability Standards.

DDR Requirements for PRC-002 & PRC-028

EEI also suggests that consideration should be given to modifying the requirements for dynamic Disturbance recording (DDR) equipment in both PRC-002 and PRC-028 in order to permit responsible entities to either install DDR equipment or Phasor Measurement Units (PMUs) since PMU equipment capture disturbance data at equal or better rates, and have the added benefit of synchronizing disturbance data from other locations utilizing existing network communications.

Data Retention Requirements for PRC-002 & PRC-028

EEI does not agree that the data retention requirements for PRC-002 (see Requirement R11 - 10 days) and PRC-028 (Requirement R7 – 20 days) should be different. Having two different data retention requirements for two Reliability Standards that have the exact same purpose is unjustified. Given the currently enforceable version of PRC-002 has a 10 day retention period, PRC-028 should have the same data retention period.

Reliability Coordinator Responsibilities for PRC-028

EEI suggests that the RC should be provided with oversight responsibilities for the placement of DDR equipment, even at IBR facilities. While EEI understands that the desire is to have DDR equipment at all IBR Facilities, as more of these facilities are added to the BPS, it is likely that there will be clusters of IBR facilities in some areas diminishing the need for this equipment at all of these facilities. We further note that the cost of this equipment is significant, and consideration should be given to the actual need and the RC would be the best judge to make this determination.

Michael Johnson - Michael Johnson On Behalf of: Marco Rios, Pacific Gas and Electric Company, 3, 1, 5; Sandra Ellis, Pacific Gas and Electric Company, 3, 1, 5; - Michael Johnson, Group Name PG&E All Segments

Answer	
Document Name	

Comment

PG&E provides the following:

As currently drafted, PRC-028 does not contain the methodology like PRC-002 to determine if SER/FR is required. However, the DT has added, "elements associated with IBRs with an aggregate nameplate rating of 20 MVA and connecting to a voltage greater than or equal to 60 kV." Therefore, PG&E agrees with EEI input that "Elements to non-BES IBR units and BES IBR units" is too broad and the manner with which EEI has clarified the facilities to which the standard is applicable.

Comment	

Capital Power supports the comments submitted by NAGF.

The NAGF notes that Project 2021-04 needs to be closely coordinated with other active NERC IBR related projects to ensure there is no conflict and/or duplication of efforts. The NAGF recommends that NERC publish a guideline/roadmap to demonstrate how all the on-going and pending IBR work activities fit together so that industry can understand how these efforts will enhance BPS/BES reliability. For example, why is it necessary for PRC-028 to be effective prior to other new IBR standards (i.e., PRC-029/PRC-030)?

In addition, for the proposed Requirement R8, it is not clear whether or not the CAP referenced in the 2nd bullet item must be complete at the end of the 90 days. If so, what then is the difference between that and the first bullet (restoring the capability). Also, why might the Regional Entity need to know of a repair plan in progress that will be completed before the 90-day limit? Further, the CAPs documentation specifications and submittals to the RE are purely administrative and should be removed from the requirement list. A simple requirement to fix any faulty equipment should accomplish the intent of R8 & R9.

The NAGF has the following comments\questions regarding Requirement R3:

• What is the driver for the 2 seconds length and the 64 samples/sec recording requirements? Existing FR equipment typically has a maximum recording time of 60 cycles and maximum of 16 or 32 samples/sec. The proposed recording requirements are not consistent with similar requirements of PRC-002 (30 cycles & 16 samples/sec).

• Requirement 3.2 will be difficult to achieve for older IBRs. FR recording equipment will need to be added to meet this requirement. Meeting these requirements at the inverter/controller level will be challenging.

• Did the SDT reach out to various manufacturers to confirm the equipment capability and more importantly, are the changes/updates available that can meet this requirement?

• Should equipment limitation be introduced as one of the requirements, similar to PRC-024 where equipment limitation is allowed but adequately reported? • Should an alternative method/requirement be provided as an option for equipment that is not capable of meeting the recording requirements? Refer to PRC-025, Options 5a and 5b as an example, where 5b option was introduced to eliminate costly replacements.

It is unclear as to what constitutes a “ride-through operation” of an IBR Unit in R1.2 and R1.3. Is this intended to be a reference to “no trip zone” identified in PRC-024? If so, as PRC-024 is not currently applicable to non-BES IBRs, how is this identified for those facilities? We believe additional guidance is needed for these requirements.

Thank you for the opportunity to comment.

Comment

For R8, it is not clear whether the CAP implementation referenced in the 2nd bullet item must be complete at the end of the 90 days specified in the R8 text. If so, what then is the difference in the first bullet (restoring the capability) and why might the Regional Entity need to know of a repair plan in progress that will be completed before the 90-day limit?

In R9.5 does the request to extend the time provided refer to any changes made to an original CAP timeline? (there are no other deadlines for completing any R9 CAP)

In R1.2 and R1.3 remove the unneeded brackets [ ] surrounding “the effective date of this standard”.

CAPS documentation specifications and submittals to the RE are purely administrative and should be removed from the requirement list. A simple requirement to fix any faulty equipment will accomplish the intent of R8 & R9. An audit can check to ensure that all broken equipment was handled properly.

What dictates a “ride-thru” event in R1? The IBR mode status?

Why is R2.2.1 needed to be the IBR Unit transformer HV side versus the LV side?

Based on research for the last ballot on the costs of having this on each feeder at a wind farm. This doesn't include solar IBRS. MRO NSRF estimates that the cost of installing DFR equipment on the high side of a pad mounted transformer at the base of a wind turbine in the last 10% of an existing wind turbine feeder will be $300-450k or 2-3 times the cost of installing the same equipment in an existing substation.

It is not understood what drives the 2 seconds length and the 64 samples/sec recording requirements. Existing FR equipment typically has a maximum recording time of 60 cycles and maximum of 16 or 32 samples/sec. Both of these are not consistent with similar requirements of PRC-002 (30 cycles & 16 samples/sec).

3.2 will be difficult to achieve for older IBRs. FR recording equipment will need to be added to meet this requirement. Meeting these requirements at the inverter/controller level will be challenging.

PacifiCorp recommends that the SDT reach out to various manufacturers to confirm the equipment capability and if any changes/updates that may be necessary for equipment can meet this requirement will become available.

PacifiCorp recommends that the SDT consider equipment limitation be introduced similar to PRC-024 where equipment limitation is allowed but adequately reported.

PacifiCorp recommends the SDT consider alternative methods/requirements be provided as an option for the equipment that are not capable of meeting the recording requirements. Refer to PRC-025, Options 5a and 5b as an example, where 5b option was introduced to eliminate costly replacements.

Comment	

On behalf of the SERC Generator Working Group:

- General comment: Should there be an assessment to determine which facilities this monitoring equipment should be installed on rather than just requiring for every IBR Unit
- R1: The data required in 1.2.1-4 and 1.3.1-4 are not currently available in all manufacturers
- R8: The two bullets say the same thing. Should it be that the CAP is submitted within 90 days and then implemented after? Otherwise implementing it within 90 days is the same as restoring the recording capability.

Comment	

PRC-028-1 Requirement R4 requires a DDR for the MPT of every 20+ MVA IBR with a connection point at a voltage of 60kV or greater . It is unclear whether these DDR (at least for BES IBR) should be included in the DDR coverage calculation in PRC-002-5 Requirement R5 Part 5.2. The SRC recommends that PRC-002-5 Requirement R5 be revised to clarify if any or all or none of the DDRs required by PRC-028-1 Requirement R4 are required (or allowed) to be included in the minimum DDR coverage under PRC-002-5 Requirement R5 Part 5.2.

PRC-028-1 Requirement R3 does not place minimum triggering thresholds on neutral overcurrent (Part 3.1.3.1), AC phase overvoltage and undervoltage (Parts 3.1.3.2 and 3.2.3.1), or overfrequency or underfrequency (Part 3.2.3.2). Improper threshold settings have led to event data being unavailable in instances where it would have been valuable for analysis. The SRC recommends that minimum triggering thresholds be added to the requirements to ensure this data is captured reliably.

PRC-028-1 Requirement R7, Part 7.2 requires that data subject to Part 7.1 be provided to the requesting entity within 30 calendar days of a request, yet Part 7.1 only requires the data to be retrievable for a period of 20 calendar days. The SRC recommends that the period to provide data under Part 7.2 be half of the data retention period under Part 7.1. In response to data requests, SRC members have often received data that does not fully cover the requested timeframes or that is incomplete and missing information. Ensuring that the response period under Part 7.2 is half of the data retention period under Part 7.1 would allow time for these types of errors to be detected and corrected before the data retention period expires and the data is lost.

PRC-028-1 Requirement R1, Part 1.3 requires currently in operation IBR units to record certain data unless they are not "capable of recording." The SRC requests that the SDT clarify what it means for an IBR Unit to not be capable of recording the required data, as the proposed language could be read to include IBR Units that have the technical capability to record the required data, but failed to record the data due to a malfunction or due to being temporarily out of service.

Requirement R5 of PRC-002-5 Includes some unnecessary administrative compliance burdens. A GO with a 500+ MVA unit or 300+ MVA unit within a 1000 MVA plant should already know that they are required to install DDR without a specific RC requirement to provide notification of their DDR obligation.

Mark Gray - Edison Electric Institute - NA - Not Applicable - NA - Not Applicable

Answer	
Document Name	

Comment

EEI offer the following additional comments:

IBR & Unit IBR Definitions:

The IBR and IBR Unit definitions should be removed from PRC-002 and PRC-028 because the associated SAR does not provide this SDT with the authority to develop or adopt a definition that is currently unapproved. Moreover, once these definitions are approved and added to the Glossary of Terms there will be no need for inclusion of the definitions within these Reliability Standards.

DDR Requirements for PRC-002 & PRC-028

EEI also suggests that consideration should be given to modifying the requirements for dynamic Disturbance recording (DDR) equipment in both PRC-002 and PRC-028 in order to permit responsible entities to either install DDR equipment or Phasor Measurement Units (PMUs) since PMU equipment capture disturbance data at equal or better rates, and have the added benefit of synchronizing disturbance data from other locations utilizing existing network communications.

Data Retention Requirements for PRC-002 & PRC-028

EEI does not agree that the data retention requirements for PRC-002 (see Requirement R11 - 10 days) and PRC-028 (Requirement R7 – 20 days) should be different. Having two different data retention requirements for two Reliability Standards that have the exact same purpose is unjustified. Given the currently enforceable version of PRC-002 has a 10 day retention period, PRC-028 should have the same data retention period.

Reliability Coordinator Responsibilities for PRC-028

EEI suggests that the RC should be provided with oversight responsibilities for the placement of DDR equipment, even at IBR facilities. While EEI understands that the desire is to have DDR equipment at all IBR Facilities, as more of these facilities are added to the BPS, it is likely that there will be clusters of IBR facilities in some areas diminishing the need for this equipment at all of these facilities. We further note that the cost of this equipment is significant, and consideration should be given to the actual need and the RC would be the best judge to make this determination.

Colin Chilcoat - Invenergy LLC - 5,6

Answer	
Document Name	

Comment

Invenergy thanks the drafting team for their work and the opportunity to provide comments.

In previous response to comments, the drafting team suggested that “FERC Order 901 reinforces the approach taken by this SDT to require monitoring for all IBRs.” In fact, FERC Order 901 states that the more limited approach taken in PRC-002 “[has] been adequate to provide the data necessary to analyze major system events in the past.” Invenergy recommends the SDT develop a methodology similar to PRC-002 Attachment 1 that Transmission Owners and Reliability Coordinators can utilize to identify key nodes where disturbance monitoring equipment should be deployed.

The SER data required in R1.2.1. and R1.2.2. is generic and should be refined to target specific categories of fault codes and alarms so as not to overburden local storage of the data. On that point, 20 days of retrievable data is simply beyond the capabilities of some inverters. Invenergy recommends the data storage requirement in R7.1. be reduced to 10 days to align with PRC-002 R11.1. Furthermore, the various requested IBR Unit level data, sampling rates, time sync, and data format present many technical challenges for existing IBRs, some of which will have no solution other than replacement of the IBR Unit. As such, we suggested changes to R9 to account for these equipment limitations in response to Question 4.

Overall wording for the sections mentioned above for PRC-028 should be cleaned up. Terms like IBR should have formal definitions, outside of PRC-028 in the NERC Glossary of Terms.

Comment	

In previous response to comments, the drafting team suggested that “FERC Order 901 reinforces the approach taken by this SDT to require monitoring for all IBRs.” In fact, FERC Order 901 states that the more limited approach taken in PRC-002 “[has] been adequate to provide the data necessary to analyze major system events in the past.” Invenergy recommends the SDT develop a methodology similar to PRC-002 Attachment 1 that Transmission Owners and Reliability Coordinators can utilize to identify key nodes where disturbance monitoring equipment should be deployed.

The SER data required in R1.2.1. and R1.2.2. is generic and should be refined to target specific categories of fault codes and alarms so as not to overburden local storage of the data. On that point, 20 days of retrievable data is simply beyond the capabilities of some inverters. Invenergy recommends the data storage requirement in R7.1. be reduced to 10 days to align with PRC-002 R11.1. Furthermore, the various requested IBR Unit level data, sampling rates, time sync, and data format present many technical challenges for existing IBRs, some of which will have no solution other than replacement of the IBR Unit. As such, we suggested changes to R9 to account for these equipment limitations in response to Question 4.

There were 73 sets of responses, including comments from approximately 173 different people from approximately 115 companies representing 10 of the Industry Segments as shown in the table on the following pages.

All comments submitted can be reviewed in their original format on the project page.

If you feel that your comment has been overlooked, let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, contact Vice President of Engineering and Standards, Soo Jin Kim (via email) or at (404) 446-9742.

Questions

1. Do you agree with the modification in "Applicability, Section 4.2. Facilities" in PRC-002-5 and PRC-028-1?

2. Do you agree the modifications made in PRC-002-5 and new Standard PRC-028-1 are cost effective?

3. Do you agree with the Implementation Plan for revised PRC-002-5 and new Standard PRC-028-1?

4. Do you agree with introduction of Requirement R9 in PRC-028-1 requiring Entities of an applicable facility that is in commercial operation before the effective date of this standard that is not able to install disturbance monitoring equipment in accordance with Requirements R1 through R7 in the time provided for compliance to develop, maintain, and implement a Corrective Action Plan?

5. Provide any additional comments for the standard drafting team to consider, if desired.

The Industry Segments are:

1 — Transmission Owners

2 — RTOs, ISOs

3 — Load-serving Entities

4 — Transmission-dependent Utilities

5 — Electric Generators

6 — Electricity Brokers, Aggregators, and Marketers

7 — Large Electricity End Users

8 — Small Electricity End Users

9 — Federal, State, Provincial Regulatory or other Government Entities

10 — Regional Reliability Organizations, Regional Entities

1. Do you agree with the modification in “Applicability, Section 4.2. Facilities” in PRC-002-5 and PRC-028-1?

Ryan Quint - Elevate Energy Consulting - NA - Not Applicable - NA - Not Applicable, Group Name Elevate Energy Consulting

Answer	No
Document Name	

Comment

The applicability section of PRC-028-1 uses “BES” and then “Non-BES” and it is unclear why the SDT could not simply say Registered IBR, since the section is essentially duplicating the definition of Registered IBR pursuant to the changes in the ROP. Furthermore, the language does not appear to exactly match those changes and uses the phrase “that either have or contribute to an aggregate…” which seems vague. Therefore, we recommend developing a more straightforward and effective approach to defining this applicability rather than slightly modifying and using redundant language as compared to the ROP.

Response

Thank you for your comment. The phrase “that either have or contribute to an aggregate…” came directly from the latest version of the NERC ROP registration criteria for GO/GOP approved by the NERC Board of Trustees (Board) in February and filed with FERC on March 19, 2024. However, the language used in the Applicability section of the next draft has been revised. It will not include any in progress definitions or the non-BES IBRs affected by the Rules of Procedure revision process.

Andy Thomas - Duke Energy - 1,3,5,6 - SERC,RF

Answer	No

Comment

Duke Energy supports and recommends implementation of EEI provided comments.

Additionally, Duke Energy recommends changing PRC-028-1 Applicability - 4.2 from "a voltage greater than or equal to 60 kV" to "a voltage greater than or equal to 40 kV" to capture a larger aggregate of resources.

Response	
Thank you for your comments. The applicability was based on the latest version of the NERC Rules of Procedure (ROP) registration criteria for GO/GOP, and the intent was to include registered IBRs. IBRs connected at 40kV do not meet that registration threshold. However, the language used in the Applicability section of the next draft has been revised. It will not include any in progress definitions or the non-BES IBRs affected by the ROP revision process. See also response to EEI comments.

No objection to the applicability for PRC-002-5. However the language for PRC-028-1 the scope of what is applicable and what isnt for IBRs needs clarification. Also, the PRC-028 defines IBR which isn't in the NERC Glossary of Terms. It would be preferable to have this term defined before use in the PRC-028 standard.

NRG agrees with NAGF's comments concerning applicability language. The language proposed for applicability to PRC-002 is acceptable but not with regards to language proposed for PRC-028. NRG supports NAGF's comments that this needs to"*align with the pending NERC Glossary of Terms GO/GOP definition revisions*".

AZPS supports the proposed language contained in the Applicabiity section for PRC-002-5. However, we do not support the proposed language contained in the Applicability section of PRC-028-1 because the phrase “The Elements associated with” is too broad and subjective. AZPS would support the language if that phrase was removed.

Comment	
For PRC-002, yes. For PRC-028, no. There is no filtering or high impact assessment of the wide-open applicability scope of the facilities in Section 4.2 as there is in PRC-002 for synchronous units. Some engineering assessment is needed to determine which subset of IBR facilities may be the critical sites based on location, vendor susceptibility to trouble, or some other valid criterion rather than requiring every site to install DME.

Response	

Thank you for your comment. This SDT has been tasked not only with making sure data is available to analyze IBR response to BES disturbances similar to what PRC-002 does for synchronous machines, but also with ensuring disturbance data is available to evaluate IBR performance and validate IBR models per FERC Order 901. The requirements of the two standards cannot be directly compared.

Buckeye Power supports the comments made by ACES:

We at ACES appreciate the efforts of the SDT to deal with the nebulous topic that is IBRs. It is certainly a difficult task to create a new Reliability Standard and carefully craft the language thereof. We see no issue with the update to Section 4.2 of PRC-002-5 draft 2 and in fact appreciate the SDT’s conciseness in this area. However, we do have several concerns with Section 4 of PRC-0028-1 draft 2. It is our opinion that taking a blanket approach for TOs with respect to non-BES IBRs creates confusion, is not in line with the latest revisions to the NERC Rules of Procedure, and represents an unreasonable level of compliance scope creep.
It is our opinion that requiring the TO to install monitoring equipment on non-BES Elements is contradictory to the scope of the TO in the NERC Rules of Procedure. We believe that the role of the TO should be limited to Facilities as defined in the NERC Glossary of Terms (i.e., BES only).
As stated in the Technical Rationale, “It is not common for Transmission Owner to own the main power transformer and/or portions of collector system associated with an IBR generating facility.” As this is an uncommon occurrence, we do not believe that exceeding the scope of the TO’s registration represents any significant reduction in risk to the BES. Therefore, we recommend modifying Section 4 of PRC-028-1 as follows:
4. Applicability:
4.1 Functional Entities:
4.1.1 Transmission Owner that owns equipment as identified in section 4.2.1.
4.1.2 Generator Owner that owns equipment identified in section 4.2.
4.2 Facilities:
4.2.1 Elements associated with a BES Inverter-Based Resource(s)
4.2.2 Elements associated with a non-BES Inverter-Based Resource(s) that is:

4.2.2.1 Connected to the Bulk Power System, and 4.2.2.2 Meets the criteria for a Category 2 GO facility.

Answer	No

Document Name	
Comment	

Black Hills Corporation agrees with NAGF comments. NAGF supports the "Applicability, Section 4.2. Facilities" language proposed for PRC-002-5. The NAGF does not support the "Applicability, Section 4.2. Facilities" language proposed for PRC-028-1. The NAGF notes that the language for PRC-028-1 needs to align with the pending NERC Glossary of Terms GO/GOP definition revisions and therefore, recommend that the PRC-028-1 "Applicability, Section 4.2. Facilities" language be revised as follows:

"4.1.1. Transmission Owner that owns equipment as identified in Facilities section

4.1.2. Generator Owner that owns equipment as identified in Facilities section

Facilities: The Elements associated with (1) BES Inverter-Based Resources; (2) – to be defined and align with the pending NERC Glossary of Terms GO/GOP definition revisions."

Additionally, Black Hills Corporation agrees with the following comment from EEI:

IBR & Unit IBR Definitions:

The IBR and IBR Unit definitions should be removed from PRC-002 and PRC-028 because the associated SAR does not provide this SDT with the authority to develop or adopt a definition that is currently unapproved. Moreover, once these definitions are approved and added to the Glossary of Terms there will be no need for inclusion of the definitions within these Reliability Standards.

Colby Galloway - Southern Company - Alabama Power Company - 1,3,5,6 - SERC, Group Name Southern Company	

Answer	No
Document Name	
Comment	
Southern Company is in agreement with EEI and does not support the language contained in the Applicability section of PRC-028-1 because the phrase “The Elements associated with” is too broad and subjective. To address this concern, we suggest deleting that phrase (see below). Facilities: [***The Elements associated with]*** **REMOVE...** (1) BES Inverter-Based Resources; and (2) Non-BES Inverter Based Resources (IBRs) that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV. In addition, Southern Company recommends the applicability section in PRC-028, should include a clause for filtering or high impact assessment of the wide-open applicability scope of the facilities in Section 4.2 as there is in PRC-002 for synchronous units. Engineering assessment is needed to determine which subset of IBR facilities may be the critical sites based on location, vendor susceptibility to trouble, or some other valid criterion (risk-based approach) rather than requiring every site to install DME. Southern agrees with the Applicability changes proposed in PRC-002-5.

EEI does not object to the proposed language contained in the Applicability section for PRC-002-5, however, we do not support the language contained in the Applicability section of PRC-028-1 because the phrase “The Elements associated with” is too broad and subjective. To address this concern, we suggest deleting that phrase (see below). Facilities: **The Elements associated with** (1) BES Inverter-Based Resources; and (2) Non-BES Inverter Based Resources (IBRs) that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

Response	
Thank you for your comments. The SDT has removed “The Elements associated with” from the Applicability section of the next draft of PRC-028.	

Michael Johnson - Michael Johnson On Behalf of: Marco Rios, Pacific Gas and Electric Company, 3, 1, 5; Sandra Ellis, Pacific Gas and Electric Company, 3, 1, 5; - Michael Johnson, Group Name PG&E All Segments	
Answer	No
Document Name	
Comment	
:PG&E agrees with the changes to PRC-002 which explicitly exclude IBRs from the standard. PG&E does not agree with the changes to PRC-028-1 Applicability, Section 4.2 Facilities. PG&E concurs with the EEI comments which indicated they do not agree with the proposed language contained in the Applicability section of PRC-028-1 for the following reasons: 1 - Given the voltage identified with Non-BES IBRs, DPs should be added to the Functional Entities section. 2 - Applying the phrase all Elements to non-BES IBR units is too broad and subjective for use with these resources. 3 - Clarity is needed as to what is and is not in scope for IBR resources.

Capital Power supports the comments submitted by NAGF. Capital Power does not agree with the modification in "Applicability, Section 4.2. Facilities" for PRC-028-1. The language for PRC-028-1 needs to align with the pending NERC Glossary of Terms GO/GOP definition revisions. Capital Power recommends that the PRC-028-1 "Applicability, Section 4.2. Facilities" language be revised as follows: 4.1.1. Transmission Owner that owns equipment as identified in Facilities section 4.1.2. Generator Owner that owns equipment as identified in Facilities section **Facilities:** The Elements associated with (1) BES Inverter-Based Resources; (2) to be defined and align with the pending NERC Glossary of Terms GO/GOP definition revisions. Capital Power agrees with the modification in "Applicability, Section 4.2. Facilities" for PRC-002-5.

Comment	
For PRC-002, yes. For PRC-028, no. There is no filtering or high impact assessment of the wide-open applicability scope of the facilities in Section 4.2 as there is in PRC-002 for synchronous units. Some engineering assessment is needed to determine which subset of IBR facilities may be the critical sites based on location, vendor susceptibility to trouble, or some other valid criterion rather than requiring every site to install DME.

Dislikes 0	
Response	
Thank you for your comment. This SDT has been tasked not only with making sure data is available to analyze IBR response to BES disturbances similar to what PRC-002 does for synchronous machines, but also with ensuring disturbance data is available to evaluate IBR performance and validate IBR models per FERC Order 901. The requirements of the two standards cannot be directly compared.

Comment
We at ACES appreciate the efforts of the SDT to deal with the nebulous topic that is IBRs. It is certainly a difficult task to create a new Reliability Standard and carefully craft the language thereof. We see no issue with the update to Section 4.2 of PRC-002-5 draft 2 and in fact appreciate the SDT's conciseness in this area. However, we do have several concerns with Section 4 of PRC-0028-1 draft 2. It is our opinion that taking a blanket approach for TOs with respect to non-BES IBRs creates confusion, is not in line with the latest revisions to the NERC Rules of Procedure, and represents an unreasonable level of compliance scope creep. It is our opinion that requiring the TO to install monitoring equipment on non-BES Elements is contradictory to the scope of the TO in the NERC Rules of Procedure. We believe that the role of the TO should be limited to Facilities as defined in the NERC Glossary of Terms (i.e., BES only). As stated in the Technical Rationale, "It is not common for Transmission Owner to own the main power transformer and/or portions of collector system associated with an IBR generating facility." As this is an uncommon occurrence, we do not believe that exceeding the scope of the TO's registration represents any significant reduction in risk to the BES. Therefore, we recommend modifying Section 4 of PRC-028-1 as follows: 4. Applicability: 4.1 Functional Entities: 4.1.1 Transmission Owner that owns equipment as identified in section 4.2.1. 4.1.2 Either of the following Generator Owner types that owns equipment identified in section 4.2:. 4.1.1.1 Category 1 Generator Owner 4.1.1.1 Category 2 Generator Owner 4.2 Facilities: Elements associated with either of the following facility types: 4.2.1 Elements associated with a BES Inverter-Based Resource(s) connected to the Bulk Electric System

4.2.2 Elements associated with an non-BES Inverter-Based Resource(s) that is: 4.2.2.1 cConnected to the Bulk Power System, that and 4.2.2.2 mMeets the criteria for a Category 2 GO facility.

Kennedy Meier - Electric Reliability Council of Texas, Inc. - 2, Group Name ISO/RTO Council Standards Review Committee (SRC)	

Answer	No
Document Name	
Comment	
The ISO/RTO Council (IRC) Standards Review Committee (SRC) asks the SDT to clarify Figure 1 in the PRC-002-5 Technical Rationale (page 2) to ensure adequate data is available to facilitate analysis of Bulk Electric System (BES) Disturbances. Currently, the title for Figure 1: "Example to Clarify Applicability of PRC-002 Versus PRC-028" uses the word "versus" which seems to denote only one or the other standard is applicable. Therefore, the SRC asks the SDT to clarify Figure 1 and the supporting text to clearly indicate that data relative to breaker #3 is subject to both PRC-002-5 and PRC-028-1. This will serve to illustrate that Facilities that are part of protection schemes that overlap with Facilities covered by PRC-028-1 are not automatically excluded from PRC-002 applicability.	
Likes 0	
Dislikes 0	
Response	
Thank you for your comment. The intent of Figure 1 in the PRC-002-5 Technical Rationale is to illustrate that breaker 3 *is only* applicable to PRC-028 as an element associated with a registered IBR. This SDT has been careful to avoid setting up a situation of double jeopardy for registered entities with PRC-002 and PRC-028.

No objection to the applicability for PRC-002-5. However, in the language for PRC-028-1 the scope of what is applicable and what isn't for IBRs needs clarification. Also, the PRC-028 defines IBR which isn't in the NERC Glossary of Terms. It would be preferable to have this term defined before use in the PRC-028 standard.

If there is a small IBR resource (<20MVA) that is connected on a collector system that connects into a >=60kV system, it wouldn’t fall under PRC-028. If a few years later a separate entity connects another IBR-based resource on that same system that brings the aggregate MVA above the threshold of 20MVA, how would the original GO know that they now fall under the PRC-028 standard?	

Similarly, if there are multiple separate entities sharing a common point of interconnect on a >=60kV system and they each contribute to a >=20MVA aggregate, is it the expectation that each of these GOs be familiar enough with the surrounding system and generation resources to know that they fall under the requirements of this new standard? Specific to PRC-028-1 R2.1., if fault recording data is measured on the high-side of the main power transformer, current injected by the inverters may be swamped out by ground current from the main power transformer for ground faults on the transmission system if the main power transformer is configured to be a ground source for transmission faults. This has been observed at IBR plants connected to Idaho Power's system. If the goal is to record plant-level current injected by the inverters, we recommend changing R2.1 to obtain FR data at the low-side of the main power transformer. These are all challenges that could develop, if not addressed.

Thank you for your support and your comments. Your first two questions are outside the scope of this SDT and would be better addressed through the NERC IBR Registration Initiative as they deal with the latest version of the NERC ROP registration criteria for GO/GOP approved by the NERC Board in February and filed with FERC on March 19, 2024. Your concern with PRC-028-1 R2.1 is addressed in the "Rationale for Requirement 2" section of the PRC-028 Technical Rationale beginning on page 7.	
Thomas Foltz - AEP - 5	
Answer	Yes
Document Name	
Comment	
While AEP agrees with the modification of the Applicability sections, we believe it would provide consistency across standards if the BPS registration criteria was referenced for the applicable IBR entities. For example, in the most recent draft of PRC-029, they simply point to the	

BPS registration criteria. Might that be considered here also? If all standards are to meet the FERC 901 order, this might be an idea to consider.

Texas RE recommends revising Section 4.2 Facilities in proposed PRC-028-1 to clarify that both Elements at either BES Inverter-Based Resources or non-BES Inverter-Based resources as described are not required, but the scenario of either or both could exist. Texas RE proposes the following verbiage: 4.2. Facilities 4.2.1 The Elements associated with BES Inverter-Based Resources 4.2.2 The Elements associated with Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

Thank you for your comments. The Applicability section has been edited and reformatted for clarity in the next draft. The phrase "The Elements associated with" has been deleted from the Facilities section, because the elements are clarified in the body of the standard. The language used will not include the non-BES IBRs affected by the Rules of Procedure revision process.	
Steven Rueckert - Western Electricity Coordinating Council - 10, Group Name WECC Entity Monitoring	
Answer	
Document Name	
Comment	
WECC has no comments on PRC-002-5. For PRC-028-1, the use of the term "Element" to describe Facilities included per "Applicability, Section 4.2 Facilities" may confuse industry as the definition of Facility references "single" BES Element. Consider dropping the phrase "The Elements associated with" as the Requirements dictate which equipment is in scope (and the "Functional Entities" section mention equipment. Would consider saying for 4.1.1 and 4.1.2 "..that owns Facilities as identified in section 4.2." to provide more clarification.

SPP has a concern about the applicability of this question.	

In reference to PRC-002, the drafting team has not provided any analytical data to show industry the potential of any cost to implement this standard. We understand that there were some non-substantive changes in the standard that would suggest no major cost. From our perspective, the question can't be answered about cost effectiveness when there is no data to review.

Additionally, the implementation plan for PRC-028 states that the standard will need various phase-in dates for the standard; however, there is no data to show what the cost will be to implement changes in reference to addressing industry's compliance need. Some type of cost analysis report should be produced to help industry measure concerns like man hours as well as installation of equipment from a compliance perspective.

SPP recommends that the drafting team provide information on cost-effectiveness (if equipment installation is required and/or man hours required to implement) to help them get a better understanding of the implementation cost and the opportunity to provide quality feedback to NERC in reference to cost effectiveness.

The SDT has not provided a cost estimate nor tangible reliability indices improvements said modifications are projected to provide. No standard should be allowed if a cost/benefit analysis is not provided by the SDT. SDT frequently asks this question but never provides a cost/benefit justification. SDTs and others, usually simply says there is a reliability gap, or a risk, but does not provide estimated, tangible, reliability indices improvement numbers or a cost estimate to fill the alleged gap or risk.

It is ACES' opinion that the proposed changes to PRC-002 are minimal and therefore should have little to no cost to implement.	

As for the proposed PRC-028-1, we agree with the approach taken by the SDT to create a new Standard to specifically address IBR facilities; however, we strongly disagree with making this new standard inclusive of all applicable IBR facilities **regardless of risk to the BES**. In the opinion of ACES, a blanket approach requiring every applicable IBR facility to install SER, FR, and/or DDR capabilities is overly gratuitous. We believe that the industry's finite resources would best be spent by first ascertaining which IBR facilities would provide the most benefit to the BES, before selectively adding such capabilities. In summary, it is our recommendation that PRC-028-1 take a similar risk-based approach as is done in PRC-002-5.

Capital Power supports the comments submitted by NAGF. Capital Power notes that requiring data monitoring equipment at all IBR facilities is unnecessary and an excessive cost burden for existing IBR facility owners to bear which may lead to unintended adverse impacts to reliability. PRC-028-1 creates a more restrictive requirement on IBR facilities for data monitoring than for synchronous generation facilities. The requirement for data monitoring equipment should align between the two types of generating resources by requiring the TOP or applicable RE to indicate that monitoring equipment is necessary for the IBR facility.	

Additional clarification regarding the language “if capable of recording” used in Requirement 1.3 is requested to better understand the cost impacts of the proposed PRC-028-1.

PRC-028 should follow PRC-002 with criteria to filter the BES Elements required to provide SER and FR data, as well as DDR data. The cost of all IBR facilities providing this data seems excessive without some analysis first of which sites will provide the most benefit. Capturing all fault codes and all fault alarms under requirements R1.2 and R1.3 will also not provide much benefit vs. the cost.

The modifications include existing IBRs now and require monitoring specific elements that may be costly to implement especially for the units that are at a distance greater then or equal to 90% of the longest collector feeder. The proposed requirements for IBRs that will be installed are reasonable as new sites can be built to include that monitoring.

Colby Galloway - Southern Company - Alabama Power Company - 1,3,5,6 - SERC, Group Name Southern Company	
Answer	No
Document Name	
Comment	
Southern Company does not agree that the modifications are cost effective. For PRC-028-1, requiring DME equipment at all IBR facilities does not comport with the NERC risk-based approach. To incorporate an informed, risk-based approach to reliability, Southern would propose limiting the applicability through an engineering assessment to evaluate critical sites based on location, vendor susceptibility to trouble, or some other valid criterion. Southern agrees that the modifications made in PRC-002-5 are cost effective.

The modifications made in this PRC-028-1 draft are an improvement in cost expenditures from the initial version. However, the implementation costs for PRC-028-1 are still appreciably higher than PRC-002. With the additional data requirements and higher sampling rates, the costs are higher per facility for PRC-028 than PRC-002. With DME required to be implemented at all BES IBR facilities and many non-BES IBR facilities, the overall costs of PRC-028 exceeds PRC-002. The level of data recording required and the amount of data that is to be collected is significantly greater than PRC-002. Also, requiring all applicable Facilities to have a DDR seems excessive. For PRC-002, the threshold for DDR is governed by a notification by the RC of applicable BES Elements however there is no comparable Requirement in PRC-028 resulting in all IBR generation being obligated to provide DDR data.	

There is a significant cost associated with the installation and maintenance of a DDR and expecting an IBR to have this level of recording when they do not meet the BES definition may be overreaching. Could this be better addressed by TOs having DDRs that could capture more information from multiple generation facilities during an event?

Thomas Foltz - AEP - 5	
Answer	No
Document Name	
Comment	

For the reasons expressed below, AEP is concerned by the cost versus perceived reliability benefit of the new Standard PRC-028-1.

AEP does not consider the inclusion of “at least one IBR Unit, per collector bus, on any of the collector feeders that is connected at a distance greater than or equal to 90% of the longest collector feeder” in PRC-028 1.2 and 1.3 as cost effective. AEP questions the reliability benefit of the data these BES Elements will provide when considering the proposed requirements of PRC-029 to a performance-based ride-through standard that ensures generators remain connected to the BPS during system disturbances and the proposed requirements of PRC-030, Unexpected Inverter-Based Resource Event Mitigation. Requirements proposed in PRC-030 clearly make the GO responsible for the performance of the Invertor-Based Resources and IBR units it owns. The proposed obligation to collect and provide FR and SER data beyond the MPT bus(es) in PRC-028 is unwarranted.

PRC-028 does not currently limit the applicability of required data, while PRC-002 provides criteria which limits the BES Elements that are required to have dynamic disturbance recording data.

AEP does not believe capturing all fault codes and fault alarms listed in R1.2 and R1.3 under this standard would be beneficial to the Transmission Planner, Planning Coordinator, Transmission Operator, Balancing Authority, Reliability Coordinator, Regional Entity, or NERC as there are several OEMs with thousands of differing fault codes and fault alarms. AEP is concerned with the ability of these entities to understand or utilize the data in an timely manner. For some entities, this data would be more akin to SCADA quality data and not delivered with the timing nor accuracy of typical SER data. In addition, under PRC-030, we are asking the GO to resolve those issues. AEP recommends the SDT for PRC-028, PRC-029 and PRC-030 review each proposed standard obligation to ensure there is an integrated plan across these standards to achieve the goal of correcting the past performance of Invertor-Based Resources and IBR units. Having a coherent strategy document that explains how these three standards complement each other (and not be duplicative) would be beneficial.

Comment	
No, simply from a value-add perspective. The standard requires IBR owners to have a robust compliance program implemented as well as event data collection process in place. However, for example, Requirement R1.2 only requires fault codes, fault alarms, mode status change, etc., from a single IBR Unit far down the feeder. This is common practice for this information to be stored on the IBR Unit inverter or logging device. This will not help any event analysis process as it will not paint an adequate picture of the IBR facility's abnormal performance, if analyzed. At a minimum, fault codes should be available from every single IBR Unit within the facility. Lack of comprehensive data has significantly affected the ERO Enterprise's ability to conduct event analysis at many facilities over the past 7 years, as reported in numerous disturbance reports. The proposed standard would lead to inadequate data available at the inverter-level to do any useful event analysis and model validation, possibly leading to ongoing inconclusive root cause analyses. This would not be cost effective for industry.

Implementation Plan Says: R1-7: Current imp plan is 50% in 3 calendar years after effective date, 100% by 1/1/2030 R8: max 9 months after effective date R9: no later than 1/1/2029	

The phased in implementation plan needs to be given in a time frame after the effective date for the standard. Specifying a fixed date may not provide adequate time for the wide scale installation of DME at all IBR facilities. PRC-028, as written, will require much more DME than did PRC-002, and the implementation plan needs to recognize this difference and provide adequate time to accomplish.

Thank you for your comment. FERC Order 901 requires that PRC-028 be effective and enforceable no later than January 1, 2030. This SDT has no option to extend that deadline. The concession provided to industry is inclusion of a process allowing the GO or TO to request an extension through its Regional Entity for IBRs in commercial operation before the effective date of PRC-028-1. This was R9 in the previous draft but has been moved to the Implementation Plan.

Buckeye Power supports the comments made by ACES: As writen, PRC-028-1 is applicable to both BES and non-BES IBRs; consequently, we recommend updating the Implementation Plan to use the term "IBR facility(ies)" in lieu of the term defined term "Facility(ies)". From the perspective of ACES, the special stipulations surrounding commercial operation are overly complex and unnecessary. For example, assume PRC-028-1 is approved by FERC and becomes effective 10/1/2024. Using the provided example, the end of the first calendar year that is 12 months following the effective date of the standard would be 12/31/2025. Thus any facilities entering commercial operation prior to 10/1/2025 would have until 12/31/2025 to be compliant while any facilities entering commercial operation on or after 10/1/2025 must be compliant immediately. We do not believe that a delay of only 1 day should move the compliance deadline forward by 3 calendar months. We recommend removing these special stipulations and instead address this specific case using a strategy akin to that used for existing facilities. We suggest the following language: "For facilities entering commercial operation a er the effective date: Entities shall comply with Requirements R1 through R7 within three (3) calendar years of the effective date of PRC-028-1."

Although the PRC-028 Implementation Plan mirrors PRC-002-2 Implementation Plan, PRC-028 requires all BES IBRs and many non-BES IBRs to have DME installed. If the GO has a large IBR fleet, numerous DME installations would be required with a demanding project schedule. With	

the large amount of DME required to be installed per PRC-028, OEMs might not be able to provide GOs with a timely supply of DME equipment.

Comment	
TransAlta recommends removing the stipulations surrounding commercial operation. There are associated project execution risks with making design changes later in a project. TransAlta would prefer to have the flexibility to install and/or configure monitoring equipment after commercial operation. Thus, TransAlta recommends updating the implementation plan to specify compliance with Requirements R1 through R7 at 50% of plants/Facilities within 3 calendar years and 100% within 6 calendar years for all plants/Facilities regardless of commercial operation date.

The PRC-028-1 standard as written, requires 50% completion within (3) calendar years and 100% completion of R1-R7 by 1/1/2030, R9 by 1/1/2029 and R8 a maximum of 9 months after the effective date. The phased-in implementation plan needs to be given in a timeframe after the effective date for the standards. Specifying a fixed date may not provide adequate time for the wide scale installation of DME at all applicable IBR facilities. PRC-028, as written, will require much more DME than PRC-002 did, and the implementation plan needs to recognize this difference and provide adequate time to accomplish. Traditional language for implementation plans in other Standards have provided a certain period after implementation instead of a fixed date (e.g. within 6 calendar years of the effective date…).

Six years would be a sufficient amount of time to plan and budget for the procurement and installation of the DDR equipment barring any supply chain risk complications or any other delays. USV recognizes the FERC directive mandating completion by 1/1/2030, however, due to	

many of the IBR sites having strict language when dealing with manufacturers warranty and having to rely on third parties, it may result in additional complications that could delay the installation and setting up of this highly specialized equipment.

4. Do you agree with introduction of Requirement R9 in PRC-028-1 requiring Entities of an applicable facility that is in commercial operation before the effective date of this standard that is not able to install disturbance monitoring equipment in accordance with Requirements R1 through R7 in the time provided for compliance to develop, maintain, and implement a Corrective Action Plan?

Rhonda Jones - Invenergy LLC - 5,6	
Answer	No
Document Name	
Comment	

Invenergy **suggests the below language** for R9:

R9. Each Generator Owner and Transmission Owner with a documented equipment limitation that would prevent an applicable IBR that is in commercial operation prior to the effective date of this standard from installing disturbance monitoring equipment in accordance with Requirements R1 through R7 shall communicate each equipment limitation to the Regional Entity.

9.1. Each Generator Owner and Transmission Owner shall include in its documentation:

- 9.1.1. Identifying information of the applicable Element and cause of the limitation
- 9.1.2. Which aspect(s) of disturbance monitoring the Element would be unable to meet

9.2. Each Generator Owner and Transmission with a previously communicated equipment limitation that repairs or replaces the equipment causing the limitation shall document and communicate such equipment change to the Regional Entity within 30 days of the equipment change.

Likes 0	
Dislikes 0	
Response	

Thank you for your comments. The intent of R9 was to allow more time for entities that may have circumstances beyond their control that delay installation of DME beyond the stated implementation deadline. It was not meant to provide technical feasibility exceptions such as in this suggested revision. FERC Order 901 requires disturbance monitoring data from the IBRs identified in the Applicability section of PRC-028.

Wayne Sipperly - North American Generator Forum - 5 - MRO,WECC,Texas RE,NPCC,SERC,RF

Response

Thank you for your comment. The requirements for new and existing IBRs are the same, but the SDT recognizes that retrofitting existing equipment can be more difficult than including the DME as part of a capital project. R9 did not allow for ongoing exceptions. The intent of R9 was to allow more time for entities that may have circumstances beyond their control that delay installation of DME beyond the stated implementation deadline.	
Patricia Ireland - DTE Energy - 4	
Answer	No
Document Name	
Comment	
The idea of allowing a corrective action plan for compliance challenges at existing operations is a good one however the circumstance that would allow for use of the CAP is poorly defined. What exactly is "not able to install" ? Does that mean within reason? cost effectively? Not able to install regardless of time or money is a very high bar and essentially unhelpful.

Thank you for your comments. The process for seeking an extension has been heavily revised and moved to the Implementation Plan for the next draft. These extensions will have to be approved by the Regional Entity.	
Kennedy Meier - Electric Reliability Council of Texas, Inc. - 2, Group Name ISO/RTO Council Standards Review Committee (SRC)	
Answer	No
Document Name	
Comment	
The SRC is concerned that the requirement as written may be overly broad. To address this, examples of legitimate reasons that an entity may be unable to “install disturbance monitoring equipment” should be provided in the Technical Rationale.	

Alternatively, this concern could be addressed by revising the standard to require all installations to be completed within the parameters of the Implementation Plan for PRC-028.

Requiring comprehensive DME for SER, FR, and DDR at all "old" facilities is unnecessary. The investigations performed into past grid disturbances have documented the trouble that legacy facilities have been experiencing. Focusing on new equipment that has been designed and built to better ride-thru system disturbances will provide more benefit and value to system reliability. R2.3 and R3.3 and their subparts are unnecessary as these devices have not been identified as causing any problems that suggest they need to be monitored.

PG&E does not agree with the language proposed. PG&E agrees with the following EEI comments: 1 - Given the voltage level identified in the Applicability section of PRC-028, DPs will likely own applicable equipment that will be impacted. For this reason, we suggest that DPs be added to R9. 2 - The use of "applicable facility" in R9 should be removed because this term has no defined meaning. To resolve this issue, we suggest replacing "of an applicable facility" with "that own equipment as identified in "Section 4.2 (Facilities)". 3 - Disturbance Monitoring Equipment is a NERC defined term and should be capitalized to ensure that responsible entities understand the scope of their responsibilities under this Reliability Standard.	
Likes 0	
Dislikes 0	

Response	
Thank you for your comments. See the response to EEI comments. 1 – The language used in the Applicability section of the next draft has been revised and will not include the non-BES IBRs affected by the Rules of Procedure revision process. 2 – The SDT will review the standard for use of “facility”. The NERC standard template uses “Facilities” under the “Applicability” section, and the SDT intended the phrase “applicable facilities” to refer back to that section. However, the SDT recognizes that this can cause confusion when “Facilities” is also a NERC Glossary term. 3 – The SDT intends to review all documents for NERC Glossary terms and associated capitalization. Thank you for noting this one.	
Steven Rueckert - Western Electricity Coordinating Council - 10, Group Name WECC Entity Monitoring	
Answer	No
Document Name	
Comment	
Conceptually, no, WECC believes there should not be a compliance loophole built into a Reliability Standard. General considerations mention three (3) calendar years to accommodate normal outage schedules. As written the entity may only have to outage one (1) IBR unit per collector feeder (and in some cases maybe only (1) IBR Unit for the entire Inverter-Based Resource), to install equipment in Parts 1.2/2.2. (as an example as it is not clear where that data is being recorded). Granted, SER/FR on circuit breakers, if not already installed at Part 1.1 locations require a complete outage but is it not already industry standard to have that capability on breakers in that voltage class? Waiting until 2029 to create a CAP per the Implementation Plan does not support reliable operations (and at least two “normal outage schedule” periods will have passed since the official start of this Project to accommodate the SER/FR additions if not present.) Part 9.2 allows too broad of a scope to be considered reliable with no support (what is “beyond the control” and who defines that?). Submitting the CAP to the Regional Entity with a request to extend time provided for compliance does not support reliability. The Regional Entity does not necessarily have the authority to grant extensions for compliance. Timelines for compliance are dictated by Implementation Plans or the Requirement language itself. There are no required timelines for the CAP which could equate to a CAP that is never implemented. WECC appreciates the idea of striking a balance between cost and reliability (with compliance impacts) but as written the reliability aspect will suffer to support being compliant.

Eric Sutlief - CMS Energy - Consumers Energy Company - 3,4,5 - RF	
Answer	No
Document Name	
Comment	
Section R3.2 seems to specify that a Schweitzer level sampling rate of 64 samples per cycle needs to be implemented which it does not appear to be within the capabilities of the event recording generated by the turbine controllers. The minimum requirements appear to be the AC and Frequency values at that high of a resolution. The GE documentation suggest the points and sampling rate of the trip files generated vary. Even if the resolution we need is possible, it may not have the correct setting dependent on the event that is recorded in the trip file. The fastest sampling rate in the GE trending software is at a 10 milli-seconds, which is significantly less than what would be required for 64 samples per 1 hz.

Colby Galloway - Southern Company - Alabama Power Company - 1,3,5,6 - SERC, Group Name Southern Company	
Answer	No
Document Name	
Comment	
R9.5 requires Entities submit the CAP to the Regional Entity. Entities will require guidance on the process with input from each Regional Entity. This is an administrative process that could cause undue delay in the CAP process while managing time constraints. It would be more	

efficient for the Entity to create and maintain its own CAP similar to PRC-026 R3 and R4. The CAP can be made available during periodic audits. There is no demonstration of how “reporting” CAPs to Regional Entities adds to system Reliability.

Requiring comprehensive DME for SER, FR, and DDR at all existing facilities is unnecessary. The investigations performed for past grid disturbances have documented the trouble that legacy facilities have been experiencing. Focusing on new equipment that has been designed and built to better ride-thru system disturbances will provide more benefit and value to system reliability. R2.3 and R3.3 and their subparts are not necessary as these devices have not been identified as causing any problems that suggest they need to be monitored.

Southern Company agrees with EEI suggested modifications to the text:

1. The use of “applicable facility” in R9 should be removed because this term has no defined meaning. To resolve this issue, it is suggested replacing “of an applicable facility” with “that own equipment as identified in Section 4.2 (Facilities)”.

2. Disturbance Monitoring Equipment is a NERC defined term and should be capitalized in order to ensure that responsible entities understand the scope of their responsibilities under this Reliability Standard.

SIGE supports the inclusion of Requirement R9; however, SIGE requests a clarification regarding disturbance monitoring equipment referenced in Requirement R9. Was the Standard Drafting team’s use of the phrase “disturbance monitoring equipment” intended to reference the equipment covered by the NERC defined term “Disturbance Monitoring Equipment”? If so, SIGE recommends capitalizing the proposed language to clarify the intent.

Additionally, SIGE recommends two revisions to R9: 1) revise R9 to mirror the language in section 4.2 Functional Entities and 2) align the Applicability section reference with other NERC Standards. Recommended revisions are shown below:

R9. Each Transmission Owner and Generator Owner ***that owns equipment as identified*** in ***Applicability*** section ***4.2*** that is in commercial operation before the effective date of this standard that is not able to install disturbance monitoring equipment in accordance with

Requirements R1 through R7 in the time provided for compliance shall develop, maintain, and implement a Corrective Action Plan to provide the required capability. For each Corrective Action Plan, the Transmission Owner and Generator Owner shall:

If the standard and implementation plan were to pass in its current form, we do not feel that 2030 would be a sufficient amount of time to implement DDR recording at all sites that meet the applicability section of PRC-028. The procurement and installation process is time-consuming due to the limited amount of vendors and having to do additional efforts for supply chain risk, etc.	
Likes 0	
Dislikes 0	
Response	
Thank you for your comments. The SDT recognizes the possibility of supply chain issues. FERC Order 901 requires that PRC-028 be effective and enforceable no later than January 1, 2030. This SDT has no option to extend that deadline. The concession provided to industry is inclusion of a process allowing the GO or TO to request an extension through its Regional Entity for IBRs in commercial operation before the effective date of PRC-028-1. This was R9 in the previous draft but has been moved to the Implementation Plan. Supply chain issues could be cited under subpart 1.3 of the extension request.

SRP agrees with industry that while these changes provide value in evaluating facilities when there are disturbances, however it is also critical to assign responsibility to IBR facilities and their owners to enforce these requirements.

Thank you for your support and comment. The SDT will review the standard for use of “facility”. The NERC standard template uses “Facilities” under the “Applicability” section, and the SDT intended the phrase “applicable facilities” to refer back to that section. However, the SDT recognizes that this can cause confusion when “Facilities” is also a NERC Glossary term.

1) In 4.3.2 of PRC-002-5, we need to clarify this trigger condition “Phase undervoltage or overcurrent”. Does “phase undervoltage” refer to phase-phase or phase-to-neutral undervoltage”? 2) Under “Facilities” of 4.1 in PRC-028-1, how was this 60 kV threshold determined? 3) In section 3.1.3.2, section 3.2.3.1 and section 3.3.3.2 of PRC-028-1, we need to clarify this trigger condition “AC phase overvoltage and undervoltage”. Does “phase undervoltage” refer to phase-phase or phase-to-neutral undervoltage”? 4) In R8 of PRC-028-1, “Submit a Corrective Action Plan (CAP) to the Regional Entity and implement it.” should probably read “Submit a Corrective Action Plan (CAP) and a CAP implementing schedule to the Regional Entity”?

It is unclear why NERC is so adamant about not adopting IEEE standards within the NERC standards, and has stated this in multiple forums related to the adoption of IEEE 2800-2022. However, then now proposes to adopt IEEE C37.111 COMTRADE standard within the new PRC-028-1 proposed standard. Inconsistency regarding NERC's approach and opinion in this area leaves industry confused, uncertain, and concerned regarding whether NERC has a clear and effective standards improvement strategy.

BC Hydro appreciates the drafting team efforts and the opportunity to comment. PRC-028-1 R1 requires an entity to record data "when triggered by ride-through operation". BC Hydro requests that drafting provides additional clarity on or criteria to determine what would constitute "ride-through operation" as it pertains to an applicable entity's compliance obligation to identify all events in scope of R1 Part 1.2. Requirement R3 Footnote 3 on "main power transformer" should use IBR instead of the undefined term "dispersed power producing resources". BC Hydro suggests that instead of this wording, which is indeed referenced in the inclusion I4 of the BES definition, the new IBR Glossary Term is preferrable. Requirement R7 requires that all SER, DDR and FR data be provided upon request by an applicable entity. BC Hydro suggests that all data may not be feasible or even required and recommends instead that the provision of the SER, DDR and FR data be done in accordance with a qualified request and within the bounds set by Part 7.1 through Part 7.5 of Requirement R7. PRC-028-1 Requirement R8 and PRC-002-5 R12 second bullet as written requires that a CAP will need to be implemented within 90 days. The VSL Table and the Technical Rationale provide clarity that it is only the CAP that requires submission within 90 days for the situations where an entity is unable to restore capability within 90 days. BC Hydro recommends that the drafting team revises the PRC-028-1 R8 and PRC-002-5 R12 wording to clarify that the 90-day timeline is only mandated for the CAP submission. Also important to clarify within the language of the Requirement is whether the 90-day timeline is based on business or calendar days. BC Hydro recommends that the implementation plan for PRC-028-1 be coordinated with the approval of the approval of the IBR and IBR Unit definitions.

Response	
These requirements at the unit level have been removed from the latest draft. This footnote has been revised. Requirement R7 is bounded by subparts 7.1 through 7.6 as the requirement states "in accordance with…" PRC-028-1 Requirement R8 and PRC-002-5 R12 have been revised for clarity. Due to the time constraints of FERC Order 901, development of PRC-028 cannot be put on hold until the IBR related glossary terms are finalized. However, the language used in the Applicability section of the next draft has been revised. It will not include any in progress definitions or the non-BES IBRs affected by the Rules of Procedure revision process.

This comment applies to PRC-028-1 R5.2. Idaho Power presently requires existing and future IBRs connecting to its transmission system to provide plant-level PMU data. This data is streamed to a central data concentrator in real time, where it is then stored in a central data historian. The message rate has been chosen to be 30 samples per second due to limitations of the communications systems. Moving this existing system to 60 samples per cycle to obtain this data may result in significant re-design and additional costs.

Thomas Foltz - AEP - 5	
Answer	
Document Name	
Comment	
AEP has concerns with several of the requirement differences between PRC-002 and PRC-028 such as ten day data retention vs. twenty day data retention, output recording rate of electrical quantities of at least 30 times per second versus 60 times per second, synchronized clock accuracy within +/- 2 milliseconds versus +/- 1 millisecond, etc.. The Technical Rational document is silent on the reason for these differences. These changes are not insignificant, and having differing requirements for synchronous vs IBR technologies, introduces a risk for human performance error. PRC-002 Attachment 1 limits the BES buses required to record SER and FR data. During the recent system disturbance events, were any IBR facility buses required to capture SER and FR data under PRC-002? What is the reliability-driven rationale behind requiring *all* IBR facility buses to capture SER and FR data in PRC-028 as opposed to a targeted set based on an engineering analysis as done for PRC-002? PRC-002 and PRC-028 should both be revised to make it clear that the ability to provide data in CSV format is for DDR or PMU data *only.*	
Likes 0	
Dislikes 0	

Response
Thank you for your comments. It has been unusual for IBR buses (as defined in PRC-002) to meet the top 10% calculation criteria in PRC-002 Attachment 1, particularly since the Attachment 1 criteria only pertain to Transmission Owners, but some were required to be monitored under PRC-002. This SDT has been tasked not only with making sure data is available to analyze IBR response to BES disturbances similar to what PRC-002 does for synchronous machines, but also ensuring disturbance data is available to evaluate IBR performance and validate IBR models per FERC Order 901. The requirements of the two standards cannot be directly compared. Please refer to the PRC-028 Technical Rationale for more details. The requirements are discussed there. The SDT has made this revision regarding data formatting in the next draft.

Rachel Coyne - Texas Reliability Entity, Inc. - 10	
Answer

Comment

Texas RE has the following additional comments:

- Texas RE suggests removing the terms “machine based” from PRC-002-5 Requirement Part 5.1.1 as simply stating “Synchronous generating resource” is sufficient.
- In PRC-028-1 Standard, Requirement Part 2.1.3 should specify Real and reactive power on a three-phase basis*:*
    - 2.1.3. Real and reactive power on a **three-phase basis.**
- In PRC-028-1 Standard, Requirement Part 2.3.3 should remove ‘Real’ from the requirement and specify the reactive power on a three-phase basis:
    - **2.3.3. Real and Reactive power on three-phase basis.**
- Remove the ending parathesis in Requirement Part 3.2.2.
- Texas RE recommends the SDT consider specifying the trigger settings for ‘overfrequency and underfrequency’ levels to be consistent with the PRC-024 requirements:

- **3.2.3.2 Overfrequency level at minimum 60.6 Hz and underfrequency level at 59.4 Hz**
- Texas RE recommends the SDT consider including an option for existing registered entities that have IBR units that are incapable of recording data to provide technical justification for the IBR unit's inability to record based on OEM specifications or based on an independent engineering assessment.

Likes 0	
Dislikes 0	

Response

Thank you for your comments.

- This SDT didn't touch any of the data requirements in the PRC-002 standard.
- The SDT has made this revision.
- This is now R 2.2.3, and the SDT has made the suggested revision.
- This requirement has been removed
- This requirement has been removed
- FERC Order 901 requires that disturbance data is not only available to analyze IBR response to BES disturbances, but also to evaluate IBR performance and validate IBR models. That directive does not leave room for exceptions. Individual unit requirements have also been removed from the latest draft.

David Vickers - David Vickers On Behalf of: Daniel Roethemeyer, Vistra Energy, 5; - David Vickers

Answer	
Document Name	

Comment

Section 1.2 and 1.3: While IBR settings are important when analyzing events, the various settings and modes may not be recorded by the inverter data recorder. At a minimum 1.3.3 and 1.3.4 should be removed for IBR units that are in commercial operation since they would have not been designed to meet the requirement.

Section 2.1.3: PRC-002 does not require real and reactive power for FR data, the same should apply for PRC-028, Most fault recording equipment does not record power or frequency in FR records, this is a calculated value and is recorded in DDR/Continuous data. Software can be used to calculate power using FR data, power and frequency would not be in the comtrade file.

Section 2.3.3: Same comment as 2.1.3

Section 3.2..2 Existing IBRs may not be able to store 2 second event records at a 64 samples/cycle.

Section 3.2.3.2 Frequency triggers should not be required for FR data. They can be difficult to set and trigger erroneous events which can fill up storage. Frequency triggers should only be required for continuous/DDR recording.

Section 5.2 Not all existing install equipment may be able to meet the 60 samples/second recording rate. Requirement in PRC-002 is 30 samples/second.

Section 7.1 Existing IBRs may not be able to store FR or DDR data for 30 days.

Likes 0	
Dislikes 0	

Response

Thank you for your comments.

All individual unit requirements have been removed from the latest draft.

This SDT has been tasked not only with making sure data is available to analyze IBR response to BES disturbances similar to what PRC-002 does for synchronous machines, but also with ensuring disturbance data is available to evaluate IBR performance and validate IBR models per FERC Order 901. The requirements of the two standards cannot be directly compared. Also, the requirement is to have data sufficient to determine the quantities, so calculated versus recorded is acceptable.

All individual unit requirements have been removed from the latest draft.

All individual unit requirements have been removed from the latest draft.

Please see PRC-028 Technical Rationale for justification of this recording rate and above response for why PRC-028 requirements cannot be directly compared to PRC-002.

All individual unit requirements have been removed from the latest draft, and the 20 day requirement should be less of an issue with equipment used to monitor at the plant level.

Ben Hammer - Western Area Power Administration - 1

Comment	

For R8, it is not clear whether the CAP implementation referenced in the 2nd bullet item must be complete at the end of the 90 days specified in the R8 text.   If so, what then is the difference in the first bullet (restoring the capability) and why might the Regional Entity need to know of a repair plan in progress that will be completed before the 90-day limit?

In R9.5 does the request to extend the time provided refer to any changes made to an original CAP timeline? (there are no other deadlines for completing any R9 CAP)

In R1.2 and R1.3 remove the unneeded brackets [ ] surrounding “the effective date of this standard”.

CAPS documentation specifications and submittals to the RE are purely administrative and should be removed from the requirement list. A simple requirement to fix any faulty equipment will accomplish the intent of R8 & R9.   An audit can check to ensure that all broken equipment was handled properly.

What dictates a “ride-thru” event in R1?   The IBR mode status?

Why is R2.2.1 needed to be the IBR Unit transformer HV side versus the LV side?

Comments on cost:

Based on research for the last ballot on the costs of having this on each feeder at a wind farm. This doesn't include solar IBRS.

In addition, the contributing entity estimates that the cost of installing DFR equipment on the high side of a pad mounted transformer at the base of a wind turbine in the last 10% of an existing wind turbine feeder will be $300-450k or 2-3 times the cost of installing the same equipment in an existing substation. For example, one wind farm has 14 feeders so installing this equipment on every feeder there would cost an estimated $4.2-6.3 million dollars for that one facility. EIA data shows that there are currently 604 wind farms with a size of 75 MW or greater with a total 975549 MW capacity. Assuming there is a feeder for every 10-20 MW worth of wind turbines and the estimate per installation, the range between $1.463-$2.195 billion dollars just to install these at the end of every feeder and does not include the substation installations that would be required. This estimate is only for feeders at wind turbines and does not include any estimates for solar farms or other IBRs so the total cost.

Response	
Thank you for your comments. R8 has been revised for clarity, and the same revisions have been applied to PRC-002-5, R12. In the next draft, the process for seeking an extension has been heavily revised and moved from R9 to the Implementation Plan. These brackets are part of the NERC standard development process. Once the standard is approved by FERC, the phrase “the effective date of this standard” is replaced by the actual effective date of the standard. R9 did not deal with faulty equipment. The intent of R9 was to allow more time for entities that may have circumstances beyond their control that delay installation of DME beyond the stated implementation deadline. Requests for extension must be approved by the Regional Entity, so they would not be valid without being filed. All individual unit requirements have been deleted from the latest draft.	
Wendy Kalidass - U.S. Bureau of Reclamation - 5	
Answer	

Document Name	
Comment	

Reclamation does not agree with the modifications to the wording of BES Elements in R6 and R7 in the "Violation Severity Levels" section. 'Element' is sufficiently defined in the NERC Glossary of terms and 'BES Element' encompasses the required equipment (elements) for Disturbance Monitoring. Reclamation recommends keeping the original wording "for all applicable BES Elements".

Reclamation concurs that all IBR resources should have and maintain their own separate standards.

Likes 0	
Dislikes 0	

Response

Thank you for your comments. The revision was necessary, because some of the circuit breakers in the monitoring requirements are not BES Elements, specifically the collector circuit breakers.

Ryan Strom - Ryan Strom On Behalf of: Jason Procuniar, Buckeye Power, Inc., 4, 5, 3; Kevin Zemanek, Buckeye Power, Inc., 4, 5, 3; Tom Schmidt, Buckeye Power, Inc., 4, 5, 3; - Ryan Strom, Group Name Buckeye Power Group

Comment	

Buckeye Power supports the comments made by ACES:

It is unclear as to what constitutes a "ride-through operation" of an IBR Unit in R1.2 and R1.3. Is this intended to be a reference to "no trip zone" identified in PRC-024? If so, as PRC-024 is not currently applicable to non-BES IBRs, how is this iden fied for those facilities? We believe additional guidance is needed for these requirements.

Comment	
Black Hills Corporation agrees with comments from NAGF and EEI, included here:	

The NAGF notes that Project 2021-04 needs to be closely coordinated with other active NERC IBR related projects to ensure there is no conflict and/or duplication of efforts. The NAGF recommends that NERC publish a guideline/roadmap to demonstrate how all the on-going and pending IBR work activities fit together so that industry can understand how these efforts will enhance BPS/BES reliability. For example, why is it necessary for PRC-028 to be effective prior to other new IBR standards (i.e., PRC-029/PRC-030/PRC-031)?

EEI offers the following additional comments:

DDR Requirements for PRC-002 & PRC-028

EEI suggests that consideration should be given to modifying the requirements for dynamic Disturbance recording (DDR) equipment in both PRC-002 and PRC-028 in order to permit responsible entities to either install DDR equipment or Phasor Measurement Units (PMUs) since PMU equipment capture disturbance data at equal or better rates, and have the added benefit of synchronizing disturbance data from other locations utilizing existing network communications.

Data Retention Requirements for PRC-002 & PRC-028

EEI does not agree that the data retention requirements for PRC-002 (see Requirement R11 - 10 days) and PRC-028 (Requirement R7 – 20 days) should be different. Having two different data retention requirements for two Reliability Standards that have the exact same purpose is unjustified. Given the currently enforceable version of PRC-002 has a 10 day retention period, PRC-028 should have the same data retention period.

Reliability Coordinator Responsibilities for PRC-028

EEI suggests that the RC should be provided with oversight responsibilities for the placement of DDR equipment, even at IBR facilities. While EEI understands that the desire is to have DDR equipment at all IBR Facilities, as more of these facilities are added to the BPS, it is likely that there will be clusters of IBR facilities in some areas diminishing the need for this equipment at all of these facilities. We further note that the cost of this equipment is significant, and consideration should be given to the actual need and the RC would be the best judge to make this determination.

AEPC thanks you for the opportunity to comment and has signed on to ACES comments. It is unclear as to what constitutes a “ride-through operation” of an IBR Unit in R1.2 and R1.3. Is this intended to be a reference to “no trip zone” identified in PRC-024? If so, as PRC- 024 is not currently applicable to non-BES IBRs, how is this identified for those facilities? We believe additional guidance is needed for these requirements.

For R8, it is not clear whether the CAP implementation referenced in the 2nd bullet item must be complete at the end of the 90 days specified in the R8 text. If so, what then is the difference in the first bullet (restoring the capability) and why might the Regional Entity need to know of a repair plan in progress that will be completed before the 90-day limit?

In R9.5 does the request to extend the time provided refer to any changes made to an original CAP timeline? (there are no other deadlines for completing any R9 CAP)

In R1.2 and R1.3 remove the unneeded brackets [ ] surrounding “the effective date of this standard”.

CAPS documentation specifications and submittals to the RE are purely administrative and should be removed from the requirement list. A simple requirement to fix any faulty equipment will accomplish the intent of R8 & R9. An audit can check to ensure that all broken equipment was handled properly.

What dictates a “ride-thru” event in R1? The IBR mode status?

Why is R2.2.1 needed to be the IBR Unit transformer HV side versus the LV side?

Based on research for the last ballot on the costs of having this on each feeder at a wind farm. This doesn't include solar IBRS. MRO NSRF estimates that the cost of installing DFR equipment on the high side of a pad mounted transformer at the base of a wind turbine in the last 10% of an existing wind turbine feeder will be $300-450k or 2-3 times the cost of installing the same equipment in an existing substation.

It is not understood what drives the 2 seconds length and the 64 samples/sec recording requirements. Existing FR equipment typically has a maximum recording time of 60 cycles and maximum of 16 or 32 samples/sec. Both of these are not consistent with similar requirements of PRC-002 (30 cycles & 16 samples/sec).

3.2 will be difficult to achieve for older IBRs. FR recording equipment will need to be added to meet this requirement. Meeting these requirements at the inverter/controller level will be challenging.

MRO NSRF recommends that the SDT reach out to various manufacturers to confirm the equipment capability and if any changes/updates that may be necessary for equipment can meet this requirement will become available.

MRO NSRF recommends that the SDT consider equipment limitation be introduced similar to PRC-024 where equipment limitation is allowed but adequately reported.

MRO NSRF recommends the SDT consider alternative methods/requirements be provided as an option for the equipment that are not capable of meeting the recording requirements. Refer to

PRC-025, Options 5a and 5b as an example, where 5b option was introduced to eliminate costly replacements.

Response

Thank you for your comments.

R8 has been revised for clarity, and the same revisions have been applied to PRC-002-5, R12.

In the next draft, the process for seeking an extension has been heavily revised and moved from R9 to the Implementation Plan.

These brackets are part of the NERC standard development process. Once the standard is approved by FERC, the phrase “the effective date of this standard” is replaced by the actual effective date of the standard.

R9 did not deal with faulty equipment. The intent of R9 was to allow more time for entities that may have circumstances beyond their control that delay installation of DME beyond the stated implementation deadline. Requests for extension must be approved by the Regional Entity, so they would not be valid without being filed.

All individual unit requirements have been deleted from the latest draft.

In summary response to your remaining comments:
This SDT has been tasked not only with making sure data is available to analyze IBR response to BES disturbances similar to what PRC-002 does for synchronous machines, but also with ensuring disturbance data is available to evaluate IBR performance and validate IBR models per FERC Order 901. The requirements of the two standards cannot be directly compared. In setting the data recording parameters, the SDT has reviewed the NERC disturbance reports, consulted with manufacturers, and considered the burden to industry. The data requirements are addressed in the PRC-028 Technical Rationale. All individual unit requirements have been removed from the latest draft, and meeting these requirements should be less of an issue with equipment used to monitor at the plant level.

We recognize that IBR's pose a reliability risk and that being able to monitor the events and have in depth data for a trip is very important. However, the granularity of the information being required by PRC-028 does not seem to be in step with what PRC-002 is asking for. Could this data be captured by TOs who have a greater situational awareness?

Likes 0	
Dislikes 0	

Response

Thank you for your comment. FERC Order 901 directs that data not only be available to analyze IBR response to BES disturbances similar to what PRC-002 does for synchronous machines, but also with ensuring disturbance data is available to evaluate IBR performance and validate IBR models. The requirements of the two standards cannot be directly compared. The responsible party for the required data is the equipment owner registered with NERC, which in most cases is going to be the GO.

Alison MacKellar - Constellation - 5

Answer

The following comments are for the PRC-002-5 standard: 1) Replace "Hydro-Québec Interconnection" with "Québec Interconnection". 2) Correct VSL table for R1 Moderate and High since the examples don't cover exactly 70% et 80%. Suggest replacing with"more than 70%, but less than or equal to 80%" for the Moderate VSL and "more than 60%, but less than or equal to 70%" for the high VSL. 3) Severe VSL E11 : should read "…provided the requested data more than 60 days" instead of "…failed to provide the requested data more than 60 calendar days". 4) Attachment 1 step 3: "If the list has 11 or fewer buses, proceed to step 7" should be moved to step 2 with the following text "If the resulting list has 11 or fewer buses, proceed to Step 7".	

The following comments are for the PRC-028-1 standard: We are concerned that the standard refers to a defined term for IBR which has yet to be adopted in project 2020-06. No changes are made in Attachment 1, as steps written as-is would result in same outcome with proposed revision. We suggest that the drafting team ensure consistent language is used in the section 4.2 “Facilities” section with the other projects such as 2020-02 (PRC-029) and 2023-02(PRC-030). Are we to understand that this is the recommended text for the facilities section in regards to the standards where IBRs are applicable and that the other projects will ensure consistent language use in line iwth the recent ROP and GO/GOP definition revisions?

For PRC-028, R8, it is not clear whether the CAP implementation in the 2nd bullet item must be complete at the end of the 90-days specified in the R8 text. If so, what then is the difference in the first bullet (restoring the capability) and why might the Regional Entity need to know of a repair plan in progress that will be completed before the 90-day limit? In PRC-028, R9.5, does the request to extend the time provided refer to any changes made to an original CAP timeline? There are no other deadlines for completing any R9 CAP.	

CAPs documentation specifications and submittals to the RE are purely administrative and should be removed from the requirements list. A simple requirement to fix any faulty equipment will accomplish the intent of PRC-028, R8 and R9. An audit can check to ensure that all broken equipment was handled properly.

What dictates a "ride-thru" event in PRC-028, R1, the IBR mode status? Clarity is recommended.

In PRC-028, R1.2 and R1.3 remove the unnecessary brackets "[]" surrounding the "effective date of this standard".

PRC-028, R1.3 has an *"if capable of recording"* clause. If the inverter is incapable of recording certain data, does the SDT contemplate an "exemption process"?

Why does PRC-028, R2.2.1 need to be the IBR Unit transformer HV side versus the LV side?

Southern Company is in agreement with EEI, recommending that the IBR and IBR Unit definitions should be removed from PRC-002 and PRC-028 because the associated SAR does not provide this SDT with the authority to develop or adopt a definition that is currently unapproved. Moreover, once these definitions are approved and added to the Glossary of Terms there will be no need for inclusion of the definitions within these Reliability Standards.

Comment

The SDT needs to coordinate with other active IBR driven NERC Projects to avoid conflicts and duplications of requirements.

PRC-028 needs to align with PRC-002 in regards to synchronized clock accurracy within +/- 2 milliseconds vs. +/- 1 millisecond.

Also, data retention requirements in PRC-028 need to align with PRC-002 which has 10 days instead of 20 days.

The RC should have oversite of the placement of DDR equipment at IBR facilities as in PRC-002.

Likes 0	
Dislikes 0	

Response

Thank you for your comments.

The PRC-028, PRC-029, & PRC-030 and their NERC facilitators are in close contact.

In summary response to your other comments, this SDT has been tasked not only with making sure data is available to analyze IBR response to BES disturbances similar to what PRC-002 does for synchronous machines, but also with ensuring disturbance data is available to evaluate IBR performance and validate IBR models per FERC Order 901. The requirements of the two standards cannot be directly compared. Please see the Technical Rationale for discussion of the monitoring requirements.

Steven Rueckert - Western Electricity Coordinating Council - 10, Group Name WECC Entity Monitoring

Answer	
Document Name	

Comment

Including post-approval references (i.e. "the effective date of this standard") should not be considered as appropriate. Essentially this is grandfathering in the operational and reliability risk of not having appropriate data. The use of "if capable of recording" will be a pivotal point to consider when reviewing equipment for grandfathered IBR Units. Should be noted that "capable" does not equate to non-implementation of recording which could be a choice. With feeder lengths and determination of feeder length varying, the 90% criteria will possibly exclude feeders and significant numbers of IBR Units. If one feeder is 10 miles long and two others at same Inverter-Based Resource are 8.9 miles long only one IBR unit with SER (per Parts 1.2/1.3)/FR (per Part 2.2) data will be required to be compliant on the 10 mile feeder. If that one IBR unit is offline, where is the risk being mitigated? To ensure compliance, CMEP staff will have to ascertain applicability based on the criteria within the Requirement (i.e., entities will have to have documentation explaining their determination.) Non-BES Inverter-Based Resources will be even more difficult to apply the criteria.

The Technical Rationale picture/examples are good and clearly show that only one IBR Unit will need disturbance monitoring data to be compliant. One IBR unit's data may still not allow for detailed analysis of events. Would reconsider Example 3's use of BES definition references in light of the definitions proposed for Inverter-Based Resources and IBR Units. Based on the Technical Rationale, to evaluate compliance for IBR units for SER, FR, and DDR data Regional Entities must access event analysis data. In PRC-002 there is a need to capture DDR for stability SOLs and Elements included in an IROL. Please confirm that the RC can identify those situations for BES and non-BES IBRs (without considering any commercial operation date limitations) which would require DDR installation. Those situations exist and the risk needs mitigated.

IBR & Unit IBR Definitions: The IBR and IBR Unit definitions should be removed from PRC-002 and PRC-028 because the associated SAR does not provide this SDT with the authority to develop or adopt a definition that is currently unapproved. Moreover, once these definitions are approved and added to the Glossary of Terms there will be no need for inclusion of the definitions within these Reliability Standards. **DDR Requirements for PRC-002 & PRC-028** EEI also suggests that consideration should be given to modifying the requirements for dynamic Disturbance recording (DDR) equipment in both PRC-002 and PRC-028 in order to permit responsible entities to either install DDR equipment or Phasor Measurement Units (PMUs) since	

PMU equipment capture disturbance data at equal or better rates, and have the added benefit of synchronizing disturbance data from other locations utilizing existing network communications.

Data Retention Requirements for PRC-002 & PRC-028

EEI does not agree that the data retention requirements for PRC-002 (see Requirement R11 - 10 days) and PRC-028 (Requirement R7 – 20 days) should be different. Having two different data retention requirements for two Reliability Standards that have the exact same purpose is unjustified. Given the currently enforceable version of PRC-002 has a 10 day retention period, PRC-028 should have the same data retention period.

Reliability Coordinator Responsibilities for PRC-028

EEI suggests that the RC should be provided with oversight responsibilities for the placement of DDR equipment, even at IBR facilities. While EEI understands that the desire is to have DDR equipment at all IBR Facilities, as more of these facilities are added to the BPS, it is likely that there will be clusters of IBR facilities in some areas diminishing the need for this equipment at all of these facilities. We further note that the cost of this equipment is significant, and consideration should be given to the actual need and the RC would be the best judge to make this determination.

Response

Thank you for your comments.

The Applicability section has been edited and reformatted for clarity in the next draft, and the language used will not include any in progress definitions or the non-BES IBRs affected by the Rules of Procedure revision process.

DDR refers to the type of data. As long as the equipment meets the specified requirements in R4 and R5, it does not matter if it is a DFR, DDR, PMU, or something else. The SDT will review the PRC-028 Technical Rationale for opportunities to clarify.

PRC-002 and PRC-028 do not have the exact same purpose. FERC Order 901 mandates that disturbance monitoring data be available not only to analyze IBR response to BES disturbances, similar to what PRC-002 does for synchronous machines, but also to evaluate IBR performance and validate IBR models. The requirements of the two standards cannot be directly compared. Also see the PRC-028 Technical Rationale.
Michael Johnson - Michael Johnson On Behalf of: Marco Rios, Pacific Gas and Electric Company, 3, 1, 5; Sandra Ellis, Pacific Gas and Electric Company, 3, 1, 5; - Michael Johnson, Group Name PG&E All Segments

Answer	
Document Name	

Comment
PG&E provides the following: As currently drafted, PRC-028 does not contain the methodology like PRC-002 to determine if SER/FR is required. However, the DT has added, "elements associated with IBRs with an aggregate nameplate rating of 20 MVA and connecting to a voltage greater than or equal to 60 kV." Therefore, PG&E agrees with EEI input that "Elements to non-BES IBR units and BES IBR units" is too broad and the manner with which EEI has clarified the facilities to which the standard is applicable.

Capital Power supports the comments submitted by NAGF.

The NAGF notes that Project 2021-04 needs to be closely coordinated with other active NERC IBR related projects to ensure there is no conflict and/or duplication of efforts. The NAGF recommends that NERC publish a guideline/roadmap to demonstrate how all the on-going and pending IBR work activities fit together so that industry can understand how these efforts will enhance BPS/BES reliability. For example, why is it necessary for PRC-028 to be effective prior to other new IBR standards (i.e., PRC-029/PRC-030)?

In addition, for the proposed Requirement R8, it is not clear whether or not the CAP referenced in the 2nd bullet item must be complete at the end of the 90 days. If so, what then is the difference between that and the first bullet (restoring the capability). Also, why might the Regional Entity need to know of a repair plan in progress that will be completed before the 90-day limit? Further, the CAPs documentation specifications and submittals to the RE are purely administrative and should be removed from the requirement list. A simple requirement to fix any faulty equipment should accomplish the intent of R8 & R9.

The NAGF has the following comments\questions regarding Requirement R3:

• What is the driver for the 2 seconds length and the 64 samples/sec recording requirements? Existing FR equipment typically has a maximum recording time of 60 cycles and maximum of 16 or 32 samples/sec. The proposed recording requirements are not consistent with similar requirements of PRC-002 (30 cycles & 16 samples/sec).

• Requirement 3.2 will be difficult to achieve for older IBRs. FR recording equipment will need to be added to meet this requirement. Meeting these requirements at the inverter/controller level will be challenging. • Did the SDT reach out to various manufacturers to confirm the equipment capability and more importantly, are the changes/updates available that can meet this requirement? • Should equipment limitation be introduced as one of the requirements, similar to PRC-024 where equipment limitation is allowed but adequately reported? • Should an alternative method/requirement be provided as an option for equipment that is not capable of meeting the recording requirements? Refer to PRC-025, Options 5a and 5b as an example, where 5b option was introduced to eliminate costly replacements.

Comment	

For R8, it is not clear whether the CAP implementation referenced in the 2nd bullet item must be complete at the end of the 90 days specified in the R8 text. If so, what then is the difference in the first bullet (restoring the capability) and why might the Regional Entity need to know of a repair plan in progress that will be completed before the 90-day limit?

In R9.5 does the request to extend the time provided refer to any changes made to an original CAP timeline? (there are no other deadlines for completing any R9 CAP)

In R1.2 and R1.3 remove the unneeded brackets [ ] surrounding "the effective date of this standard".

CAPS documentation specifications and submittals to the RE are purely administrative and should be removed from the requirement list. A simple requirement to fix any faulty equipment will accomplish the intent of R8 & R9. An audit can check to ensure that all broken equipment was handled properly.

What dictates a "ride-thru" event in R1? The IBR mode status?

Why is R2.2.1 needed to be the IBR Unit transformer HV side versus the LV side?

Based on research for the last ballot on the costs of having this on each feeder at a wind farm. This doesn't include solar IBRS. MRO NSRF estimates that the cost of installing DFR equipment on the high side of a pad mounted transformer at the base of a wind turbine in the last 10% of an existing wind turbine feeder will be $300-450k or 2-3 times the cost of installing the same equipment in an existing substation.

It is not understood what drives the 2 seconds length and the 64 samples/sec recording requirements. Existing FR equipment typically has a maximum recording time of 60 cycles and maximum of 16 or 32 samples/sec. Both of these are not consistent with similar requirements of PRC-002 (30 cycles & 16 samples/sec).

3.2 will be difficult to achieve for older IBRs. FR recording equipment will need to be added to meet this requirement. Meeting these requirements at the inverter/controller level will be challenging. PacifiCorp recommends that the SDT reach out to various manufacturers to confirm the equipment capability and if any changes/updates that may be necessary for equipment can meet this requirement will become available. PacifiCorp recommends that the SDT consider equipment limitation be introduced similar to PRC-024 where equipment limitation is allowed but adequately reported. PacifiCorp recommends the SDT consider alternative methods/requirements be provided as an option for the equipment that are not capable of meeting the recording requirements. Refer to PRC-025, Options 5a and 5b as an example, where 5b option was introduced to eliminate costly replacements.

Thank you for your comments. R8 has been revised for clarity, and the same revisions have been applied to PRC-002-5, R12. In the next draft, the process for seeking an extension has been heavily revised and moved from R9 to the Implementation Plan. These brackets are part of the NERC standard development process. Once the standard is approved by FERC, the phrase “the effective date of this standard” is replaced by the actual effective date of the standard.	

R9 did not deal with faulty equipment. The intent of R9 was to allow more time for entities that may have circumstances beyond their control that delay installation of DME beyond the stated implementation deadline. Requests for extension must be approved by the Regional Entity, so they would not be valid without being filed.

All individual unit requirements have been deleted from the latest draft.

In summary response to your remaining comments:
This SDT has been tasked not only with making sure data is available to analyze IBR response to BES disturbances similar to what PRC-002 does for synchronous machines, but also with ensuring disturbance data is available to evaluate IBR performance and validate IBR models per FERC Order 901. The requirements of the two standards cannot be directly compared. In setting the data recording parameters, the SDT has reviewed the NERC disturbance reports, consulted with manufacturers, and considered the burden to industry. The requirements are addressed in the PRC-028 Technical Rationale. All individual unit requirements have been removed from the latest draft, and meeting these requirements should be less of an issue with equipment used to monitor at the plant level.

Dave Krueger - SERC Reliability Corporation - 10

Comment

On behalf of the SERC Generator Working Group:

- General comment: Should there be an assessment to determine which facilities this monitoring equipment should be installed on rather than just requiring for every IBR Unit
- R1: The data required in 1.2.1-4 and 1.3.1-4 are not currently available in all manufacturers
- R8: The two bullets say the same thing. Should it be that the CAP is submitted within 90 days and then implemented after? Otherwise implementing it within 90 days is the same as restoring the recording capability.

Response

Thank you for your comments.

- This SDT has been tasked with not only making sure data is available to analyze IBR response to BES disturbances, but also, with the added directives of FERC Order 901, ensuring disturbance data is available to evaluate IBR performance and validate IBR models. That expanded scope makes monitoring at all IBRs important.
- All individual unit requirements have been deleted from the latest draft.
- R8 has been revised for clarity, and the same revisions have been applied to PRC-002-5, R12.

PRC-028-1 Requirement R4 requires a DDR for the MPT of every 20+ MVA IBR with a connection point at a voltage of 60kV or greater . It is unclear whether these DDR (at least for BES IBR) should be included in the DDR coverage calculation in PRC-002-5 Requirement R5 Part 5.2. The SRC recommends that PRC-002-5 Requirement R5 be revised to clarify if any or all or none of the DDRs required by PRC-028-1 Requirement R4 are required (or allowed) to be included in the minimum DDR coverage under PRC-002-5 Requirement R5 Part 5.2.

PRC-028-1 Requirement R3 does not place minimum triggering thresholds on neutral overcurrent (Part 3.1.3.1), AC phase overvoltage and undervoltage (Parts 3.1.3.2 and 3.2.3.1), or overfrequency or underfrequency (Part 3.2.3.2). Improper threshold settings have led to event data being unavailable in instances where it would have been valuable for analysis. The SRC recommends that minimum triggering thresholds be added to the requirements to ensure this data is captured reliably.

PRC-028-1 Requirement R7, Part 7.2 requires that data subject to Part 7.1 be provided to the requesting entity within 30 calendar days of a request, yet Part 7.1 only requires the data to be retrievable for a period of 20 calendar days. The SRC recommends that the period to provide data under Part 7.2 be half of the data retention period under Part 7.1. In response to data requests, SRC members have often received data that does not fully cover the requested timeframes or that is incomplete and missing information. Ensuring that the response period under Part 7.2 is half of the data retention period under Part 7.1 would allow time for these types of errors to be detected and corrected before the data retention period expires and the data is lost.

PRC-028-1 Requirement R1, Part 1.3 requires currently in operation IBR units to record certain data unless they are not “capable of recording.” The SRC requests that the SDT clarify what it means for an IBR Unit to not be capable of recording the required data, as the proposed language could be read to include IBR Units that have the technical capability to record the required data, but failed to record the data due to a malfunction or due to being temporarily out of service.

Requirement R5 of PRC-002-5 Includes some unnecessary administrative compliance burdens. A GO with a 500+ MVA unit or 300+ MVA unit within a 1000 MVA plant should already know that they are required to install DDR without a specific RC requirement to provide notification of their DDR obligation.

Response

Thank you for your comments.

PRC-002-5 does not apply to IBRs, so the DDR requirements in PRC-028 do not count toward PRC-002. No elements should be covered under both standards as this would set up a double jeopardy situation.

The SDT is leaving trigger settings up to engineering judgement.

Revision to part 7.2 has been made to shorten the response time.

This requirement has been deleted from the latest draft.

This is outside the scope of this SDT. We did not change any of the monitoring requirements in PRC-002.

Comment

EEI offer the following additional comments:

IBR & Unit IBR Definitions:

The IBR and IBR Unit definitions should be removed from PRC-002 and PRC-028 because the associated SAR does not provide this SDT with the authority to develop or adopt a definition that is currently unapproved. Moreover, once these definitions are approved and added to the Glossary of Terms there will be no need for inclusion of the definitions within these Reliability Standards.

DDR Requirements for PRC-002 & PRC-028

EEI also suggests that consideration should be given to modifying the requirements for dynamic Disturbance recording (DDR) equipment in both PRC-002 and PRC-028 in order to permit responsible entities to either install DDR equipment or Phasor Measurement Units (PMUs) since PMU equipment capture disturbance data at equal or better rates, and have the added benefit of synchronizing disturbance data from other locations utilizing existing network communications.

Data Retention Requirements for PRC-002 & PRC-028

EEI does not agree that the data retention requirements for PRC-002 (see Requirement R11 - 10 days) and PRC-028 (Requirement R7 – 20 days) should be different. Having two different data retention requirements for two Reliability Standards that have the exact same purpose is unjustified. Given the currently enforceable version of PRC-002 has a 10 day retention period, PRC-028 should have the same data retention period.

Reliability Coordinator Responsibilities for PRC-028

EEI suggests that the RC should be provided with oversight responsibilities for the placement of DDR equipment, even at IBR facilities. While EEI understands that the desire is to have DDR equipment at all IBR Facilities, as more of these facilities are added to the BPS, it is likely that there will be clusters of IBR facilities in some areas diminishing the need for this equipment at all of these facilities. We further note that the cost of this equipment is significant, and consideration should be given to the actual need and the RC would be the best judge to make this determination.

Response

Thank you for your comments.

The IBR-related definitions have been removed from the upcoming draft.

DDR is intended to refer to the type of data. As long as the data is sufficient to meet the specified requirements, the type of installed equipment does not matter; it can be a DFR, DDR, PMU, or something else. The SDT will review the PRC-028 Technical Rationale for opportunities to clarify.

Combined response to the last two comments: PRC-002 and PRC-028 do not have the exact same purpose. FERC Order 901 mandates that disturbance monitoring data be available not only to analyze IBR response to BES disturbances, similar to what PRC-002 does for synchronous machines, but also to evaluate IBR performance and validate IBR models. The requirements of the two standards cannot be directly compared. Also, see the PRC-028 Technical Rationale for discussion of the differing requirements.

Comment	

Invenergy thanks the drafting team for their work and the opportunity to provide comments.

In previous response to comments, the drafting team suggested that “FERC Order 901 reinforces the approach taken by this SDT to require monitoring for all IBRs.” In fact, FERC Order 901 states that the more limited approach taken in PRC-002 “[has] been adequate to provide the data necessary to analyze major system events in the past.” Invenergy recommends the SDT develop a methodology similar to PRC-002 Attachment 1 that Transmission Owners and Reliability Coordinators can utilize to identify key nodes where disturbance monitoring equipment should be deployed.

The SER data required in R1.2.1. and R1.2.2. is generic and should be refined to target specific categories of fault codes and alarms so as not to overburden local storage of the data. On that point, 20 days of retrievable data is simply beyond the capabilities of some inverters. Invenergy recommends the data storage requirement in R7.1. be reduced to 10 days to align with PRC-002 R11.1. Furthermore, the various requested IBR Unit level data, sampling rates, time sync, and data format present many technical challenges for existing IBRs, some of which will have no solution other than replacement of the IBR Unit. As such, we suggested changes to R9 to account for these equipment limitations in response to Question 4.

Response

Thank you for your comments. The section of FERC Order 901 quoted above is only the first half of a sentence that ends with “… NERC has found that the existing disturbance monitoring equipment is not sufficient (e.g., lack of high speed data captured at the IBR or plant level controller and low resolution time stamping of inverter sequence of event recorder information) to analyze the widespread system events that have become more common since 2016.” This justifies the development of a modified approach as the SDT has stated.

This SDT has been tasked not only with making sure data is available to analyze IBR response to BES disturbances similar to what PRC-002 does for synchronous machines, but also ensuring disturbance data is available to evaluate IBR performance and validate IBR models per FERC Order 901. The requirements of the two standards cannot be directly compared. See the PRC-028-1 Technical Rationale for discussion of the requirements.

The IBR Unit level monitoring requirements have been removed from the next draft of the standard, and meeting these requirements should be less of an issue with equipment used to monitor at the plant level.

The NAGF notes that Project 2021-04 needs to be closely coordinated with other active NERC IBR related projects to ensure there is no conflict and/or duplication of efforts. The NAGF recommends that NERC publish a guideline/roadmap to demonstrate how all the on-going and pending IBR work activities fit together so that industry can understand how these efforts will enhance BPS/BES reliability. For example, why is it necessary for PRC-028 to be effective prior to other new IBR standards (i.e., PRC-029/PRC-030)?

In addition, for the proposed Requirement R8, it is not clear whether or not the CAP referenced in the 2nd bullet item must be complete at the end of the 90 days. If so, what then is the difference between that and the first bullet (restoring the capability). Also, why might the Regional Entity need to know of a repair plan in progress that will be completed before the 90-day limit? Further, the CAPs documentation specifications and submittals to the RE are purely administrative and should be removed from the requirement list. A simple requirement to fix any faulty equipment should accomplish the intent of R8 & R9.

The NAGF has the following comments\questions regarding Requirement R3:

- *What is the driver for the 2 seconds length and the 64 samples/sec recording requirements? Existing FR equipment typically has a maximum recording time of 60 cycles and maximum of 16 or 32 samples/sec. The proposed recording requirements are not consistent with similar requirements of PRC-002 (30 cycles & 16 samples/sec).*
- *Requirement 3.2 will be difficult to achieve for older IBRs. FR recording equipment will need to be added to meet this requirement. Meeting these requirements at the inverter/controller level will be challenging.*
- *Did the SDT reach out to various manufacturers to confirm the equipment capability and more importantly, are the changes/updates available that can meet this requirement?*
- *Should equipment limitation be introduced as one of the requirements, similar to PRC-024 where equipment limitation is allowed but adequately reported?*
- *Should an alternative method/requirement be provided as an option for equipment that is not capable of meeting the recording requirements? Refer to PRC-025, Options 5a and 5b as an example, where 5b option was introduced to eliminate costly replacements.*

Response

Thank you for your comments.

- PRC-028, PRC-029, & PRC-030 all have to be delivered to FERC by 11/1/2024 and fully effective and enforceable no later than January 1, 2030 per FERC Order 901 and NERC's Response to it. NERC has published multiple resources on its website regarding the standards roadmap and workplan. These drafting teams and their NERC facilitators communicate regularly.
- The intent of R8 is to prioritize the repair of equipment. The SDT has revised PRC-028, R8 for clarity, and the same revisions have been applied to PRC-002-5, R12. Please, also refer to the PRC-028 Technical Rationale.
- PRC-028, R9 did not deal with faulty equipment. The intent of R9 was to allow more time for entities that may have circumstances beyond their control that delay installation of DME beyond the stated implementation deadline. Requests for extension must be approved by the Regional Entity, so they would not be valid without being filed. In the next draft, the process for seeking an extension has been heavily revised and moved from R9 to the Implementation Plan.
- Regarding PRC-028, R3:

  This SDT has been tasked not only with making sure data is available to analyze IBR response to BES disturbances similar to what PRC-002 does for synchronous machines, but also with ensuring disturbance data is available to evaluate IBR performance and validate IBR models per FERC Order 901. The requirements of the two standards cannot be directly compared. In setting the data recording parameters, the SDT has reviewed the NERC disturbance reports, consulted with manufacturers, and considered the burden to industry. The data requirements are addressed in the PRC-028 Technical Rationale. All individual unit requirements have been removed from the latest draft, and meeting these requirements should be less of an issue with equipment used to monitor at the plant level.

Overall wording for the sections mentioned above for PRC-028 should be cleaned up. Terms like IBR should have formal definitions, outside of PRC-028 in the NERC Glossary of Terms.

The IBR Unit level monitoring requirements have been removed from the next draft of the standard, and meeting these requirements should be less of an issue with equipment used to monitor at the plant level.

Reminder
Standards Announcement
Project 2021-04 Modifications to PRC-002 - Phase II

Additional Ballots and Non-binding Polls Open through April 11, 2024

Now Available

Additional ballots for **Project 2021-04 Modifications to PRC-002 - Phase II** and non-binding polls of the associated Violation Risk Factors and Violation Severity Levels are open through **8 p.m. Eastern, Thursday, April 11, 2024** for the following standards and implementation plan:

- PRC-002-5 – Disturbance Monitoring and Reporting Requirements
- PRC-028-1 – Disturbance Monitoring and Reporting Requirements for Inverter-Based Resources
- Implementation Plan

The standard drafting team's considerations of the responses received from the last comment period are reflected in this draft of the standard.

Reminder Regarding Corporate RBB Memberships
Under the NERC Rules of Procedure, each entity and its affiliates is collectively permitted one voting membership per Registered Ballot Body Segment. Each entity that undergoes a change in corporate structure (such as a merger or acquisition) that results in the entity or affiliated entities having more than the one permitted representative in a particular Segment must withdraw the duplicate membership(s) prior to joining new ballot pools or voting on anything as part of an existing ballot pool. Contact ballotadmin@nerc.net to assist with the removal of any duplicate registrations.

Balloting
Members of the ballot pools associated with this project can log in and submit their votes by accessing the Standards Balloting and Commenting System (SBS) here.

Note: Votes cast in previous ballots will not carry over to additional ballots. It is the responsibility of the registered voter in the ballot pools to place votes again. To ensure a quorum is reached, if you do not want to vote affirmative or negative, cast an abstention.

- *Contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern) for problems regarding accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out.*
- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*

- *Please be mindful of ballot and comment period closing dates. We ask to **allow at least 48 hours** for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts **prior to the last day** of a comment/ballot period.*

Next Steps

The ballot results will be announced and posted on the project page. The drafting team will review all responses received during the comment period and determine the next steps of the project.

For information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Senior Standards Developer**,** Ben Wu (via email) or at 470-542-6882. Subscribe to this project's observer mailing list by selecting "NERC Email Distribution Lists" from the "Service" drop-down menu and specify “Project 2021-04 Modifications to PRC-002 observer list” in the Description Box.

3	Southern Company - Alabama Power Company	Joel Dembowski		Negative	Comments Submitted
5	Choctaw Generation Limited Partnership, LLLP	Rob Watson		Negative	Comments Submitted
1	Platte River Power Authority	Marissa Archie		Affirmative	N/A
5	Tri-State G and T Association, Inc.	Sergio Banuelos		Abstain	N/A
6	Constellation	Kimberly Turco		Negative	Comments Submitted
5	Constellation	Alison MacKellar		Negative	Comments Submitted
1	NB Power Corporation	Jeffrey Streifling		Abstain	N/A
5	Nebraska Public Power District	Ronald Bender		Abstain	N/A
2	Southwest Power Pool, Inc. (RTO)	Joshua Phillips		Affirmative	N/A
3	Seminole Electric Cooperative, Inc.	Marc Sedor		Abstain	N/A
3	Associated Electric Cooperative, Inc.	Todd Bennett		Affirmative	N/A
1	Nebraska Public Power District	Jamison Cawley		Abstain	N/A
3	M and A Electric Power Cooperative	Gary Dollins		Affirmative	N/A
3	NW Electric Power Cooperative, Inc.	Heath Henry		Affirmative	N/A
3	Northeast Missouri Electric Power Cooperative	Skyler Wiegmann		Affirmative	N/A
1	Santee Cooper	Chris Wagner		Abstain	N/A

3	Santee Cooper	Vicky Budreau		Abstain	N/A
5	Santee Cooper	Don Cribb		Abstain	N/A
6	Santee Cooper	Marty Watson		Abstain	N/A
3	Sho-Me Power Electric Cooperative	Jarrod Murdaugh		Affirmative	N/A
1	APS - Arizona Public Service Co.	Daniela Atanasovski		Affirmative	N/A
6	APS - Arizona Public Service Co.	Marcus Bortman		Affirmative	N/A
1	N.W. Electric Power Cooperative, Inc.	Mark Ramsey		Affirmative	N/A
5	Lower Colorado River Authority	Teresa Krabe		Affirmative	N/A
3	APS - Arizona Public Service Co.	Jessica Lopez		Affirmative	N/A
5	Evergy	Jeremy Harris	Alan Kloster	Negative	Comments Submitted
6	New York Power Authority	Shelly Dineen		Affirmative	N/A
3	KAMO Electric Cooperative	Tony Gott		Affirmative	N/A
2	PJM Interconnection, L.L.C.	Thomas Foster	Elizabeth Davis	Affirmative	N/A
3	DTE Energy - Detroit Edison Company	Marvin Johnson		Abstain	N/A
3	Tri-State G and T Association, Inc.	Ryan Walter		None	N/A
3	Omaha Public Power District	David Heins		Negative	Comments Submitted
5	APS - Arizona Public Service Co.	Andrew Smith		Affirmative	N/A
5	OTP - Otter Tail Power Company	Stacy Wahlund		Negative	Comments Submitted
3	OTP - Otter Tail Power Company	Wendi Olson		Negative	Comments Submitted
6	Edison International - Southern California Edison Company	Stephanie Kenny		Affirmative	N/A
6	Muscatine Power and Water	Nicholas Burns		Affirmative	N/A
5	Muscatine Power and Water	Neal Nelson		Negative	Comments Submitted
6	Tacoma Public Utilities (Tacoma, WA)	Terry Gifford	Jennie Wike	Abstain	N/A
5	Associated Electric Cooperative, Inc.	Chuck Booth		Affirmative	N/A
5	BC Hydro and Power Authority	Quincy Wang		Abstain	N/A
1	Imperial Irrigation District	Jesus Sammy Alcaraz	Denise Sanchez	Affirmative	N/A
1	Sho-Me Power Electric Cooperative	Olivia Olson		None	N/A
6	Imperial Irrigation District	Diana Torres	Denise Sanchez	Affirmative	N/A
6	Powerex Corporation	Raj Hundal		Abstain	N/A
6	Austin Energy	Imane Mrini		Abstain	N/A
1	Hydro One Networks, Inc.	Emma Halilovic	Ijad Dewan	Abstain	N/A
6	Associated Electric Cooperative, Inc.	Brian Ackermann		Affirmative	N/A
5	Austin Energy	Michael Dillard		Abstain	N/A
6	Lakeland Electric	Paul Shipps		Negative	Comments Submitted
10	Midwest Reliability Organization	Mark Flanary		Affirmative	N/A
3	Austin Energy	Lovita Griffin		Abstain	N/A

3	Nebraska Public Power District	Tony Eddleman		Abstain	N/A
3	Lakeland Electric	Steven Marshall		Negative	Comments Submitted
1	Balancing Authority of Northern California	Kevin Smith	Tim Kelley	Affirmative	N/A
1	Austin Energy	Thomas Standifur		Abstain	N/A
3	Central Electric Power Cooperative (Missouri)	Adam Weber		Affirmative	N/A
3	Bonneville Power Administration	Ron Sporseen		Affirmative	N/A
1	Sacramento Municipal Utility District	Wei Shao	Tim Kelley	Affirmative	N/A
5	Sempra - San Diego Gas and Electric	Jennifer Wright		Affirmative	N/A
3	Edison International - Southern California Edison Company	Romel Aquino		Affirmative	N/A
5	Sacramento Municipal Utility District	Ryder Couch	Tim Kelley	Affirmative	N/A
5	Ontario Power Generation Inc.	Constantin Chitescu		Affirmative	N/A
5	Edison International - Southern California Edison Company	Selene Willis		Affirmative	N/A
6	Sacramento Municipal Utility District	Charles Norton	Tim Kelley	Affirmative	N/A
5	CMS Energy - Consumers Energy Company	David Greyerbiehl		None	N/A
5	Tennessee Valley Authority	Darren Boehm		None	N/A
1	Sunflower Electric Power Corporation	Paul Mehlhaff		None	N/A
5	Entergy - Entergy Services, Inc.	Gail Golden		None	N/A
6	Salt River Project	Timothy Singh	Israel Perez	Affirmative	N/A
1	Brazos Electric Power Cooperative, Inc.	Tony Kroskey		None	N/A
4	Tacoma Public Utilities (Tacoma, WA)	Hien Ho	Jennie Wike	Abstain	N/A
5	Orlando Utilities Commission	Dania Colon		None	N/A
5	Tacoma Public Utilities (Tacoma, WA)	Ozan Ferrin	Jennie Wike	Abstain	N/A
3	Snohomish County PUD No. 1	Holly Chaney		Affirmative	N/A
5	Platte River Power Authority	Jon Osell		Affirmative	N/A
3	Platte River Power Authority	Richard Kiess		Affirmative	N/A
1	Unisource - Tucson Electric Power Co.	Jessica Cordero		None	N/A
3	CMS Energy - Consumers Energy Company	Karl Blaszkowski		Negative	Comments Submitted
1	Central Iowa Power Cooperative	Kevin Lyons		Negative	Comments Submitted
1	Long Island Power Authority	Isidoro Behar		Abstain	N/A
6	Platte River Power Authority	Sabrina Martz		Affirmative	N/A
3	Salt River Project	Mathew Weber	Israel Perez	Affirmative	N/A
5	AES - AES Corporation	Ruchi Shah		None	N/A
1	Pedernales Electric Cooperative, Inc.	Bradley Collard		None	N/A
5	LS Power Development, LLC	C. A. Campbell		None	N/A
4	Public Utility District No. 2 of Grant County, Washington	Karla Weaver		Abstain	N/A
1	Bonneville Power Administration	Kamala Rogers-Holliday		None	N/A
1	Georgia Transmission Corporation	Greg Davis		Affirmative	N/A

10	New York State Reliability Council	Wesley Yeomans		Affirmative	N/A
3	Exelon	Kinte Whitehead		Negative	Comments Submitted
1	Exelon	Daniel Gacek		Negative	Comments Submitted
5	Pine Gate Renewables	Michiko Sell		None	N/A
5	JEA	John Babik		Affirmative	N/A
1	Hydro-Quebec (HQ)	Nicolas Turcotte	Chantal Mazza	Negative	Comments Submitted
5	Hydro-Quebec (HQ)	Junji Yamaguchi		Negative	Comments Submitted
1	Seminole Electric Cooperative, Inc.	Kristine Ward		Abstain	N/A
4	Alliant Energy Corporation Services, Inc.	Larry Heckert		Negative	Comments Submitted
10	Texas Reliability Entity, Inc.	Rachel Coyne		Affirmative	N/A
3	New York Power Authority	David Rivera		Affirmative	N/A
5	Black Hills Corporation	Sheila Suurmeier	Carly Miller	Negative	Comments Submitted
5	Salt River Project	Thomas Johnson	Israel Perez	Affirmative	N/A
1	Arizona Electric Power Cooperative, Inc.	Jennifer Bray		Negative	Comments Submitted
5	Public Utility District No. 1 of Snohomish County	Becky Burden		Affirmative	N/A
4	Illinois Municipal Electric Agency	Mary Ann Todd		Abstain	N/A
4	CMS Energy - Consumers Energy Company	Aric Root		Negative	Comments Submitted
1	JEA	Joseph McClung		Affirmative	N/A
1	Salt River Project	Sarah Blankenship	Israel Perez	Affirmative	N/A
3	PNM Resources - Public Service Company of New Mexico	Amy Wesselkamper		Affirmative	N/A
4	Sacramento Municipal Utility District	Foung Mua	Tim Kelley	Affirmative	N/A
3	Sacramento Municipal Utility District	Nicole Looney	Tim Kelley	Affirmative	N/A
3	JEA	Marilyn Williams		Affirmative	N/A
1	Omaha Public Power District	Doug Peterchuck		Negative	Comments Submitted
6	Omaha Public Power District	Shonda McCain		Negative	Comments Submitted
5	Decatur Energy Center LLC	Megan Melham		Negative	Comments Submitted
1	Northeast Missouri Electric Power Cooperative	Brett Douglas		Affirmative	N/A
6	Los Angeles Department of Water and Power	Anton Vu		Abstain	N/A
5	Los Angeles Department of Water and Power	Glenn Barry		Abstain	N/A
3	Los Angeles Department of Water and Power	Fausto Serratos		None	N/A
5	Omaha Public Power District	Kayleigh Wilkerson		Negative	Comments Submitted
1	Glencoe Light and Power Commission	Terry Volkmann		Affirmative	N/A

4	Buckeye Power, Inc.	Jason Procuniar	Ryan Strom	Negative	Comments Submitted
5	TransAlta Corporation	Ashley Scheelar	Adam Burlock	Abstain	N/A
5	New York Power Authority	Zahid Qayyum		Affirmative	N/A
5	Buckeye Power, Inc.	Kevin Zemanek	Ryan Strom	Negative	Comments Submitted
3	Buckeye Power, Inc.	Tom Schmidt	Ryan Strom	Negative	Comments Submitted
2	New York Independent System Operator	Gregory Campoli		None	N/A
4	Utility Services, Inc.	Carver Powers		Negative	Comments Submitted
6	Public Utility District No. 2 of Grant County, Washington	Mike Stussy		None	N/A
2	Independent Electricity System Operator	Helen Lainis		Affirmative	N/A
3	City Utilities of Springfield, Missouri	Jessica Morrissey		Negative	Comments Submitted
6	Seminole Electric Cooperative, Inc.	Bret Galbraith		Abstain	N/A

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

PRC-002-5 is posted for a formal comment period with additional ballot.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	January 20, 2021
SAR posted for comment	June 14, 2021 – July 13, 2021

Anticipated Actions	Date
45-day formal comment period with ballot	August 1, 2023 – September 14, 2023
25-day formal or informal comment period with additional ballot	March 18, 2024 – April 11, 2024
15-day formal or informal comment period with additional ballot	May 31, 2024 – June 14, 2024
10-day final ballot	September 15, 2024 – September 24, 2024
Board adoption	October 15, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

N/A.

A. Introduction

1. **Title:** Disturbance Monitoring and Reporting Requirements
2. **Number:** PRC-002-5
3. **Purpose:** To have adequate data available to facilitate analysis of Bulk Electric System (BES) Disturbances.
4. **Applicability:**
   - **4.1. Functional Entities:**
     - **4.1.1.** Reliability Coordinator
     - **4.1.2.** Transmission Owner
     - **4.1.3.** Generator Owner
   - **4.2. Facilities:** BES Elements, excluding inverter-based resources.[1]
5. **Effective Date:** See Implementation Plan

B. Requirements and Measures

R1. Each Transmission Owner shall: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

1.1. Identify BES buses for which sequence of events recording (SER) and fault recording (FR) data is required by using the methodology in PRC-002-5, Attachment 1.

1.2. Notify the other owners of BES Elements directly connected[2] to those BES buses, that SER or FR data is required for those BES Elements, only if the Transmission Owner who identified the BES buses in Part 1.1 does not have SER or FR data. This notification is required within 90 calendar days of completion of Part 1.1.

1.3. Re-evaluate all BES buses at least once every five calendar years in accordance with Part 1.1 and notify other owners in accordance with Part 1.2.

M1. The Transmission Owner for Requirement R1, Part 1.1 has a dated (electronic or hard copy) list of BES buses for which SER and FR data is required, identified in accordance with PRC-002-5, Attachment 1; has dated (electronic or hard copy) evidence that it notified other owners in accordance with Requirement R1, Part 1.2; and evidence that all BES buses have been re-evaluated within the required intervals under Requirement R1, Part 1.3.

R2. Each Transmission Owner and Generator Owner shall have SER data for circuit breaker position (open/close) for each circuit breaker it owns directly connected to the BES

[1] Disturbance monitoring and reporting requirements for inverter-based resources are addressed in PRC-028.

[2] For the purposes of this standard, "directly connected" BES Elements are BES Elements connected at the same voltage level within the same physical location sharing a common ground grid with the BES bus identified under Attachment 1. Transformers that have a low-side operating voltage of less than 100 kV are excluded.

buses identified in Requirement R1 and associated with the BES Elements at those BES buses. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

M2. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of SER data for circuit breaker position as specified in Requirement R2. Evidence may include, but is not limited to: (1) documents describing the device interconnections and configurations which may include a single design standard as representative for common installations; or (2) actual data recordings; or (3) station drawings.

R3. Each Transmission Owner and Generator Owner shall have FR data to determine the following electrical quantities for each triggered FR for the BES Elements it owns directly connected to the BES buses identified in Requirement R1: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

3.1. Phase-to-neutral voltage for each phase of each specified BES bus.

3.2. Each phase current and the residual or neutral current for the following BES Elements:

3.2.1. Transformers that have a low-side operating voltage of 100 kV or above.

3.2.2. Transmission Lines.

M3. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of FR data that is sufficient to determine electrical quantities as specified in Requirement R3. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations which may include a single design standard as representative for common installations; or (2) actual data recordings or derivations; or (3) station drawings.

R4. Each Transmission Owner and Generator Owner shall have FR data as specified in Requirement R3 that meets the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

4.1. A single record or multiple records that include:

- A pre-trigger record length of at least two cycles and a total record length of at least 30 cycles for the same trigger point, or
- At least two cycles of the pre-trigger data, the first three cycles of the post-trigger data, and the final cycle of the fault as seen by the fault recorder.

4.2. A minimum recording rate of 16 samples per cycle.

4.3. Trigger settings for at least the following:

4.3.1. Neutral (residual) overcurrent.

4.3.2. Phase undervoltage or overcurrent.

M4. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that FR data meets Requirement R4. Evidence may include, but is not limited to: (1)

documents describing the device specification (R4, Part 4.2) and device configuration or settings (R4, Parts 4.1 and 4.3), or (2) actual data recordings or derivations.

R5. Each Reliability Coordinator shall: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

5.1. Identify BES Elements for which dynamic Disturbance recording (DDR) data is required, including the following:

5.1.1. Synchronous generating resource(s) with:

5.1.1.1. Gross individual nameplate rating greater than or equal to 500 MVA.

5.1.1.2. Gross individual nameplate rating greater than or equal to 300 MVA where the gross plant/facility aggregate nameplate rating is greater than or equal to 1,000 MVA.

5.1.2. Any one BES Element that is part of a stability (angular or voltage) related System Operating Limit (SOL).

5.1.3. Each terminal of a high voltage direct current (HVDC) circuit with a nameplate rating greater than or equal to 300 MVA, on the alternating current (AC) portion of the converter.

5.1.4. One or more BES Elements that are part of an Interconnection Reliability Operating Limit (IROL).

5.1.5. Any one BES Element within a major voltage sensitive area as defined by an area with an in-service undervoltage load shedding (UVLS) program.

5.2. Identify a minimum DDR coverage, inclusive of those BES Elements identified in Part 5.1, of at least:

5.2.1. One BES Element; and

5.2.2. One BES Element per 3,000 MW of the Reliability Coordinator’s historical simultaneous peak System Demand.

5.3. Notify all owners of identified BES Elements, within 90 calendar days of completion of Part 5.1, that their respective BES Elements require DDR data.

5.4. Re-evaluate all BES Elements within its Reliability Coordinator Area at least once every five calendar years in accordance with Parts 5.1 and 5.2, and notify owners in accordance with Part 5.3.

M5. The Reliability Coordinator has a dated (electronic or hard copy) list of BES Elements for which DDR data is required, developed in accordance with Requirement R5, Part 5.1 and Part 5.2; and re-evaluated in accordance with Part 5.4. The Reliability Coordinator has dated evidence (electronic or hard copy) that each Transmission Owner or Generator Owner has been notified in accordance with Requirement 5, Part 5.3. Evidence may include, but is not limited to letters, emails, electronic files, or hard copy records demonstrating transmittal of information.

R6. Each Transmission Owner shall have DDR data to determine the following electrical quantities for each BES Element it owns for which it received notification as identified in Requirement R5: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

6.1. One phase-to-neutral or positive sequence voltage.

6.2. The phase current for the same phase at the same voltage corresponding to the voltage in Requirement R6, Part 6.1, or the positive sequence current.

6.3. Real Power and Reactive Power flows expressed on a three-phase basis corresponding to all circuits where current measurements are required.

6.4. Frequency of any one of the voltage(s) in Requirement R6, Part 6.1.

M6. The Transmission Owner has evidence (electronic or hard copy) of DDR data to determine electrical quantities as specified in Requirement R6. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (2) actual data recordings or derivations; or (3) station drawings.

R7. Each Generator Owner shall have DDR data to determine the following electrical quantities for each BES Element it owns for which it received notification as identified in Requirement R5: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

7.1. One phase-to-neutral, phase-to-phase, or positive sequence voltage at either the generator step-up transformer (GSU) high-side or low-side voltage level.

7.2. The phase current for the same phase at the same voltage corresponding to the voltage in Requirement R7, Part 7.1, phase current(s) for any phase-to-phase voltages, or positive sequence current.

7.3. Real Power and Reactive Power flows expressed on a three-phase basis corresponding to all circuits where current measurements are required.

7.4. Frequency of at least one of the voltages in Requirement R7, Part 7.1.

M7. The Generator Owner has evidence (electronic or hard copy) of DDR data to determine electrical quantities as specified in Requirement R7. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (2) actual data recordings or derivations; or (3) station drawings.

R8. Each Transmission Owner and Generator Owner responsible for DDR data for the BES Elements identified in Requirement R5 shall have continuous data recording and storage. If the equipment was installed prior to the effective date of the Reliability Standard PRC-002-2[3] and is not capable of continuous recording, triggered records

[3] The effective date of the Reliability Standard PRC-002-2 in the U.S. was July 1, 2016. The effective date may be different for other jurisdictions.

must meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

8.1. Triggered record lengths of at least three minutes.

8.2. At least one of the following three triggers:

- Off nominal frequency trigger set at:

	Low	High
o Eastern Interconnection	<59.75 Hz	>61.0 Hz
o Western Interconnection	<59.55 Hz	>61.0 Hz
o ERCOT Interconnection	<59.35 Hz	>61.0 Hz
o Quebec Interconnection	<58.55 Hz	>61.5 Hz

- Rate of change of frequency trigger set at:

o Eastern Interconnection	< -0.03125 Hz/sec	>0.125 Hz/sec
o Western Interconnection	< -0.05625 Hz/sec	>0.125 Hz/sec
o ERCOT Interconnection	< -0.08125 Hz/sec	>0.125 Hz/sec
o Quebec Interconnection	< -0.18125 Hz/sec	>0.1875 Hz/sec

- Undervoltage trigger set no lower than 85 percent of normal operating voltage for a duration of 5 seconds.

M8. Each Transmission Owner and Generator Owner has dated evidence (electronic or hard copy) of data recordings and storage in accordance with Requirement R8. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (2) actual data recordings.

R9. Each Transmission Owner and Generator Owner responsible for DDR data for the BES Elements identified in Requirement R5 shall have DDR data that meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

9.1. Input sampling rate of at least 960 samples per second.

9.2. Output recording rate of electrical quantities of at least 30 times per second.

M9. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that DDR data meets Requirement R9. Evidence may include, but is not limited to: (1) documents describing the device specification, device configuration, or settings (R9, Part 9.1; R9, Part 9.2); or (2) actual data recordings (R9, Part 9.2).

R10. Each Transmission Owner and Generator Owner shall time synchronize all SER and FR data for the BES buses identified in Requirement R1 and DDR data for the BES Elements identified in Requirement R5 to meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

10.1. Synchronization to Coordinated Universal Time (UTC) with or without a local time offset.

10.2. Synchronized device clock accuracy within ± 2 milliseconds of UTC.

M10. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of time synchronization described in Requirement R10. Evidence may include, but is not limited to: (1) documents describing the device specification, configuration, or setting; (2) time synchronization indication or status; or 3) station drawings.

R11. Each Transmission Owner and Generator Owner shall provide, upon request, all SER and FR data for the BES buses identified in Requirement R1 and DDR data for the BES Elements identified in Requirement R5 to the Reliability Coordinator, Regional Entity, or NERC in accordance with the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

11.1. Data will be retrievable for the period of 10 calendar days, inclusive of the day the data was recorded.

11.2. Data subject to Part 11.1 will be provided within 30 calendar days of a request unless an extension is granted by the requestor.

11.3. SER data will be provided in ASCII Comma Separated Value (CSV) format following Attachment 2.

11.4. FR data will be provided in electronic files that are formatted in conformance with C37.111, IEEE Standard Common Format for Transient Data Exchange (COMTRADE), revision C37.111-1999 or later.

11.5. DDR data will be provided either in CSV format with appropriate headers or in electronic files that are formatted in conformance with C37.111, IEEE Standard Common Format for Transient Data Exchange (COMTRADE), revision C37.111-1999 or later.

11.6. Data files will be named in conformance with C37.232, IEEE Standard for Common Format for Naming Time Sequence Data Files (COMNAME), revision C37.232-2011 or later.

M11. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that data was submitted upon request in accordance with Requirement R11. Evidence may include, but is not limited to: (1) dated transmittals to the requesting entity with formatted records; (2) documents describing data storage capability, device specification, configuration or settings; or (3) actual data recordings.

R12. Each Transmission Owner and Generator Owner shall, upon the discovery of a failure of the recording capability for the SER, FR or DDR data: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

- Restore the recording capability within 90 calendar days, or
- Submit a Corrective Action Plan (CAP) to the Regional Entity within 90 calendar days and then implement it according to CAP timeline.

M12. The Transmission Owner or Generator Owner has dated evidence (electronic or hard copy) that meets Requirement R12. Evidence may include, but is not limited to: (1) dated reports of discovery of a failure, (2) documentation noting the date the data recording was restored, (3) SCADA records, or (4) dated CAP transmittals to the Regional Entity and evidence that it implemented the CAP.

R13. Each Transmission Owner and Generator Owner shall: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

13.1. Within three (3) calendar years of completing a re-evaluation or receiving notification under Requirement R1, Part 1.3, have SER or FR data as applicable for BES Elements directly connected to the identified BES buses.

13.2. Within three (3) calendar years of receiving notification under Requirement R5, Part 5.4, have DDR data for BES Elements identified during the re-evaluation.

M13. The Transmission Owner or Generator Owner has dated evidence (electronic or hard copy) that meets Requirement R13. Evidence may include, but is not limited to: letters, emails, drawings, or settings files.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention:

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner, Generator Owner, and Reliability Coordinator shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

The Transmission Owner shall retain evidence of Requirement R1 for five calendar years.

The Reliability Coordinator shall retain evidence of Requirement R5 for five

calendar years.

The Transmission Owner shall retain evidence of Requirement R6 for three calendar years.

The Generator Owner shall retain evidence of Requirement R7 for three calendar years.

The Transmission Owner and Generator Owner shall retain evidence of Requirements R2, R3, R4, R8, R9, R10, R11, and R12 for three calendar years.

The Transmission Owner and Generator Owner as applicable shall retain evidence of Requirement R13 for five calendar years.

If a Transmission Owner, Generator Owner, or Reliability Coordinator is found non-compliant, it shall keep information related to the non-compliance until mitigation is completed and approved or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records, and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The Transmission Owner identified the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3 for more than 80 percent, but less than 100 percent of the required BES buses that they own. OR The Transmission Owner evaluated the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3, but was late by 30 calendar days or less. OR The Transmission Owner as directed by Requirement R1, Part 1.2 was late in notifying the other owners that their BES Elements require SER or FR data by 10 calendar days or less.	The Transmission Owner identified the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3 for more than 70 percent, but less than or equal to 80 percent of the required BES buses that they own. Attachment 1

Methodology for Selecting Buses for Capturing Sequence of Events Recording (SER) and Fault Recording (FR) Data

(Requirement R1)

To identify monitored Bulk Electric System (BES) buses for SER and FR data required by Requirement 1, each Transmission Owner shall follow sequentially, unless otherwise noted, the steps listed below:

Step 1. Determine a complete list of BES buses that it owns. Refer to section 4.2 Facilities for exclusion.

For the purposes of this standard, a single BES bus includes physical buses with breakers connected at the same voltage level within the same physical location sharing a common ground grid. These buses may be modeled or represented by a single node in fault studies. For example, ring bus or breaker-and-a-half bus configurations are considered to be a single bus.

Step 2. Reduce the list to those BES buses that have a maximum available calculated three-phase short circuit MVA of 1,500 MVA or greater. If there are no buses on the resulting list, proceed to Step 7.

Step 3. Determine the 11 BES buses on the list with the highest maximum available calculated three-phase short circuit MVA level. If the list has 11 or fewer buses, proceed to Step 7.

Step 4. Calculate the median MVA level of the 11 BES buses determined in Step 3.

Step 5. Multiply the median MVA level determined in Step 4 by 20 percent.

Step 6. Reduce the BES buses on the list to only those that have a maximum available calculated three-phase short circuit MVA higher than the greater of:

- 1,500 MVA or
- 20 percent of median MVA level determined in Step 5.

Step 7. <u>If there are no BES buses on the list:</u> the procedure is complete, and no FR and SER data will be required. Proceed to Step 9.

<u>If the list has 1 or more, but less than or equal to 11 BES buses:</u> FR and SER data is required at the BES bus with the highest maximum available calculated three-phase short circuit MVA as determined in Step 3.

During re-evaluation per Requirement R1, Part 1.3, if the three-phase short circuit MVA of the newly identified BES bus is within 15% of the three-phase short circuit MVA of the currently applicable BES bus with SER and FR data then it is not necessary to change the applicable BES bus. Proceed to Step 9.

<u>If the list has more than 11 BES buses:</u> SER and FR data is required on at least the 10 percent of the BES buses determined in Step 6 with the highest maximum

available calculated three-phase short circuit MVA. Proceed to Step 8.

Step 8. SER and FR data is required at additional BES buses on the list determined in Step 6. The aggregate of the number of BES buses determined in Step 7 and this Step will be at least 20 percent of the BES buses determined in Step 6.

The additional BES buses are selected, at the Transmission Owner's discretion, to provide maximum wide-area coverage for SER and FR data. The following BES bus locations are recommended:

- Electrically distant buses or electrically distant from other Disturbance Monitoring Equipment (DME) devices.
- Voltage sensitive areas.
- Cohesive load and generation zones.
- BES buses with a relatively high number of incident Transmission circuits.
- BES buses with reactive power devices.
- Major Facilities interconnecting outside the Transmission Owner's area.

Step 9. The list of monitored BES buses for SER and FR data for Requirement R1 is the aggregate of the BES buses determined in Steps 7 and 8.

Attachment 2

Sequence of Events Recording (SER) Data Format

(Requirement R11, Part 11.3)

Date, Time, Local Time Code, Substation, Device, State[4]

08/27/13, 23:58:57.110, -5, Sub 1, Breaker 1, Close

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

PRC-002-5 is posted for a formal comment period with additional ballot.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	January 20, 2021
SAR posted for comment	June 14, 2021 – July 13, 2021

Anticipated Actions	Date
45-day formal comment period with ballot	August 1, 2023 – September 14, 2023
25-day formal or informal comment period with additional ballot	March 18, 2024 – April 11, 2024
25-day formal or informal comment period with additional ballot	May 31, 2024 – June 14, 2024
10-day final ballot	September 15, 2024 – September 24, 2024
Board adoption	October 15, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

~~The term Inverter-Based Resource (IBR) refers to the proposed definition being developed under the Project 2020-06 Verifications of Models and Data for Generators.~~

~~As of this posting, this definition is:~~

~~**Inverter-Based Resource**: A plant/facility that is connected to the electric system, consisting of one or more IBR Unit(s) operated as a single resource at a common point of interconnection. IBRs include, but are not limited to, solar photovoltaic (PV), Type 3 and Type 4 wind, battery energy storage system (BESS), and fuel cell.~~

A. Introduction

1. **Title:** Disturbance Monitoring and Reporting Requirements
2. **Number:** PRC-002-~~4~~5
3. **Purpose:** To have adequate data available to facilitate analysis of Bulk Electric System (BES) Disturbances.
4. **Applicability:**

   4.1. Functional Entities:

   4.1.1. Reliability Coordinator

   4.1.2. Transmission Owner

   4.1.3. Generator Owner

   4.2. Facilities: BES Elements, excluding ~~I~~inverter-~~B~~based ~~R~~resources.[1]
5. **Effective Date:** See Implementation Plan

B. Requirements and Measures

R1. Each Transmission Owner shall: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

1.1. Identify BES buses for which sequence of events recording (SER) and fault recording (FR) data is required by using the methodology in PRC-002-~~4~~5, Attachment 1.

1.2. Notify the other owners of BES Elements directly connected[2] to those BES buses, that SER or FR data is required for those BES Elements, only if the Transmission Owner who identified the BES buses in Part 1.1 does not have SER or FR data. This notification is required within 90 calendar days of completion of Part 1.1.

1.3. Re-evaluate all BES buses at least once every five calendar years in accordance with Part 1.1 and notify other owners in accordance with Part 1.2.

M1. The Transmission Owner for Requirement R1, Part 1.1 has a dated (electronic or hard copy) list of BES buses for which SER and FR data is required, identified in accordance with PRC-002-~~4~~5, Attachment 1; has dated (electronic or hard copy) evidence that it notified other owners in accordance with Requirement R1, Part 1.2; and evidence that all BES buses have been re-evaluated within the required intervals under Requirement R1, Part 1.3.

[1] Disturbance monitoring and reporting requirements for ~~I~~inverter-~~B~~based ~~R~~resources are addressed in PRC-028.

[2] For the purposes of this standard, "directly connected" BES Elements are BES Elements connected at the same voltage level within the same physical location sharing a common ground grid with the BES bus identified under Attachment 1. Transformers that have a low-side operating voltage of less than 100 kV are excluded.

R2. Each Transmission Owner and Generator Owner shall have SER data for circuit breaker position (open/close) for each circuit breaker it owns directly connected to the BES buses identified in Requirement R1 and associated with the BES Elements at those BES buses. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

M2. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of SER data for circuit breaker position as specified in Requirement R2. Evidence may include, but is not limited to: (1) documents describing the device interconnections and configurations which may include a single design standard as representative for common installations; or (2) actual data recordings; or (3) station drawings.

R3. Each Transmission Owner and Generator Owner shall have FR data to determine the following electrical quantities for each triggered FR for the BES Elements it owns directly connected to the BES buses identified in Requirement R1: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

3.1. Phase-to-neutral voltage for each phase of each specified BES bus.

3.2. Each phase current and the residual or neutral current for the following BES Elements:

3.2.1. Transformers that have a low-side operating voltage of 100 kV or above.

3.2.2. Transmission Lines.

M3. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of FR data that is sufficient to determine electrical quantities as specified in Requirement R3. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations which may include a single design standard as representative for common installations; or (2) actual data recordings or derivations; or (3) station drawings.

R4. Each Transmission Owner and Generator Owner shall have FR data as specified in Requirement R3 that meets the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

4.1. A single record or multiple records that include:

- A pre-trigger record length of at least two cycles and a total record length of at least 30 cycles for the same trigger point, or
- At least two cycles of the pre-trigger data, the first three cycles of the post-trigger data, and the final cycle of the fault as seen by the fault recorder.

4.2. A minimum recording rate of 16 samples per cycle.

4.3. Trigger settings for at least the following:

4.3.1. Neutral (residual) overcurrent.

4.3.2. Phase undervoltage or overcurrent.

M4. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that FR data meets Requirement R4. Evidence may include, but is not limited to: (1) documents describing the device specification (R4, Part 4.2) and device configuration or settings (R4, Parts 4.1 and 4.3), or (2) actual data recordings or derivations.

R5. Each Reliability Coordinator shall: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

5.1. Identify BES Elements for which dynamic Disturbance recording (DDR) data is required, including the following:

5.1.1. Synchronous ~~machine based~~ generating resource(s) with:

5.1.1.1. Gross individual nameplate rating greater than or equal to 500 MVA.

5.1.1.2. Gross individual nameplate rating greater than or equal to 300 MVA where the gross plant/facility aggregate nameplate rating is greater than or equal to 1,000 MVA.

5.1.2. Any one BES Element that is part of a stability (angular or voltage) related System Operating Limit (SOL).

5.1.3. Each terminal of a high voltage direct current (HVDC) circuit with a nameplate rating greater than or equal to 300 MVA, on the alternating current (AC) portion of the converter.

5.1.4. One or more BES Elements that are part of an Interconnection Reliability Operating Limit (IROL).

5.1.5. Any one BES Element within a major voltage sensitive area as defined by an area with an in-service undervoltage load shedding (UVLS) program.

5.2. Identify a minimum DDR coverage, inclusive of those BES Elements identified in Part 5.1, of at least:

5.2.1. One BES Element; and

5.2.2. One BES Element per 3,000 MW of the Reliability Coordinator’s historical simultaneous peak System Demand.

5.3. Notify all owners of identified BES Elements, within 90 calendar days of completion of Part 5.1, that their respective BES Elements require DDR data.

5.4. Re-evaluate all BES Elements within its Reliability Coordinator Area at least once every five calendar years in accordance with Parts 5.1 and 5.2, and notify owners in accordance with Part 5.3.

M5. The Reliability Coordinator has a dated (electronic or hard copy) list of BES Elements for which DDR data is required, developed in accordance with Requirement R5, Part 5.1 and Part 5.2; and re-evaluated in accordance with Part 5.4. The Reliability Coordinator has dated evidence (electronic or hard copy) that each Transmission Owner or Generator Owner has been notified in accordance with Requirement 5, Part

5.3. Evidence may include, but is not limited to letters, emails, electronic files, or hard copy records demonstrating transmittal of information.

R6. Each Transmission Owner shall have DDR data to determine the following electrical quantities for each BES Element it owns for which it received notification as identified in Requirement R5: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

6.1. One phase-to-neutral or positive sequence voltage.

6.2. The phase current for the same phase at the same voltage corresponding to the voltage in Requirement R6, Part 6.1, or the positive sequence current.

6.3. Real Power and Reactive Power flows expressed on a three-phase basis corresponding to all circuits where current measurements are required.

6.4. Frequency of any one of the voltage(s) in Requirement R6, Part 6.1.

M6. The Transmission Owner has evidence (electronic or hard copy) of DDR data to determine electrical quantities as specified in Requirement R6. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (2) actual data recordings or derivations; or (3) station drawings.

R7. Each Generator Owner shall have DDR data to determine the following electrical quantities for each BES Element it owns for which it received notification as identified in Requirement R5: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

7.1. One phase-to-neutral, phase-to-phase, or positive sequence voltage at either the generator step-up transformer (GSU) high-side or low-side voltage level.

7.2. The phase current for the same phase at the same voltage corresponding to the voltage in Requirement R7, Part 7.1, phase current(s) for any phase-to-phase voltages, or positive sequence current.

7.3. Real Power and Reactive Power flows expressed on a three-phase basis corresponding to all circuits where current measurements are required.

7.4. Frequency of at least one of the voltages in Requirement R7, Part 7.1.

M7. The Generator Owner has evidence (electronic or hard copy) of DDR data to determine electrical quantities as specified in Requirement R7. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (2) actual data recordings or derivations; or (3) station drawings.

R8. Each Transmission Owner and Generator Owner responsible for DDR data for the BES Elements identified in Requirement R5 shall have continuous data recording and storage. If the equipment was installed prior to the effective date of the Reliability

Standard PRC-002-2[3] and is not capable of continuous recording, triggered records must meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

8.1. Triggered record lengths of at least three minutes.

8.2. At least one of the following three triggers:

- Off nominal frequency trigger set at:

	Low	High
○ Eastern Interconnection	<59.75 Hz	>61.0 Hz
○ Western Interconnection	<59.55 Hz	>61.0 Hz
○ ERCOT Interconnection	<59.35 Hz	>61.0 Hz
○ ~~Hydro-~~Quebec Interconnection	<58.55 Hz	>61.5 Hz

- Rate of change of frequency trigger set at:

○ Eastern Interconnection	< -0.03125 Hz/sec	>0.125 Hz/sec
○ Western Interconnection	< -0.05625 Hz/sec	>0.125 Hz/sec
○ ERCOT Interconnection	< -0.08125 Hz/sec	>0.125 Hz/sec
○ ~~Hydro-~~Quebec Interconnection	< -0.18125 Hz/sec	>0.1875 Hz/sec

- Undervoltage trigger set no lower than 85 percent of normal operating voltage for a duration of 5 seconds.

M8. Each Transmission Owner and Generator Owner has dated evidence (electronic or hard copy) of data recordings and storage in accordance with Requirement R8. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (2) actual data recordings.

R9. Each Transmission Owner and Generator Owner responsible for DDR data for the BES Elements identified in Requirement R5 shall have DDR data that meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

9.1. Input sampling rate of at least 960 samples per second.

9.2. Output recording rate of electrical quantities of at least 30 times per second.

M9. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that DDR data meets Requirement R9. Evidence may include, but is not limited to: (1) documents describing the device specification, device configuration, or settings (R9, Part 9.1; R9, Part 9.2); or (2) actual data recordings (R9, Part 9.2).

R10. Each Transmission Owner and Generator Owner shall time synchronize all SER and FR data for the BES buses identified in Requirement R1 and DDR data for the BES

---

[3] The effective date of the Reliability Standard PRC-002-2 in the U.S. was July 1, 2016. The effective date may be different for other jurisdictions.

Elements identified in Requirement R5 to meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

10.1. Synchronization to Coordinated Universal Time (UTC) with or without a local time offset.

10.2. Synchronized device clock accuracy within ± 2 milliseconds of UTC.

M10. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of time synchronization described in Requirement R10. Evidence may include, but is not limited to: (1) documents describing the device specification, configuration, or setting; (2) time synchronization indication or status; or 3) station drawings.

R11. Each Transmission Owner and Generator Owner shall provide, upon request, all SER and FR data for the BES buses identified in Requirement R1 and DDR data for the BES Elements identified in Requirement R5 to the Reliability Coordinator, Regional Entity, or NERC in accordance with the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

11.1. Data will be retrievable for the period of 10 calendar days, inclusive of the day the data was recorded.

11.2. Data subject to Part 11.1 will be provided within 30 calendar days of a request unless an extension is granted by the requestor.

11.3. SER data will be provided in ASCII Comma Separated Value (CSV) format following Attachment 2.

11.4. FR ~~and DDR~~ data will be provided in ~~either in CSV format or~~ electronic files that are formatted in conformance with C37.111, IEEE Standard Common Format for Transient Data Exchange (COMTRADE), revision C37.111-1999 or later.

~~11.4.~~11.5. DDR data will be provided either in CSV format with appropriate headers or in electronic files that are formatted in conformance with C37.111, IEEE Standard Common Format for Transient Data Exchange (COMTRADE), revision C37.111-1999 or later.

~~11.5.~~11.6. Data files will be named in conformance with C37.232, IEEE Standard for Common Format for Naming Time Sequence Data Files (COMNAME), revision C37.232-2011 or later.

M11. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that data was submitted upon request in accordance with Requirement R11. Evidence may include, but is not limited to: (1) dated transmittals to the requesting entity with formatted records; (2) documents describing data storage capability, device specification, configuration or settings; or (3) actual data recordings.

R12. Each Transmission Owner and Generator Owner shall, upon~~within 90 calendar days of~~ the discovery of a failure of the recording capability for the SER, FR or DDR data~~, either~~: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

- Restore the recording capability within 90 calendar days, or
- Submit a Corrective Action Plan (CAP) to the Regional Entity within 90 calendar days and then implement it according to CAP timeline.

M12. The Transmission Owner or Generator Owner has dated evidence (electronic or hard copy) that meets Requirement R12. Evidence may include, but is not limited to: (1) dated reports of discovery of a failure, (2) documentation noting the date the data recording was restored, (3) SCADA records, or (4) dated CAP transmittals to the Regional Entity and evidence that it implemented the CAP.

R13. Each Transmission Owner and Generator Owner shall: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

13.1. Within three (3) calendar years of completing a re-evaluation or receiving notification under Requirement R1, Part 1.3, have SER or FR data as applicable for BES Elements directly connected to the identified BES buses.

13.2. Within three (3) calendar years of receiving notification under Requirement R5, Part 5.4, have DDR data for BES Elements identified during the re-evaluation.

M13. The Transmission Owner or Generator Owner has dated evidence (electronic or hard copy) that meets Requirement R13. Evidence may include, but is not limited to: letters, emails, drawings, or settings files.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention:

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner, Generator Owner, and Reliability Coordinator shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

The Transmission Owner shall retain evidence of Requirement R1, for five calendar years.

The Reliability Coordinator shall retain evidence of Requirement R5, for five calendar years.

The Transmission Owner shall retain evidence of Requirement R6, for three calendar years.

The Generator Owner shall retain evidence of Requirement R7, for three calendar years.

The Transmission Owner and Generator Owner shall retain evidence of Requirements R2, R3, R4, R8, R9, R10, R11, and R12, for three calendar years.

The Transmission Owner and Generator Owner as applicable shall retain evidence of Requirement R13, for five calendar years.

If a Transmission Owner, Generator Owner, or Reliability Coordinator is found non- compliant, it shall keep information related to the non-compliance until mitigation is completed and approved or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records, and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, “Compliance Monitoring and Enforcement Program” refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The Transmission Owner identified the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3 for more than 80 percent, but less than 100 percent of the required BES buses that they own. OR The Transmission Owner evaluated the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3, but was late by 30 calendar days or less. OR The Transmission Owner as directed by Requirement R1, Part 1.2 was late in notifying the other owners that their BES Elements require SER or FR data by 10 calendar days or less.	The Transmission Owner identified the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3 for more than 70 percent, but less than or equal to 80 percent of the required BES buses that they own. OR The Transmission Owner evaluated the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3, but was late by greater than 30 calendar days and less than or equal to 60 calendar days. OR The Transmission Owner as directed by Requirement R1, Part 1.2 was late in notifying the other owners that their BES Elements require SER or FR data by greater than 10 calendar	The Transmission Owner identified the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3 for more than 60 percent, but less than or equal to 70 percent of the required BES buses that they own. OR The Transmission Owner evaluated the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3, but was late by greater than 60 calendar days and less than or equal to 90 calendar days. OR The Transmission Owner as directed by Requirement R1, Part 1.2 was late in notifying the other owners that their BES Elements require SER or FR data by greater than	The Transmission Owner identified the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3 for less than or equal to 60 percent of the required BES buses that they own. OR The Transmission Owner evaluated the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3, but was late by greater than 90 calendar days. OR The Transmission Owner as directed by Requirement R1, Part 1.2 was late in notifying one or more other owners that their BES Elements require SER or FR data by greater than 30 calendar days.

		days, but less than or equal to 20 calendar days.	20 calendar days, but less than or equal to 30 calendar days.	
R2	Each Transmission Owner or Generator Owner as directed by Requirement R2 had more than 80 percent, but less than 100 percent of the total SER data for circuit breaker position (open/close) for each of the circuit breakers at the BES buses identified in Requirement R1.	Each Transmission Owner or Generator Owner as directed by Requirement R2 had more than 70 percent, but less than or equal to 80 percent of the total SER data for circuit breaker position (open/close) for each of the circuit breakers at the BES buses identified in Requirement R1.	Each Transmission Owner or Generator Owner as directed by Requirement R2 had more than 60 percent but less than or equal to 70 percent of the total SER data for circuit breaker position (open/close) for each of the circuit breakers at the BES buses identified in Requirement R1.	Each Transmission Owner or Generator Owner as directed by Requirement R2 for less than or equal to 60 percent of the total SER data for circuit breaker position (open/close) for each of the circuit breakers at the BES buses identified in Requirement R1.
R3	The Transmission Owner or Generator Owner had FR data as directed by Requirement R3, Parts 3.1 and 3.2 that covers more than 80 percent, but less than 100 percent of the total required electrical quantities, which is the product of the total number of monitored BES Elements and the number of specified electrical	The Transmission Owner or Generator Owner had FR data as directed by Requirement R3, Parts 3.1 and 3.2 that covers more than 70 percent, but less than or equal to 80 percent of the total required electrical quantities, which is the product of the total number of monitored BES Elements and the number of specified electrical	The Transmission Owner or Generator Owner had FR data as directed by Requirement R3, Parts 3.1 and 3.2 that covers more than 60 percent, but less than or equal to 70 percent of the total required electrical quantities, which is the product of the total number of monitored BES Elements and the number of specified electrical	The Transmission Owner or Generator Owner had FR data as directed by Requirement R3, Parts 3.1 and 3.2 that covers less than or equal to 60 percent of the total required electrical quantities, which is the product of the total number of monitored BES Elements and the number of specified electrical

	quantities for each BES Element.	quantities for each BES Element.	quantities for each BES Element.	quantities for each BES Element.
R4	The Transmission Owner or Generator Owner had FR data that meets more than 80 percent, but less than 100 percent of the total recording parameters as specified in Requirement R4.	The Transmission Owner or Generator Owner had FR data that meets more than 70 percent, but less than or equal to 80 percent of the total recording parameters as specified in Requirement R4.	The Transmission Owner or Generator Owner had FR data that meets more than 60 percent, but less than or equal to 70 percent of the total recording parameters as specified in Requirement R4.	The Transmission Owner or Generator Owner had FR data that meets less than or equal to 60 percent of the total recording parameters as specified in Requirement R4.
R5	The Reliability Coordinator identified the BES Elements for which DDR data is required as directed by Requirement R5 for more than 80 percent, but less than 100 percent of the required BES Elements included in Part 5.1. OR The Reliability Coordinator identified the BES Elements for DDR as directed by Requirement R5, Part 5.1 or Part 5.4, but was late by 30 calendar days or less.	The Reliability Coordinator identified the BES Elements for which DDR data is required as directed by Requirement R5 for more than 70 percent, but less than or equal to 80 percent of the required BES Elements included in Part 5.1. OR The Reliability Coordinator identified the BES Elements for DDR as directed by Requirement R5, Part 5.1 or Part 5.4, but was late by greater than 30 calendar	The Reliability Coordinator identified the BES Elements for which DDR data is required as directed by Requirement R5 for more than 60 percent, but less than or equal to 70 percent of the required BES Elements included in Part 5.1. Attachment 1

Methodology for Selecting Buses for Capturing Sequence of Events Recording (SER) and Fault Recording (FR) Data

(Requirement R1)

To identify monitored Bulk Electric System (BES) buses for SER and FR data required by Requirement 1, each Transmission Owner shall follow sequentially, unless otherwise noted, the steps listed below:

Step 1. Determine a complete list of BES buses that it owns. Refer to section 4.2 Facilities for exclusion.

For the purposes of this standard, a single BES bus includes physical buses with breakers connected at the same voltage level within the same physical location sharing a common ground grid. These buses may be modeled or represented by a single node in fault studies. For example, ring bus or breaker-and-a-half bus configurations are considered to be a single bus.

Step 2. Reduce the list to those BES buses that have a maximum available calculated three-phase short circuit MVA of 1,500 MVA or greater. If there are no buses on the resulting list, proceed to Step 7.

Step 3. Determine the 11 BES buses on the list with the highest maximum available calculated three-phase short circuit MVA level. If the list has 11 or fewer buses, proceed to Step 7.

Step 4. Calculate the median MVA level of the 11 BES buses determined in Step 3.

Step 5. Multiply the median MVA level determined in Step 4 by 20 percent.

Step 6. Reduce the BES buses on the list to only those that have a maximum available calculated three-phase short circuit MVA higher than the greater of:

- 1,500 MVA or
- 20 percent of median MVA level determined in Step 5.

Step 7. If there are no BES buses on the list: the procedure is complete, and no FR and SER data will be required. Proceed to Step 9.

If the list has 1 or more but less than or equal to 11 BES buses: FR and SER data is required at the BES bus with the highest maximum available calculated three-phase short circuit MVA as determined in Step 3.

During re-evaluation per Requirement R1, Part 1.3, if the three-phase short circuit MVA of the newly identified BES bus is within 15% of the three-phase short circuit MVA of the currently applicable BES bus with SER and FR data then it is not necessary to change the applicable BES bus. Proceed to Step 9.

If the list has more than 11 BES buses: SER and FR data is required on at least the 10 percent of the BES buses determined in Step 6 with the highest maximum

available calculated three-phase short circuit MVA. Proceed to Step 8.

Step 8. SER and FR data is required at additional BES buses on the list determined in Step 6. The aggregate of the number of BES buses determined in Step 7 and this Step will be at least 20 percent of the BES buses determined in Step 6.

The additional BES buses are selected, at the Transmission Owner's discretion, to provide maximum wide-area coverage for SER and FR data. The following BES bus locations are recommended:

- Electrically distant buses or electrically distant from other Disturbance Monitoring Equipment (DME) devices.
- Voltage sensitive areas.
- Cohesive load and generation zones.
- BES buses with a relatively high number of incident Transmission circuits.
- BES buses with reactive power devices.
- Major Facilities interconnecting outside the Transmission Owner's area.

Step 9. The list of monitored BES buses for SER and FR data for Requirement R1 is the aggregate of the BES buses determined in Steps 7 and 8.

Attachment 2

Sequence of Events Recording (SER) Data Format

(Requirement R11, Part 11.3)

Date, Time, Local Time Code, Substation, Device, State[4]

08/27/13, 23:58:57.110, -5, Sub 1, Breaker 1, Close

08/27/13, 23:58:57.082, -5, Sub 2, Breaker 2, Close

08/27/13, 23:58:47.217, -5, Sub 1, Breaker 1, Open

08/27/13, 23:58:47.214, -5, Sub 2, Breaker 2, Open

[4] "OPEN" and "CLOSE" are used as examples. Other terminology such as TRIP, TRIP TO LOCKOUT, RECLOSE, etc. is also acceptable.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

PRC-002-5 is posted for a formal comment period with additional ballot.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	January 20, 2021
SAR posted for comment	June 14, 2021 – July 13, 2021

Anticipated Actions	Date
45-day formal comment period with ballot	August 1, 2023 – September 14, 2023
25-day formal or informal comment period with additional ballot	March 18, 2024 – April 11, 2024
15-day formal or informal comment period with additional ballot	May 31, 2024 – June 14, 2024
10-day final ballot	September 15, 2024 – September 24, 2024
Board adoption	October 15, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

N/A.

A. Introduction

1. **Title:** Disturbance Monitoring and Reporting Requirements

2. **Number:** PRC-002-54

3. **Purpose:** To have adequate data available to facilitate analysis of Bulk Electric System (BES) Disturbances.

4. **Applicability:**

    4.1. Functional Entities:

    4.1.1. Reliability Coordinator

    4.1.2. Transmission Owner

    4.1.3. Generator Owner

    4.2. **Facilities:** BES Elements, excluding inverter-based resources.[1]

5. **Effective Date:** See Implementation Plan

B. Requirements and Measures

R1. Each Transmission Owner shall: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

1.1. Identify BES buses for which sequence of events recording (SER) and fault recording (FR) data is required by using the methodology in PRC-002-54, Attachment 1.

1.2. Notify the other owners of BES Elements directly connected[2] to those BES buses, that SER or FR data is required for those BES Elements, only if the Transmission Owner who identified the BES buses in Part 1.1 does not have SER or FR data. This notification is required within 90 calendar days of completion of Part 1.1.

1.3. Re-evaluate all BES buses at least once every five calendar years in accordance with Part 1.1 and notify other owners in accordance with Part 1.2.

M1. The Transmission Owner for Requirement R1, Part 1.1 has a dated (electronic or hard copy) list of BES buses for which SER and FR data is required, identified in accordance with PRC-002-54, Attachment 1; has dated (electronic or hard copy) evidence that it notified other owners in accordance with Requirement R1, Part 1.2; and evidence that all BES buses have been re-evaluated within the required intervals under Requirement R1, Part 1.3.

---

[1] Disturbance monitoring and reporting requirements for inverter-based resources are addressed in PRC-028.

[2] For the purposes of this standard, "directly connected" BES Elements are BES Elements connected at the same voltage level within the same physical location sharing a common ground grid with the BES bus identified under Attachment 1. Transformers that have a low-side operating voltage of less than 100 kV are excluded.

R2. Each Transmission Owner and Generator Owner shall have SER data for circuit breaker position (open/close) for each circuit breaker it owns directly connected to the BES buses identified in Requirement R1 and associated with the BES Elements at those BES buses. *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

M2. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of SER data for circuit breaker position as specified in Requirement R2. Evidence may include, but is not limited to: (1) documents describing the device interconnections and configurations which may include a single design standard as representative for common installations; or (2) actual data recordings; or (3) station drawings.

R3. Each Transmission Owner and Generator Owner shall have FR data to determine the following electrical quantities for each triggered FR for the BES Elements it owns directly connected to the BES buses identified in Requirement R1: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

3.1. Phase-to-neutral voltage for each phase of each specified BES bus.

3.2. Each phase current and the residual or neutral current for the following BES Elements:

3.2.1. Transformers that have a low-side operating voltage of 100 kV or above.

3.2.2. Transmission Lines.

M3. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of FR data that is sufficient to determine electrical quantities as specified in Requirement R3. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations which may include a single design standard as representative for common installations; or (2) actual data recordings or derivations; or (3) station drawings.

R4. Each Transmission Owner and Generator Owner shall have FR data as specified in Requirement R3 that meets the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

4.1. A single record or multiple records that include:

- A pre-trigger record length of at least two cycles and a total record length of at least 30 cycles for the same trigger point, or
- At least two cycles of the pre-trigger data, the first three cycles of the post-trigger data, and the final cycle of the fault as seen by the fault recorder.

4.2. A minimum recording rate of 16 samples per cycle.

4.3. Trigger settings for at least the following:

4.3.1. Neutral (residual) overcurrent.

4.3.2. Phase undervoltage or overcurrent.

M4. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that FR data meets Requirement R4. Evidence may include, but is not limited to: (1) documents describing the device specification (R4, Part 4.2) and device configuration or settings (R4, Parts 4.1 and 4.3), or (2) actual data recordings or derivations.

R5. Each Reliability Coordinator shall: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

5.1. Identify BES Elements for which dynamic Disturbance recording (DDR) data is required, including the following:

5.1.1. Synchronous ~~G~~generating resource(s) with:

5.1.1.1. Gross individual nameplate rating greater than or equal to 500 MVA.

5.1.1.2. Gross individual nameplate rating greater than or equal to 300 MVA where the gross plant/facility aggregate nameplate rating is greater than or equal to 1,000 MVA.

5.1.2. Any one BES Element that is part of a stability (angular or voltage) related System Operating Limit (SOL).

5.1.3. Each terminal of a high voltage direct current (HVDC) circuit with a nameplate rating greater than or equal to 300 MVA, on the alternating current (AC) portion of the converter.

5.1.4. One or more BES Elements that are part of an Interconnection Reliability Operating Limit (IROL).

5.1.5. Any one BES Element within a major voltage sensitive area as defined by an area with an in-service undervoltage load shedding (UVLS) program.

5.2. Identify a minimum DDR coverage, inclusive of those BES Elements identified in Part 5.1, of at least:

5.2.1. One BES Element; and

5.2.2. One BES Element per 3,000 MW of the Reliability Coordinator's historical simultaneous peak System Demand.

5.3. Notify all owners of identified BES Elements, within 90 calendar days of completion of Part 5.1, that their respective BES Elements require DDR data.

5.4. Re-evaluate all BES Elements within its Reliability Coordinator Area at least once every five calendar years in accordance with Parts 5.1 and 5.2, and notify owners in accordance with Part 5.3.

M5. The Reliability Coordinator has a dated (electronic or hard copy) list of BES Elements for which DDR data is required, developed in accordance with Requirement R5, Part 5.1 and Part 5.2; and re-evaluated in accordance with Part 5.4. The Reliability Coordinator has dated evidence (electronic or hard copy) that each Transmission Owner or Generator Owner has been notified in accordance with Requirement 5, Part

5.3. Evidence may include, but is not limited to~~:~~ letters, emails, electronic files, or hard copy records demonstrating transmittal of information.

R6. Each Transmission Owner shall have DDR data to determine the following electrical quantities for each BES Element it owns for which it received notification as identified in Requirement R5: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

6.1. One phase-to-neutral or positive sequence voltage.

6.2. The phase current for the same phase at the same voltage corresponding to the voltage in Requirement R6, Part 6.1, or the positive sequence current.

6.3. Real Power and Reactive Power flows expressed on a three~~-~~-phase basis corresponding to all circuits where current measurements are required.

6.4. Frequency of any one of the voltage(s) in Requirement R6, Part 6.1.

M6. The Transmission Owner has evidence (electronic or hard copy) of DDR data to determine electrical quantities as specified in Requirement R6. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (2) actual data recordings or derivations; or (3) station drawings.

R7. Each Generator Owner shall have DDR data to determine the following electrical quantities for each BES Element it owns for which it received notification as identified in Requirement R5: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

7.1. One phase-to-neutral, phase-to-phase, or positive sequence voltage at either the generator step-up transformer (GSU) high-side or low-side voltage level.

7.2. The phase current for the same phase at the same voltage corresponding to the voltage in Requirement R7, Part 7.1, phase current(s) for any phase-to-phase voltages, or positive sequence current.

7.3. Real Power and Reactive Power flows expressed on a three~~-~~-phase basis corresponding to all circuits where current measurements are required.

7.4. Frequency of at least one of the voltages in Requirement R7, Part 7.1.

M7. The Generator Owner has evidence (electronic or hard copy) of DDR data to determine electrical quantities as specified in Requirement R7. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (2) actual data recordings or derivations; or (3) station drawings.

R8. Each Transmission Owner and Generator Owner responsible for DDR data for the BES Elements identified in Requirement R5 shall have continuous data recording and storage. If the equipment was installed prior to the effective date of the Reliability

Standard PRC-002-2[3] and is not capable of continuous recording, triggered records must meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

8.1. Triggered record lengths of at least three minutes.

8.2. At least one of the following three triggers:

- Off nominal frequency trigger set at:

	Low	High
o Eastern Interconnection	<59.75 Hz	>61.0 Hz
o Western Interconnection	<59.55 Hz	>61.0 Hz
o ERCOT Interconnection	<59.35 Hz	>61.0 Hz
o ~~Hydro-~~Quebec Interconnection	<58.55 Hz	>61.5 Hz

- Rate of change of frequency trigger set at:

o Eastern Interconnection	< -0.03125 Hz/sec	>0.125 Hz/sec
o Western Interconnection	< -0.05625 Hz/sec	>0.125 Hz/sec
o ERCOT Interconnection	< -0.08125 Hz/sec	>0.125 Hz/sec
o ~~Hydro-~~Quebec Interconnection	< -0.18125 Hz/sec	>0.1875 Hz/sec

- Undervoltage trigger set no lower than 85 percent of normal operating voltage for a duration of 5 seconds.

M8. Each Transmission Owner and Generator Owner has dated evidence (electronic or hard copy) of data recordings and storage in accordance with Requirement R8. Evidence may include, but is not limited to: (1) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (2) actual data recordings.

R9. Each Transmission Owner and Generator Owner responsible for DDR data for the BES Elements identified in Requirement R5 shall have DDR data that meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

9.1. Input sampling rate of at least 960 samples per second.

9.2. Output recording rate of electrical quantities of at least 30 times per second.

M9. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that DDR data meets Requirement R9. Evidence may include, but is not limited to: (1) documents describing the device specification, device configuration, or settings (R9, Part 9.1; R9, Part 9.2); or (2) actual data recordings (R9, Part 9.2).

R10. Each Transmission Owner and Generator Owner shall time synchronize all SER and FR data for the BES buses identified in Requirement R1 and DDR data for the BES

[3] The effective date of the Reliability Standard PRC-002-2 in the U.S. was July 1, 2016. The effective date may be different for other jurisdictions.

Elements identified in Requirement R5 to meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

10.1. Synchronization to Coordinated Universal Time (UTC) with or without a local time offset.

10.2. Synchronized device clock accuracy within ± 2 milliseconds of UTC.

M10. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of time synchronization described in Requirement R10. Evidence may include, but is not limited to: (1) documents describing the device specification, configuration, or setting; (2) time synchronization indication or status; or 3) station drawings.

R11. Each Transmission Owner and Generator Owner shall provide, upon request, all SER and FR data for the BES buses identified in Requirement R1 and DDR data for the BES Elements identified in Requirement R5 to the Reliability Coordinator, Regional Entity, or NERC in accordance with the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

11.1. Data will be retrievable for the period of 10 calendar days, inclusive of the day the data was recorded.

11.2. Data subject to Part 11.1 will be provided within 30 calendar days of a request unless an extension is granted by the requestor.

11.3. SER data will be provided in ASCII Comma Separated Value (CSV) format following Attachment 2.

11.4. FR ~~and DDR~~ data will be provided in electronic files that are formatted in conformance with C37.111, ~~(~~IEEE Standard Common Format for Transient Data Exchange (COMTRADE), revision C37.111-1999 or later.

~~**11.4.**~~**11.5.** DDR data will be provided either in CSV format with appropriate headers or in electronic files that are formatted in conformance with C37.111, IEEE Standard Common Format for Transient Data Exchange (COMTRADE), revision C37.111-1999 or later.

~~**11.5.**~~**11.6.** Data files will be named in conformance with C37.232, IEEE Standard for Common Format for Naming Time Sequence Data Files (COMNAME), revision C37.232-2011 or later.

M11. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that data was submitted upon request in accordance with Requirement R11. Evidence may include, but is not limited to: (1) dated transmittals to the requesting entity with formatted records; (2) documents describing data storage capability, device specification, configuration or settings; or (3) actual data recordings.

R12. Each Transmission Owner and Generator Owner shall, upon~~within 90 calendar days of~~ the discovery of a failure of the recording capability for the SER, FR or DDR data~~, either~~: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

- Restore the recording capability within 90 calendar days, or
- Submit a Corrective Action Plan (CAP) to the Regional Entity within 90 calendar days and then implement it according to CAP timeline.

M12. The Transmission Owner or Generator Owner has dated evidence (electronic or hard copy) that meets Requirement R12. Evidence may include, but is not limited to: (1) dated reports of discovery of a failure, (2) documentation noting the date the data recording was restored, (3) SCADA records, or (4) dated CAP transmittals to the Regional Entity and evidence that it implemented the CAP.

R13. Each Transmission Owner and Generator Owner shall: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

13.1. Within three (3) calendar years of completing a re-evaluation or receiving notification under Requirement R1, Part 1.3, have SER or FR data as applicable for BES Elements directly connected to the identified BES buses.

13.2. Within three (3) calendar years of receiving notification under Requirement R5, Part 5.4, have DDR data for BES Elements identified during the re-evaluation.

M13. The Transmission Owner or Generator Owner has dated evidence (electronic or hard copy) that meets Requirement R13. Evidence may include, but is not limited to: letters, emails, drawings, or settings files.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. ~~Data~~Evidence Retention:

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner, Generator Owner, and Reliability Coordinator shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

The Transmission Owner shall retain evidence of Requirement R1,~~ Measure M1~~ for five calendar years.

The Reliability Coordinator shall retain evidence of Requirement R5, ~~Measure M5~~ for five calendar years.

The Transmission Owner shall retain evidence of Requirement R6, ~~Measure M6~~ for three calendar years.

The Generator Owner shall retain evidence of Requirement R7, ~~Measure M7~~ for three calendar years.

The Transmission Owner and Generator Owner shall retain evidence of ~~requested data provided as per~~ Requirements R2, R3, R4, R8, R9, R10, R11, and R12, ~~Measures M2, M3, M4, M8, M9, M10, M11, and M12~~ for three calendar years.

The Transmission Owner and Generator Owner as applicable shall retain evidence of Requirement R13, ~~Measure 13~~ for five calendar years.

If a Transmission Owner, Generator Owner, or Reliability Coordinator is found non-~~-~~compliant, it shall keep information related to the non-compliance until mitigation is completed and approved or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records, and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with associated Reliability Standard.

- ~~Compliance Audit~~

Attachment 1

Methodology for Selecting Buses for Capturing Sequence of Events Recording (SER) and Fault Recording (FR) Data

(Requirement R1)

To identify monitored Bulk Electric System (BES) buses for ~~sequence of events recording (~~SER~~)~~ and ~~Fault recording (~~FR~~)~~ data required by Requirement 1, each Transmission Owner shall follow sequentially, unless otherwise noted, the steps listed below:

Step 1. Determine a complete list of BES buses that it owns. Refer to section 4.2 Facilities for exclusion.

For the purposes of this standard, a single BES bus includes physical buses with breakers connected at the same voltage level within the same physical location sharing a common ground grid. These buses may be modeled or represented by a single node in fault studies. For example, ring bus or breaker-and-a-half bus configurations are considered to be a single bus.

Step 2. Reduce the list to those BES buses that have a maximum available calculated three~~-~~-phase short circuit MVA of 1,500 MVA or greater. If there are no buses on the resulting list, proceed to Step 7.

Step 3. Determine the 11 BES buses on the list with the highest maximum available calculated three~~-~~-phase short circuit MVA level. If the list has 11 or fewer buses, proceed to Step 7.

Step 4. Calculate the median MVA level of the 11 BES buses determined in Step 3.

Step 5. Multiply the median MVA level determined in Step 4 by 20 percent.

Step 6. Reduce the BES buses on the list to only those that have a maximum available calculated three~~-~~-phase short circuit MVA higher than the greater of:

- 1,500 MVA or
- 20 percent of median MVA level determined in Step 5.

Step 7. If there are no BES buses on the list: the procedure is complete, and no FR and SER data will be required. Proceed to Step 9.

If the list has 1 or more but less than or equal to 11 BES buses: FR and SER data is required at the BES bus with the highest maximum available calculated three~~-~~-phase short circuit MVA as determined in Step 3.

During re-evaluation per Requirement R1, Part 1.3, if the three~~-~~-phase short circuit MVA of the newly identified BES bus is within 15% of the three~~-~~-phase short circuit MVA of the currently applicable BES bus with SER and FR data then it is not necessary to change the applicable BES bus. Proceed to Step 9.

If the list has more than 11 BES buses: SER and FR data is required on at least the 10 percent of the BES buses determined in Step 6 with the highest maximum

available calculated three-~~-~~phase short circuit MVA. Proceed to Step 8.

Step 8. SER and FR data is required at additional BES buses on the list determined in Step 6. The aggregate of the number of BES buses determined in Step 7 and this Step will be at least 20 percent of the BES buses determined in Step 6.

The additional BES buses are selected, at the Transmission Owner's discretion, to provide maximum wide-area coverage for SER and FR data. The following BES bus locations are recommended:

- Electrically distant buses or electrically distant from other Disturbance Monitoring Equipment (DME) devices.
- Voltage sensitive areas.
- Cohesive load and generation zones.
- BES buses with a relatively high number of incident Transmission circuits.
- BES buses with reactive power devices.
- Major Facilities interconnecting outside the Transmission Owner's area.

Step 9. The list of monitored BES buses for SER and FR data for Requirement R1 is the aggregate of the BES buses determined in Steps 7 and 8.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

PRC-028-1 is posted for a formal comment period with additional ballot.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	January 20, 2021
SAR posted for comment	June 14, 2021 – July 13, 2021

Anticipated Actions	Date
45-day formal comment period with ballot	August 1, 2023 – September 14, 2023
25-day formal or informal comment period with additional ballot	March 18, 2024 – April 11, 2024
15-day formal or informal comment period with additional ballot	May 31, 2024 – June 14, 2024
10-day final ballot	September 15, 2024 – September 24, 2024
Board adoption	October 15, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

N/A

A. Introduction

1. **Title:** Disturbance Monitoring and Reporting Requirements for Inverter-Based Resources

2. **Number:** PRC-028-1

3. **Purpose:** To have adequate data available from inverter-based resources[1] to evaluate inverter-based resource ride-through performance during Bulk Electric System (BES) Disturbances and to provide data for inverter-based resource model validation.

4. **Applicability:**

   4.1. Functional Entities:

   4.1.1. Transmission Owner that owns equipment as identified in section 4.2

   4.1.2. Generator Owner that owns equipment as identified in section 4.2

   4.2. Facilities: BES inverter-based resources

5. **Effective Date:** See Implementation Plan

B. Requirements and Measures

R1. Each Transmission Owner and Generator Owner shall have circuit breaker position (open/close) sequence of event recording (SER) data for circuit breakers that it owns associated with: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

1.1. Main power transformer(s)[2].

1.2. Collector bus(es), including collector feeder breakers.

1.3. Shunt static or dynamic reactive device(s).

1.4. AC-DC and DC-AC converters, if any, in case of VSC HVDC system with a dedicated connection to inverter-based resource.

M1. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of data, as applicable, as specified in Requirement R1. Evidence may include, but is not limited to: (1) actual data recordings; or (2) documents describing the device interconnections and configurations which may include a single design standard as representative for common installations; or (3) station or equipment drawings.

---

[1] For the purpose of this standard, "inverter-based resources" refers to a collection of individual solar photovoltaic (PV), Type 3 and Type 4 wind turbines, battery energy storage system (BESS), or fuel cells that operate as a single plant/resource. In case of offshore wind plants connecting via a dedicated voltage source converter high voltage direct current (VSC HVDC) line, the inverter-based resource includes VSC HVDC line.

[2] For the purpose of this standard, the main power transformer is the power transformer that steps up voltage from the collection system voltage to the nominal transmission/interconnecting system voltage for inverter-based resources. In case of dedicated VSC HVDC system connecting to an inverter-based resource, transformer isolating the DC-AC converter from the transmission system is considered main power transformer.

R2. Each Transmission Owner and Generator Owner shall have triggered fault recording (FR) data to determine the following electrical quantities for Elements that it owns: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

2.1. High-side of the main power transformer FR data:

2.1.1. Phase-to-neutral voltage for each phase.

2.1.2. Each phase current and the residual or neutral current.

2.1.3. Real and reactive power expressed on a three-phase basis.

2.2. Shunt dynamic reactive device data:

2.2.1. Phase-to-neutral voltage for each phase.

2.2.2. Each phase current and the residual or neutral current.

2.2.3. Reactive power output expressed on a three-phase basis.

M2. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of FR data that is sufficient to determine electrical quantities as specified in Requirement R2. Evidence may include, but is not limited to: (1) actual data recordings or derivations; or (2) documents describing the device specifications and configurations which may include a single design standard as representative for common installations; or (3) station or equipment drawings.

R3. Each Transmission Owner and Generator Owner shall have FR data as specified in Requirement R2 that meets the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

3.1. High-side of the main power transformer FR data

3.1.1. A single record or multiple records that include a pre-trigger record length of at least two cycles and a total record length of at least 2.0 seconds for the same trigger point.

3.1.2. A minimum recording rate of 64 samples per cycle.

3.1.3. Trigger settings for at least the following:

3.1.3.1. Neutral (residual) overcurrent.

3.1.3.2. AC phase overvoltage and undervoltage.

3.2. Shunt dynamic reactive device FR data

3.2.1. A single record or multiple records that include a pre-trigger record length of at least two cycles and a total record length of at least 2.0 seconds for the same trigger point.

3.2.2. A minimum recording rate of 64 samples per cycle.

3.2.3. Trigger settings for at least the following:

3.2.3.1. Neutral (residual) overcurrent.

3.2.3.2. AC phase overvoltage and undervoltage.

M3. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that FR data meets Requirement R3. Evidence may include, but is not limited to: (1) actual data recordings or derivations, or (2) documents describing the device specification and device configuration or settings.

R4. Each Generator Owner and Transmission Owner shall have continuous dynamic disturbance recording (DDR) data and storage to determine the following electrical quantities for each main power transformer(s) it owns: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

4.1. One phase-to-neutral or positive sequence voltage on high-side of the main power transformer(s).

4.2. The phase current for the same phase at the same voltage corresponding to the voltage in Requirement R4, Part 4.1, or the positive sequence current.

4.3. Real Power and Reactive Power flows expressed on a three-phase basis corresponding to each main power transformer(s) where current measurements are required.

4.4. Frequency of any one of the voltage(s) in Requirement R4, Part 4.1.

M4. The Generator Owner or Transmission Owner has evidence (electronic or hard copy) of continuous DDR data recording and storage to determine electrical quantities as specified in Requirement R4. Evidence may include, but is not limited to: (1) actual data recordings or derivations; or (2) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (3) station drawings.

R5. Each Transmission Owner and Generator Owner responsible for DDR data for the electrical quantities identified in Requirement R4 shall have DDR data that meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

5.1. Input sampling rate of at least 960 samples per second.

5.2. Output recording rate of electrical quantities of at least 60 times per second.

M5. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that DDR data meets Requirement R5. Evidence may include, but is not limited to: (1) documents describing the device specification, device configuration, or settings (R5, Part 5.1; R5, Part 5.2); or (2) actual data recordings (R5, Part 5.2).

R6. Each Transmission Owner and Generator Owner shall time synchronize all SER, FR, and DDR data to meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

6.1. Synchronization to Coordinated Universal Time (UTC) with or without a local time offset.

6.2. Synchronized device clock accuracy within ± 1 milliseconds of UTC.

M6. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of time synchronization described in Requirement R6. Evidence may include, but is not limited to: (1) documents describing the device specification, configuration, or setting; (2) time synchronization indication or status; or 3) station drawings.

R7. Each Transmission Owner and Generator Owner shall provide all requested SER, FR, and DDR data to its Transmission Planner, Planning Coordinator, Transmission Operator, Balancing Authority, Reliability Coordinator, Regional Entity, or NERC in accordance with the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

7.1. Data shall be retrievable for the period of 20 calendar days, inclusive of the day the data was recorded.

7.2. Data subject to Part 7.1 shall be provided within 15 calendar days of a request unless an extension is granted by the requestor.

7.3. SER data shall be provided in ASCII[3] Comma Separated Value (CSV) format following Attachment 1.

7.4. FR data shall be provided in electronic files that are formatted in conformance with C37.111, IEEE Standard Common Format for Transient Data Exchange (COMTRADE), revision C37.111-1999 or later.

7.5. DDR data shall be provided either in CSV format with appropriate headers or in electronic files that are formatted in conformance with C37.111, IEEE Standard Common Format for Transient Data Exchange (COMTRADE), revision C37.111-1999 or later.

7.6. Data files shall be named in conformance with C37.232, IEEE Standard for Common Format for Naming Time Sequence Data Files (COMNAME), revision C37.232-2011 or later.

M7. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that data was submitted upon request in accordance with Requirement R7. Evidence may include, but is not limited to: (1) actual data recordings; (2) dated transmittals to the requesting entity with formatted records; or (3) documents describing data storage capability, device specification, configuration, or settings.

R8. Each Transmission Owner and Generator Owner shall, upon the discovery of a failure of the recording capability for the SER, FR, or DDR data: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

- Restore the recording capability within 90 calendar days, or
- Submit a Corrective Action Plan (CAP) to the Regional Entity within 90 calendar days and then implement it according to CAP timeline.

---

[3] American Standard Code for Information Exchange

M8. The Transmission Owner or Generator Owner has dated evidence (electronic or hard copy) that meets Requirement R8. Evidence may include, but is not limited to: (1) dated reports of the discovery of a failure, (2) documentation noting the date the data recording was restored, (3) SCADA records, or (4) dated Corrective Action Plan transmittals to the Regional Entity and evidence of Corrective Action Plan implementation.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention:

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner and Generator Owner shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

The Transmission Owner and Generator Owner shall retain evidence, as per Requirements R1 through R8, for three calendar years.

If a Transmission Owner or Generator Owner is found non-compliant, it shall keep information related to the non-compliance until mitigation is completed and approved or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records, and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	Each Transmission Owner or Generator Owner as directed by Requirement R1 to have the required SER data had more than 80 percent, but less than 100 percent of the circuit breaker(s) identified in Requirement R1.	Each Transmission Owner or Generator Owner as directed by Requirement R1 to have the required SER data had more than 70 percent, but less than or equal to 80 percent of the circuit breaker(s) identified in Requirement R1.	Each Transmission Owner or Generator Owner as directed by Requirement R1 to have the required SER data had more than 60 percent, but less than or equal to 70 percent of the circuit breaker(s) identified in Requirement R1.	Each Transmission Owner or Generator Owner as directed by Requirement R1 to have the required SER data had less than or equal to 60 percent of the circuit breaker(s) identified in Requirement R1.
R2	The Transmission Owner or Generator Owner had FR data as directed by Requirement R2, Parts 2.1, 2.2, and 2.3 that covers more than 80 percent, but less than 100 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The Transmission Owner or Generator Owner had FR data as directed by Requirement R2, Parts 2.1, 2.2, and 2.3 that covers more than 70 percent, but less than or equal to 80 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The Transmission Owner or Generator Owner had FR data as directed by Requirement R2, Parts 2.1, 2.2, and 2.3 that covers more than 60 percent, but less than or equal to 70 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The Transmission Owner or Generator Owner had FR data as directed by Requirement R2, Parts 2.1, 2.2, and 2.3 that covers less than or equal to 60 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.

R3	The Transmission Owner or Generator Owner had FR data that meets more than 80 percent, but less than 100 percent of the total recording parameters as specified in Requirement R3.	The Transmission Owner or Generator Owner had FR data that meets more than 70 percent, but less than or equal to 80 percent of the total recording parameters as specified in Requirement R3.	The Transmission Owner or Generator Owner had FR data that meets more than 60 percent, but less than or equal to 70 percent of the total recording parameters as specified in Requirement R3.	The Transmission Owner or Generator Owner had FR data that meets less than or equal to 60 percent of the total recording parameters as specified in Requirement R3.
R4	The Transmission Owner or Generator Owner had DDR data as directed by Requirement R4, Parts 4.1 through 4.4 that covered more than 80 percent, but less than 100 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The Transmission Owner or Generator Owner had DDR data as directed by Requirement R4, Parts 4.1 through 4.4 for more than 70 percent, but less than or equal to 80 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The Transmission Owner or Generator Owner had DDR data as directed by Requirement R4, Parts 4.1 through 4.4 for more than 60 percent, but less than or equal to 70 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The Transmission Owner or Generator Owner had DDR data as directed by Requirement R4, Parts 4.1 through 4.4 for less than or equal to 60 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.
R5	The Transmission Owner or Generator Owner had DDR data that meets more than 80 percent, but less than 100 percent of the	The Transmission Owner or Generator Owner had DDR data that meets more than 70 percent, but less than or equal to 80 percent of the	The Transmission Owner or Generator Owner had DDR data that meets more than 60 percent, but less than or equal to 70	The Transmission Owner or Generator Owner had DDR data that meets less than or equal to 60 percent of the total

	total recording parameters as specified in Requirement R5.	total recording properties as specified in Requirement R5.	percent of the total recording properties as specified in Requirement R5.	recording properties as specified in Requirement R5.
R6	The Transmission Owner or Generator Owner had time synchronized SER, FR, or DDR data per Requirement R6, Parts 6.1 and 6.2 for more than 90 percent, but less than 100 percent of the Elements.	The Transmission Owner or Generator Owner had time synchronized SER, FR, or DDR data per Requirement R6, Parts 6.1 and 6.2 for more than 80 percent, but less than or equal to 90 percent of the Elements.	The Transmission Owner or Generator Owner had time synchronized SER, FR, or DDR data per Requirement R6, Parts 6.1 and 6.2 for more than 70 percent, but less than or equal to 80 percent of the Elements.	The Transmission Owner or Generator Owner failed to have time synchronized SER, FR, or DDR data per Requirement R6, Parts 6.1 and 6.2 for less than or equal to 70 percent of the Elements.
R7	The Transmission Owner or Generator Owner as directed by Requirement R7 provided more than 90 percent, but less than 100 percent of the requested data. OR The Transmission Owner or Generator Owner as directed by Requirement R7, Part 7.2 provided the requested data more than 15 calendar days, but less than or equal to 25 calendar days after the	The Transmission Owner or Generator Owner as directed by Requirement R7 provided more than 80 percent, but less than or equal to 90 percent of the requested data. Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

PRC-028-1 is posted for a formal comment period with additional ballot.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	January 20, 2021
SAR posted for comment	June 14, 2021 – July 13, 2021

Anticipated Actions	Date
45-day formal comment period with ballot	August 1, 2023 – September 14, 2023
25-day formal or informal comment period with additional ballot	March 18, 2024 – April 11, 2024
15-day formal or informal comment period with additional ballot	May 31, 2024 – June 14, 2024
10-day final ballot	September 15, 2024 – September 24, 2024
Board adoption	October 15, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

N/A~~The terms Inverter-Based Resource (IBR) and IBR unit refers to the proposed definitions being developed under the Project 2020-06 Verifications of Models and Data for Generators.~~

~~As of this posting, these~~ this ~~definitions are~~is~~:~~

~~**Inverter-Based Resource**: A plant/facility that is connected to the electric system, consisting of one or more IBR Unit(s) operated as a single resource at a common point of interconnection. IBRs include, but are not limited to, solar photovoltaic (PV), Type 3 and Type 4 wind, battery energy storage system (BESS), and fuel cell.~~

~~**IBR Unit**: An individual device that uses a power electronic interface, such as an inverter or converter, capable of exporting Real Power from a primary energy source or energy storage system, and that connects at a single point on the collector system; or a grouping of multiple devices that uses a power electronic interface(s), such as an inverter or converter, capable of exporting Real Power from a primary energy source or energy storage system, and that connect together at a single point on the collector system.~~

A. Introduction

1. **Title:** Disturbance Monitoring and Reporting Requirements for ~~I~~inverter-~~B~~based ~~R~~resources

2. **Number:** PRC-028-1

3. **Purpose:** To have adequate data available from ~~I~~inverter-~~B~~based ~~R~~resources[1] ~~(IBR)~~ to evaluate ~~facilitate analysis of IBR~~inverter-based resource ride-through performance during Bulk Electric System (BES) Disturbances and to provide data for ~~IBR~~inverter-based resource model validation.

4. **Applicability:**

   4.1. Functional Entities:

   4.1.1. Transmission Owner that owns equipment as identified in section 4.2

   4.1.2. Generator Owner that owns equipment as identified in section 4.2

   Facilities:

   4.2. ~~The Elements associated with (1)~~ BES ~~I~~inverter-~~B~~based ~~R~~resources~~; and (2) Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV~~.

5. **Effective Date:** See Implementation Plan

B. Requirements and Measures

R1. Each Transmission Owner and Generator Owner shall have ~~sequence of event recording (SER) data for the following Elements~~ circuit breaker position (open/close) sequence of event recording (SER) data for circuit breakers that it owns associated with: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

1.1. ~~Circuit breaker position (open/close) for circuit breakers associated with the main~~ Main power transformer(s)[2].

1.2. ~~c~~Collector bus(es), including collector feeder breakers~~, and~~.

1.3. ~~s~~Shunt static or dynamic reactive device(s), including any filter banks.

[1] For the purpose of this standard, "inverter-based resources" refers to a collection of individual solar photovoltaic (PV), Type 3 and Type 4 wind turbines, battery energy storage system (BESS), or fuel cells that operate as a single plant/resource. In case of offshore wind plants connecting via a dedicated voltage source converter high voltage direct current (VSC HVDC) line, the inverter-based resource includes VSC HVDC line.

[2] For the purpose of this standard, the main power transformer is the power transformer that steps up voltage from the collection system voltage to the nominal transmission/interconnecting system voltage for ~~dispersed power producing~~inverter-based ~~resources~~resources. In case of dedicated VSC HVDC system connecting to an inverter-based resource, transformer isolating the DC-AC converter from the transmission system is considered main power transformer.

~~1.1.~~1.4. AC-DC and DC-AC converters, if any, in case of VSC HVDC line with a dedicated connection to inverter-based resources.

~~**1.2.** For IBR Units in commercial operation after [the effective date of this standard]: at least one IBR Unit, per collector bus, on any of the collector feeders that is connected at a distance greater than or equal to 90% of the longest collector feeder. The following data shall be recorded when triggered by ride-through operation or tripping of an IBR Unit.~~

~~**1.2.1.** All fault codes.~~

~~**1.2.2.** All fault alarms.~~

~~**1.2.3.** High and low voltage ride-through mode status.~~

~~**1.2.4.** High and low frequency ride-through mode status.~~

~~**1.3.** For IBR Units in commercial operation prior to [the effective date of this standard]: at least one IBR Unit, per collector bus, on any of the collector feeders that is connected at a distance greater than or equal to 90% of the longest collector feeder. The following data shall be recorded, if capable of recording, when triggered by ride-through operation or tripping of an IBR Unit.~~

~~**1.3.1.** All fault codes.~~

~~**1.3.2.** All fault alarms.~~

~~**1.3.3.** High and low voltage ride-through mode status.~~

~~High and low frequency ride-through mode status.~~

M1. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of data, as applicable, as specified in Requirement R1. Evidence may include, but is not limited to: (1) actual data recordings; or (2) documents describing the device interconnections and configurations which may include a single design standard as representative for common installations; or (3) station or equipment drawings.

R2. Each Transmission Owner and Generator Owner shall have triggered fault recording (FR) data to determine the following electrical quantities for Elements that it owns: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

2.1. High-side of the main power transformer FR data:

2.1.1. Phase-to-neutral voltage for each phase.

2.1.2. Each phase current and the residual or neutral current.

2.1.3. Real and reactive power expressed on a three-phase basis.

~~**2.2.** IBR Unit FR data from at least one IBR Unit, per collector bus, on any of the collector feeders that is connected at a distance greater than or equal to 90% of the longest collector feeder:~~

~~**2.2.1.** Each AC phase-to-neutral or phase-to-phase voltage, as applicable, at IBR Unit terminals or on high-side of the IBR Unit transformer.~~

~~**2.2.2.** Each AC phase current and the residual or neutral current, as applicable, on IBR Unit terminals or on high-side of the IBR Unit transformer.~~

~~**2.3.**~~**2.2.** Shunt dynamic reactive device data:

~~**2.3.1.**~~**2.2.1.** Phase-to-neutral voltage for each phase.

~~**2.3.2.**~~**2.2.2.** Each phase current and the residual or neutral current.

~~**2.3.3.**~~**2.2.3.** ~~Real and r~~Reactive power output expressed on a three-phase basis.

M2. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of FR data that is sufficient to determine electrical quantities as specified in Requirement R2. Evidence may include, but is not limited to: (1) actual data recordings or derivations; or (2) documents describing the device specifications and configurations which may include a single design standard as representative for common installations; or (3) station or equipment drawings.

R3. Each Transmission Owner and Generator Owner shall have FR data as specified in Requirement R2 that meets the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

3.1. High-side of the main power transformer FR data

3.1.1. A single record or multiple records that include a pre-trigger record length of at least two cycles and a total record length of at least 2.0 seconds for the same trigger point.

3.1.2. A minimum recording rate of 64 samples per cycle.

3.1.3. Trigger settings for at least the following:

3.1.3.1. Neutral (residual) overcurrent.

3.1.3.2. AC phase overvoltage and undervoltage.

~~**3.2.** IBR Unit level data~~

~~**3.2.1.** A single record or multiple records that include a pre-trigger record length of at least two cycles and a total record length of at least 2 seconds for the same trigger point.~~

~~**3.2.2.** A minimum recording rate of 64 samples per cycle).~~

~~**3.2.3.** Trigger settings for at least the following:~~

~~**3.2.3.1.** AC Phase overvoltage and undervoltage.~~

~~**3.2.3.2.** Overfrequency and underfrequency.~~

~~**3.3.**~~**3.2.** Shunt dynamic reactive device FR data

~~3.3.1.~~3.2.1. A single record or multiple records that include a pre-trigger record length of at least two cycles and a total record length of at least 2.0 seconds for the same trigger point.

~~3.3.2.~~3.2.2. A minimum recording rate of 64 samples per cycle.

~~3.3.3.~~3.2.3. Trigger settings for at least the following:

~~3.3.3.1.~~3.2.3.1. Neutral (residual) overcurrent.

~~3.3.3.2.~~3.2.3.2. AC phase overvoltage and undervoltage.

M3. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that FR data meets Requirement R3. Evidence may include, but is not limited to: (1) actual data recordings or derivations, or (2) documents describing the device specification and device configuration or settings.

R4. Each Generator Owner and Transmission Owner shall have continuous dynamic disturbance recording (DDR) data and storage to determine the following electrical quantities for each main power transformer(s) it owns: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

4.1. One phase-to-neutral or positive sequence voltage on high-side of the main power transformer(s).

4.2. The phase current for the same phase at the same voltage corresponding to the voltage in Requirement R4, Part 4.1, or the positive sequence current.

4.3. Real Power and Reactive Power flows expressed on a three-phase basis corresponding to each main power transformer(s) where current measurements are required.

4.4. Frequency of any one of the voltage(s) in Requirement R4, Part 4.1.

M4. The Generator Owner or Transmission Owner has evidence (electronic or hard copy) of continuous DDR data recording and storage to determine electrical quantities as specified in Requirement R4. Evidence may include, but is not limited to: (1) actual data recordings or derivations; or (2) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (3) station drawings.

R5. Each Transmission Owner and Generator Owner responsible for DDR data for the electrical quantities identified in Requirement R4 shall have DDR data that meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

5.1. Input sampling rate of at least 960 samples per second.

5.2. Output recording rate of electrical quantities of at least 60 times per second.

M5. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that DDR data meets Requirement R5. Evidence may include, but is not limited to: (1) documents describing the device specification, device configuration, or settings (R5, Part 5.1; R5, Part 5.2); or (2) actual data recordings (R5, Part 5.2).

R6. Each Transmission Owner and Generator Owner shall time synchronize all SER, FR, and DDR data to meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

6.1. Synchronization to Coordinated Universal Time (UTC) with or without a local time offset.

6.2. Synchronized device clock accuracy within ± 1 milliseconds of UTC.

M6. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) of time synchronization described in Requirement R6. Evidence may include, but is not limited to: (1) documents describing the device specification, configuration, or setting; (2) time synchronization indication or status; or 3) station drawings.

R7. Each Transmission Owner and Generator Owner shall provide all ~~, upon~~ requested~~, all~~ SER, FR, and DDR data to its Transmission Planner, Planning Coordinator, Transmission Operator, Balancing Authority, Reliability Coordinator, Regional Entity, or NERC in accordance with the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

7.1. Data shall be retrievable for the period of 20 calendar days, inclusive of the day the data was recorded.

7.2. Data subject to Part 7.1 shall be provided within ~~30~~ 15 calendar days of a request unless an extension is granted by the requestor.

7.3. SER data shall be provided in ASCII[3] Comma Separated Value (CSV) format following Attachment 1.

7.4. FR ~~and DDR~~ data shall be provided ~~either in CSV format or~~ in electronic files that are formatted in conformance with C37.111, IEEE Standard Common Format for Transient Data Exchange (COMTRADE), revision C37.111-1999 or later.

~~7.4.~~7.5. DDR data shall be provided either in CSV format with appropriate headers or in electronic files that are formatted in conformance with C37.111, IEEE Standard Common Format for Transient Data Exchange (COMTRADE), revision C37.111-1999 or later.

~~7.5.~~7.6. Data files shall be named in conformance with C37.232, IEEE Standard for Common Format for Naming Time Sequence Data Files (COMNAME), revision C37.232-2011 or later.

M7. The Transmission Owner or Generator Owner has evidence (electronic or hard copy) that data was submitted upon request in accordance with Requirement R7. Evidence may include, but is not limited to: (1) actual data recordings; (2) dated transmittals to the requesting entity with formatted records; or (3) documents describing data storage capability, device specification, configuration, or settings.

---

[3] American Standard Code for Information Exchange

R8. Each Transmission Owner and Generator Owner shall, upon~~within 90 calendar days of~~ the discovery of a failure of the recording capability for the SER, FR, or DDR data~~,~~ ~~either~~: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

- Restore the recording capability within 90 calendar days, or
- Submit a Corrective Action Plan (CAP) to the Regional Entity within 90 calendar days and then implement it according to CAP timeline.

M8. The Transmission Owner or Generator Owner has dated evidence (electronic or hard copy) that meets Requirement R8. Evidence may include, but is not limited to: (1) dated reports of the discovery of a failure, (2) documentation noting the date the data recording was restored, (3) SCADA records, or (4) dated Corrective Action Plan transmittals to the Regional Entity and evidence of Corrective Action Plan implementation.

~~**R9.** Each Transmission Owner and Generator Owner of an applicable facility as specified in section A.4.2 that is in commercial operation before the effective date of this standard that is not able to install disturbance monitoring equipment in accordance with Requirements R1 through R7 in the time provided for compliance shall develop, maintain, and implement a Corrective Action Plan to provide the required capability. For each Corrective Action Plan, the Transmission Owner and Generator Owner shall: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*~~

~~**9.1.** Identify corrective actions and a timetable for completion.~~

~~**9.2.** Specify the circumstances causing the delay for fully or partially implementing Requirements R1 through R7 and explain how those circumstances are beyond the control of the responsible entity.~~

~~**9.3.** Identify revisions to the selected actions in Part 9.1, if any.~~

~~**9.4.** Identify updates to the timetable for implementing the selected actions in Part 9.1, if any.~~

~~**9.5.** Submit the Corrective Action Plan, and any revisions, to the Regional Entity, with a request to extend the time provided for compliance.~~

~~**M9.** The Transmission Owner or Generator Owner has dated evidence (electronic or hard copy) that meets Requirement R9. Evidence may include, but is not limited to, documentation noting the date the Corrective Action Plan was developed or revised, documentation noting the date the Corrective Action Plan was submitted to the Regional Entity with request to extend the time provided for compliance, and evidence of Corrective Action Plan implementation.~~

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an

Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention:

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner and Generator Owner shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

The Transmission Owner and Generator Owner shall retain evidence, as per Requirements R1 through R8, for three calendar years.

If a Transmission Owner or Generator Owner is found non-compliant, it shall keep information related to the non-compliance until mitigation is completed and approved or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records, and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	Each Transmission Owner or Generator Owner as directed by Requirement R1 to have the required SER data had more than 80 percent, but less than 100 percent of the ~~Elements (~~circuit breaker(s)~~ or IBR Units)~~ identified in Requirement R1~~Section 4.2 Facilities~~.	Each Transmission Owner or Generator Owner as directed by Requirement R1 to have the required SER data had more than 70 percent, but less than or equal to 80 percent of the ~~Elements (~~circuit breaker(s) ~~or IBR Units)~~ identified in Requirement R1~~Section 4.2 Facilities~~.	Each Transmission Owner or Generator Owner as directed by Requirement R1 to have the required SER data had more than 60 percent but less than or equal to 70 percent of the ~~Elements (~~circuit breaker(s)~~ or IBR Units)~~ identified in Requirement R1~~Section 4.2 Facilities~~.	Each Transmission Owner or Generator Owner as directed by Requirement R1 to have the required SER data had less than or equal to 60 percent of the ~~Elements (~~circuit breaker(s)~~ or IBR Units)~~ identified in Requirement R1~~Section 4.2 Facilities~~.
R2	The Transmission Owner or Generator Owner had FR data as directed by Requirement R2, Parts 2.1, 2.2, and 2.3 that covers more than 80 percent, but less than 100 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical	The Transmission Owner or Generator Owner had FR data as directed by Requirement R2, Parts 2.1, 2.2, and 2.3 that covers more than 70 percent, but less than or equal to 80 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified	The Transmission Owner or Generator Owner had FR data as directed by Requirement R2, Parts 2.1, 2.2, and 2.3 that covers more than 60 percent, but less than or equal to 70 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical	The Transmission Owner or Generator Owner had FR data as directed by Requirement R2, Parts 2.1, 2.2, and 2.3 that covers less than or equal to 60 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical

Implementation Plan

Project 2021-04
Reliability Standards PRC-002-5 and PRC-028-1

Applicable Standard(s)

- PRC-002-5 Disturbance Monitoring and Reporting Requirements
- PRC-028-1 Disturbance Monitoring and Reporting Requirements for inverter-based resources

Requested Retirement(s)

- PRC-002-4 – Disturbance Monitoring and Reporting Requirements

Applicable Entities

- Reliability Coordinator
- Transmission Owner (TO)
- Generator Owner (GO)

General Considerations

Additional time to implement Reliability Standard PRC-002-5 is not provided because the revisions are clarifying in nature to exclude inverter-based resources from PRC-002 applicability as they are included in PRC-028. The revision to PRC-002 does not require any procurement or installation of Disturbance Monitoring Equipment.

The Reliability Standard PRC-028-1 is expected to have wide ranging impact on TOs and GOs, as many existing and new facilities would be required to have Disturbance Monitoring Equipment. A graduated approach to implementation recognizes that progress will be made while attempting to minimize any potential significant impact to the entities. The Implementation Plan takes into account scheduling outages needed to implement sequence of events recording, fault recording, and dynamic disturbance recording capability. An entity owning only one (1) identified inverter-based resource is allowed three (3) calendar years for implementation to accommodate normal outage schedules. The Implementation Plan accounts for any increase in requests to vendors for this technology or capability that could impact implementation timelines for the respective entities. The Implementation Plan recognizes Federal Energy Regulatory Commission's directive to have this standard effective and enforceable before 2030.[1]

[1] See Order No. 901 at P226.

Effective Date of PRC-002-5

Where approval by an Applicable Governmental Authority is required, Reliability Standard PRC-002-5 shall become effective on the first day of the first calendar quarter after the effective date of the Applicable Governmental Authority's order approving the standard or as otherwise provided for by the Applicable Governmental Authority.

Where approval by an Applicable Governmental Authority is not required, Reliability Standard PRC-002-5 shall become effective the first day of the first calendar quarter after the date the standard is adopted by the NERC Board of Trustees or as otherwise provided for in that jurisdiction.

Effective Date of PRC-028-1 and Phased-in Compliance Dates

The effective date for proposed Reliability Standard PRC-028-1 is provided below. Where the standard drafting team identified the need for a longer implementation period for compliance with a particular section of a proposed Reliability Standard (i.e., an entire Requirement or a portion thereof), the additional time for compliance with that section is specified below. The phased-in compliance date for those particular sections represents the date that entities must begin to comply with that particular section of the Reliability Standard, even where the Reliability Standard goes into effect at an earlier date.

Reliability Standard PRC-028-1

Where approval by an Applicable Governmental Authority is required, Reliability Standard PRC-028-1 shall become effective on the first day of the first calendar quarter after the effective date of the Applicable Governmental Authority's order approving the standard or as otherwise provided for by the Applicable Governmental Authority.

Where approval by an Applicable Governmental Authority is not required, Reliability Standard PRC-028-1 shall become effective on the first day of the first calendar quarter after the date the standard is adopted by the NERC Board of Trustees or as otherwise provided for in that jurisdiction.

Compliance Date for PRC-028-1 Requirements R1-R7

For inverter-based resources in commercial operation on or before the effective date:

Entities shall comply with Requirements R1 through R7 at 50% of their inverter-based resources within three (3) calendar years of the effective date of PRC-028-1 and 100% of their inverter-based resources by January 1, 2030.

Entities that are required to monitor only one (1) inverter-based resource shall comply with Requirements R1 through R7 within three (3) calendar years of the effective date of Reliability Standard PRC-028-1.

For inverter-based resources entering commercial operation after the effective date: Entities shall comply with Requirements R1 through R7 within 15 calendar months following the effective date of the standard or the commercial operation date, whichever is later.

Compliance Date for PRC-028-1 Requirement R8

Entities shall comply with Requirement R8 by no later than nine (9) months after the effective date of Reliability Standard PRC-028-1.

Process for Seeking an Extension from Compliance Dates

Each GO and TO that owns one or more applicable inverter-based resources that are in commercial operation before the effective date of Reliability Standard PRC-028-1 may seek an extension from the above-listed compliance dates if circumstances beyond its control prevent the installation of Disturbance Monitoring Equipment on one or more of its inverter-based resources.

To seek an extension, the entity shall develop and submit to its Regional Entity[2] a request for extension that contains at a minimum the following information:

1.1. Identification of the inverter-based resource(s) for which the entity seeks the extension;

1.2. A plan for installing the Disturbance Monitoring Equipment and a timetable for completion;

1.3. A description of the circumstances precluding the timely installation of Disturbance Monitoring Equipment and how those circumstances are beyond the control of the entity; and

1.4. Any other information the entity deems relevant to the Regional Entity's consideration of its request.

The entity shall provide any information requested by the Regional Entity in connection with its request, including any information specified in a supporting process document. If the request is granted, the entity shall implement the plan in accordance with the provided timetable. Should additional time be required, the entity shall submit an updated request to its Regional Entity.

Requests should be submitted as soon as the entity identifies circumstances prescribing the timely implementation of Reliability Standard PRC-028-1, but no later than three months prior to the compliance date for which the entity seeks an extension.

Retirement Date

Reliability Standard PRC-002-4 shall be retired immediately prior to the effective date of Reliability Standard PRC-002-5 in the particular jurisdiction in which the revised standard is becoming effective.

[2] This is the Regional Entity that will receive any Corrective Action Plans developed in accordance with Requirement R8.

Effective Date of PRC-002-5

Where approval by an Applicable Governmental Authority is required, Reliability Standard PRC-002-5 shall become effective on the first day of the first calendar quarter after the effective date of the Applicable Governmental Authority's order approving the standard or as otherwise provided for by the Applicable Governmental Authority.

Where approval by an Applicable Governmental Authority is not required, Reliability Standard PRC-002-5 shall become effective the first day of the first calendar quarter after the date the standard is adopted by the NERC Board of Trustees or as otherwise provided for in that jurisdiction.

Effective Date of PRC-028-1 and Phased-in Compliance Dates

The effective date for proposed Reliability Standard PRC-028-1 is provided below. Where the standard drafting team identified the need for a longer implementation period for compliance with a particular section of a proposed Reliability Standard (i.e., an entire Requirement or a portion thereof), the additional time for compliance with that section is specified below. The phased-in compliance date for those particular sections represents the date that entities must begin to comply with that particular section of the Reliability Standard, even where the Reliability Standard goes into effect at an earlier date.

Reliability Standard PRC-028-1

Where approval by an Applicable Governmental Authority is required, Reliability Standard PRC-028-1 shall become effective on the first day of the first calendar quarter after the effective date of the Applicable Governmental Authority's order approving the standard or as otherwise provided for by the Applicable Governmental Authority.

Where approval by an Applicable Governmental Authority is not required, Reliability Standard PRC-028-1 shall become effective on the first day of the first calendar quarter after the date the standard is adopted by the NERC Board of Trustees or as otherwise provided for in that jurisdiction.

Compliance Date for PRC-028-1 Requirements R1-R7

For inverter-based resources ~~Plants/Ff~~acilities in commercial operation on or before the effective date:

Entities shall comply with Requirements R1 through R7 at 50% of their ~~generating plants/Facilitie~~inverter-based resources within three (3) calendar years of the effective date of PRC-028-1 and 100% of their ~~generating plant/Facilitie~~inverter-based resources by January 1, 2030.

Entities that are required to monitor only one (1) ~~generating plant/Facility~~inverter-based resource shall comply with Requirements R1 through R7 within three (3) calendar years of the effective date of Reliability Standard PRC-028-1.

For inverter-based resources~~facilities~~ entering commercial operation after the effective date: Entities shall comply with Requirements R1 through R7 within 15 calendar months following the effective date of the standard or the commercial operation date, whichever is later.

~~**For Plants/Facilities entering commercial operation within one year after the effective date:** Entities shall comply with Requirements R1 through R7 by the end of the first calendar year that is 12 months following the effective date of the standard.~~

~~**For Plants/Facilities entering commercial operation one year or later after the effective date:** Entities shall comply with Requirements R1 through R7 at the date of entering commercial operation.~~

Compliance Date for PRC-028-1 Requirement R8

Entities shall comply with Requirement R8 by no later than nine (9) months after the effective date of Reliability Standard PRC-028-1.

~~Compliance Date for PRC-028-1 Requirement R9~~

~~Entities shall comply with Requirement R9, as applicable, by no later than January 1, 2029.~~

Process for Seeking an Extension from Compliance Dates

Each GO and TO that owns one or more applicable inverter-based resources that are in commercial operation before the effective date of Reliability Standard PRC-028-1 may seek an extension from the above-listed compliance dates if circumstances beyond its control prevent the installation of Disturbance Monitoring Equipment on one or more of its inverter-based resources.

To seek an extension, the entity shall develop and submit to its Regional Entity[2] a request for extension that contains at a minimum the following information:

1.1. Identification of the inverter-based resource(s) for which the entity seeks the extension;

1.2. A plan for installing the Disturbance Monitoring Equipment and a timetable for completion;

1.3. A description of the circumstances precluding the timely installation of Disturbance Monitoring Equipment and how those circumstances are beyond the control of the entity; and

1.4. Any other information the entity deems relevant to the Regional Entity's consideration of its request.

The entity shall provide any information requested by the Regional Entity in connection with its request, including any information specified in a supporting process document. If the request is

[2] This is the Regional Entity that will receive any Corrective Action Plans developed in accordance with Requirement R8.

granted, the entity shall implement the plan in accordance with the provided timetable. Should additional time be required, the entity shall submit an updated request to its Regional Entity.

Requests should be submitted as soon as the entity identifies circumstances prescribing the timely implementation of Reliability Standard PRC-028-1, but no later than three months prior to the compliance date for which the entity seeks an extension.

Retirement Date

Reliability Standard PRC-002-4 shall be retired immediately prior to the effective date of Reliability Standard PRC-002-5 in the particular jurisdiction in which the revised standard is becoming effective.

Unofficial Comment Form

Project 2021-04 Modifications to PRC-002 – Phase II

Do not use this form for submitting comments. Use the Standards Balloting and Commenting System (SBS) to submit comments on **Project 2021-04 Modifications to PRC-002 – Phase II** by **8 p.m. Eastern, Friday, June 14, 2024.**

Additional information is available on the project page. If you have questions, contact Senior Standards Developer, Ben Wu (via email), or at 470-542-6882.

Background Information

This project will be completed in two phases. The first phase addressed the scope regarding notifications relative to the sequence of events recording (SER) and fault recording (FR) data, and to clearly identify the BES Element owners that need to have SER and FR data for transformers and transmission lines with the associated identified bus in the Glencoe Light and Power SAR.

The second phase will address gaps the Inverter-Based Resource Performance Task Force (IRPTF) identified within the PRC-002. The goal is to modify the requirements to ensure adequate data is available and periodically assessed to facilitate the analysis of BES disturbances, including in areas of the Bulk Power System (BPS) that may not be covered by the existing requirements.

Questions

1. Do you agree with the modification in "**Applicability, Section 4.2. Facilities**" in PRC-028-1 to remove "Non-BES Inverter Based Resources …"?

   ☐ Yes
   ☐ No

   Comments:

2. Do you agree with removing "**Inverter Based Resources**" and "**IBR Unit**" under Term(s) for Reliability Standards PRC-002-5 and PRC-028-1?

   ☐ Yes
   ☐ No

   Comments:

3. Do you agree with the standard drafting team removing Requirement R9 in Reliability Standard PRC-028-1 and adding it to the Implementation Plan since it is more like a process, not a Requirement?

   ☐ Yes
   ☐ No

   Comments:

4. Do you agree with the Implementation Plan for revised PRC-002-5 and new Standard PRC-028-1?

   ☐ Yes
   ☐ No

   Comments:

5. Do you agree the modifications made in PRC-002-5 and new Standard PRC-028-1 are cost effective?

   ☐ Yes
   ☐ No

   Comments:

6. Provide any additional comments for the standard drafting team to consider, if desired.

   Comments:

Violation Risk Factor and Violation Severity Level Justifications

Project 2021-04 Modifications to PRC-002 – Phase II (PRC-002-5)

This document provides the standard drafting team's (SDT's) justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-002-5. Each requirement is assigned a VRF and a VSL. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the Electric Reliability Organizations (ERO) Sanction Guidelines. The SDT applied the following NERC criteria and FERC Guidelines when developing the VRFs and VSLs for the requirements.

NERC Criteria for Violation Risk Factors

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures, or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures, or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System. However, violation of a medium risk requirement is unlikely to lead to Bulk Electric System instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to Bulk Electric System instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement
A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System.

FERC Guidelines for Violation Risk Factors

Guideline (1) – Consistency with the Conclusions of the Final Blackout Report
FERC seeks to ensure that VRFs assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System. In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief.

Guideline (2) – Consistency within a Reliability Standard
FERC expects a rational connection between the sub-Requirement VRF assignments and the main Requirement VRF assignment.

Guideline (3) – Consistency among Reliability Standards
FERC expects the assignment of VRFs corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) – Consistency with NERC's Definition of the Violation Risk Factor Level
Guideline (4) was developed to evaluate whether the assignment of a particular VRF level conforms to NERC's definition of that risk level.

Guideline (5) – Treatment of Requirements that Co-mingle More Than One Obligation
Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

NERC Criteria for Violation Severity Levels

VSLs define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple "degrees" of noncompliant performance and may have only one, two, or three VSLs.

VSLs should be based on NERC's overarching criteria shown in the table below:

Lower VSL	Moderate VSL	High VSL	Severe VSL
The performance or product measured almost meets the full intent of the requirement.	The performance or product measured meets the majority of the intent of the requirement.	The performance or product measured does not meet the majority of the intent of the requirement, but does meet some of the intent.	The performance or product measured does not substantively meet the intent of the requirement.

FERC Order of Violation Severity Levels

The FERC VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in the standard meet the FERC Guidelines for assessing VSLs:

Guideline (1) – Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline (2) – Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a "binary" type requirement must be a "Severe" VSL.

Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline (3) – Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline (4) – Violation Severity Level Assignment Should Be Based on a Single Violation, Not on a Cumulative Number of Violations

Unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

VRF Justification for PRC-002-5, Requirement R1

The VRF did not change from the previously FERC approved PRC-002-4 Reliability Standard.

VSL Justifications for PRC-002-5, Requirement R1			
Lower	**Moderate**	**High**	**Severe**
The Transmission Owner identified the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3 for more than 80 percent, but less than 100 percent of the required BES buses that they own. OR The Transmission Owner evaluated the BES buses as directed by Requirement R1, Part 1.1 or Part 1.3, but was late by 30 calendar days or less. OR The Transmission Owner as directed by Requirement R1, Part 1.2 was late in notifying the other owners that their BES Elements require SER or FR data by 10 calendar days or less. Violation Risk Factor and Violation Severity Level Justifications

Project 2021-04 Modifications to PRC-002 – Phase II (PRC-002-5)

This document provides the standard drafting team's (SDT's) justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-002-5. Each requirement is assigned a VRF and a VSL. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the Electric Reliability Organizations (ERO) Sanction Guidelines. The SDT applied the following NERC criteria and FERC Guidelines when developing the VRFs and VSLs for the requirements.

NERC Criteria for Violation Risk Factors

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures, or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures, or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System. However, violation of a medium risk requirement is unlikely to lead to Bulk Electric System instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to Bulk Electric System instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement
A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System.

FERC Guidelines for Violation Risk Factors

Guideline (1) – Consistency with the Conclusions of the Final Blackout Report
FERC seeks to ensure that VRFs assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System. In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief.

Guideline (2) – Consistency within a Reliability Standard

FERC expects a rational connection between the sub-Requirement VRF assignments and the main Requirement VRF assignment.

Guideline (3) – Consistency among Reliability Standards

FERC expects the assignment of VRFs corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) – Consistency with NERC's Definition of the Violation Risk Factor Level

Guideline (4) was developed to evaluate whether the assignment of a particular VRF level conforms to NERC's definition of that risk level.

Guideline (5) – Treatment of Requirements that Co-mingle More Than One Obligation

Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

NERC Criteria for Violation Severity Levels

VSLs define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple “degrees” of noncompliant performance and may have only one, two, or three VSLs.

VSLs should be based on NERC’s overarching criteria shown in the table below:

Lower VSL	Moderate VSL	High VSL	Severe VSL
The performance or product measured almost meets the full intent of the requirement.	The performance or product measured meets the majority of the intent of the requirement.	The performance or product measured does not meet the majority of the intent of the requirement, but does meet some of the intent.	The performance or product measured does not substantively meet the intent of the requirement.

FERC Order of Violation Severity Levels

The FERC VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in the standard meet the FERC Guidelines for assessing VSLs:

Guideline (1) – Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline (2) – Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a “binary” type requirement must be a “Severe” VSL.

Do not use ambiguous terms such as “minor” and “significant” to describe noncompliant performance.

Guideline (3) – Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline (4) – Violation Severity Level Assignment Should Be Based on a Single Violation, Not on a Cumulative Number of Violations

Unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the “default” for penalty calculations.

VRF Justification for PRC-002-5, Requirement R1

The VRF did not change from the previously FERC approved PRC-002-4 Reliability Standard.

Violation Risk Factor and Violation Severity Level Justifications

Project 2021-04 Modifications to PRC-002 – Phase II (PRC-028-1)

This document provides the standard drafting team's (SDT's) justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-028-1. Each requirement is assigned a VRF and a VSL. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the Electric Reliability Organizations (ERO) Sanction Guidelines. The SDT applied the following NERC criteria and FERC Guidelines when developing the VRFs and VSLs for the requirements.

NERC Criteria for Violation Risk Factors

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures, or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures, or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System. However, violation of a medium risk requirement is unlikely to lead to Bulk Electric System instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to Bulk Electric System instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement
A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System.

FERC Guidelines for Violation Risk Factors

Guideline (1) – Consistency with the Conclusions of the Final Blackout Report
FERC seeks to ensure that VRFs assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System. In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief.

Guideline (2) – Consistency within a Reliability Standard
FERC expects a rational connection between the sub-Requirement VRF assignments and the main Requirement VRF assignment.

Guideline (3) – Consistency among Reliability Standards
FERC expects the assignment of VRFs corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) – Consistency with NERC's Definition of the Violation Risk Factor Level
Guideline (4) was developed to evaluate whether the assignment of a particular VRF level conforms to NERC's definition of that risk level.

Guideline (5) – Treatment of Requirements that Co-mingle More Than One Obligation
Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

NERC Criteria for Violation Severity Levels

VSLs define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple "degrees" of noncompliant performance and may have only one, two, or three VSLs.

VSLs should be based on NERC's overarching criteria shown in the table below:

Lower VSL	Moderate VSL	High VSL	Severe VSL
The performance or product measured almost meets the full intent of the requirement.	The performance or product measured meets the majority of the intent of the requirement.	The performance or product measured does not meet the majority of the intent of the requirement, but does meet some of the intent.	The performance or product measured does not substantively meet the intent of the requirement.

FERC Order of Violation Severity Levels

The FERC VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in the standard meet the FERC Guidelines for assessing VSLs:

Guideline (1) – Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline (2) – Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a "binary" type requirement must be a "Severe" VSL.

Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline (3) – Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline (4) – Violation Severity Level Assignment Should Be Based on a Single Violation, Not on a Cumulative Number of Violations

Unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

PRC-028-1

VRF Justifications for PRC-028-1, Requirement R1	
Proposed VRF	**Lower**
NERC VRF Discussion	A VRF of Lower is appropriate due to this Requirement is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System; or a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System. Therefore, it is consistent with the definition of a Lower VRF.
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is consistent with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The VRF for Requirement R1 is consistent with those connections between the sub-Requirement VRF assignments and the main Requirement VRF assignment.
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	This VRF is consistent with other VRFs that address similar reliability goals in different Reliability Standards.
FERC VRF G4 Discussion Guideline 4- Consistency with NERC Definitions of VRFs	This VRF is consistent with the definition of a lower VRF requirement per the criteria filed with FERC as part of the ERO's Sanctions Guidelines.

VRF Justifications for PRC-028-1, Requirement R1	
Proposed VRF	**Lower**
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not mingle a higher risk reliability objective and a lesser risk reliability objective. Therefore, the VRF reflects the risk of the whole requirement.

VSLs for PRC-028-1, Requirement R1			
Lower	**Moderate**	**High**	**Severe**
Each Transmission Owner or Generator Owner as directed by Requirement R1 to have the required SER data had more than 80 percent, but less than 100 percent of the circuit breaker(s) identified in Requirement R1.	Each Transmission Owner or Generator Owner as directed by Requirement R1 to have the required SER data had more than 70 percent, but less than or equal to 80 percent of the circuit breaker(s) identified in Requirement R1.	Each Transmission Owner or Generator Owner as directed by Requirement R1 to have the required SER data had more than 60 percent, but less than or equal to 70 percent of the circuit breaker(s) identified in Requirement R1.	Each Transmission Owner or Generator Owner as directed by Requirement R1 to have the required SER data had less than or equal to 60 percent of the circuit breaker(s) identified in Requirement R1.

VSL Justifications for PRC-028-1, Requirement R1	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement is new. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and	The proposed VSLs are not binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VSL Justifications for PRC-028-1, Requirement R1	
Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

VRF Justifications for PRC-028-1, Requirement R2	
Proposed VRF	**Lower**
NERC VRF Discussion	A VRF of Lower is appropriate due to this Requirement is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System; or a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System. Therefore, it is consistent with the definition of a Lower VRF.

VRF Justifications for PRC-028-1, Requirement R2	
Proposed VRF	**Lower**
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is consistent with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The VRF for Requirement R1 is consistent with those connections between the sub-Requirement VRF assignments and the main Requirement VRF assignment
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	This VRF is consistent with other VRFs that address similar reliability goals in different Reliability Standards.
FERC VRF G4 Discussion Guideline 4- Consistency with NERC Definitions of VRFs	This VRF is consistent with the definition of a lower VRF requirement per the criteria filed with FERC as part of the ERO's Sanctions Guidelines.
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not mingle a higher risk reliability objective and a lesser risk reliability objective. Therefore, the VRF reflects the risk of the whole requirement.

Violation Risk Factor and Violation Severity Level Justifications

Project 2021-04 Modifications to PRC-002 – Phase II
(PRC-028-1)

This document provides the standard drafting team's (SDT's) justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-028-1. Each requirement is assigned a VRF and a VSL. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the Electric Reliability Organizations (ERO) Sanction Guidelines. The SDT applied the following NERC criteria and FERC Guidelines when developing the VRFs and VSLs for the requirements.

NERC Criteria for Violation Risk Factors

High Risk Requirement
A requirement that, if violated, could directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures, or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures, or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement
A requirement that, if violated, could directly affect the electrical state or the capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System. However, violation of a medium risk requirement is unlikely to lead to Bulk Electric System instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to Bulk Electric System instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System.

FERC Guidelines for Violation Risk Factors

Guideline (1) – Consistency with the Conclusions of the Final Blackout Report

FERC seeks to ensure that VRFs assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System. In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief.

Guideline (2) – Consistency within a Reliability Standard

FERC expects a rational connection between the sub-Requirement VRF assignments and the main Requirement VRF assignment.

Guideline (3) – Consistency among Reliability Standards

FERC expects the assignment of VRFs corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) – Consistency with NERC's Definition of the Violation Risk Factor Level

Guideline (4) was developed to evaluate whether the assignment of a particular VRF level conforms to NERC's definition of that risk level.

Guideline (5) – Treatment of Requirements that Co-mingle More Than One Obligation

Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

NERC Criteria for Violation Severity Levels

VSLs define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple “degrees” of noncompliant performance and may have only one, two, or three VSLs.

VSLs should be based on NERC’s overarching criteria shown in the table below:

Lower VSL	Moderate VSL	High VSL	Severe VSL
The performance or product measured almost meets the full intent of the requirement.	The performance or product measured meets the majority of the intent of the requirement.	The performance or product measured does not meet the majority of the intent of the requirement, but does meet some of the intent.	The performance or product measured does not substantively meet the intent of the requirement.

FERC Order of Violation Severity Levels

The FERC VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in the standard meet the FERC Guidelines for assessing VSLs:

Guideline (1) – Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline (2) – Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a “binary” type requirement must be a “Severe” VSL.

Do not use ambiguous terms such as “minor” and “significant” to describe noncompliant performance.

Guideline (3) – Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline (4) – Violation Severity Level Assignment Should Be Based on a Single Violation, Not on a Cumulative Number of Violations

Unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

PRC-028-1

VRF Justifications for PRC-028-1, Requirement R1	
Proposed VRF	**Lower**
NERC VRF Discussion	A VRF of Lower is appropriate due to this Requirement is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System; or a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System. Therefore, it is consistent with the definition of a Lower VRF.
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is consistent with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The VRF for Requirement R1 is consistent with those connections between the sub-Requirement VRF assignments and the main Requirement VRF assignment
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	This VRF is consistent with other VRFs that address similar reliability goals in different Reliability Standards.
FERC VRF G4 Discussion Guideline 4- Consistency with NERC Definitions of VRFs	This VRF is consistent with the definition of a lower VRF requirement per the criteria filed with FERC as part of the ERO's Sanctions Guidelines.

VRF Justifications for PRC-028-1, Requirement R1	
Proposed VRF	**Lower**
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not mingle a higher risk reliability objective and a lesser risk reliability objective. Therefore, the VRF reflects the risk of the whole requirement.

VSLs for PRC-028-1, Requirement R1			
Lower	**Moderate**	**High**	**Severe**
Each Transmission Owner or Generator Owner as directed by Requirement R1 to have the required SER data had more than 80 percent, but less than 100 percent of the ~~Elements (~~circuit breaker(s) ~~or IBR units)~~ identified in ~~Section 4.2 Facilities~~Requirement R1.	Each Transmission Owner or Generator Owner as directed by Requirement R1 to have the required SER data had more than 70 percent, but less than or equal to 80 percent of the ~~Elements (~~circuit breaker(s~~)~~) ~~or IBR units)~~ identified in ~~Section 4.2 Facilities~~Requirement R1.	Each Transmission Owner or Generator Owner as directed by Requirement R1 to have the required SER data had more than 60 percent, but less than or equal to 70 percent of the ~~Elements (~~circuit breaker(s) ~~or IBR units)~~ identified in ~~Section 4.2 Facilities~~Requirement R1. VSL Justifications for PRC-028-1, Requirement R8	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement is new. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties <u>Guideline 2a</u>: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent <u>Guideline 2b</u>: Violation Severity Level Assignments that Contain	The proposed VSLs are not binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VSL Justifications for PRC-028-1, Requirement R8	
Ambiguous Language	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Technical Rationale for Reliability Standard PRC-002-5

May 2024

PRC-002-5 – Disturbance Monitoring and Reporting Requirements

Rationale for Applicability Section

Because the Reliability Coordinator has the best wide-area view of the BES, the Reliability Coordinator is most suited to be responsible for determining the BES Elements for which dynamic Disturbance recording (DDR) data is required. The Transmission Owners and Generator Owners will have the responsibility for ensuring that adequate data is available for those BES Elements selected. BES buses where sequence of events recording (SER) and fault recording (FR) data is required are best selected by Transmission Owners because they have the required tools, information, and working knowledge of their Systems to determine those buses. The Transmission Owners and Generator Owners that own BES Elements on those BES buses will have the responsibility for ensuring that adequate data is available.

The recent disturbance reports (e.g., Blue Cut Fire, Canyon 2 Fire, Odessa disturbances) have identified a need for disturbance monitoring for inverter-based resources to aid with event analysis, performance monitoring, and disturbance-based inverter-based resource model validation. The purpose of Reliability Standard PRC-002 is to capture event data to understand large scale system disturbances occurring on the Bulk Electric System (BES). Even with changing resource mix, the Reliability Standard PRC-002 serves the purpose. Introducing inverter-based resource monitoring requirements to Reliability Standard PRC-002 may create unintended consequences to purpose of Reliability Standard PRC-002 and may lead to industry confusion. Hence, to address needs identified in the Standard Authorization Request (SAR) submitted by the Inverter-Based Resource Performance Task Force (IRPTF), a new standard for monitoring requirements for inverter-based resources is created instead of revising the Reliability Standard PRC-002. To avoid any overlap between the Reliability Standards PRC-002 and PRC-028, BES Elements within inverter-based resources meeting the criteria set by Inclusion I4 of the BES definition are excluded from Reliability Standard PRC-002. Example in Figure 1 is provided to clarify applicability of Reliability Standards PRC-002 and PRC-028. The inverter-based resource in this example meets the criteria in inclusion I4 of the BES definition. The BES bus in substation Scott is the identified BES bus per methodology in Attachment 1 of the Reliability Standard PRC-002. The SER and FR data requirements for BES Elements associated with the identified BES bus are per the Reliability Standard PRC-002, except for Elements associated with the inverter-based resource, i.e., circuit breaker 3. The SER, FR, and DDR data requirements for the inverter-based resource are specified in the Reliability Standard PRC-028.

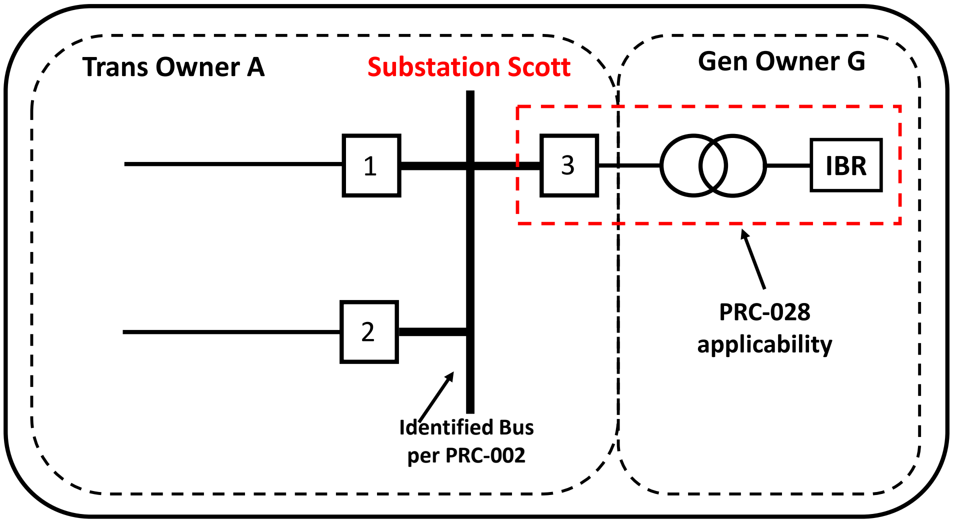

Figure 1: Example to Clarify Applicability of PRC-002 Versus PRC-028

Rationale for Requirement R1

Analysis and reconstruction of BES events requires SER and FR data from key BES buses. Attachment 1 provides a uniform methodology to identify those BES buses. Repeated testing of the Attachment 1 methodology has demonstrated the proper distribution of SER and FR data collection. Review of actual BES short circuit data received from the industry in response to the DMSDT's data request (June 5, 2013 through July 5, 2013) illuminated a strong correlation between the available short circuit MVA at a Transmission bus and its relative size and importance to the BES based on (i) its voltage level, (ii) the number of Transmission Lines and other BES Elements connected to the BES bus, and (iii) the number and size of generating units connected to the bus. BES buses with a large short circuit MVA level are BES Elements that have a significant effect on System reliability and performance. Conversely, BES buses with very low short circuit MVA levels seldom cause wide-area or cascading System events, so SER and FR data from those BES Elements are not as significant. After analyzing and reviewing the collected data submittals from across the continent, the threshold MVA values were chosen to provide sufficient data for event analysis using engineering and operational judgment.

Concerns have existed that the defined methodology for bus selection will overly concentrate data to selected BES buses. For the purpose of PRC-002-5, there are a minimum number of BES buses for which SER and FR data is required based on the short circuit level. With these concepts and the objective being sufficient recording coverage for event analysis, the DMSDT developed the procedure in Attachment 1 that utilizes the maximum available calculated three-phase short circuit MVA. This methodology ensures comparable and sufficient coverage for SER and FR data regardless of variations in the size and System topology of Transmission Owners across all Interconnections. Additionally, this methodology provides a degree of flexibility for the use of judgment in the selection process to ensure sufficient distribution.

BES buses, where SER and FR data is required, are best selected by Transmission Owners because they have the required tools, information, and working knowledge of their Systems to determine those buses.

Each Transmission Owner must re-evaluate the list of BES buses at least every five calendar years to

address System changes since the previous evaluation. Changes to the BES do not mandate immediate inclusion of BES buses into the currently enforced list, but the list of BES buses will be re-evaluated at least every five calendar years to address System changes since the previous evaluation.

Since there may be multiple owners of equipment that comprise a BES bus, the notification required in R1 is necessary to ensure all owners are notified.

A 90-calendar day notification deadline provides adequate time for the Transmission Owner to make the appropriate determination and notification.

Sequence of events and fault recording for the analysis, reconstruction, and reporting of System Disturbances is important. However, SER and FR data is not required at every BES bus on the BES to conduct adequate or thorough analysis of a Disturbance. As major tools of event analysis, the time synchronized time stamp for a breaker change of state and the recorded waveforms of voltage and current for individual circuits allows the precise reconstruction of events of both localized and wide-area Disturbances.

More quality information is always better than less when performing event analysis. However, 100 percent coverage of all BES Elements is not practical nor required for effective analysis of wide-area Disturbances. Therefore, selectivity of required BES buses to monitor is important for the following reasons:

1. Identify key BES buses with breakers where crucial information is available when required.
2. Avoid excessive overlap of coverage.
3. Avoid gaps in critical coverage.
4. Provide coverage of BES Elements that could propagate a Disturbance.
5. Avoid mandates to cover BES Elements that are more likely to be a casualty of a Disturbance rather than a cause.
6. Establish selection criteria to provide effective coverage in different regions of the continent.

The major characteristics available to determine the selection process are:

1. System voltage level;
2. The number of Transmission Lines into a substation or switchyard;
3. The number and size of connected generating units;
4. The available short circuit levels.

5. Although it is straightforward to establish criteria for the application of identified BES buses, analysis was required to establish a sound technical basis to fulfill the required objectives.

To answer these questions and establish criteria for BES buses of SER and FR, the DMSDT established a sub-team referred to as the Monitored Value Analysis Team (MVA Team). The MVA Team collected information from a wide variety of Transmission Systems throughout the continent to analyze Transmission buses by the characteristics previously identified for the selection process.

The MVA Team learned that the development of criteria is not possible for adequate SER and FR coverage, based solely upon simple, bright line characteristics, such as the number of lines into a substation or switchyard at a particular voltage level or at a set level of short circuit current. To provide the appropriate coverage, a relatively simple but effective Methodology for Selecting Buses for Capturing Sequence of Events Recording (SER) and Fault Recording (FR) Data was developed. This Procedure, included as Attachment 1, assists entities in fulfilling Requirement R1 of the standard.

The Methodology for Selecting Buses for Capturing Sequence of Events Recording (SER) and Fault Recording (FR) Data is weighted to buses with higher short circuit levels. This is chosen for the following reasons:

1. The method is voltage level independent.
2. It is likely to select buses near large generation centers.
3. It is likely to select buses where delayed clearing can cause Cascading.
4. Selected buses directly correlate to the Universal Power Transfer equation: Lower Impedance – increased power flows – greater System impact.

To perform the calculations of Attachment 1, the following information below is required and the following steps (provided in summary form) are required for Systems with more than 11 BES buses with three phase short circuit levels above 1,500 MVA.

1. Total number of BES buses in the Transmission System under evaluation.
    a. Only tangible substation or switchyard buses are included.
    b. Pseudo buses created for analysis purposes in System models are excluded.
2. Determine the three-phase short circuit MVA for each BES bus.
3. Exclude BES buses from the list with short circuit levels below 1,500 MVA.
4. Determine the median short circuit for the top 11 BES buses on the list (position number 6).
5. Multiply median short circuit level by 20 percent.
6. Reduce the list of BES buses to those with short circuit levels higher than the greater of 1500 MVA or 20 percent of the median MVA level determined in Step 5.

7. Apply SER and FR at BES buses with short circuit levels in the top 10 percent of the list (from 6).
8. Apply SER and FR at BES buses at an additional 10 percent of the list using engineering judgment, and allowing flexibility to factor in the following considerations:
    - Electrically distant BES buses or electrically distant from other DME devices
    - Voltage sensitive areas
    - Cohesive load and generation zones
    - BES buses with a relatively high number of incident Transmission circuits
    - BES buses with reactive power devices
    - Major facilities interconnecting outside the Transmission Owner's area.

Per the methodology in Attachment 1, FR/SER data is required at the BES bus with highest maximum available three phase short circuit MVA when the list in Step 6 has one or more, but less than or equal to 11, BES buses. Requirement R1, Part 1.3 requires re-evaluation of BES buses at least once every five calendar years in accordance with Part 1.1. Depending on results of this re-evaluation, the location at which SER/FR data is required could change due to a minor change in the three phase short circuit MVA. This is especially true for small Transmission Owners which are only required to have SER/FR data for one (1) BES bus per allowance based on the methodology in Attachment 1. To help avoid cost and compliance burden, a criterion that constitutes a change in fault current levels, which would require changing SER and FR data recording locations, is included in Attachment 1. During the re-evaluation per Requirement R1, Part 1.3, if the three phase short circuit MVA of the newly identified BES bus is within 15% of the three phase short circuit MVA of the currently applicable BES bus with SER and FR data, then it is not necessary to change the applicable BES bus.

As an example, during an initial evaluation, three BES buses A, B and C are identified in Step 6. The maximum three phase short circuit MVA of buses A, B, and C is 1600 MVA, 1500 MVA, and 1550 MVA, respectively. The SER/FR data is required at Bus A. During a first re-evaluation, the same three buses are identified in Step 6. The maximum three phase short circuit MVA of buses A, B, and C is 1550 MVA, 1675 MVA, and 1600 MVA, respectively. The bus B is the one with highest maximum three phase short circuit MVA now. The three phase short circuit MVA of bus B is within 15% of the three phase short circuit MVA of bus A (1675 is only 8% above 1550) where SER/FR data is being recorded. Hence, it is not necessary to change SER/FR data recording location to bus B. During a next re-evaluation, the same three buses are identified again in Step 6. The maximum three phase short circuit MVA of buses A, B and C is 1500 MVA, 1750 MVA and 1650 MVA respectively. The three phase short circuit MVA of bus B is greater than 15% of three phase short circuit MVA of bus A (1750 is 16.7% above the 1500) where SER/FR data is being recorded. Hence, it is necessary to change SER/FR data recording location to bus B.

For event analysis purposes, more valuable information is attained about generators and their response to System events pre- and post-contingency through DDR data versus SER or FR records. SER data of the opening of the primary generator output interrupting devices (e.g., synchronizing breaker) may not reliably indicate the actual time that a generator tripped; for instance, when it trips on reverse power after loss of its prime mover (e.g., combustion or steam turbine). As a result, this standard requires DDR data. Refer to Rationale for Requirement R5 for more details.

Since there may be multiple owners of equipment that comprise a BES bus, the notification required in Requirement R1, Part 1.2 is necessary to ensure all owners of “directly connected” BES Elements are notified. For the purposes of this standard, “directly connected” BES elements are BES elements connected at the same voltage level within the same physical location sharing a common ground grid with the BES bus identified under Attachment 1. Transformers that have a low-side operating voltage of less than 100kV are excluded. The following examples are provided to clarify notification requirement.

The straight and ring bus configurations shown in Figures 2 and 3 respectively, are the simplest BES bus configurations. Transmission Owner A owns the identified BES bus, including physical bus(es) as well as all three circuit breakers. Circuit breakers 1, 2, and 3 are BES Elements that are directly connected to the identified BES bus. The Transmission Owner A records SER/FR data for all three circuit breakers. In these cases, Transmission Owner A is not required to send notification to Transmission Owner B.

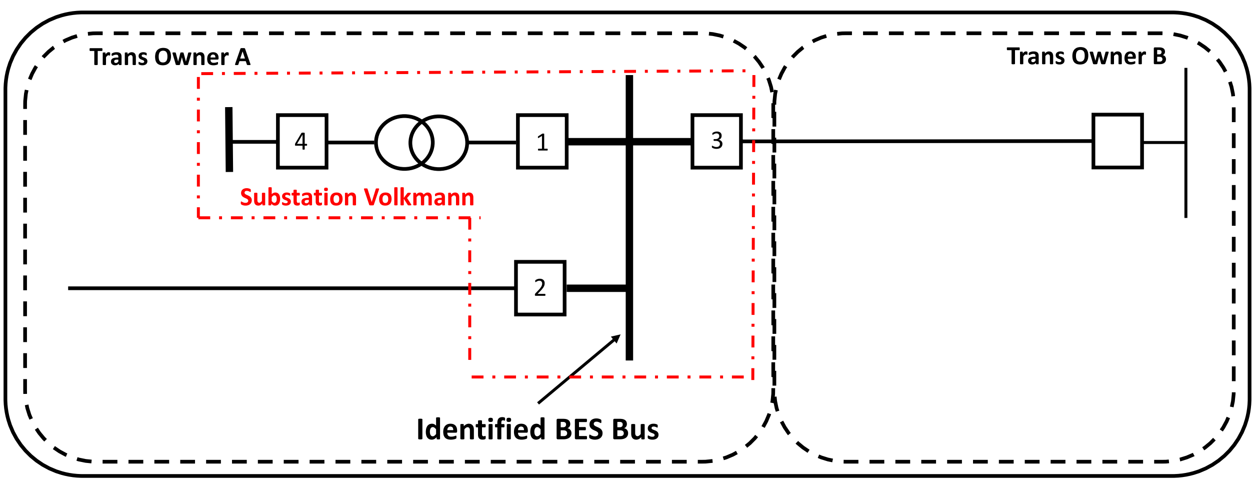

Figure 2: Straight Bus Configuration – Single Owner

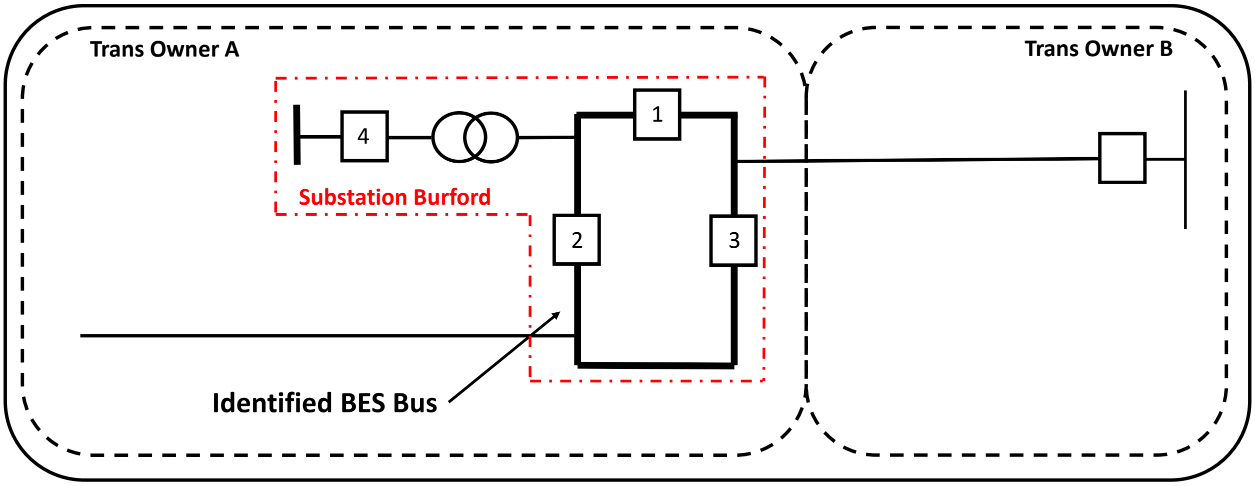

Figure 3: Ring Bus Configuration – Single Owner

Figures 4 and 5 show straight and ring bus configurations respectively, but with equipment that comprise a BES bus owned by multiple owners. Circuit breakers 1, 2, and 3 are BES Elements that are directly connected to the identified BES bus. The Transmission Owner A identifies a BES bus for which SER and FR data is required per Requirement R1, Part 1.1 and methodology included in Attachment 1. Transmission Owner A owns a portion of the physical bus(es) as well as circuit breakers 1 and 2. Transmission Owner B owns the remaining portion of the physical bus(es) and directly connected circuit breaker 3. All equipment (physical bus(es) and circuit breakers) that comprise the BES bus is located within the same physical space, i.e., substation Kealy, regardless of ownership.

In these cases, Transmission Owner A is responsible for SER and FR data for circuit breakers 1 and 2. The Transmission Owner B is owner of circuit breaker 3. Per Requirement R1, Part 1.2, if Transmission Owner A does not record SER and FR data for circuit breaker 3, then Transmission Owner B must be notified that SER/FR data is required for circuit breaker 3.

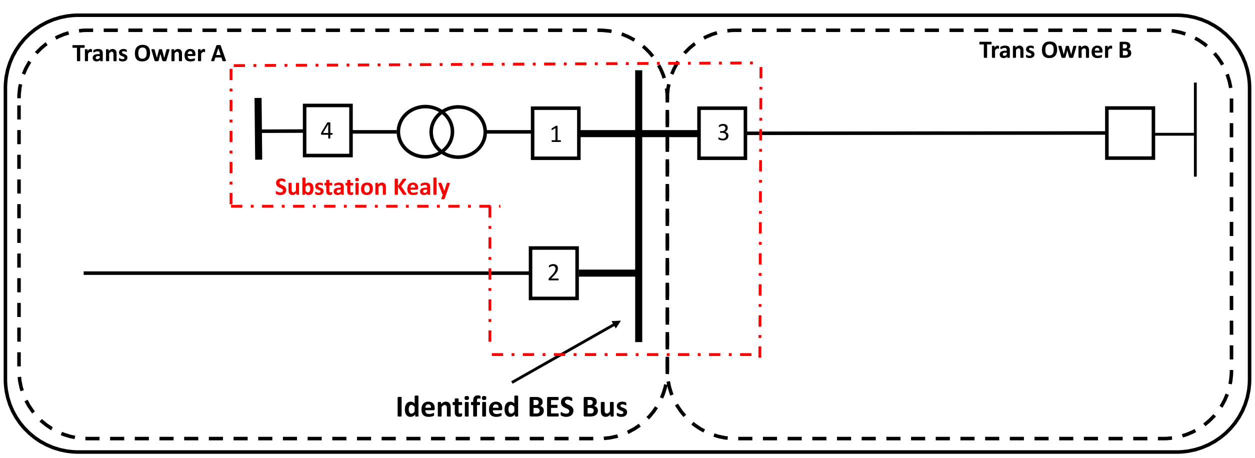

Figure 4: Straight Bus Configuration – Multiple Owners

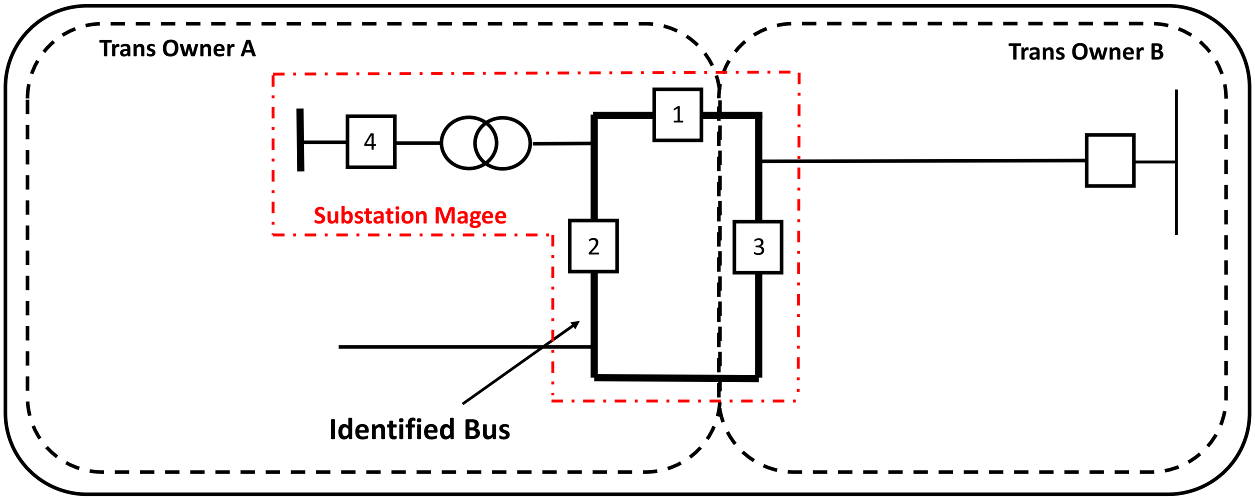

Figure 5: Ring Bus Configuration – Multiple Owners

For examples in Figures 4 and 5, if Transmission Owner A records SER/FR data for circuit breaker 3 (even though owned by Transmission Owner B), then Transmission Owner A is not required to notify Transmission Owner B.

Figure 6 shows an example with a generator interconnection. Circuit breakers 1, 2, and 3 are BES Elements that are directly connected to the identified BES bus. Transmission Owner A identifies a BES bus for which SER and FR data is required per Requirement R1, Part 1.1. Transmission Owner A owns the physical bus as well as directly connected circuit breakers 1 and 2. Generator Owner G owns directly connected circuit breaker 3. All equipment (physical bus(es) and circuit breakers) that comprise a BES bus is located within the same physical space, i.e., substation Burkart, regardless of ownership.

Transmission Owner A is responsible for SER and FR data for circuit breakers 1 and 2. The Generator Owner G is owner of circuit breaker 3. Per Requirement R1, Part 1.2, if Transmission Owner A does not record SER data for circuit breaker 3, then Generator Owner G must be notified that SER data is required for circuit breaker 3. Per the criteria in Requirement R3, Part 3.2.1, FR data is not required for circuit breaker 3.

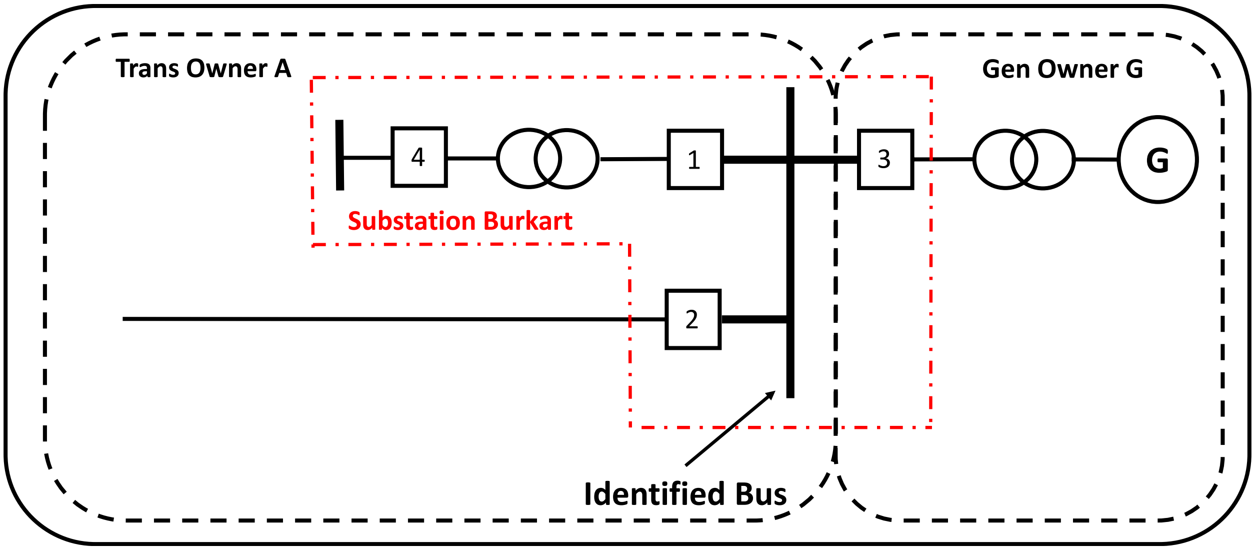

Figure 6: Generator Interconnection to Straight Bus

For a generator interconnection to a ring bus, as shown in Figure 7, Transmission Owner A is responsible for SER data for circuit breakers 1, 2, and 3. The Transmission Owner A is required to record FR data for contributions from the transmission line (circuit breakers 2 and 3) and transformer (circuit breakers 1 and 2). However, per the criteria in Requirement R3, Part 3.2.1, FR data is not required for contribution from the generator.

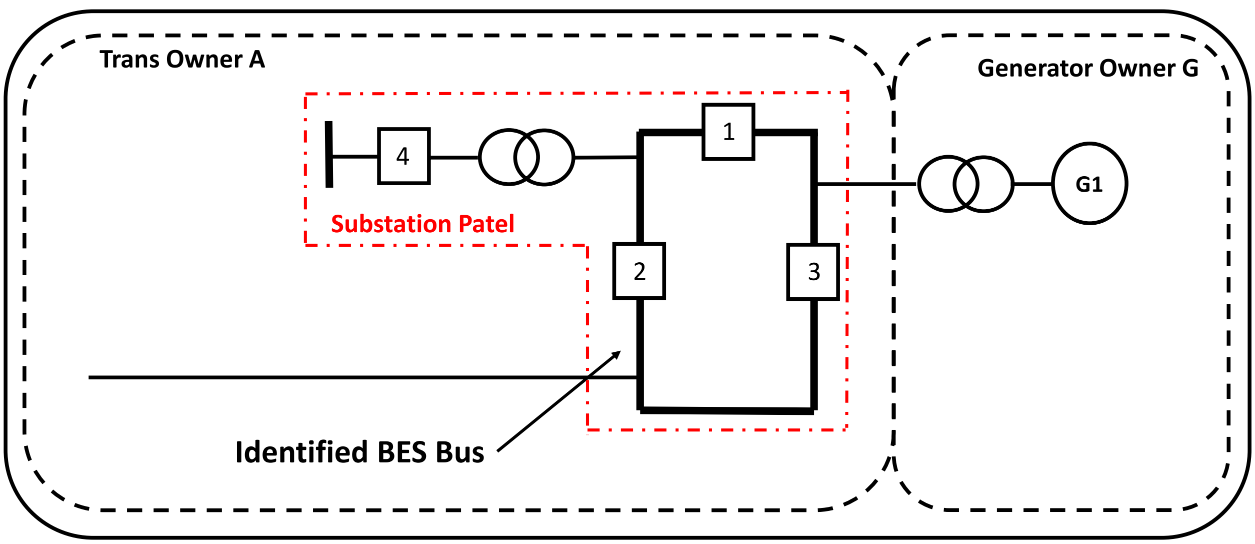

Figure 7: Generator Interconnection to Ring Bus

Figure 8 shows another example of a generator interconnection where generating units/a plant is connected via a transmission line to the identified BES bus for which SER and FR data is required. Circuit breakers 1, 2, and 3 are BES Elements that are directly connected to the identified BES bus. Transmission Owner A owns the physical bus as well as circuit breakers 1 and 2. Generator Owner G owns directly connected circuit breaker 3 and a short transmission line to the generating plant. All equipment (physical

bus(es) and circuit breakers) that comprise a BES bus is located within the same physical space, i.e., substation Key, regardless of ownership.

Transmission Owner A is responsible for SER and FR data for circuit breakers 1 and 2. The Generator Owner G is owner of circuit breaker 3. Per Requirement R1, Part 1.2, if Transmission Owner A does not record SER data for circuit breaker 3, then Generator Owner G must be notified that SER data is required for circuit breaker 3. Per rationale for Requirement R3, FR data is not required for circuit breaker 3 because the transmission line (connecting the generating plant to the Transmission System) is used to exclusively export energy from the generating plant.

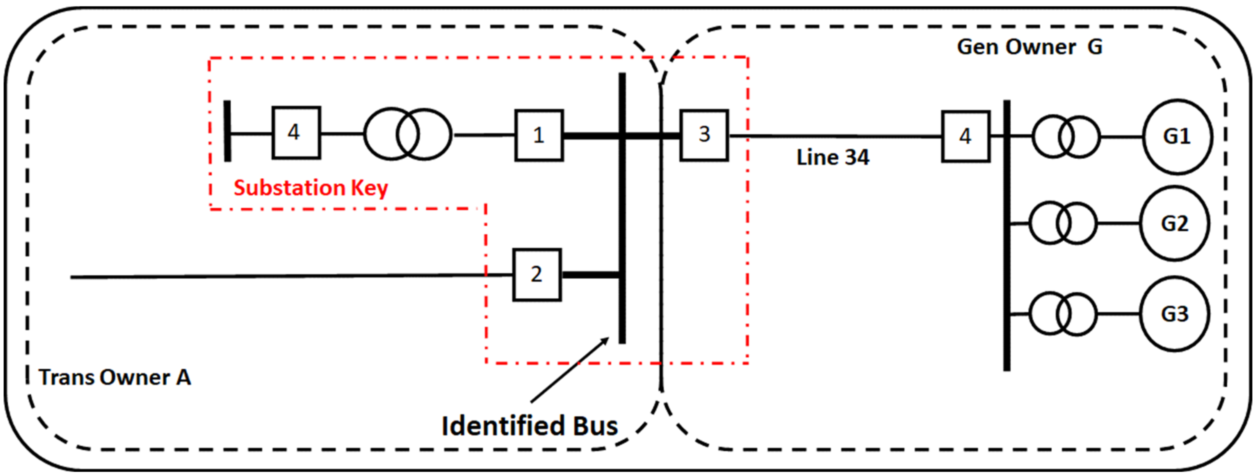

Figure 8: Generator Interconnection via Line 34

Figure 9 shows an example of a generator interconnection via multiple lines that creates a transmission loop. Circuit breakers 1, 2, 3, and 5 are BES Elements that are directly connected to the identified BES bus. Transmission Owner A owns the physical bus as well as circuit breakers 1 and 2. Generator Owner G owns directly connected circuit breakers 3 and 5 and both transmission lines to the generating plant. All equipment (physical bus(es) and circuit breakers) that comprise a BES bus is located within the same physical space, i.e., substation Milan, regardless of ownership.

Transmission Owner A is responsible for SER and FR data for circuit breakers 1 and 2. The loop is created by Line 36 and Line 57. These lines are exclusively used to export power from the generating plant to the transmission system. The FR data is not required for these lines, however, SER data is required on circuit breakers 3 and 5. Per Requirement R1, Part 1.2, if Transmission Owner A does not record SER data for circuit breakers 3 and 5, then Generator Owner G must be notified that SER data is required for circuit breakers 3 and 5.

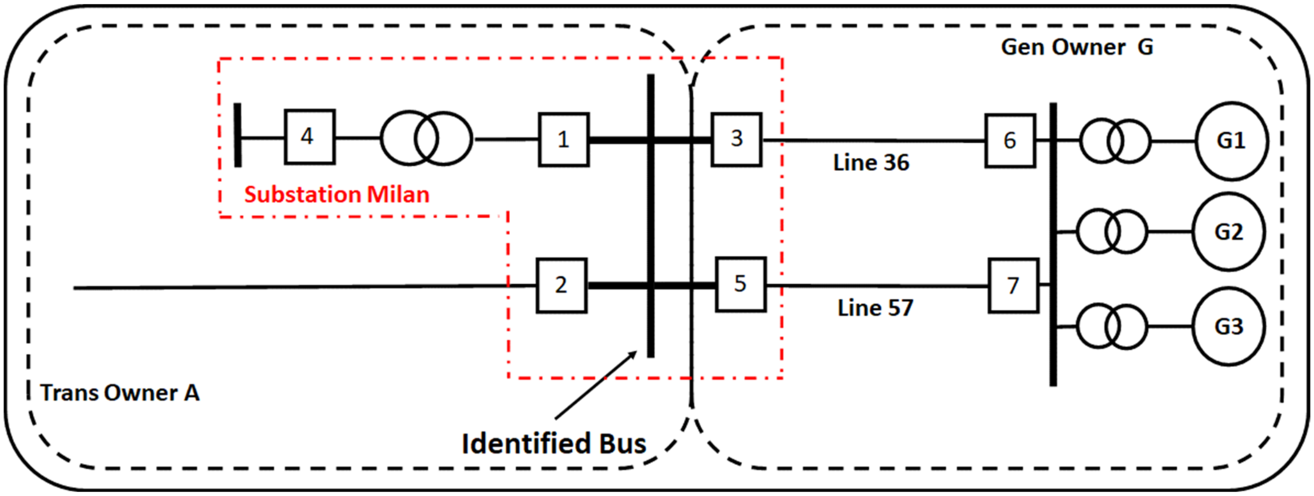

Figure 9: Generator Interconnection via Multiple Lines

The following is an example of a notification provided by Transmission Owner A to Transmission Owner B:

Notification details:

FROM	Transmission Owner A
TO	Transmission Owner B
CC	
BCC	NA
SUBJECT	PRC-002 R1.2 2027 Notification_TransmissionOwnerB

Greetings,

In accordance with NERC Standard PRC-002-5, Requirement R1.1, Transmission Owner A has identified its BES buses for which sequence of events recording (SER) and fault recording (FR) data is required, using the methodology in Attachment 1.

Per Requirement R1.2, you are being notified that the below BES Elements have been determined to be directly connected to one of the buses identified in R1.1 and owned by Transmission Owner B. Transmission Owner A does not have SER and/or FR data on the BES Elements listed below, and thus Transmission Owner B is required to have SER and/or FR data on the following BES Elements:

Transmission Owner A Bus (R1.1)	Directly connected BES Element owned by Transmission Owner B	BES Element Type	Data Required
KEALY 500 kV	Breakers: 3	Breaker	SER
MAGEE 500 kV	Breakers: 3	Breaker	SER
MILAN 500 kV	Lines: 36, 57	Line	FR
MILAN 500 kV	Breakers: 3, 5	Breaker	SER

BURKART 500kV	Breakers: 3	Breaker	SER
EXAMPLE 500kV	Transformer	Transformer	FR

If you have any questions about this notification, analysis or otherwise, please email Transmission Owner A.

Thank you,
Transmission Owner A

The re-evaluation interval of five years was chosen based on the experience of the DMSDT to address changing System configurations while creating balance in the frequency of re-evaluations.

Rationale for Requirement R2
The intent is to capture SER data for the status (open/close) of the circuit breakers that can interrupt the current flow through each BES Element directly connected to a BES bus. Change of state of circuit breaker position and time stamped according to Requirement R10 to a time synchronized clock, provides the basis for assembling the detailed sequence of events timeline of a power System Disturbance. Other status monitoring nomenclature can be used for devices other than circuit breakers.

Analyses of wide-area Disturbances often begin by evaluation of SERs to help determine the initiating event(s) and follow the Disturbance propagation. Recording of breaker operations help determine the interruption of line flows while generator loading is best determined by DDR data, since generator loading can be essentially zero regardless of breaker position.

However, generator breakers directly connected to an identified BES bus are required to have SER data captured. It is important in event analysis to know when a BES bus is cleared regardless of a generator's loading.

Generator Owners are included in this requirement because a Generator Owner may, in some instances, own breakers directly connected to the Transmission Owner's BES bus.

Examples in Figures 10, 11, and 12 show BES Elements directly connected to an identified BES bus that are required to have SER data captured.

Rationale for Requirement R3
The required electrical quantities may either be directly measured or determinable if sufficient FR data is captured (e.g., residual or neutral current if the phase currents are directly measured). In order to cover all possible fault types, all BES bus phase-to-neutral voltages are required to be determinable for each BES bus identified in Requirement R1. BES bus voltage data is adequate for System Disturbance analysis. Phase current and residual current are required to distinguish between phase faults and ground faults. It also facilitates determination of the fault location and cause of relay operation. For transformers (Part 3.2.1), the data may be from either the high-side or the low-side of the transformer. Generator step-up transformers (GSUs) and leads that connect the GSU transformer(s) to the Transmission System that are

used exclusively to export energy directly from a BES generating unit or generating plant are excluded from Requirement R3 because the fault current contribution from a generator to a fault on the Transmission System will be captured by FR data on the Transmission System, and Transmission System FR will capture faults on the generator interconnection.

The BES buses for which FR data is required are determined based on the methodology described in Attachment 1 of the standard. The BES Elements directly connected to those BES buses for which FR data is required include:

- Transformers with a low-side operating voltage of 100kV or above
- Transmission Lines

Only those BES Elements that are identified as BES as defined in the latest in effect NERC definition are to be monitored. For example, radial lines or transformers with low-side voltage less than 100kV are not included.

FR data must be determinable from each terminal of a BES Element directly connected to applicable BES buses.

Generator step-up transformers (GSU) are excluded from the above based on the following:

- Current contribution from a generator in case of fault on the Transmission System will be captured by FR data on the Transmission System.
- For faults on the interconnection to generating facilities, it is sufficient to have fault current data from the Transmission station end of the interconnection. Current contribution from a generator can be readily calculated if needed.

Examples in Figures 10, 11, and 12 show BES Elements directly connected to an identified BES bus that are required to have FR data captured.

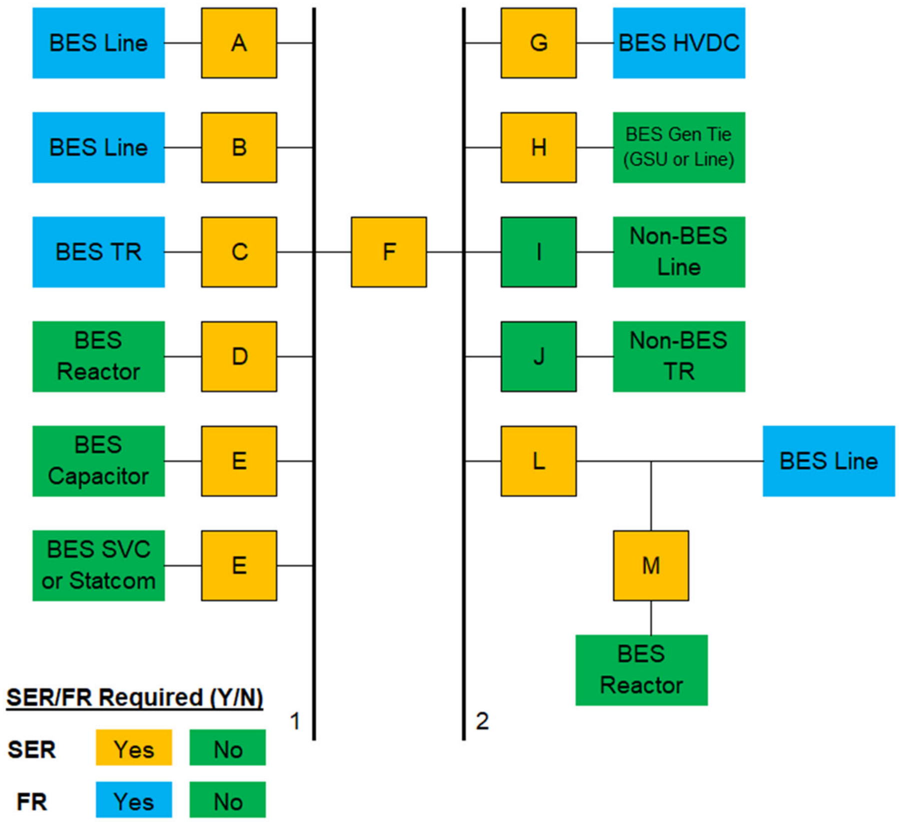

Figure 10: Straight BES Buses

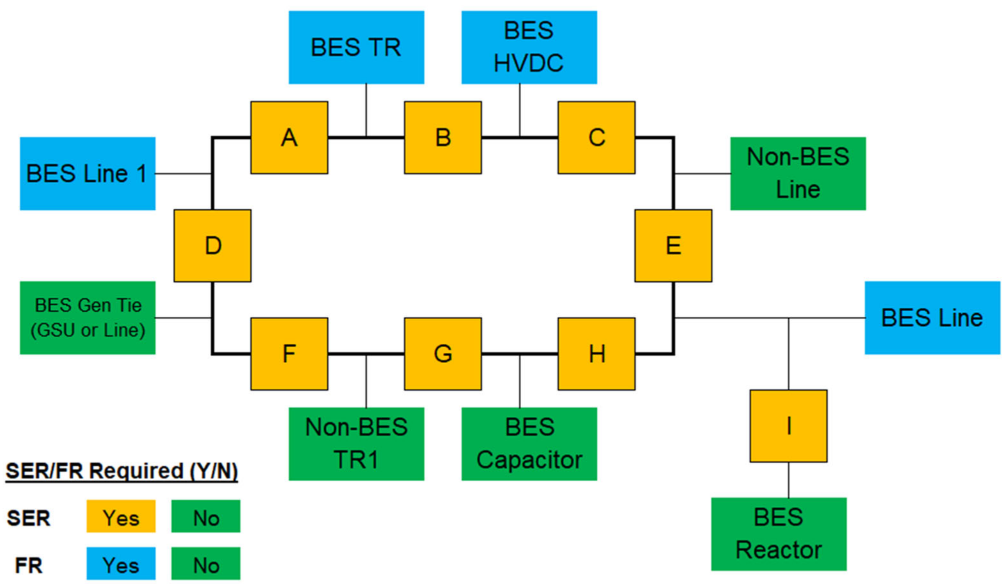

Figure 11: Ring BES Bus

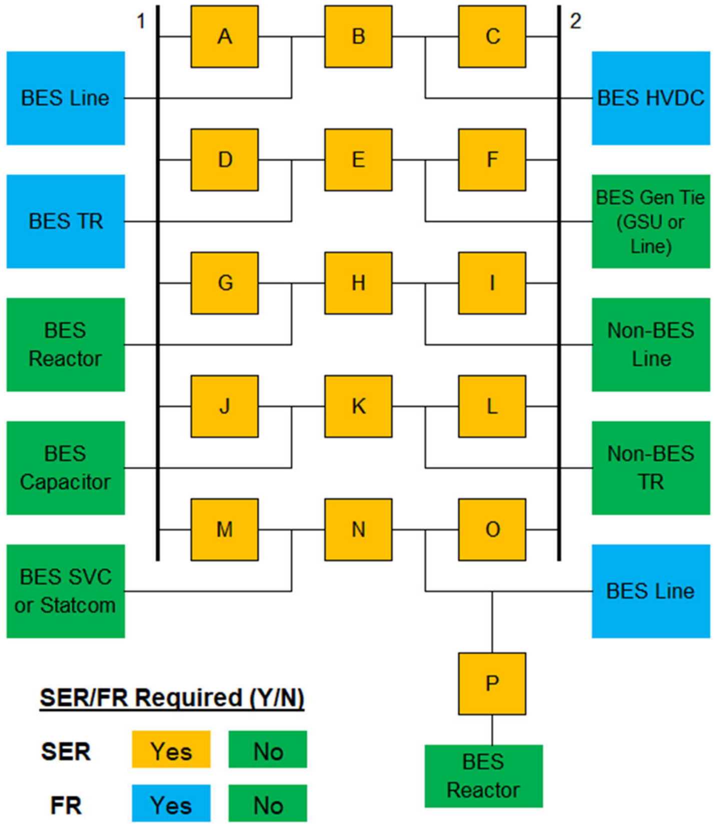

Figure 12: Breaker and Half BES Bus

The DMSDT, after consulting with NERC's Event Analysis group, determined that DDR data from selected generator locations was more important for event analysis than FR data.

Recording of Electrical Quantities

For effective fault analysis it is necessary to know values of all phase and neutral currents and all phase-to-neutral voltages. Based on such FR data, it is possible to determine all fault types. FR data also augments SERs in evaluating circuit breaker operation.

Current Recordings

The required electrical quantities are normally directly measured. Certain quantities can be derived if sufficient data is measured, for example residual or neutral currents. Since a Transmission System is generally well balanced, with phase currents having essentially similar magnitudes and phase angle differences of 120°, during normal conditions there is negligible neutral (residual) current. In case of a ground fault, the resulting phase current imbalance produces residual current that can be either measured or calculated.

Neutral current, also known as ground or residual current $\mathbf{I}_{r,}$ is calculated as a sum of vectors of three

phase currents:

$\mathbf{I}_r = 3 \bullet \mathbf{I}_0 = \mathbf{I}_A + \mathbf{I}_B + \mathbf{I}_C$

$\mathbf{I}_0$ - Zero-sequence current

$\mathbf{I}_A$, $\mathbf{I}_B$, $\mathbf{I}_C$ - Phase current (vectors)

Another example of how required electrical quantities can be derived is based on Kirchhoff's Law. Fault currents for one of the BES Elements connected to a particular BES bus can be derived as a vectorial sum of fault currents recorded at the other BES Elements connected to that BES bus.

<u>Voltage Recordings</u>
Voltages are to be recorded or accurately determined at applicable BES buses.

Rationale for Requirement R4
Time stamped pre- and post-trigger fault data aid in the analysis of power System operations and determination if operations were as intended. System faults generally persist for a short time period, thus a 30-cycle total minimum record length is adequate. Multiple records allow for legacy microprocessor relays which, when time-synchronized, are capable of providing adequate fault data, but not capable of providing fault data in a single record with 30- contiguous cycles total.

A minimum recording rate of 16 samples per cycle (960 Hz) is required to get sufficient points on wave data for recreating accurate fault conditions.

Pre- and post-trigger fault data along with the SER breaker data, all time stamped to a common clock at millisecond accuracy, aid in the analysis of Protection System operations after a fault to determine if a Protection System operated as designed. Generally speaking, BES faults persist for a very short time period, approximately 1 to 30 cycles, thus a 30-cycle record length provides adequate data. Multiple records allow for legacy microprocessor relays which, when time synchronized to a common clock, are capable of providing adequate fault data, but not capable of providing fault data in a single record with 30-contiguous cycles total.

A minimum recording rate of 16 samples per cycle is required to get accurate waveforms and to get 1 millisecond resolution for any digital input which may be used for FR.

FR triggers can be set so that when the monitored value on the recording device goes above or below the trigger value, data is recorded. Requirement R4, sub-Part 4.3.1 specifies a neutral (residual) overcurrent trigger for ground faults. Requirement R4, sub-Part 4.3.2 specifies a phase undervoltage or overcurrent trigger for phase-to-phase faults.

Rationale for Requirement R5
DDR is used for capturing the BES transient and post-transient response following Disturbances, and the data is used for event analysis and validating System performance. DDR plays a critical role in wide-area Disturbance analysis, and Requirement R5 ensures there is adequate wide-area coverage of DDR data for

specific BES Elements to facilitate accurate and efficient event analysis. The Reliability Coordinator has the best wide-area view of the System and needs to ensure that there are sufficient BES Elements identified for DDR data capture. The identification of BES Elements requiring DDR data, as per Requirement R5, is based upon industry experience with wide-area Disturbance analysis and the need for adequate data to facilitate event analysis. Ensuring data is captured for these BES Elements will significantly improve the accuracy of analysis and understanding of why an event occurred, not simply what occurred.

From its experience with changes to the Bulk Electric System that would affect DDR, the DMSDT decided that the five calendar year re-evaluation of the list is a reasonable interval for this review. Changes to the BES do not mandate immediate inclusion of BES Elements into the in force list, but the list of BES Elements will be re-evaluated at least every five calendar years to address System changes since the previous evaluation. However, this standard does not preclude the Reliability Coordinator from performing this re-evaluation more frequently to capture updated BES Elements.

The Reliability Coordinator must notify all owners of the selected BES Elements that DDR data is required for this standard. The Reliability Coordinator is only required to share the list of selected BES Elements that each Transmission Owner and Generator Owner respectively owns, not the entire list. This communication of selected BES Elements is required to ensure that the owners of the respective BES Elements are aware of their responsibilities under this standard.

Implementation of the monitoring equipment is the responsibility of the respective Transmission Owners and Generator Owners, the timeline for installing this capability is outlined in the Implementation Plan, and starts from notification of the list from the Reliability Coordinator. Data for each BES Element as defined by the Reliability Coordinator must be provided; however, this data can be either directly measured or accurately calculated. With the exception of HVDC circuits, DDR data is only required for one end or terminal of the BES Elements selected. For example, DDR data must be provided for at least one terminal of a Transmission Line or generator step-up (GSU) transformer, but not both terminals. For an interconnection between two Reliability Coordinators, each Reliability Coordinator will consider this interconnection independently, and are expected to work cooperatively to determine how to monitor the BES Elements that require DDR data. For an interconnection between two TO's, or a TO and a GO, the Reliability Coordinator will determine which entity will provide the data. The Reliability Coordinator will notify the owners that their BES Elements require DDR data.

Refer to the Guidelines and Technical Basis Section for more detail on the rationale and technical reasoning for each identified BES Element in Requirement R5, Part 5.1; monitoring these BES Elements with DDR will facilitate thorough and informative event analysis of wide-area Disturbances on the BES. Part 5.2 is included to ensure wide-area coverage across all Reliability Coordinators. It is intended that each Reliability Coordinator will have DDR data for one BES Element and at least one additional BES Element per 3,000 MW of its historical simultaneous peak System Demand.

DDR data is used for wide-area Disturbance monitoring to determine the System's electromechanical transient and post-transient response and validate System model performance. DDR is typically located based on strategic studies which include angular, frequency, voltage, and

oscillation stability. However, for adequately monitoring the System's dynamic response and ensuring sufficient coverage to determine System performance, DDR is required for key BES Elements in addition to a minimum requirement of DDR coverage.

Each Reliability Coordinator is required to identify sufficient DDR data capture for, at a minimum, one BES Element and then one additional BES Element per 3,000 MW of historical simultaneous peak System Demand. This DDR data is included to provide adequate System-wide coverage across an Interconnection. To clarify, if any of the key BES Elements requiring DDR monitoring are within the Reliability Coordinator Area, DDR data capability is required. If a Reliability Coordinator does not meet the requirements of Part 5.1, additional coverage has to be specified.

Loss of large generating resources poses a frequency and angular stability risk for all Interconnections across North America. Data capturing the dynamic response of these machines during a Disturbance helps the analysis of large Disturbances. Having data regarding generator dynamic response to Disturbances greatly improves understanding of ***why*** an event occurs rather than what occurred. To determine and provide the basis for unit size criteria, the DMSDT acquired specific generating unit data from NERC's Generating Availability Data System (GADS) program. The data contained generating unit size information for each generating unit in North America which was reported in 2013 to the NERC GADS program. The DMSDT analyzed the spreadsheet data to determine: (i) how many units were above or below selected size thresholds; and (ii) the aggregate sum of the ratings of the units within the boundaries of those thresholds. Statistical information about this data was then produced, i.e., averages, means, and percentages. The DMSDT determined the following basic information about the generating units of interest (current North America fleet, i.e., units reporting in 2013) included in the spreadsheet:

- The number of individual generating units in total included in the spreadsheet.
- The number of individual generating units rated at 20 MW or larger included in the spreadsheet. These units would generally require that their owners be registered as GOs in the NERC CMEP.
- The total number of units within selected size boundaries.
- The aggregate sum of ratings, in MWs, of the units within the boundaries of those thresholds.

The information in the spreadsheet does not provide information by which the plant information location of each unit can be determined, i.e., the DMSDT could not use the information to determine which units were located together at a given generation site or facility.

From this information, the DMSDT was able to reasonably speculate the generating unit size thresholds proposed in Requirement R5, sub-Part 5.1.1 of the standard. Generating resources intended for DDR data recording are those individual units with gross nameplate ratings "greater than or equal to 500 MVA". The 500 MVA individual unit size threshold was selected because this number roughly accounts for 47 percent of the generating capacity in NERC footprint while only requiring DDR coverage on about 12.5 percent of the generating units. As mentioned, there was no data pertaining to unit location for aggregating plant/facility sizes.

However, Requirement R5, sub-Part 5.1.1 is included to capture larger units located at large generating plants which could pose a stability risk to the System if multiple large units were lost due to electrical or non-electrical contingencies. For generating plants, each individual generator at the plant/facility with a gross nameplate rating greater than or equal to 300 MVA must have DDR where the gross nameplate rating of the plant/facility is greater than or equal to 1,000 MVA. The 300 MVA threshold was chosen based on the DMSDT's judgment and experience. The incremental impact to the number of units requiring monitoring is expected to be relatively low. For combined cycle plants where only one generator has a rating greater than or equal to 300MVA, that is the only generator that would need DDR.

Permanent System Operating Limits (SOLs) are used to operate the System within reliable and secure limits. In particular, SOLs related to angular or voltage stability have a significant impact on BES reliability and performance. Therefore, at least one BES Element of an SOL should be monitored.

The draft standard requires "One or more BES Elements that are part of an Interconnection Reliability Operating Limits (IROLs)." Interconnection Reliability Operating Limits (IROLs) are included because the risk of violating these limits poses a risk to System stability and the potential for cascading outages. IROLs may be defined by a single or multiple monitored BES Element(s) and contingent BES Element(s). The standard does not dictate selection of the contingent and/or monitored BES Elements. Rather, the drafting team believes this determination is best made by the Reliability Coordinator for each IROL considered based on the severity of violating this IROL.

Locations where an undervoltage load shedding (UVLS) program is deployed are prone to voltage instability since they are generally areas of significant Demand. The Reliability Coordinator will identify these areas where a UVLS is in service and identify a useful and effective BES Element to monitor for DDR, such that action of the UVLS or voltage instability on the BES could be captured. For example, a major 500kV or 230kV substation on the EHV System close to the load pocket where the UVLS is deployed would likely be a valuable electrical location for DDR coverage and would aid in post-Disturbance analysis of the load area's response to large System excursions (voltage, frequency, etc.).

Rationale for Requirement R6

DDR is used to measure transient response to System Disturbances during a relatively balanced post-fault condition. Therefore, it is sufficient to provide a phase-to-neutral voltage or positive sequence voltage. The electrical quantities can be determined (calculated, derived, etc.).

Because all of the BES buses within a location are at the same frequency, one frequency measurement is adequate.

The data requirements for PRC-002-5 are based on a System configuration assuming all normally closed circuit breakers on a BES bus are closed.

DDR data shows transient response to System Disturbances after a fault is cleared (post-fault), under a relatively balanced operating condition. Therefore, it is sufficient to provide a single phase-to-neutral

voltage or positive sequence voltage. Recording of all three phases of a circuit is not required, although this may be used to compute and record the positive sequence voltage.

The bus where a voltage measurement is required is based on the list of BES Elements defined by the Reliability Coordinator in Requirement R5. The intent of the standard is not to require a separate voltage measurement of each BES Element where a common bus voltage measurement is available. For example, a breaker-and-a-half or double-bus configuration with a North (or East) Bus and South (or West) Bus, would require both buses to have voltage recording because either can be taken out of service indefinitely with the targeted BES Element remaining in service. This may be accomplished either by recording both bus voltages separately, or by providing a selector switch to connect either of the bus voltage sources to a single recording input of the DDR device. This component of the requirement is therefore included to mitigate the potential of failed frequency, phase angle, real power, and reactive power calculations due to voltage measurements removed from service while sufficient voltage measurement is actually available during these operating conditions.

It must be emphasized that the data requirements for PRC-002-5 are based on a System configuration assuming all normally closed circuit breakers on a bus are closed.

When current recording is required, it should be on the same phase as the voltage recording taken at the location if a single phase-to-neutral voltage is provided. Positive sequence current recording is also acceptable.

For all circuits where current recording is required, Real and Reactive Power will be recorded on a three-phase basis. These recordings may be derived either from phase quantities or from positive sequence quantities.

Rationale for Requirement R7

A crucial part of wide-area Disturbance analysis is understanding the dynamic response of generating resources. Therefore, it is necessary for Generator Owners to have DDR at eitherthe high- or low-side of the generator step-up transformer (GSU) measuring the specified electrical quantities to adequately capture generator response. This standard defines the ‘what’ of DDR, not the ‘how’. Generator Owners may install this capability or, where the Transmission Owners already have suitable DDR data, contract with the Transmission Owner. However, the Generator Owner is still responsible for the provision of this data.

All Guidelines specified for Requirement R6 apply to Requirement R7. Since either the high- or low-side windings of the generator step-up transformer (GSU) may be connected in delta, phase-to-phase voltage recording is an acceptable voltage recording. As was explained in the Guideline for Requirement R6, the BES is operating under a relatively balanced operating condition and, if needed, phase-to-neutral quantities can be derived from phase-to-phase quantities.

Again, it must be emphasized that the data requirements for PRC-002-5 are based on a System configuration assuming all normally closed circuit breakers on a bus are closed.

Rationale for Requirement R8

Large scale System outages generally are an evolving sequence of events that occur over an extended period of time, making DDR data essential for event analysis. Data available pre- and post-contingency helps identify the causes and effects of each event leading to outages. Therefore, continuous recording and storage are necessary to ensure sufficient data is available for the entire event.

Existing DDR data recording across the BES may not record continuously. To accommodate its use for the purposes of this standard, triggered records are acceptable if the equipment was installed prior to the effective date of this standard. The frequency triggers are defined based on the dynamic response associated with each Interconnection. The undervoltage trigger is defined to capture possible delayed undervoltage conditions such as Fault Induced Delayed Voltage Recovery (FIDVR).

Wide-area System outages are generally an evolving sequence of events that occur over an extended period of time, making DDR data essential for event analysis. Pre- and post- contingency data helps identify the causes and effects of each event leading to the outages. This drives a need for continuous recording and storage to ensure sufficient data is available for the entire Disturbance.

Transmission Owners and Generator Owners are required to have continuous DDR for the BES Elements identified in Requirement R6. However, this requirement recognizes that legacy equipment may exist for some BES Elements that do not have continuous data recording capabilities. For equipment that was installed prior to the effective date of the standard, triggered DDR records of three minutes are acceptable using at least one of the trigger types specified in Requirement R8, Part 8.2:

- Off nominal frequency triggers are used to capture high- or low-frequency excursions of significant size based on the Interconnection size and inertia.
- Rate of change of frequency triggers are used to capture major changes in System frequency which could be caused by large changes in generation or load, or possibly changes in System impedance.
- The undervoltage trigger specified in this standard is provided to capture possible sustained undervoltage conditions such as Fault Induced Delayed Voltage Recovery (FIDVR) events. A sustained voltage of 85 percent is outside normal schedule operating voltages and is sufficiently low to capture abnormal voltage conditions on the BES.

Rationale for Requirement R9

An input sampling rate of at least 960 samples per second, which corresponds to 16 samples per cycle on the input side of the DDR equipment, ensures adequate accuracy for calculation of recorded measurements such as complex voltage and frequency.

An output recording rate of electrical quantities of at least 30 times per second refers to the recording and measurement calculation rate of the device. Recorded measurements of at least 30 times per second provide adequate recording speed to monitor the low frequency oscillations typically of interest during power System Disturbances.

DDR data contains the dynamic response of a power System to a Disturbance and is used for analyzing complex power System events. This recording is typically used to capture short-term and long-term Disturbances, such as a power swing. Since the data of interest is changing over time, DDR data is normally stored in the form of RMS values or phasor values, as opposed to directly sampled data as found in FR data.

The issue of the sampling rate used in a recording instrument is quite important for at least two reasons: the anti-aliasing filter selection and accuracy of signal representation. The anti-aliasing filter selection is associated with the requirement of a sampling rate at least twice the highest frequency of a sampled signal. At the same time, the accuracy of signal representation is also dependent on the selection of the sampling rate. In general, the higher the sampling rate, the better the representation. In the abnormal conditions of interest (e.g., faults or other Disturbances); the input signal may contain frequencies in the range of 0-400 Hz. Hence, the rate of 960 samples per second (16 samples/cycle) is considered an adequate sampling rate that satisfies the input signal requirements.

In general, dynamic events of interest are: inter-area oscillations, local generator oscillations, wind turbine generator torsional modes, HVDC control modes, exciter control modes, and steam turbine torsional modes. Their frequencies range from 0.1-20 Hz. In order to reconstruct these dynamic events, a minimum recording time of 30 times per second is required.

Rationale for Requirement R10

Time synchronization of Disturbance monitoring data is essential for time alignment of large volumes of geographically dispersed records from diverse recording sources. Coordinated Universal Time (UTC) is a recognized time standard that utilizes atomic clocks for generating precision time measurements. All data must be provided in UTC formatted time either with or without the local time offset, expressed as a negative number (the difference between UTC and the local time zone where the measurements are recorded).

Accuracy of time synchronization applies only to the clock used for synchronizing the monitoring equipment. The equipment used to measure the electrical quantities must be time synchronized to ± 2 ms accuracy; however, accuracy of the application of this time stamp and therefore, the accuracy of the data itself is not mandated. This is because of inherent delays associated with measuring the electrical quantities and events such as breaker closing, measurement transport delays, algorithm and measurement calculation techniques, etc.

Ensuring that the monitoring devices internal clocks are within ± 2 ms accuracy will suffice with respect to providing time synchronized data.

Time synchronization of Disturbance monitoring data allows for the time alignment of large volumes of geographically dispersed data records from diverse recording sources. A universally recognized time standard is necessary to provide the foundation for this alignment.

Coordinated Universal Time (UTC) is the foundation used for the time alignment of records. It is an

international time standard utilizing atomic clocks for generating precision time measurements at fractions of a second level. The local time offset, expressed as a negative number, is the difference between UTC and the local time zone where the measurements are recorded.

Accuracy of time synchronization applies only to the clock used for synchronizing the monitoring equipment.

Time synchronization accuracy is specified in response to Recommendation 12b in the NERC August, 2003, Blackout Final NERC Report Section V Conclusions and Recommendations:

"Recommendation 12b: Facilities owners shall, in accordance with regional criteria, upgrade existing dynamic recorders to include GPS time synchronization…"

Also, from the U.S.-Canada Power System Outage Task Force Interim Report: Causes of the August 14th Blackout, November 2003, in the United States and Canada, page 103:

"Establishing a precise and accurate sequence of outage-related events was a critical building block for the other parts of the investigation. One of the key problems in developing this sequence was that although much of the data pertinent to an event was time-stamped, there was some variance from source to source in how the time-stamping was done, and not all of the time-stamps were synchronized…"

From NPCC's SP6 Report Synchronized Event Data Reporting, revised March 31, 2005, the investigation by the authoring working group revealed that existing GPS receivers can be expected to provide a time code output which has an uncertainty on the order of 1 millisecond, uncertainty being a quantitative descriptor.

Rationale for Requirement R11

Wide-area Disturbance analysis includes data recording from many devices and entities. Standardized formatting and naming conventions of these files significantly improves timely analysis.

Providing the data within 30 calendar days (or the granted extension time), subject to Part 11.2, allows for reasonable time to collect the data and perform any necessary computations or formatting.

Data is required to be retrievable for 10 calendar days inclusive of the day the data was recorded, i.e., a 10-calendar day rolling window of available data. Data hold requests are usually initiated the same or next day following a major event for which data is requested. A10-calendar day time frame provides a practical limit on the duration of data required to be stored and informs the requesting entities as to how long the data will be available. The requestor of data has to be aware of the Part 11.1 10-calendar day retrievability because requiring data retention for a longer period of time is expensive and unnecessary.

SER data shall be provided in a simple ASCII .CSV format as outlined in Attachment 2. Either equipment can provide the data or a simple conversion program can be used to convert files into this format. This will significantly improve the data format for event records, enabling the use of software tools for analyzing the SER data.

This requirement directs the applicable entities, upon requests from the Reliability Coordinator, Regional Entity or NERC, to provide SER and FR data for BES buses determined in Requirement R1 and DDR data for BES Elements determined as per Requirement R5. To facilitate the analysis of BES Disturbances, it is important that the data is provided to the requestor within a reasonable period of time.

Requirement R11, Part 11.2 specifies the maximum time frame of 30 calendar days to provide the data. Thirty calendar days is a reasonable time frame to allow for the collection of data, and submission to the requestor. An entity may request an extension of the 30-day submission requirement. If granted by the requestor, the entity must submit the data within the approved extended time.

Requirement R11, Part 11.1 specifies that the minimum time period of 10 calendar days inclusive of the day the data was recorded for which the data will be retrievable. With the equipment in use that has the capability of recording data, having the data retrievable for the 10 calendar days is realistic and doable. It is important to note that applicable entities should account for any expected delays in retrieving data and this may require devices to have data available for more than 10 days. To clarify the 10-calendar day time frame, an incident occurs on Day 1. If a request for data is made on Day 6, then that data has to be provided to the requestor within 30 calendar days after a request or a granted time extension. However, if a request for the data is made on Day 11, that is outside the 10 calendar days specified in the requirement, and an entity would not be out of compliance if it did not have the data.

Requirement R11, Part 11.3 specifies a Comma Separated Value (CSV) format according to Attachment 2 for the SER data. It is necessary to establish a standard format as it will be incorporated with other submitted data to provide a detailed sequence of events timeline of a power System Disturbance.

Requirement R11, Part 11.4 specifies the IEEE C37.111 COMTRADE format for the FR data. The IEEE C37.111 is the Standard for Common Format for Transient Data Exchange and is well established in the industry. It is necessary to specify a standard format as multiple submissions of data from many sources will be incorporated to provide a detailed analysis of a power System Disturbance.

Requirement R11, Part 11.5 specifies that the DDR data shall be either in CSV format with appropriate headers or in electronic files that are formatted in conformance with IEEE C37.111. The latest revision of COMTRADE (C37.111-2013) includes an annex describing the application of the COMTRADE standard to synchrophasor data.

Requirement R11, Part 11.6 specifies the IEEE C37.232 COMNAME format for naming the data files of the SER, FR and DDR. The IEEE C37.232 is the Standard for Common Format for Naming Time

Sequence Data Files. The first version was approved in 2007. From the August 14, 2003 blackout there were thousands of Fault Recording data files collected. The collected data files did not have a common naming convention and it was therefore difficult to discern which files came from which utilities and which ones were captured by which devices. The lack of a common naming practice seriously hindered the investigation process. Subsequently, and in its initial report on the blackout, NERC stressed the need for having a common naming practice and listed it as one of its top ten recommendations.

Rationale for Requirement R12

Each Transmission Owner and Generator Owner who owns equipment used for collecting the data required for this standard must repair any failures within 90 calendar days to ensure that adequate data is available for event analysis. If the Disturbance monitoring capability cannot be restored within 90 calendar days (e.g., budget cycle, service crews, vendors, needed outages, etc.), the entity must develop a Corrective Action Plan (CAP) for restoring the data recording capability. The timeline required for the CAP depends on the entity and the type of data required. It is treated as a failure if the recording capability is out of service for maintenance and/or testing for greater than 90 calendar days. An outage of the monitored BES Element does not constitute a failure of the Disturbance monitoring capability.

This requirement directs the respective owners of Transmission and Generator equipment to be alert to the proper functioning of equipment used for SER, FR, and DDR data capabilities for the BES buses and BES Elements, which were established in Requirements R1 and R5. The owners are to restore the capability within 90 calendar days of discovery of a failure. This requirement is structured to recognize that the existence of a “reasonable” amount of capability out-of-service does not result in lack of sufficient data for coverage of the System.

Furthermore, 90 calendar days is typically sufficient time for repair or maintenance to be performed. However, in recognition of the fact that there may be occasions for which it is not possible to restore the capability within 90 calendar days, the requirement further provides that, for such cases, the entity submit a Corrective Action Plan (CAP) to the Regional Entity and implement it. These actions are considered to be appropriate to provide for robust and adequate data availability.

Rationale for Requirement R13

Three (3) calendar years of completing a re-evaluation or receiving notification by the Transmission Owner or the Reliability Coordinator is more time than provided in the Implementation Plan of previous versions of this NERC Reliability Standard. The Implementation Plan of previous versions of this Standard provided three years. This time period pertains to those new Elements appearing on the list due to re-evaluation pursuant to Requirement R1, Part 1.3 or Requirement R5, Part 5.4. Having the period built into Requirement R13 maintains visibility of the required time to install monitoring equipment to collect necessary data.

Requirement R13 requires the Transmission Owner and Generator Owner to install monitoring equipment to record required data within three (3) calendar years of completing a re-evaluation or receiving notification that new Elements were identified during re-evaluation pursuant to

Requirement R1, Part 1.3 or Requirement R5, Part 5.4 by the Transmission Owner or the Reliability Coordinator.

Technical Rationale for Reliability Standard PRC-002-5

~~July 2022~~May 2024

PRC-002-5 – Disturbance Monitoring and Reporting Requirements

Rationale for Applicability Section

Because the Reliability Coordinator has the best wide-area view of the BES, the Reliability Coordinator is most suited to be responsible for determining the BES Elements for which dynamic Disturbance recording (DDR) data is required. The Transmission Owners and Generator Owners will have the responsibility for ensuring that adequate data is available for those BES Elements selected. BES buses where sequence of events recording (SER) and fault recording (FR) data is required are best selected by Transmission Owners because they have the required tools, information, and working knowledge of their Systems to determine those buses. The Transmission Owners and Generator Owners that own BES Elements on those BES buses will have the responsibility for ensuring that adequate data is available.

The recent disturbance reports (e.g., Blue Cut Fire, Canyon 2 Fire, Odessa disturbances) have identified a need for disturbance monitoring for inverter-based resources ~~(IBRs)~~ to aid with event analysis, performance monitoring, and disturbance-based ~~IBR generating facility~~ inverter-based resource model validation. The purpose of Reliability Standard PRC-002 is to capture event data to understand large scale system disturbances occurring on the Bulk Electric System (BES). Even with changing resource mix, the Reliability Standard PRC-002 serves the purpose. Introducing ~~IBR~~inverter-based resource monitoring requirements to Reliability Standard PRC-002 may create unintended consequences to purpose of Reliability Standard PRC-002 and may lead to industry confusion. Hence, to address needs identified in the Standard Authorization Request (SAR) submitted by the Inverter-Based Resource Performance Task Force (IRPTF), a new standard for monitoring requirements for ~~IBR~~inverter-based resources is created instead of revising the Reliability Standard PRC-002. To avoid any overlap between the Reliability Standards PRC-002 and PRC-028, BES Elements within inverter-based resources meeting the criteria set by Inclusion I4 of the BES definition are excluded from Reliability Standard PRC-002. Example in Figure 1 is provided to clarify applicability of Reliability Standards PRC-002 and PRC-028. The ~~IBR generating facility~~ inverter-based resource in this example meets the criteria in inclusion I4 of the BES definition. The BES bus in substation Scott is the identified BES bus per methodology in Attachment 1 of the Reliability Standard PRC-002. The SER and FR data requirements for BES Elements associated with the identified BES bus are per the Reliability Standard PRC-002 except for Elements associated with the ~~IBR generating facility~~inverter-based resource, i.e., circuit breaker 3. The SER, FR, and DDR data requirements for the ~~IBR generating facility~~inverter-based resource are specified in the Reliability Standard PRC-028.

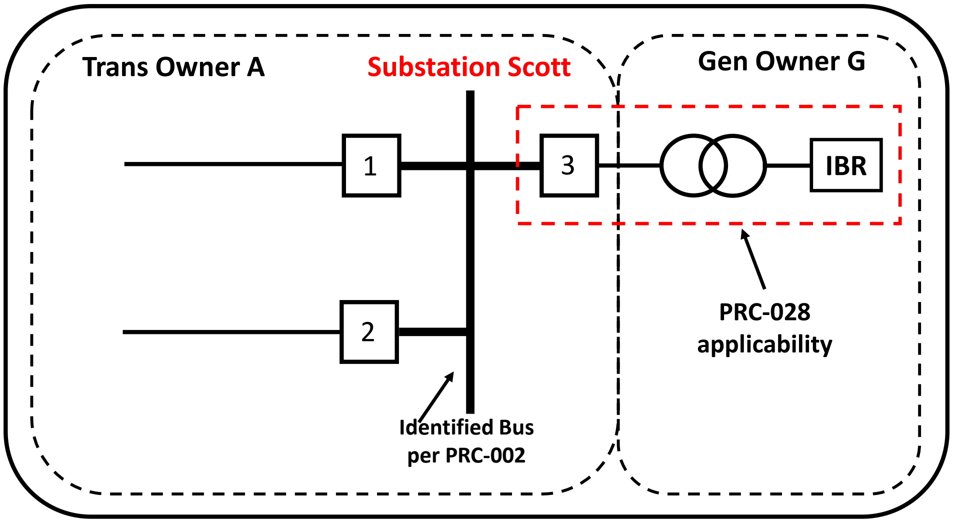

Figure 1: Example to Clarify Applicability of PRC-002 Versus PRC-028

Rationale for Requirement R1

Analysis and reconstruction of BES events requires SER and FR data from key BES buses. Attachment 1 provides a uniform methodology to identify those BES buses. Repeated testing of the Attachment 1 methodology has demonstrated the proper distribution of SER and FR data collection. Review of actual BES short circuit data received from the industry in response to the DMSDT's data request (June 5, 2013 through July 5, 2013) illuminated a strong correlation between the available short circuit MVA at a Transmission bus and its relative size and importance to the BES based on (i) its voltage level, (ii) the number of Transmission Lines and other BES Elements connected to the BES bus, and (iii) the number and size of generating units connected to the bus. BES buses with a large short circuit MVA level are BES Elements that have a significant effect on System reliability and performance. Conversely, BES buses with very low short circuit MVA levels seldom cause wide-area or cascading System events, so SER and FR data from those BES Elements are not as significant. After analyzing and reviewing the collected data submittals from across the continent, the threshold MVA values were chosen to provide sufficient data for event analysis using engineering and operational judgment.

Concerns have existed that the defined methodology for bus selection will overly concentrate data to selected BES buses. For the purpose of PRC-002-5, there are a minimum number of BES buses for which SER and FR data is required based on the short circuit level. With these concepts and the objective being sufficient recording coverage for event analysis, the DMSDT developed the procedure in Attachment 1 that utilizes the maximum available calculated three-phase short circuit MVA. This methodology ensures comparable and sufficient coverage for SER and FR data regardless of variations in the size and System topology of Transmission Owners across all Interconnections. Additionally, this methodology provides a degree of flexibility for the use of judgment in the selection process to ensure sufficient distribution.

BES buses where SER and FR data is required are best selected by Transmission Owners because they have the required tools, information, and working knowledge of their Systems to determine those buses.

Each Transmission Owner must re-evaluate the list of BES buses at least every five calendar years to

address System changes since the previous evaluation. Changes to the BES do not mandate immediate inclusion of BES buses into the currently enforced list, but the list of BES buses will be re-evaluated at least every five calendar years to address System changes since the previous evaluation.

Since there may be multiple owners of equipment that comprise a BES bus, the notification required in R1 is necessary to ensure all owners are notified.

A 90-calendar day notification deadline provides adequate time for the Transmission Owner to make the appropriate determination and notification.

Sequence of events and fault recording for the analysis, reconstruction, and reporting of System Disturbances is important. However, SER and FR data is not required at every BES bus on the BES to conduct adequate or thorough analysis of a Disturbance. As major tools of event analysis, the time synchronized time stamp for a breaker change of state and the recorded waveforms of voltage and current for individual circuits allows the precise reconstruction of events of both localized and wide-area Disturbances.

More quality information is always better than less when performing event analysis. However, 100 percent coverage of all BES Elements is not practical nor required for effective analysis of wide-area Disturbances. Therefore, selectivity of required BES buses to monitor is important for the following reasons:

1. Identify key BES buses with breakers where crucial information is available when required.
2. Avoid excessive overlap of coverage.
3. Avoid gaps in critical coverage.
4. Provide coverage of BES Elements that could propagate a Disturbance.
5. Avoid mandates to cover BES Elements that are more likely to be a casualty of a Disturbance rather than a cause.
6. Establish selection criteria to provide effective coverage in different regions of the continent.

The major characteristics available to determine the selection process are:

1. System voltage level;
2. The number of Transmission Lines into a substation or switchyard;
3. The number and size of connected generating units;
4. The available short circuit levels.

5. Although it is straightforward to establish criteria for the application of identified BES buses, analysis was required to establish a sound technical basis to fulfill the required objectives.

To answer these questions and establish criteria for BES buses of SER and FR, the DMSDT established a sub-team referred to as the Monitored Value Analysis Team (MVA Team). The MVA Team collected information from a wide variety of Transmission Systems throughout the continent to analyze Transmission buses by the characteristics previously identified for the selection process.

The MVA Team learned that the development of criteria is not possible for adequate SER and FR coverage, based solely upon simple, bright line characteristics, such as the number of lines into a substation or switchyard at a particular voltage level or at a set level of short circuit current. To provide the appropriate coverage, a relatively simple but effective Methodology for Selecting Buses for Capturing Sequence of Events Recording (SER) and Fault Recording (FR) Data was developed. This Procedure, included as Attachment 1, assists entities in fulfilling Requirement R1 of the standard.

The Methodology for Selecting Buses for Capturing Sequence of Events Recording (SER) and Fault Recording (FR) Data is weighted to buses with higher short circuit levels. This is chosen for the following reasons:

1. The method is voltage level independent.
2. It is likely to select buses near large generation centers.
3. It is likely to select buses where delayed clearing can cause Cascading.
4. Selected buses directly correlate to the Universal Power Transfer equation: Lower Impedance – increased power flows – greater System impact.

To perform the calculations of Attachment 1, the following information below is required and the following steps (provided in summary form) are required for Systems with more than 11 BES buses with three phase short circuit levels above 1,500 MVA.

1. Total number of BES buses in the Transmission System under evaluation.
    a. Only tangible substation or switchyard buses are included.
    b. Pseudo buses created for analysis purposes in System models are excluded.
2. Determine the three-phase short circuit MVA for each BES bus.
3. Exclude BES buses from the list with short circuit levels below 1,500 MVA.
4. Determine the median short circuit for the top 11 BES buses on the list (position number 6).
5. Multiply median short circuit level by 20 percent.
6. Reduce the list of BES buses to those with short circuit levels higher than the greater of 1500 MVA or 20 percent of the median MVA level determined in Step 5.

7. Apply SER and FR at BES buses with short circuit levels in the top 10 percent of the list (from 6).
8. Apply SER and FR at BES buses at an additional 10 percent of the list using engineering judgment, and allowing flexibility to factor in the following considerations:
    - Electrically distant BES buses or electrically distant from other DME devices
    - Voltage sensitive areas
    - Cohesive load and generation zones
    - BES buses with a relatively high number of incident Transmission circuits
    - BES buses with reactive power devices
    - Major facilities interconnecting outside the Transmission Owner's area.

Per the methodology in Attachment 1, FR/SER data is required at the BES bus with highest maximum available three phase short circuit MVA when the list in Step 6 has one or more, but less than or equal to 11, BES buses. Requirement R1, Part 1.3 requires re-evaluation of BES buses at least once every five calendar years in accordance with Part 1.1. Depending on results of this re-evaluation, the location at which SER/FR data is required could change due to a minor change in the three phase short circuit MVA. This is especially true for small Transmission Owners which are only required to have SER/FR data for one (1) BES bus per allowance based on the methodology in Attachment 1. To help avoid cost and compliance burden, a criterion that constitutes a change in fault current levels, which would require changing SER and FR data recording locations, is included in Attachment 1. During the re-evaluation per Requirement R1, Part 1.3, if the three phase short circuit MVA of the newly identified BES bus is within 15% of the three phase short circuit MVA of the currently applicable BES bus with SER and FR data, then it is not necessary to change the applicable BES bus.

As an example, during an initial evaluation, three BES buses A, B and C are identified in Step 6. The maximum three phase short circuit MVA of buses A, B and C is 1600 MVA, 1500 MVA and 1550 MVA respectively. The SER/FR data is required at Bus A. During a first re-evaluation, the same three buses are identified in Step 6. The maximum three phase short circuit MVA of buses A, B and C is 1550 MVA, 1675 MVA and 1600 MVA respectively. The bus B is the one with highest maximum three phase short circuit MVA now. The three phase short circuit MVA of bus B is within 15% of the three phase short circuit MVA of bus A (1675 is only 8% above 1550) where SER/FR data is being recorded. Hence, it is not necessary to change SER/FR data recording location to bus B. During a next re-evaluation, the same three buses are identified again in Step 6. The maximum three phase short circuit MVA of buses A, B and C is 1500 MVA, 1750 MVA and 1650 MVA respectively. The three phase short circuit MVA of bus B is greater than 15% of three phase short circuit MVA of bus A (1750 is 16.7% above the 1500) where SER/FR data is being recorded. Hence, it is necessary to change SER/FR data recording location to bus B.

For event analysis purposes, more valuable information is attained about generators and their response to System events pre- and post-contingency through DDR data versus SER or FR records. SER data of the opening of the primary generator output interrupting devices (e.g. synchronizing breaker) may not reliably indicate the actual time that a generator tripped; for instance, when it trips on reverse

power after loss of its prime mover (e.g. combustion or steam turbine). As a result, this standard requires DDR data. Refer to Rationale for Requirement R5 for more details.

Since there may be multiple owners of equipment that comprise a BES bus, the notification required in Requirement R1, Part 1.2 is necessary to ensure all owners of "directly connected" BES Elements are notified. For the purposes of this standard, "directly connected" BES elements are BES elements connected at the same voltage level within the same physical location sharing a common ground grid with the BES bus identified under Attachment 1. Transformers that have a low-side operating voltage of less than 100kV are excluded. The following examples are provided to clarify notification requirement.

The straight and ring bus configurations shown in Figures 2 and 3 respectively, are the simplest BES bus configurations. Transmission Owner A owns the identified BES bus, including physical bus(es) as well as all three circuit breakers. Circuit breakers 1, 2 and 3 are BES Elements that are directly connected to the identified BES bus. The Transmission Owner A records SER/FR data for all three circuit breakers. In these cases, Transmission Owner A is not required to send notification to Transmission Owner B.

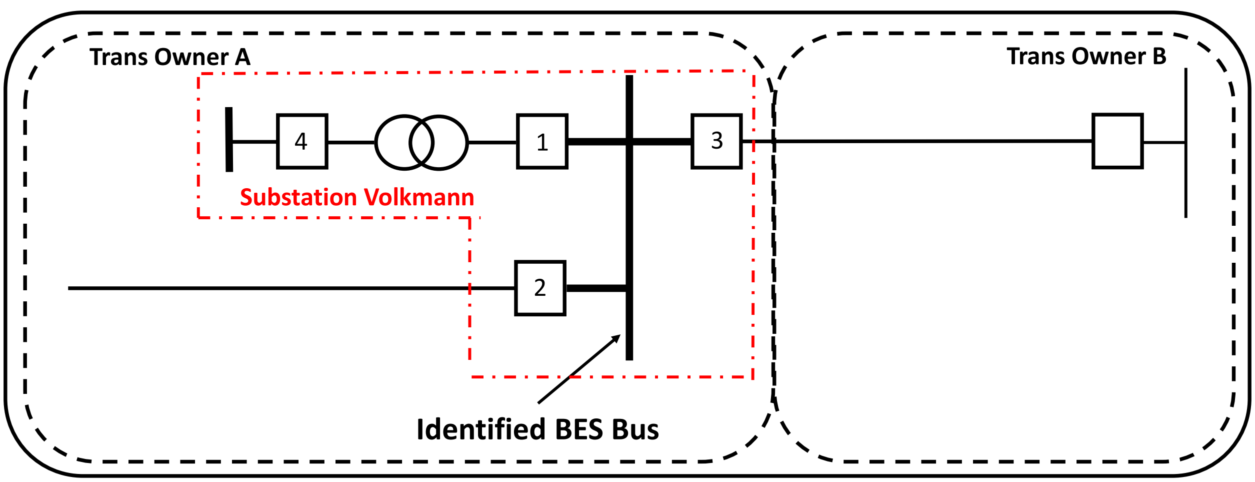

Figure 2: Straight Bus Configuration – Single Owner

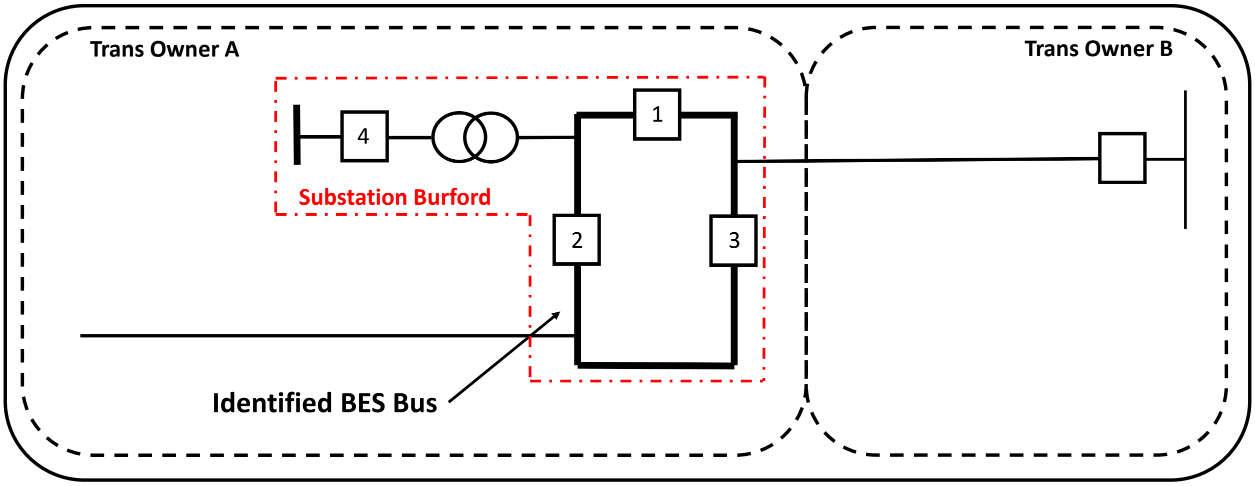

Figure 3: Ring Bus Configuration – Single Owner

Figures 4 and 5 show straight and ring bus configurations respectively, but with equipment that comprise a BES bus owned by multiple owners. Circuit breakers 1, 2 and 3 are BES Elements that are directly connected to the identified BES bus. The Transmission Owner A identifies a BES bus for which SER and FR data is required per Requirement R1, Part 1.1 and methodology included in Attachment 1. Transmission Owner A owns a portion of the physical bus(es) as well as circuit breakers 1 and 2. Transmission Owner B owns the remaining portion of the physical bus(es) and directly connected circuit breaker 3. All equipment (physical bus(es) and circuit breakers) that comprise the BES bus is located within the same physical space, i.e., substation Kealy, regardless of ownership.

In these cases, Transmission Owner A is responsible for SER and FR data for circuit breakers 1 and 2. The Transmission Owner B is owner of circuit breaker 3. Per Requirement R1, Part 1.2, if Transmission Owner A does not record SER and FR data for circuit breaker 3, then Transmission Owner B must be notified that SER/FR data is required for circuit breaker 3.

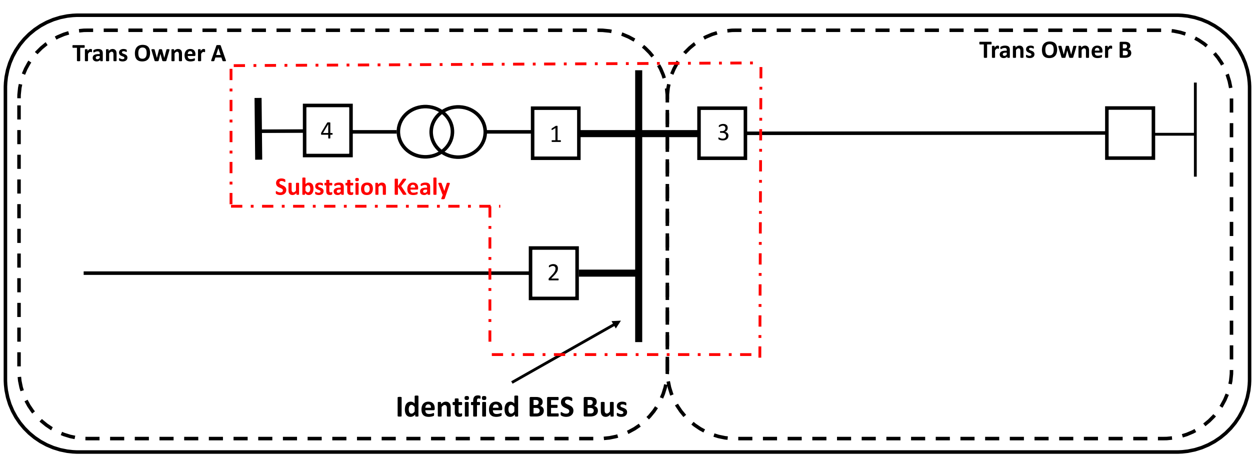

Figure 4: Straight Bus Configuration – Multiple Owners

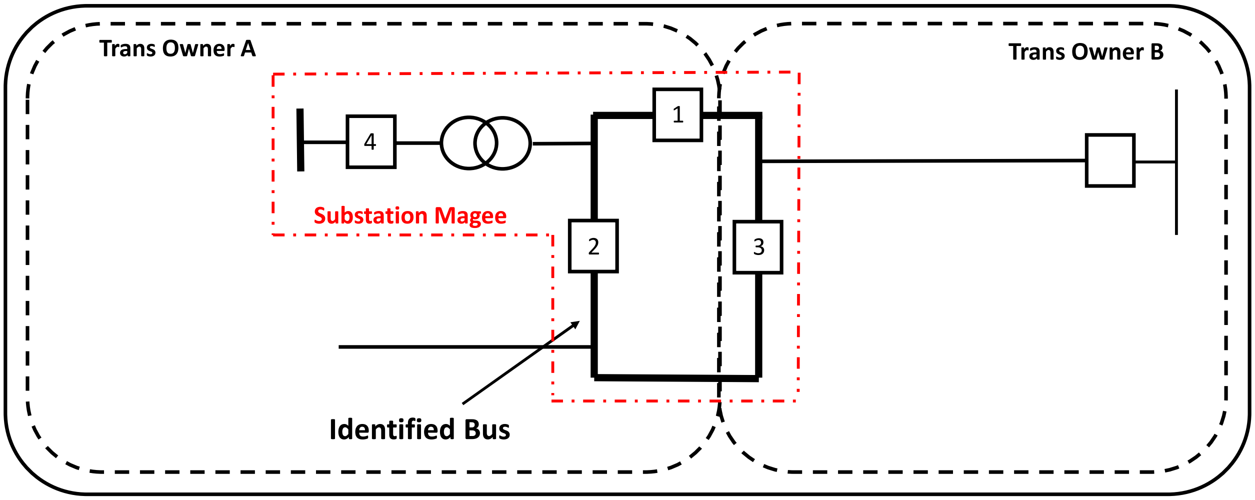

Figure 5: Ring Bus Configuration – Multiple Owners

For examples in Figures 4 and 5, if Transmission Owner A records SER/FR data for circuit breaker 3 (even though owned by Transmission Owner B), then Transmission Owner A is not required to notify Transmission Owner B.

Figure 6 shows an example with a generator interconnection. Circuit breakers 1, 2 and 3 are BES Elements that are directly connected to the identified BES bus. Transmission Owner A identifies a BES bus for which SER and FR data is required per Requirement R1, Part 1.1. Transmission Owner A owns the physical bus as well as directly connected circuit breakers 1 and 2. Generator Owner G owns directly connected circuit breaker 3. All equipment (physical bus(es) and circuit breakers) that comprise a BES bus is located within the same physical space, i.e., substation Burkart, regardless of ownership.

Transmission Owner A is responsible for SER and FR data for circuit breakers 1 and 2. The Generator Owner G is owner of circuit breaker 3. Per Requirement R1, Part 1.2, if Transmission Owner A does not record SER data for circuit breaker 3, then Generator Owner G must be notified that SER data is required for circuit breaker 3. Per the criteria in Requirement R3, Part 3.2.1, FR data is not required for circuit breaker 3.

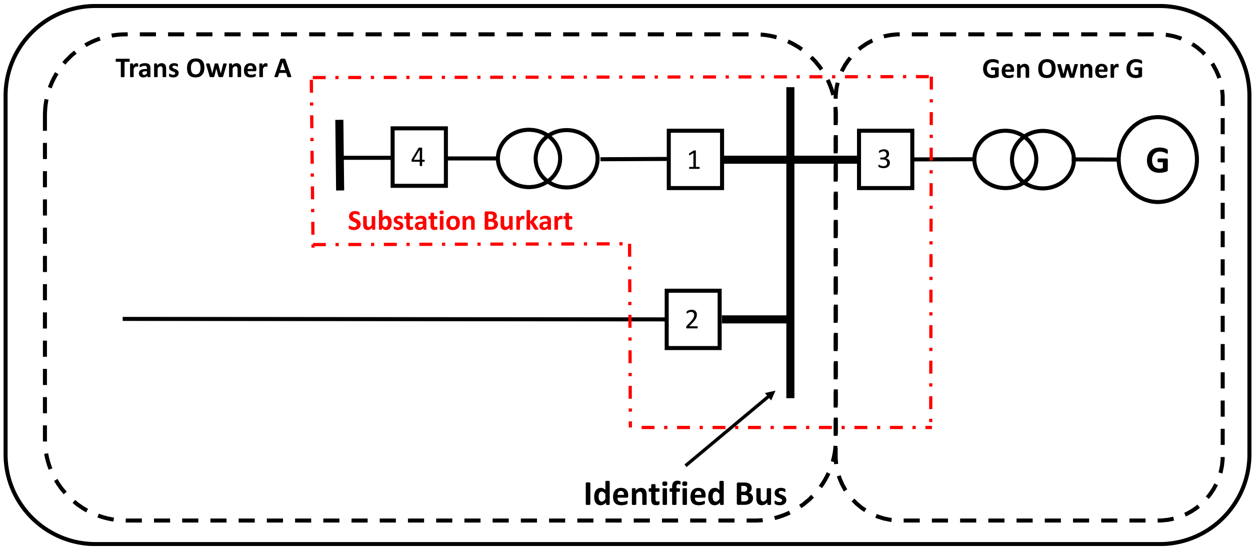

Figure 6: Generator Interconnection to Straight Bus

For a generator interconnection to a ring bus, as shown in Figure 7, Transmission Owner A is responsible for SER data for circuit breakers 1, 2, and 3. The Transmission Owner A is required to record FR data for contributions from the transmission line (circuit breakers 2 and 3) and transformer (circuit breakers 1 and 2). However, per the criteria in Requirement R3, Part 3.2.1, FR data is not required for contribution from the generator.

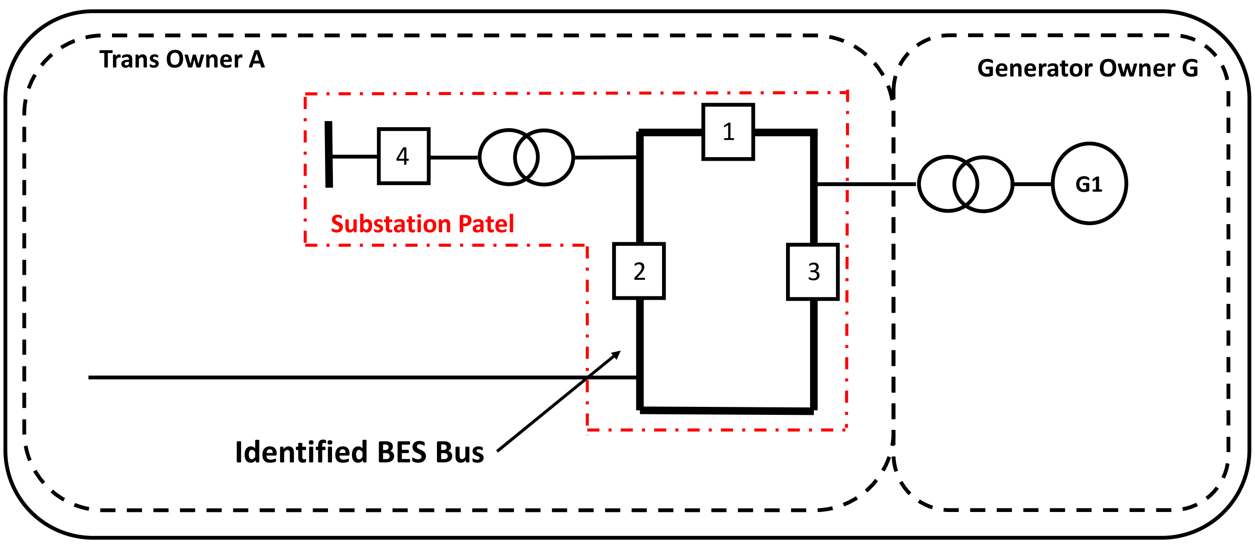

Figure 7: Generator Interconnection to Ring Bus

Figure 8 shows another example of a generator interconnection where generating units/a plant is connected via a transmission line to the identified BES bus for which SER and FR data is required. Circuit breakers 1, 2 and 3 are BES Elements that are directly connected to the identified BES bus. Transmission Owner A owns the physical bus as well as circuit breakers 1 and 2. Generator Owner G owns directly connected circuit breaker 3 and a short transmission line to the generating plant. All equipment (physical

bus(es) and circuit breakers) that comprise a BES bus is located within the same physical space, i.e., substation Key, regardless of ownership.

Transmission Owner A is responsible for SER and FR data for circuit breakers 1 and 2. The Generator Owner G is owner of circuit breaker 3. Per Requirement R1, Part 1.2, if Transmission Owner A does not record SER data for circuit breaker 3, then Generator Owner G must be notified that SER data is required for circuit breaker 3. Per rationale for Requirement R3, FR data is not required for circuit breaker 3 because the transmission line (connecting the generating plant to the Transmission System) is used to exclusively export energy from the generating plant.

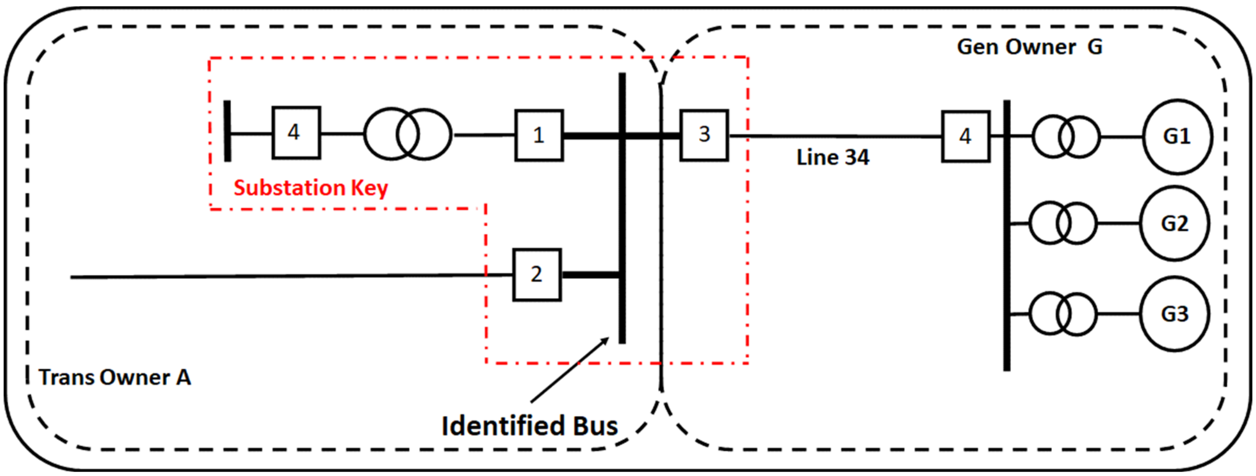

Figure 8: Generator Interconnection via Line 34

Figure 9 shows an example of a generator interconnection via multiple lines that creates a transmission loop. Circuit breakers 1, 2, 3 and 5 are BES Elements that are directly connected to the identified BES bus. Transmission Owner A owns the physical bus as well as circuit breakers 1 and 2. Generator Owner G owns directly connected circuit breakers 3 and 5 and both transmission lines to the generating plant. All equipment (physical bus(es) and circuit breakers) that comprise a BES bus is located within the same physical space, i.e., substation Milan, regardless of ownership.

Transmission Owner A is responsible for SER and FR data for circuit breakers 1 and 2. The loop is created by Line 36 and Line 57. These lines are exclusively used to export power from the generating plant to the transmission system. The FR data is not required for these lines, however, SER data is required on circuit breakers 3 and 5. Per Requirement R1, Part 1.2, if Transmission Owner A does not record SER data for circuit breakers 3 and 5, then Generator Owner G must be notified that SER data is required for circuit breakers 3 and 5.

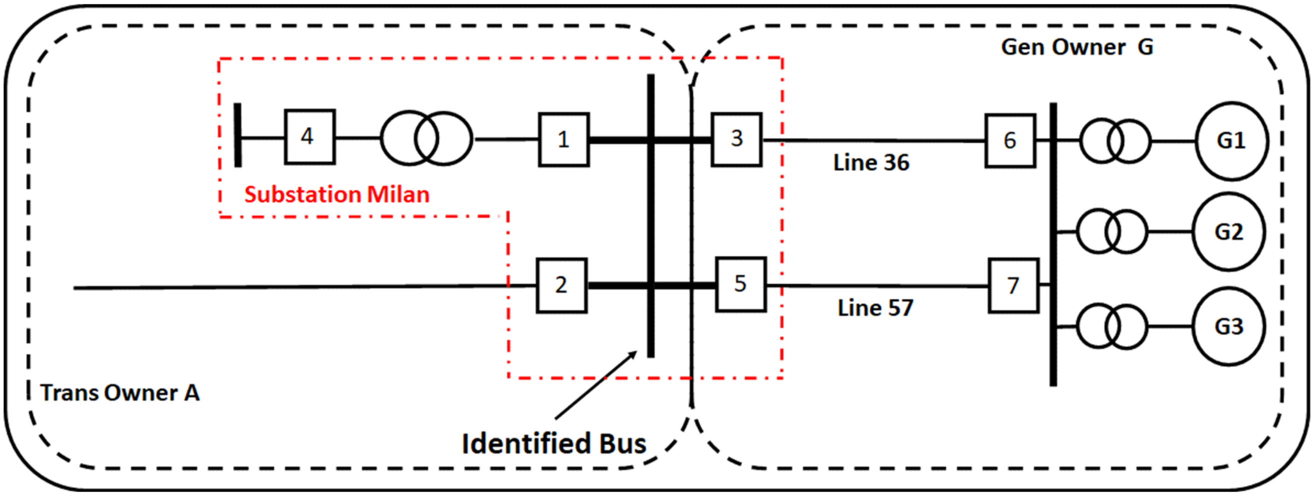

Figure 9: Generator Interconnection via Multiple Lines

The following is an example of a notification provided by Transmission Owner A to Transmission Owner B:

Notification details:

FROM	Transmission Owner A
TO	Transmission Owner B
CC	
BCC	NA
SUBJECT	PRC-002 R1.2 2027 Notification_TransmissionOwnerB

Greetings,

In accordance with NERC Standard PRC-002-5, Requirement R1.1, Transmission Owner A has identified its BES buses for which sequence of events recording (SER) and fault recording (FR) data is required, using the methodology in Attachment 1.

Per Requirement R1.2, you are being notified that the below BES Elements have been determined to be directly connected to one of the buses identified in R1.1 and owned by Transmission Owner B. Transmission Owner A does not have SER and/or FR data on the BES Elements listed below, and thus Transmission Owner B is required to have SER and/or FR data on the following BES Elements:

Transmission Owner A Bus (R1.1)	Directly connected BES Element owned by Transmission Owner B	BES Element Type	Data Required
KEALY 500 kV	Breakers: 3	Breaker	SER
MAGEE 500 kV	Breakers: 3	Breaker	SER
MILAN 500 kV	Lines: 36, 57	Line	FR
MILAN 500 kV	Breakers: 3, 5	Breaker	SER

BURKART 500kV	Breakers: 3	Breaker	SER
EXAMPLE 500kV	Transformer	Transformer	FR

If you have any questions about this notification, analysis or otherwise, please email Transmission Owner A.

Thank you,
Transmission Owner A

The re-evaluation interval of five years was chosen based on the experience of the DMSDT to address changing System configurations while creating balance in the frequency of re-evaluations.

Rationale for Requirement R2

The intent is to capture SER data for the status (open/close) of the circuit breakers that can interrupt the current flow through each BES Element directly connected to a BES bus. Change of state of circuit breaker position and time stamped according to Requirement R10 to a time synchronized clock, provides the basis for assembling the detailed sequence of events timeline of a power System Disturbance. Other status monitoring nomenclature can be used for devices other than circuit breakers.

Analyses of wide-area Disturbances often begin by evaluation of SERs to help determine the initiating event(s) and follow the Disturbance propagation. Recording of breaker operations help determine the interruption of line flows while generator loading is best determined by DDR data, since generator loading can be essentially zero regardless of breaker position.

However, generator breakers directly connected to an identified BES bus are required to have SER data captured. It is important in event analysis to know when a BES bus is cleared regardless of a generator's loading.

Generator Owners are included in this requirement because a Generator Owner may, in some instances, own breakers directly connected to the Transmission Owner's BES bus.

Examples in Figures 10, 11 and 12 show BES Elements directly connected to an identified BES bus that are required to have SER data captured.

Rationale for Requirement R3

The required electrical quantities may either be directly measured or determinable if sufficient FR data is captured (e.g. residual or neutral current if the phase currents are directly measured). In order to cover all possible fault types, all BES bus phase-to-neutral voltages are required to be determinable for each BES bus identified in Requirement R1. BES bus voltage data is adequate for System Disturbance analysis. Phase current and residual current are required to distinguish between phase faults and ground faults. It also facilitates determination of the fault location and cause of relay operation. For transformers (Part 3.2.1), the data may be from either the high-side or the low-side of the transformer. Generator step-up transformers (GSUs) and leads that connect the GSU transformer(s) to the Transmission System that are

used exclusively to export energy directly from a BES generating unit or generating plant are excluded from Requirement R3 because the fault current contribution from a generator to a fault on the Transmission System will be captured by FR data on the Transmission System, and Transmission System FR will capture faults on the generator interconnection.

The BES buses for which FR data is required are determined based on the methodology described in Attachment 1 of the standard. The BES Elements directly connected to those BES buses for which FR data is required include:

- Transformers with a low-side operating voltage of 100kV or above
- Transmission Lines

Only those BES Elements that are identified as BES as defined in the latest in effect NERC definition are to be monitored. For example, radial lines or transformers with low-side voltage less than 100kV are not included.

FR data must be determinable from each terminal of a BES Element directly connected to applicable BES buses.

Generator step-up transformers (GSU) are excluded from the above based on the following:

- Current contribution from a generator in case of fault on the Transmission System will be captured by FR data on the Transmission System.
- For faults on the interconnection to generating facilities, it is sufficient to have fault current data from the Transmission station end of the interconnection. Current contribution from a generator can be readily calculated if needed.

Examples in Figures 10, 11 and 12 show BES Elements directly connected to an identified BES bus that are required to have FR data captured.

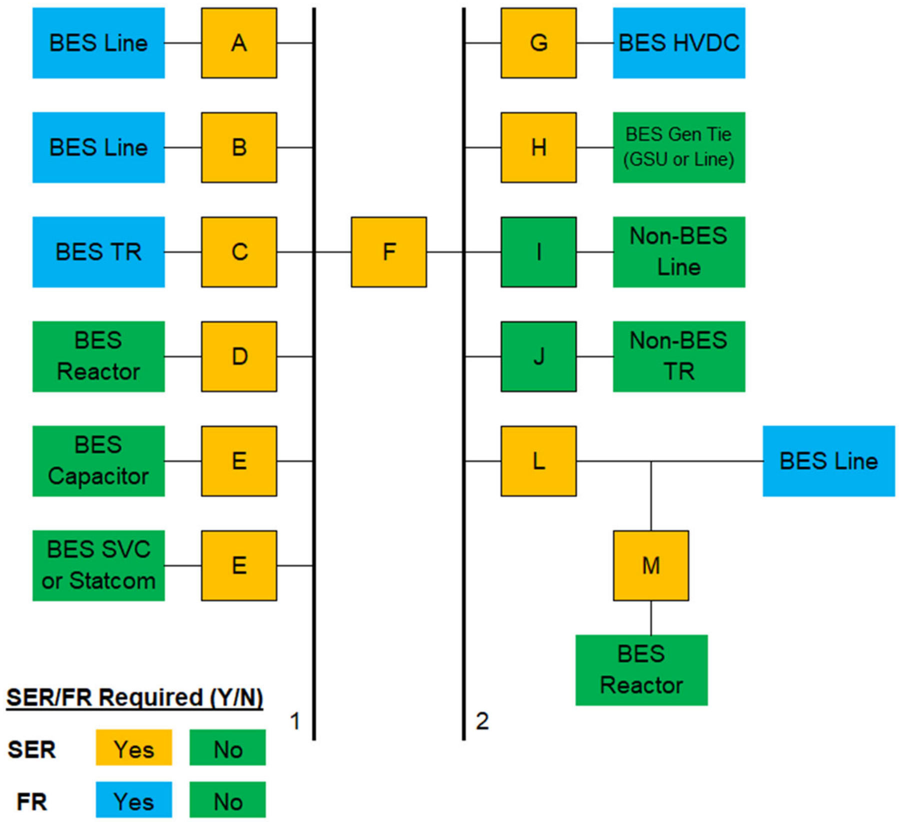

Figure 10: Straight BES Buses

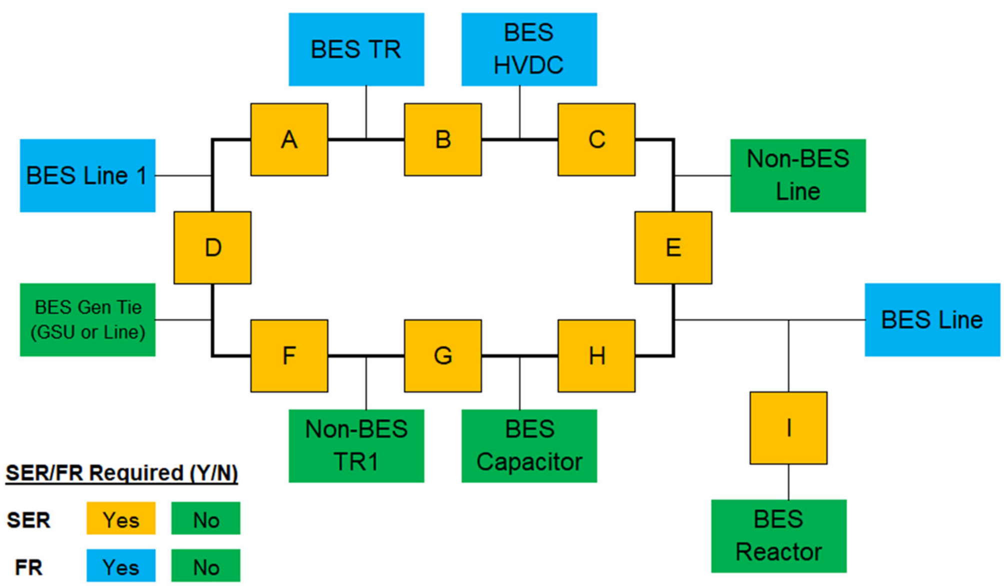

Figure 11: Ring BES Bus

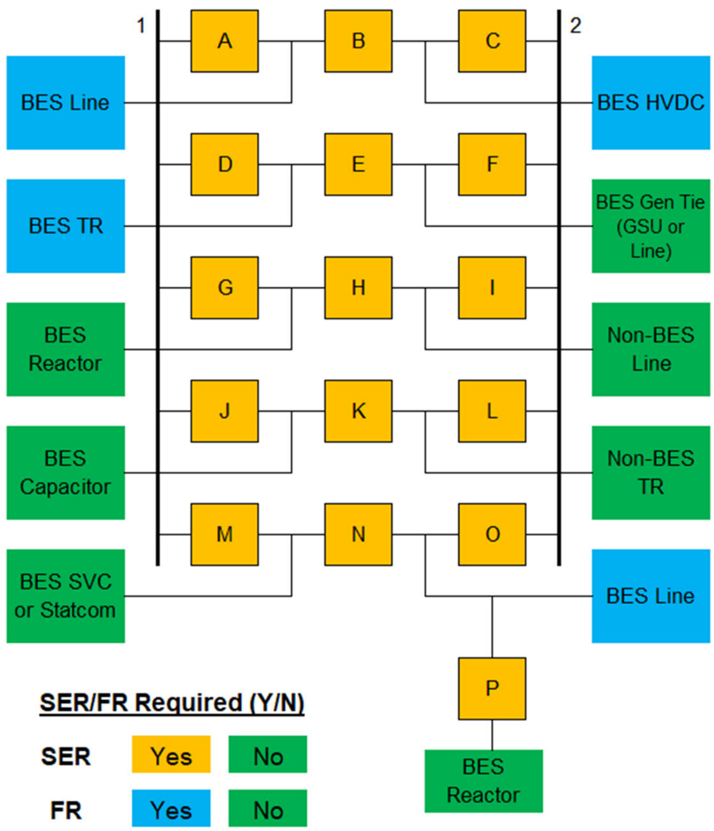

Figure 12: Breaker and Half BES Bus

The DMSDT, after consulting with NERC's Event Analysis group, determined that DDR data from selected generator locations was more important for event analysis than FR data.

Recording of Electrical Quantities

For effective fault analysis it is necessary to know values of all phase and neutral currents and all phase-to-neutral voltages. Based on such FR data, it is possible to determine all fault types. FR data also augments SERs in evaluating circuit breaker operation.

Current Recordings

The required electrical quantities are normally directly measured. Certain quantities can be derived if sufficient data is measured, for example residual or neutral currents. Since a Transmission System is generally well balanced, with phase currents having essentially similar magnitudes and phase angle differences of 120°, during normal conditions there is negligible neutral (residual) current. In case of a ground fault, the resulting phase current imbalance produces residual current that can be either measured or calculated.

Neutral current, also known as ground or residual current $\mathbf{I}_{r,}$ is calculated as a sum of vectors of three

phase currents:

$$\mathbf{I}_r = 3 \bullet \mathbf{I}_0 = \mathbf{I}_A + \mathbf{I}_B + \mathbf{I}_C$$

$\mathbf{I}_0$ - Zero-sequence current

$\mathbf{I}_A$, $\mathbf{I}_B$, $\mathbf{I}_C$ - Phase current (vectors)

Another example of how required electrical quantities can be derived is based on Kirchhoff's Law. Fault currents for one of the BES Elements connected to a particular BES bus can be derived as a vectorial sum of fault currents recorded at the other BES Elements connected to that BES bus.

Voltage Recordings
Voltages are to be recorded or accurately determined at applicable BES buses

Rationale for Requirement R4
Time stamped pre- and post-trigger fault data aid in the analysis of power System operations and determination if operations were as intended. System faults generally persist for a short time period, thus a 30-cycle total minimum record length is adequate. Multiple records allow for legacy microprocessor relays which, when time-synchronized, are capable of providing adequate fault data but not capable of providing fault data in a single record with 30- contiguous cycles total.

A minimum recording rate of 16 samples per cycle (960 Hz) is required to get sufficient point on wave data for recreating accurate fault conditions.

Pre- and post-trigger fault data along with the SER breaker data, all time stamped to a common clock at millisecond accuracy, aid in the analysis of Protection System operations after a fault to determine if a Protection System operated as designed. Generally speaking, BES faults persist for a very short time period, approximately 1 to 30 cycles, thus a 30-cycle record length provides adequate data. Multiple records allow for legacy microprocessor relays which, when time synchronized to a common clock, are capable of providing adequate fault data but not capable of providing fault data in a single record with 30-contiguous cycles total.

A minimum recording rate of 16 samples per cycle is required to get accurate waveforms and to get 1 millisecond resolution for any digital input which may be used for FR.

FR triggers can be set so that when the monitored value on the recording device goes above or below the trigger value, data is recorded. Requirement R4, sub-Part 4.3.1 specifies a neutral (residual) overcurrent trigger for ground faults. Requirement R4, sub-Part 4.3.2 specifies a phase undervoltage or overcurrent trigger for phase-to-phase faults.

Rationale for Requirement R5
DDR is used for capturing the BES transient and post-transient response following Disturbances, and the data is used for event analysis and validating System performance. DDR plays a critical role in wide-area Disturbance analysis, and Requirement R5 ensures there is adequate wide-area coverage of DDR data for

specific BES Elements to facilitate accurate and efficient event analysis. The Reliability Coordinator has the best wide-area view of the System and needs to ensure that there are sufficient BES Elements identified for DDR data capture. The identification of BES Elements requiring DDR data, as per Requirement R5, is based upon industry experience with wide-area Disturbance analysis and the need for adequate data to facilitate event analysis. Ensuring data is captured for these BES Elements will significantly improve the accuracy of analysis and understanding of why an event occurred, not simply what occurred.

From its experience with changes to the Bulk Electric System that would affect DDR, the DMSDT decided that the five calendar year re-evaluation of the list is a reasonable interval for this review. Changes to the BES do not mandate immediate inclusion of BES Elements into the in force list, but the list of BES Elements will be re-evaluated at least every five calendar years to address System changes since the previous evaluation. However, this standard does not preclude the Reliability Coordinator from performing this re-evaluation more frequently to capture updated BES Elements.

The Reliability Coordinator must notify all owners of the selected BES Elements that DDR data is required for this standard. The Reliability Coordinator is only required to share the list of selected BES Elements that each Transmission Owner and Generator Owner respectively owns, not the entire list. This communication of selected BES Elements is required to ensure that the owners of the respective BES Elements are aware of their responsibilities under this standard.

Implementation of the monitoring equipment is the responsibility of the respective Transmission Owners and Generator Owners, the timeline for installing this capability is outlined in the Implementation Plan, and starts from notification of the list from the Reliability Coordinator. Data for each BES Element as defined by the Reliability Coordinator must be provided; however, this data can be either directly measured or accurately calculated. With the exception of HVDC circuits, DDR data is only required for one end or terminal of the BES Elements selected. For example, DDR data must be provided for at least one terminal of a Transmission Line or generator step-up (GSU) transformer, but not both terminals. For an interconnection between two Reliability Coordinators, each Reliability Coordinator will consider this interconnection independently, and are expected to work cooperatively to determine how to monitor the BES Elements that require DDR data. For an interconnection between two TO's, or a TO and a GO, the Reliability Coordinator will determine which entity will provide the data. The Reliability Coordinator will notify the owners that their BES Elements require DDR data.

Refer to the Guidelines and Technical Basis Section for more detail on the rationale and technical reasoning for each identified BES Element in Requirement R5, Part 5.1; monitoring these BES Elements with DDR will facilitate thorough and informative event analysis of wide-area Disturbances on the BES. Part 5.2 is included to ensure wide-area coverage across all Reliability Coordinators. It is intended that each Reliability Coordinator will have DDR data for one BES Element and at least one additional BES Element per 3,000 MW of its historical simultaneous peak System Demand.
DDR data is used for wide-area Disturbance monitoring to determine the System's electromechanical transient and post-transient response and validate System model performance.
DDR is typically located based on strategic studies which include angular, frequency, voltage, and oscillation stability. However, for adequately monitoring the System's dynamic response and

ensuring sufficient coverage to determine System performance, DDR is required for key BES Elements in addition to a minimum requirement of DDR coverage.

Each Reliability Coordinator is required to identify sufficient DDR data capture for, at a minimum, one BES Element and then one additional BES Element per 3,000 MW of historical simultaneous peak System Demand. This DDR data is included to provide adequate System-wide coverage across an Interconnection. To clarify, if any of the key BES Elements requiring DDR monitoring are within the Reliability Coordinator Area, DDR data capability is required. If a Reliability Coordinator does not meet the requirements of Part 5.1, additional coverage had to be specified.

Loss of large generating resources poses a frequency and angular stability risk for all Interconnections across North America. Data capturing the dynamic response of these machines during a Disturbance helps the analysis of large Disturbances. Having data regarding generator dynamic response to Disturbances greatly improves understanding of ***why*** an event occurs rather than what occurred. To determine and provide the basis for unit size criteria, the DMSDT acquired specific generating unit data from NERC's Generating Availability Data System (GADS) program. The data contained generating unit size information for each generating unit in North America which was reported in 2013 to the NERC GADS program. The DMSDT analyzed the spreadsheet data to determine: (i) how many units were above or below selected size thresholds; and (ii) the aggregate sum of the ratings of the units within the boundaries of those thresholds. Statistical information about this data was then produced, i.e. averages, means, and percentages. The DMSDT determined the following basic information about the generating units of interest (current North America fleet, i.e. units reporting in 2013) included in the spreadsheet:

- The number of individual generating units in total included in the spreadsheet.
- The number of individual generating units rated at 20 MW or larger included in the spreadsheet. These units would generally require that their owners be registered as GOs in the NERC CMEP.
- The total number of units within selected size boundaries.
- The aggregate sum of ratings, in MWs, of the units within the boundaries of those thresholds.

The information in the spreadsheet does not provide information by which the plant information location of each unit can be determined, i.e. the DMSDT could not use the information to determine which units were located together at a given generation site or facility.

From this information, the DMSDT was able to reasonably speculate the generating unit size thresholds proposed in Requirement R5, sub-Part 5.1.1 of the standard. Generating resources intended for DDR data recording are those individual units with gross nameplate ratings "greater than or equal to 500 MVA". The 500 MVA individual unit size threshold was selected because this number roughly accounts for 47 percent of the generating capacity in NERC footprint while only requiring DDR coverage on about 12.5 percent of the generating units. As mentioned, there was no data pertaining to unit location for aggregating plant/facility sizes.

However, Requirement R5, sub-Part 5.1.1 is included to capture larger units located at large generating plants which could pose a stability risk to the System if multiple large units were lost due to electrical or non-electrical contingencies. For generating plants, each individual generator at the plant/facility with a gross nameplate rating greater than or equal to 300 MVA must have DDR where the gross nameplate rating of the plant/facility is greater than or equal to 1,000 MVA. The 300 MVA threshold was chosen based on the DMSDT's judgment and experience. The incremental impact to the number of units requiring monitoring is expected to be relatively low. For combined cycle plants where only one generator has a rating greater than or equal to 300MVA, that is the only generator that would need DDR.

Permanent System Operating Limits (SOLs) are used to operate the System within reliable and secure limits. In particular, SOLs related to angular or voltage stability have a significant impact on BES reliability and performance. Therefore, at least one BES Element of an SOL should be monitored.

The draft standard requires "One or more BES Elements that are part of an Interconnection Reliability Operating Limits (IROLs)." Interconnection Reliability Operating Limits (IROLs) are included because the risk of violating these limits poses a risk to System stability and the potential for cascading outages. IROLs may be defined by a single or multiple monitored BES Element(s) and contingent BES Element(s). The standard does not dictate selection of the contingent and/or monitored BES Elements. Rather, the drafting team believes this determination is best made by the Reliability Coordinator for each IROL considered based on the severity of violating this IROL.

Locations where an undervoltage load shedding (UVLS) program is deployed are prone to voltage instability since they are generally areas of significant Demand. The Reliability Coordinator will identify these areas where a UVLS is in service and identify a useful and effective BES Element to monitor for DDR, such that action of the UVLS or voltage instability on the BES could be captured. For example, a major 500kV or 230kV substation on the EHV System close to the load pocket where the UVLS is deployed would likely be a valuable electrical location for DDR coverage and would aid in post-Disturbance analysis of the load area's response to large System excursions (voltage, frequency, etc.).

Rationale for Requirement R6

DDR is used to measure transient response to System Disturbances during a relatively balanced post-fault condition. Therefore, it is sufficient to provide a phase-to-neutral voltage or positive sequence voltage. The electrical quantities can be determined (calculated, derived, etc.).

Because all of the BES buses within a location are at the same frequency, one frequency measurement is adequate.

The data requirements for PRC-002-5 are based on a System configuration assuming all normally closed circuit breakers on a BES bus are closed.

DDR data shows transient response to System Disturbances after a fault is cleared (post-fault), under a relatively balanced operating condition. Therefore, it is sufficient to provide a single phase-to-neutral

voltage or positive sequence voltage. Recording of all three phases of a circuit is not required, although this may be used to compute and record the positive sequence voltage.

The bus where a voltage measurement is required is based on the list of BES Elements defined by the Reliability Coordinator in Requirement R5. The intent of the standard is not to require a separate voltage measurement of each BES Element where a common bus voltage measurement is available. For example, a breaker-and-a-half or double-bus configuration with a North (or East) Bus and South (or West) Bus, would require both buses to have voltage recording because either can be taken out of service indefinitely with the targeted BES Element remaining in service. This may be accomplished either by recording both bus voltages separately, or by providing a selector switch to connect either of the bus voltage sources to a single recording input of the DDR device. This component of the requirement is therefore included to mitigate the potential of failed frequency, phase angle, real power, and reactive power calculations due to voltage measurements removed from service while sufficient voltage measurement is actually available during these operating conditions.

It must be emphasized that the data requirements for PRC-002-5 are based on a System configuration assuming all normally closed circuit breakers on a bus are closed.

When current recording is required, it should be on the same phase as the voltage recording taken at the location if a single phase-to-neutral voltage is provided. Positive sequence current recording is also acceptable.

For all circuits where current recording is required, Real and Reactive Power will be recorded on a three-phase basis. These recordings may be derived either from phase quantities or from positive sequence quantities.

Rationale for Requirement R7
A crucial part of wide-area Disturbance analysis is understanding the dynamic response of generating resources. Therefore, it is necessary for Generator Owners to have DDR at either the high- or low-side of the generator step-up transformer (GSU) measuring the specified electrical quantities to adequately capture generator response. This standard defines the 'what' of DDR, not the 'how'. Generator Owners may install this capability or, where the Transmission Owners already have suitable DDR data, contract with the Transmission Owner. However, the Generator Owner is still responsible for the provision of this data.

All Guidelines specified for Requirement R6 apply to Requirement R7. Since either the high- or low-side windings of the generator step-up transformer (GSU) may be connected in delta, phase-to-phase voltage recording is an acceptable voltage recording. As was explained in the Guideline for Requirement R6, the BES is operating under a relatively balanced operating condition and, if needed, phase-to-neutral quantities can be derived from phase-to-phase quantities.

Again, it must be emphasized that the data requirements for PRC-002-5 are based on a System configuration assuming all normally closed circuit breakers on a bus are closed.

Rationale for Requirement R8

Large scale System outages generally are an evolving sequence of events that occur over an extended period of time, making DDR data essential for event analysis. Data available pre- and post-contingency helps identify the causes and effects of each event leading to outages. Therefore, continuous recording and storage are necessary to ensure sufficient data is available for the entire event.

Existing DDR data recording across the BES may not record continuously. To accommodate its use for the purposes of this standard, triggered records are acceptable if the equipment was installed prior to the effective date of this standard. The frequency triggers are defined based on the dynamic response associated with each Interconnection. The undervoltage trigger is defined to capture possible delayed undervoltage conditions such as Fault Induced Delayed Voltage Recovery (FIDVR).

Wide-area System outages are generally an evolving sequence of events that occur over an extended period of time, making DDR data essential for event analysis. Pre- and post- contingency data helps identify the causes and effects of each event leading to the outages. This drives a need for continuous recording and storage to ensure sufficient data is available for the entire Disturbance.

Transmission Owners and Generator Owners are required to have continuous DDR for the BES Elements identified in Requirement R6. However, this requirement recognizes that legacy equipment may exist for some BES Elements that do not have continuous data recording capabilities. For equipment that was installed prior to the effective date of the standard, triggered DDR records of three minutes are acceptable using at least one of the trigger types specified in Requirement R8, Part 8.2:

- Off nominal frequency triggers are used to capture high- or low-frequency excursions of significant size based on the Interconnection size and inertia.
- Rate of change of frequency triggers are used to capture major changes in System frequency which could be caused by large changes in generation or load, or possibly changes in System impedance.
- The undervoltage trigger specified in this standard is provided to capture possible sustained undervoltage conditions such as Fault Induced Delayed Voltage Recovery (FIDVR) events. A sustained voltage of 85 percent is outside normal schedule operating voltages and is sufficiently low to capture abnormal voltage conditions on the BES.

Rationale for Requirement R9

An input sampling rate of at least 960 samples per second, which corresponds to 16 samples per cycle on the input side of the DDR equipment, ensures adequate accuracy for calculation of recorded measurements such as complex voltage and frequency.

An output recording rate of electrical quantities of at least 30 times per second refers to the recording and measurement calculation rate of the device. Recorded measurements of at least 30 times per second provide adequate recording speed to monitor the low frequency oscillations typically of interest during power System Disturbances.

DDR data contains the dynamic response of a power System to a Disturbance and is used for analyzing complex power System events. This recording is typically used to capture short-term and long-term Disturbances, such as a power swing. Since the data of interest is changing over time, DDR data is normally stored in the form of RMS values or phasor values, as opposed to directly sampled data as found in FR data.

The issue of the sampling rate used in a recording instrument is quite important for at least two reasons: the anti-aliasing filter selection and accuracy of signal representation. The anti-aliasing filter selection is associated with the requirement of a sampling rate at least twice the highest frequency of a sampled signal. At the same time, the accuracy of signal representation is also dependent on the selection of the sampling rate. In general, the higher the sampling rate, the better the representation. In the abnormal conditions of interest (e.g. faults or other Disturbances); the input signal may contain frequencies in the range of 0-400 Hz. Hence, the rate of 960 samples per second (16 samples/cycle) is considered an adequate sampling rate that satisfies the input signal requirements.

In general, dynamic events of interest are: inter-area oscillations, local generator oscillations, wind turbine generator torsional modes, HVDC control modes, exciter control modes, and steam turbine torsional modes. Their frequencies range from 0.1-20 Hz. In order to reconstruct these dynamic events, a minimum recording time of 30 times per second is required.

Rationale for Requirement R10
Time synchronization of Disturbance monitoring data is essential for time alignment of large volumes of geographically dispersed records from diverse recording sources. Coordinated Universal Time (UTC) is a recognized time standard that utilizes atomic clocks for generating precision time measurements. All data must be provided in UTC formatted time either with or without the local time offset, expressed as a negative number (the difference between UTC and the local time zone where the measurements are recorded).

Accuracy of time synchronization applies only to the clock used for synchronizing the monitoring equipment. The equipment used to measure the electrical quantities must be time synchronized to ± 2 ms accuracy; however, accuracy of the application of this time stamp and therefore, the accuracy of the data itself is not mandated. This is because of inherent delays associated with measuring the electrical quantities and events such as breaker closing, measurement transport delays, algorithm and measurement calculation techniques, etc.

Ensuring that the monitoring devices internal clocks are within ± 2 ms accuracy will suffice with respect to providing time synchronized data.

Time synchronization of Disturbance monitoring data allows for the time alignment of large volumes of geographically dispersed data records from diverse recording sources. A universally recognized time standard is necessary to provide the foundation for this alignment.
Coordinated Universal Time (UTC) is the foundation used for the time alignment of records. It is an

international time standard utilizing atomic clocks for generating precision time measurements at fractions of a second levels. The local time offset, expressed as a negative number, is the difference between UTC and the local time zone where the measurements are recorded.

Accuracy of time synchronization applies only to the clock used for synchronizing the monitoring equipment.

Time synchronization accuracy is specified in response to Recommendation 12b in the NERC August, 2003, Blackout Final NERC Report Section V Conclusions and Recommendations:

"Recommendation 12b: Facilities owners shall, in accordance with regional criteria, upgrade existing dynamic recorders to include GPS time synchronization…"

Also, from the U.S.-Canada Power System Outage Task Force Interim Report: Causes of the August 14th Blackout, November 2003, in the United States and Canada, page 103:

"Establishing a precise and accurate sequence of outage-related events was a critical building block for the other parts of the investigation. One of the key problems in developing this sequence was that although much of the data pertinent to an event was time-stamped, there was some variance from source to source in how the time-stamping was done, and not all of the time-stamps were synchronized…"

From NPCC's SP6 Report Synchronized Event Data Reporting, revised March 31, 2005, the investigation by the authoring working group revealed that existing GPS receivers can be expected to provide a time code output which has an uncertainty on the order of 1 millisecond, uncertainty being a quantitative descriptor.

Rationale for Requirement R11

Wide-area Disturbance analysis includes data recording from many devices and entities. Standardized formatting and naming conventions of these files significantly improves timely analysis.

Providing the data within 30 calendar days (or the granted extension time), subject to Part 11.2, allows for reasonable time to collect the data and perform any necessary computations or formatting.

Data is required to be retrievable for 10 calendar days inclusive of the day the data was recorded, i.e. a 10-calendar day rolling window of available data. Data hold requests are usually initiated the same or next day following a major event for which data is requested. A10-calendar day time frame provides a practical limit on the duration of data required to be stored and informs the requesting entities as to how long the data will be available. The requestor of data has to be aware of the Part 11.1 10-calendar day retrievability because requiring data retention for a longer period of time is expensive and unnecessary.

SER data shall be provided in a simple ASCII .CSV format as outlined in Attachment 2. Either equipment can provide the data or a simple conversion program can be used to convert files into this format. This will significantly improve the data format for event records, enabling the use of software tools for analyzing the SER data.

This requirement directs the applicable entities, upon requests from the Reliability Coordinator, Regional Entity or NERC, to provide SER and FR data for BES buses determined in Requirement R1 and DDR data for BES Elements determined as per Requirement R5. To facilitate the analysis of BES Disturbances, it is important that the data is provided to the requestor within a reasonable period of time.

Requirement R11, Part 11.2 specifies the maximum time frame of 30 calendar days to provide the data. Thirty calendar days is a reasonable time frame to allow for the collection of data, and submission to the requestor. An entity may request an extension of the 30-day submission requirement. If granted by the requestor, the entity must submit the data within the approved extended time.

Requirement R11, Part 11.1 specifies that the minimum time period of 10 calendar days inclusive of the day the data was recorded for which the data will be retrievable. With the equipment in use that has the capability of recording data, having the data retrievable for the 10 calendar days is realistic and doable. It is important to note that applicable entities should account for any expected delays in retrieving data and this may require devices to have data available for more than 10 days. To clarify the 10-calendar day time frame, an incident occurs on Day 1. If a request for data is made on Day 6, then that data has to be provided to the requestor within 30 calendar days after a request or a granted time extension. However, if a request for the data is made on Day 11, that is outside the 10 calendar days specified in the requirement, and an entity would not be out of compliance if it did not have the data.

Requirement R11, Part 11.3 specifies a Comma Separated Value (CSV) format according to Attachment 2 for the SER data. It is necessary to establish a standard format as it will be incorporated with other submitted data to provide a detailed sequence of events timeline of a power System Disturbance.

Requirement R11, Part 11.4 specifies the IEEE C37.111 COMTRADE format for the FR ~~and DDR~~ data. The IEEE C37.111 is the Standard for Common Format for Transient Data Exchange and is well established in the industry. It is necessary to specify a standard format as multiple submissions of data from many sources will be incorporated to provide a detailed analysis of a power System Disturbance. ~~The latest revision of COMTRADE (C37.111-2013) includes an annex describing the application of the COMTRADE standard to synchrophasor data.~~

Requirement R11, Part 11.5 specifies that the DDR data shall be either in CSV format with appropriate headers or in electronic files that are formatted in conformance with IEEE C37.111. The latest revision of COMTRADE (C37.111-2013) includes an annex describing the application of the COMTRADE standard to synchrophasor data.

Requirement R11, Part 11.6~~5~~ specifies the IEEE C37.232 COMNAME format for naming the data files of the SER, FR and DDR. The IEEE C37.232 is the Standard for Common Format for Naming Time Sequence Data Files. The first version was approved in 2007. From the August 14, 2003 blackout there were thousands of Fault Recording data files collected. The collected data files did not have a common naming convention and it was therefore difficult to discern which files came from which utilities and which ones were captured by which devices. The lack of a common naming practice seriously hindered the investigation process. Subsequently, and in its initial report on the blackout, NERC stressed the need for having a common naming practice and listed it as one of its top ten recommendations.

Rationale for Requirement R12

Each Transmission Owner and Generator Owner who owns equipment used for collecting the data required for this standard must repair any failures within 90 calendar days to ensure that adequate data is available for event analysis. If the Disturbance monitoring capability cannot be restored within 90 calendar days (e.g. budget cycle, service crews, vendors, needed outages, etc.), the entity must develop a Corrective Action Plan (CAP) for restoring the data recording capability. The timeline required for the CAP depends on the entity and the type of data required. It is treated as a failure if the recording capability is out of service for maintenance and/or testing for greater than 90 calendar days. An outage of the monitored BES Element does not constitute a failure of the Disturbance monitoring capability.

This requirement directs the respective owners of Transmission and Generator equipment to be alert to the proper functioning of equipment used for SER, FR, and DDR data capabilities for the BES buses and BES Elements, which were established in Requirements R1 and R5. The owners are to restore the capability within 90 calendar days of discovery of a failure. This requirement is structured to recognize that the existence of a “reasonable” amount of capability out-of-service does not result in lack of sufficient data for coverage of the System.

Furthermore, 90 calendar days is typically sufficient time for repair or maintenance to be performed. However, in recognition of the fact that there may be occasions for which it is not possible to restore the capability within 90 calendar days, the requirement further provides that, for such cases, the entity submit a Corrective Action Plan (CAP) to the Regional Entity and implement it. These actions are considered to be appropriate to provide for robust and adequate data availability.

Rationale for Requirement R13

Three (3) calendar years of completing a re-evaluation or receiving notification by the Transmission Owner or the Reliability Coordinator is more time than provided in the Implementation Plan of previous versions of this NERC Reliability Standard. The Implementation Plan of previous versions of this Standard provided three years. This time period pertains to those new Elements appearing on the list due to re-evaluation pursuant to Requirement R1, Part 1.3 or Requirement R5, Part 5.4. Having the period built into Requirement R13 maintains visibility of the required time to install monitoring equipment to collect necessary data.

Requirement R13 requires the Transmission Owner and Generator Owner to install monitoring equipment to record required data within three (3) calendar years of completing a re-evaluation or receiving notification that new Elements were identified during re-evaluation pursuant to Requirement R1, Part 1.3 or Requirement R5, Part 5.4 by the Transmission Owner or the Reliability Coordinator.

Technical Rationale for Reliability Standard PRC-028-1

2024

PRC-028-1 – Disturbance Monitoring and Reporting Requirements for Inverter Based Resources

The recent disturbance reports (e.g., Blue Cut Fire, Canyon 2 Fire, Odessa disturbances) have identified a need for disturbance monitoring for inverter-based resources[1] to aid with event analysis, performance monitoring, and disturbance-based inverter-based resource model validation. These disturbance reports recommended to install disturbance monitoring equipment (DME) at wind and solar photovoltaic (PV) resources to ensure adequate data is available for event analysis, performance monitoring, and validating inverter-based resource models. The recommendation included plant-level high resolution oscillography data, plant SCADA data with a resolution of one second, inverter level of sequence of events recording data that include all fault codes and high resolution oscillography data. However, in a first version of this standard, recording of inverter level data is not required.

The purpose of Reliability Standard PRC-002 is to capture event data to understand large scale system disturbances occurring on the Bulk Electric System (BES). Even with changing resource mix, the Reliability Standard PRC-002 serves the purpose. The recent disturbance analyses of events involving inverter-bases resources (e.g., Blue Cut Fire, Canyon 2 Fire, Odessa disturbances) have demonstrated that inverter-based resource's response to a normally cleared few cycle fault is undesirable and poses risk to system reliability. All these disturbance analyses have identified that inverter-based resources involved did not have sufficient monitoring data to understand the plants' responses. The initiating event, e.g., a normally cleared transmission fault, was not a large-scale system disturbance; however, inverter-based resource's undesirable response due to a system fault resulted in a larger system disturbance. Adequate monitoring data is required to understand inverter-based resource's performance. Most of the inverter-based resources involved in these disturbances did not have, and were not required to have adequate disturbance monitoring data. The lack of disturbance monitoring data available from these facilities led to difficulty in adequately assessing the events. Introducing inverter-based resource monitoring requirements to Reliability Standard PRC-002 may create unintended consequences to purpose of Reliability Standard PRC-002 and may lead to industry confusion. Hence, to address needs identified in the Standard Authorization Request (SAR) submitted by the Inverter-Based Resource Performance Task Force (IRPTF), a new standard

[1] For the purpose of this standard, "inverter-based resources" refers to a collection of individual solar photovoltaic (PV), Type 3 and Type 4 wind turbines, battery energy storage system (BESS), or fuel cells that operate as a single plant/resource. In case of offshore wind plants connecting via a dedicated voltage source converter high voltage direct current (VSC HVDC) line, the inverter-based resource includes VSC HVDC line.

for monitoring requirements for inverter-based resources is created instead of revising the Reliability Standard PRC-002.

The Transmission Owners and Generator Owners, as applicable, will have the responsibility for ensuring that adequate data is available for applicable Elements at the applicable inverter-based resources. This standard requires that sequence of events recording (SER), fault recording (FR), and dynamic disturbance recording (DDR) data is available from the applicable inverter-based resources.

Rationale for Applicability Section

Functional Entities

The two functional entities that are responsible for implementing disturbance monitoring equipment and collecting recording data are: Generator Owner and Transmission Owner. The standard is only applicable to Transmission Owner in case where Transmission Owner owns equipment (e.g., circuit breaker(s), main step-up transformer, collector bus, dynamic reactive device, etc.) within the inverter-based resource.

Applicable Facilities

The BES inverter-based resources are in the scope of this standard. The inverter-based resources that connect via a dedicated voltage source converter high voltage direct current (VSC HVDC) are also in the scope of this standard.

The following Elements associated with inverter-based resources noted above are in the scope of this standard:

- Circuit breaker(s)
- Main power transformer(s)
- Collector bus
- Shunt static or dynamic reactive device(s), including any filter banks
- AC-DC and DC-AC converters, if any, in case of VSC HVDC line with a dedicated connection to inverter-based resources

The following examples are provided to clarify applicability of the PRC-028 standard.

Example 1: Applicability of PRC-028

Figure 1 shows a typical single line diagram of an inverter-based resource. The inverter-based resource is connected to the transmission system via a short tie-line. This inverter-based resource is equipped with a dynamic reactive device (e.g., synchronous condenser, static VAR compensator etc.) connected to the collector bus.

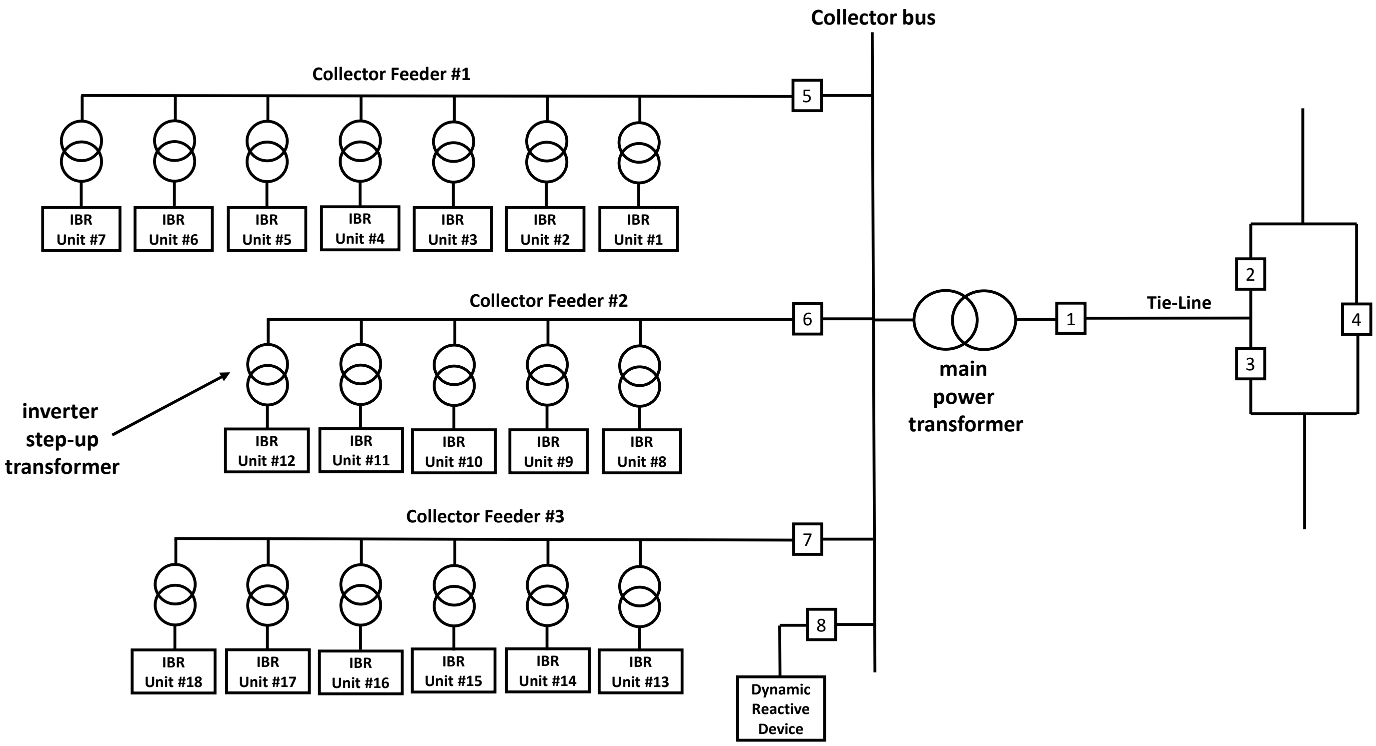

Figure 1: Typical inverter-based resource Single Line Diagram

SER Data: The SER data is required for circuits breaker 1, 5, 6, 7, and 8. Circuit breaker 1 is associated with the main power transformer. Circuit breakers 5, 6, 7, and 8 are associated with the collector bus.

FR Data: The FR data is required from high side terminals of the main power transformer. In this example, the inverter-based resource consists of only one main power transformer. If the inverter-based resource consists of more than one main power transformer, then FR data for each main power transformer is required. As the inverter-based resource is equipped with the dynamic reactive device, the FR data for it also required.

DDR Data: The DDR data is required from high side terminals of the main power transformer. If the inverter-based resource consists of more than one main power transformer, then DDR data for each main power transformer is required.

<u>Example 2: Applicability of PRC-028 (Facility with two collector buses and main power transformers)</u>
Figure 2 shows a single line diagram of an inverter-based resource with two collector buses and main power transformers. The inverter-based resource is connected to the transmission system via a short tie-line. The collector feeders #1 and #2 are connected to collector bus #1. The collector feeders #3 and #4 are connected to collector bus #2.

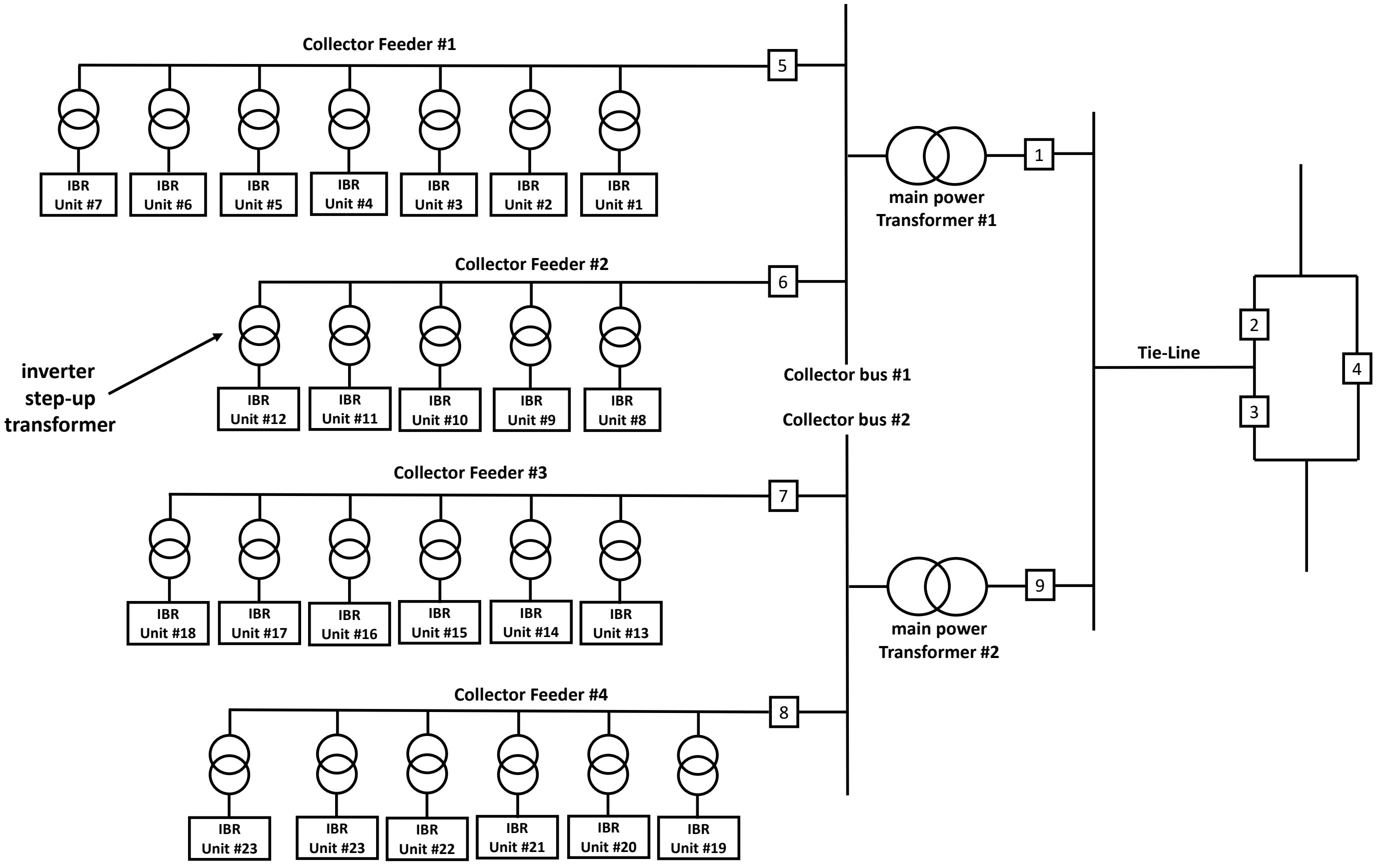

Figure 2: Typical inverter-based resource with two collector buses and main power transformers

SER Data: The SER data is required for circuits breaker 1, 5, 6, 7, 8, and 9. Circuit breakers 1 and 9 are associated with main power transformers. Circuit breakers 5, 6, 7, and 8 are associated with collector buses #1 and #2.

FR Data: The FR data is required from high side terminals of both main power transformers.

DDR Data: The DDR data is required from high side terminals of both main power transformers.

Example 3: Applicability of PRC-028 (VSC HVDC system with a dedicated connection to inverter-based resources)

Figure 3 shows an example of dedicated VSC HVDC system connecting the inverter-based resource. Transformers on both sides of the HVDC system are considered main power transformer.

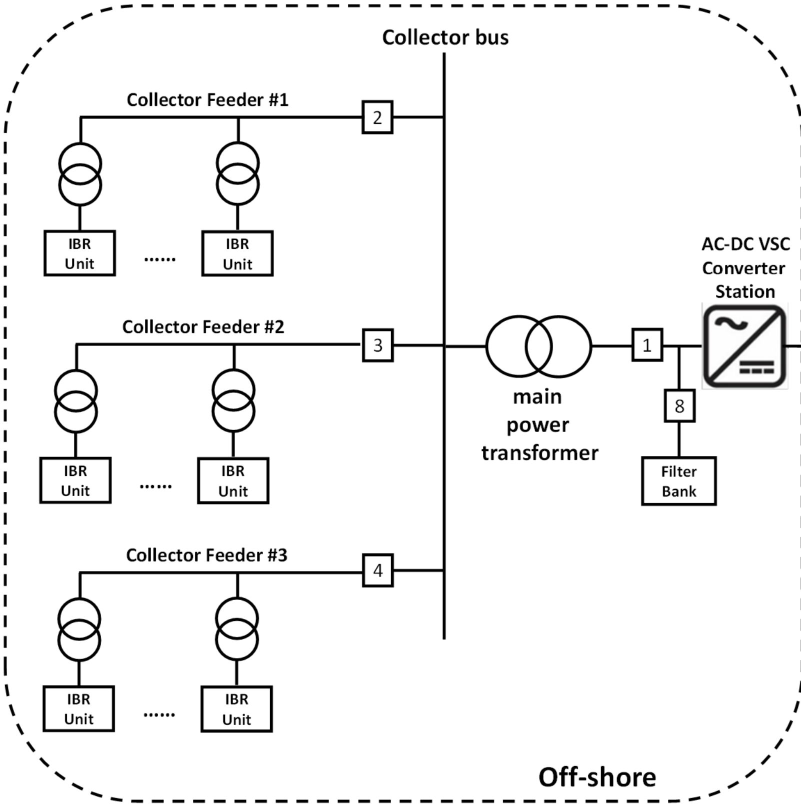

Figure 3: Typical inverter-based resource connected via dedicated VSC HVDC

SER Data: The SER data is required for circuits breaker 1, 2, 3, 4, 5, 6, 7 and 8. Circuit breakers 1 and 7 are associated with main power transformers. Circuit breakers 2, 3, and 4 are associated with the collector bus. Circuit breakers 6 and 8 are associated with filter banks and circuit breaker 5 is associated with shunt dynamic reactive device.

FR Data: The FR data is required from high side terminals of both main power transformers.

DDR Data: The DDR data is required from high side terminals of both main power transformers.

Example 4: Applicability of PRC-002 versus PRC-028

Figure 4 shows an example of inverter-based resource interconnection to the transmission system via Line 34. The BES bus in substation Wu is the identified BES bus per methodology in Attachment 1 of the Reliability Standard PRC-002. The SER and FR data requirements for the identified BES bus are per the requirements in the Reliability Standard PRC-002. The Reliability Standard PRC-028 is applicable to the inverter-based resource.

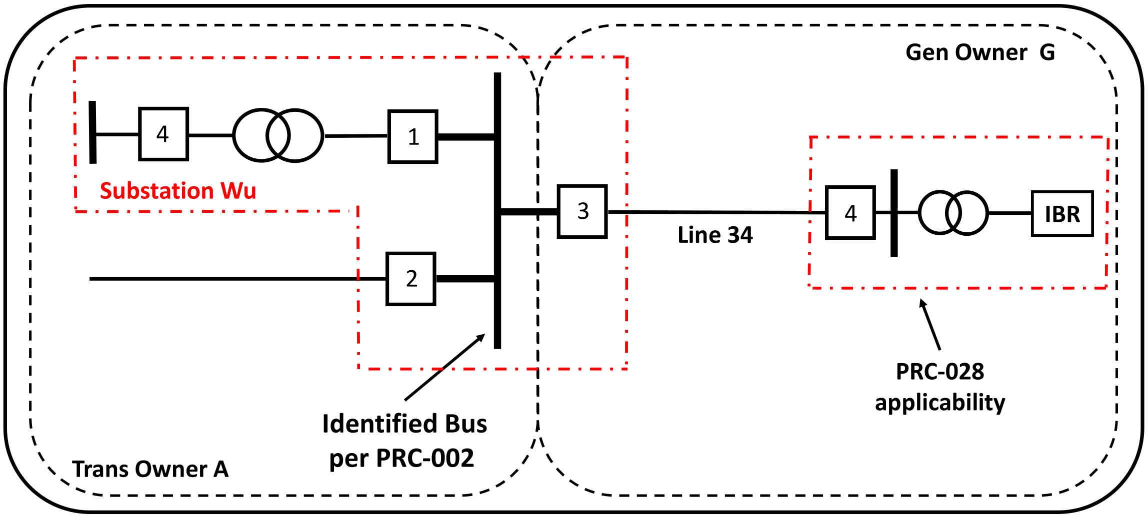

Figure 4: Inverter-based resource Interconnection – Applicability of PRC-002 versus PRC-028

Example 5: Transmission Owner owned Equipment within the inverter-based resource

Figure 5 shows an example of an inverter-based resource interconnection where Transmission Owner A owns circuit breaker 3 associated with an inverter-based resource. In this case, Transmission Owner A is responsible for SER data for circuit breaker 3. It is not common for Transmission Owner to own the main power transformer and/or portions of collector system associated with an inverter-based resource. However, in cases where this is true, Transmission Owner is responsible for SER, FR, and DDR data, as applicable, required by the Reliability Standard PRC-028.

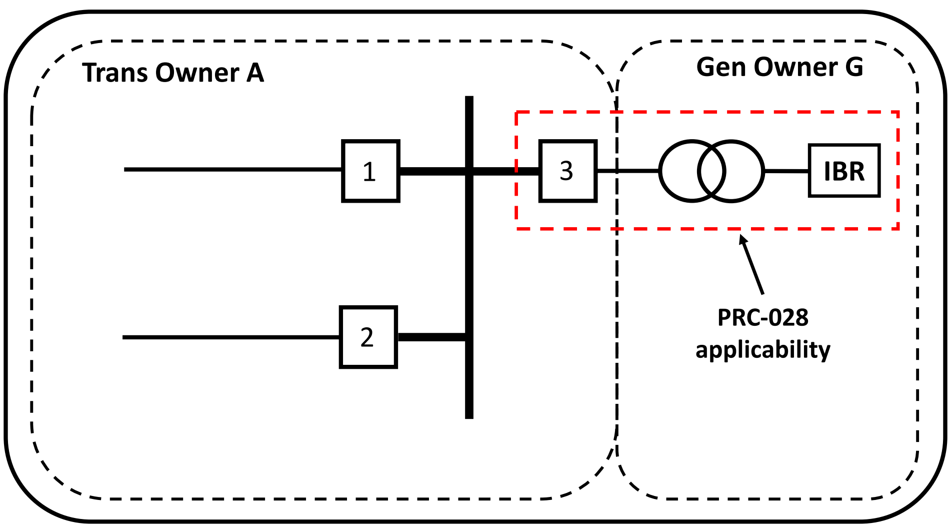

Figure 5: Transmission Owner owned Equipment within an inverter-based resource

Rationale for Requirement R1

The standard requires to capture SER data from circuit breakers within the inverter-based resource associated with:

- Main power transformer(s)

- Collector bus(es), including collector feeder breakers
- Shunt static or dynamic reactive device(s), including any filter banks
- AC-DC and DC-AC converters, if any, in case of VSC HVDC system with a dedicated connection to inverter-based resources.

Change of state of circuit breaker position, time stamped according to Requirement R7 to a time synchronized clock, provides the basis for assembling the detailed sequence of events timeline of inverter-based resource's response during a power System disturbance. Analyses of system disturbances often begin by evaluation of SERs to help determine the initiating event(s) and follow the disturbance propagation. Recording of breaker operations helps determine the interruption of flows during the disturbances.

Rationale for Requirement R2
The intent is to capture sufficient FR data for Elements at each inverter-based resource to analyze the overall response of the inverter-based resource to a system disturbance. Analyses of disturbances involving widespread reduction of power output from inverter-based resources in recent years has shown that expansion of monitoring at inverter-based resource sites is necessary. The required electrical quantities may either be directly measured or determinable if sufficient FR data is captured (e.g., residual or neutral current if the phase currents are directly measured).

The plant level FR measurements, i.e., measured on high-side terminals of the main power transformer, specified in Requirement R2, Part 2.1 provide data at the inverter-based resource interconnection to the bulk power system. To cover all possible fault types, phase-to-neutral voltage recording for each phase is required to be determinable. Each phase current and residual current are required to distinguish between phase faults and ground faults. This data also facilitates determination of the fault location and cause of relay operation. The measurements of active and reactive power provide data on the overall generating facility's response to the system disturbance.

In some cases, the dynamic reactive device is used within the inverter-based resource and often connected to medium voltage collector bus. Regardless of where dynamic reactive device is connected, the output of it during system disturbances is important to understand overall performance of the plant during a disturbance. The measured or determined electrical quantities for dynamic reactive device are the same as those specified to be measured/determined from high-side of main power transformer.

Recording of Electrical Quantities
For effective fault analysis, it is necessary to know values of all phase and neutral currents and all phase-to-neutral voltages. Based on such FR data, it is possible to determine all fault types. FR data also augments SERs in evaluating circuit breaker operation. FR also shows generator output response to a system disturbance.

Current Recordings
The required electrical quantities are normally directly measured. Certain quantities can be derived if sufficient data is measured, for example residual or neutral currents. Since a Transmission System is generally well balanced, with phase currents having essentially similar magnitudes and phase angle

differences of 120 degrees, during normal conditions there is negligible neutral (residual) current. In case of a ground fault, the resulting phase current imbalance produces residual current that can be either measured or calculated.

Neutral current, also known as ground or residual current Ir, is calculated as a sum of vectors of three phase currents:

$\mathbf{I}_r = 3 \bullet \mathbf{I}_0 = \mathbf{I}_A + \mathbf{I}_B + \mathbf{I}_C$

$\mathbf{I}_0$ - Zero-sequence current

$\mathbf{I}_A$, $\mathbf{I}_B$, $\mathbf{I}_C$ - Phase current (vectors)

Voltage Recordings

Voltages are to be recorded or accurately determined at applicable Elements as outlined in Requirement R2.

Rationale for Requirement R3

Time stamped pre- and post-trigger FR data aid in the analysis of power system operations and determination if operations were as intended.

The “Odessa Disturbance” report from September 2021 recommended high resolution oscillography data at the point of interconnection. The minimum recording rate of 64 samples per cycle is specified recognizing state-of-the-art for DME including storage any storage capability limitations and provides sufficient data to recreate accurate response of the inverter-based resource to system disturbances.

Pre- and post-trigger fault data along with the SER data, all time stamped to a common clock, aid in the analysis of Protection System operations after a fault to determine if a Protection System operated as designed. Additionally, inverter-based resources employ fast acting control systems (with built in protection functions) dictating inverter-based resource’s response to system disturbance. Generally speaking, BES faults persist for a very short time period, approximately 1 to 30 cycles. To capture the full response of inverter-based resource spread over a large geographic area, a 2 second total minimum record length synchronized to a common clock is necessary for FR data. Multiple records allow for legacy microprocessor relays which, when time synchronized to a common clock, can provide adequate fault data, but are not capable of providing fault data in a single record with 120 continuous cycles total.

FR triggers can be set so that when the monitored value on the recording device goes above or below the trigger value, data is recorded. Requirement R3, Part 3.1.3.1 specifies a neutral (residual) overcurrent trigger for ground faults. Requirement R3, sub-Part 3.1.3.2 specifies a phase overvoltage or undervoltage trigger during voltage ride-through events.

The triggers specified in Requirement R3, Part 3.3 for dynamic reactive device FR data are similar to ones specified in Requirement R3, Part 3.1 for plant level FR data measured or determined on high-side of the main power transformer.

Rationale for Requirement R4

Large scale system disturbances generally are an evolving sequence of events that occur over an extended period of time, making DDR data essential for event analysis. Data available pre- and post-contingency helps identify the causes and inverter-based resource's response to large scale system disturbances. Therefore, continuous recording and storage are necessary to ensure sufficient data is available for the entire event. The state-of-the-art DDR equipment is capable of continuous recording.

DDR data contains the dynamic response of the inverter-based resource to a system disturbance and is used for analyzing complex power system events. This recording is typically used to capture short-term and long-term disturbances. Since the data of interest is changing over time, DDR data is normally stored in the form of RMS values or phasor values, as opposed to directly sampled data as found in FR data.

DDR is used to measure transient response to system disturbances during a relatively balanced post-fault condition. Therefore, it is sufficient to provide a single phase-to-neutral voltage or positive sequence voltage and current from the same phase or positive sequence for each applicable main power transformer for analysis. It is also sufficient to provide a single frequency for any of the provided voltages since all main power transformers within an inverter-based resource are at the same frequency. Recording of all three phases of voltage/current is not required, although this may be used to compute and record the positive sequence value(s). The electrical quantities for Real Power and Reactive Power on a three-phase basis can be measured/recorded or determined (calculated, derived, etc.).

The data requirements for PRC-028-1 are based on a system configuration assuming all normally closed circuit breakers on a BES bus are closed.

A crucial part of disturbance analysis is understanding the dynamic response of generating resources. Therefore, it is necessary to have DDR on high-side of the main power transformer(s) measuring the specified electrical quantities to adequately capture inverter-based resource's response.

The Requirement R4, Part 4.1 requires either one phase-to-neutral or positive sequence voltage. However, the phase-to-phase voltage recording is acceptable. Since the BES operates under a relatively balanced operating condition and, if needed, phase-to-neutral quantities can be derived from phase-to-phase quantities.

Rationale for Requirement R5

An input sampling rate of at least 960 samples per second, which corresponds to 16 samples per cycle on the input side of the DDR equipment, ensures adequate accuracy for calculation of recorded measurements such as complex voltages and frequency. The input sampling rate specified is the same as the one specified in the Reliability Standard PRC-002.

An output recording rate of electrical quantities of at least 60 times per second refers to the recording rate of the device. Recorded measurements of at least 60 times per second provide adequate recording speed to monitor the inverter-based resource's response during power system disturbances. Since control system associated with inverter-based resources is fast acting, higher frequency recording is necessary to accurately reconstruct events. An output recording rate of 60 times per second provides this higher frequency recording while not greatly increasing data storage requirements.

Rationale for Requirement R6

Time synchronization of disturbance monitoring data is essential for time alignment of large volumes of geographically dispersed records from diverse recording sources. Coordinated Universal Time (UTC) is a recognized time standard that utilizes atomic clocks for generating precision time measurements. All data must be provided in UTC formatted time either with or without the local time offset, expressed as a negative number (the difference between UTC and the local time zone where the measurements are recorded).

Accuracy of time synchronization applies only to the clock used for synchronizing the monitoring equipment. The equipment used to measure the electrical quantities must be time synchronized to ± 1 millisecond accuracy; however, accuracy of the application of this time stamp and therefore, the accuracy of the data itself is not mandated. This is because of inherent delays associated with measuring the electrical quantities and events such as breaker closing, measurement transport delays, algorithm and measurement calculation techniques, etc.

Ensuring that the monitoring devices internal clocks are within ± 1 millisecond accuracy will suffice with respect to providing time synchronized data. Accuracy of time synchronization applies only to the clock used for synchronizing the monitoring equipment. Note that the recently published IEEE Std 2800 requires the DME recording plant level data be synchronized to the clock with accuracy of ± 1 microsecond accuracy; however, the accuracy requirement is set to ± 1 millisecond to strike a balance between need of accuracy and practical limitations of equipment necessary to achieve the stated accuracy.

The inverter-based resources, which are not affected by inertial time constants, make changes in power production very rapidly. To understand and analyze control decisions during system disturbances and the reasons behind them over dozens of plants requires a high level of accurate time synchronization. Following provide some examples of inverter-based resource's fast response:

- Typical 90% response to a three-phase fault is <40 ms.
- Central power plant controllers issue updated commands in as little as 40 ms upon detection of change in system conditions.
- Standard closed loop voltage control response can be <200 ms.
- Instantaneous Inverter protective trip decisions such as AC or DC overvoltage or reverse DC current can be made in less than 10 ms.

Rationale for Requirement R7

Requirement R7, Part 7.1 specifies a minimum time period of 20 calendar days inclusive of the day the data was recorded for which the data is to be retrievable. Data hold requests are usually initiated the same or next day following a major event, however, it takes a longer time to determine which data from which generating facility needs to be retrieved for event analysis. A 20 calendar day time period provides enough time for communication between various Entities regarding the event and need for data retrieval from DME at various generating facilities. The requestor of data has to be aware of 20 calendar day retrievability limit to ensure timely data hold requests. Requiring data retention for a longer period of time is expensive and unnecessary.

With the state-of-the-art equipment, having the data retrievable for the 20 calendar days is realistic and doable. It is important to note that applicable entities should account for any expected delays in retrieving data and this may require devices to have data available for more than 20 days. To clarify the 20 calendar day time frame, let's assume that event occurs on Day 1. If a request for data is made on Day 6, then that data has to be provided to the requestor within 20 calendar days after a request or a granted time extension. However, if a request for the data is made on Day 21, that is outside the 20 calendar days specified in the requirement, and an entity would not be out of compliance if it did not have the data.

This requirement directs the applicable entities, upon requests from the Reliability Coordinator, Regional Entity or NERC, to provide SER, FR and DDR data for generating facilities as per the applicability. To facilitate the analysis of system disturbances, it is important that the data is provided to the requestor within a reasonable time. Providing the data within 15 calendar days (or the granted extension time), subject to Requirement R7, Part 7.2, allows for reasonable time to collect the data and perform any necessary computations or formatting. An entity may request an extension of the 15 calendar days submission requirement. If granted by the requestor, the entity must submit the data within the approved extended time.

Disturbance analysis includes reviewing data recording from many devices and entities. Standardized formatting and naming conventions of these files significantly improve timely analysis. The formatting and naming convention requirements for SER, FR, and DDR are consistent with same requirements in the Reliability Standard PRC-002.

SER data: Requirement R7, Part 7.3 specifies a simple ASCII Comma Separated Value (CSV) format according to Attachment 1. It is necessary to establish a standard format as it allows data submitted by one entity or facility to be incorporated with same data provided by other entities or facilities to develop a detailed sequence of events timeline of a power system disturbance.

FR data: Requirement R7, Part 7.4 specifies the IEEE C37.111 Standard for Common Format for Transient Data Exchange (COMTRADE) format for the FR data. The IEEE C37.111 is well established in the industry. Exchanging data in a standard format helps in analysis of a power system disturbance, especially considering multiple data submission from many sources.

DDR data: Requirement R7, Part 7.5 specifies either CSV format with appropriate headers or the IEEE C37.111 Standard for Common Format for Transient Data Exchange (COMTRADE) format for the DDR data. The IEEE C37.111 is well established in the industry. Exchanging data in a standard format helps in analysis of a power system disturbance, especially considering multiple data submission from many sources. The 2013 revision of the IEEE C37.111 includes an annex describing the application of the COMTRADE standard to synchrophasor data.

Requirement R7, Part 7.6 specifies the IEEE C37.232 Standard for Common Format for Naming Time Sequence Data Files (COMNAME) format for naming the SER, FR and DDR data files. The lack of a common naming practice seriously hinders the event analysis and investigation process.

Rationale for Requirement R8

The standard requires that Entity restore the recording capability for SER, FR, or DDR data within 90 calendar days of the discovery of a failure. The 90 calendar day time period permitted in this requirement strikes a balance between reasonable time needed to restore capability while ensuring that recording capability is not out of service for an extended duration. If the recording capability cannot be restored within 90 calendar days due to limitations such as budget cycle, service crews, vendors, needed outages, etc., the entity is required to submit a Corrective Action Plan for restoring the recording capability to the Regional Entity and implement it. It is treated as a failure if the recording capability is out of service for maintenance and/or testing for greater than 90 calendar days. An outage of the monitored Element does not constitute a failure of the disturbance monitoring capability.

NERC
NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Technical Rationale for Reliability Standard PRC-028-1

2024~~3~~

PRC-028-1 – Disturbance Monitoring and Reporting Requirements for Inverter Based Resources

The recent disturbance reports (e.g., Blue Cut Fire, Canyon 2 Fire, Odessa disturbances) have identified a need for disturbance monitoring for ~~I~~inverter-~~B~~based ~~R~~resources[1] ~~(IBRs)~~ to aid with event analysis, performance monitoring, and disturbance-based ~~IBR~~inverter-based resource ~~generating facility~~ model validation. These disturbance reports recommended to install disturbance monitoring equipment (DME) at wind and solar photovoltaic (PV) resources to ensure adequate data is available for event analysis, performance monitoring, and validating ~~IBR~~inverter-based resource ~~generating facility~~ models. The recommendation included plant-level high resolution oscillography data, plant SCADA data with a resolution of one second, ~~sequence of events recording for all IBR Units[2]~~ inverter level of sequence of events recording data that include all fault codes~~,~~ and ~~at least one IBR Unit on each collector feeder configured to capture~~ high resolution oscillography data~~ within the IBR Unit~~. However, in a first version of this standard, recording of ~~IBR unit~~inverter level data is not required.

The purpose of Reliability Standard PRC-002 is to capture event data to understand large scale system disturbances occurring on the Bulk Electric System (BES). Even with changing resource mix, the Reliability Standard PRC-002 serves the purpose. The recent disturbance analyses of events involving ~~IBRs~~ inverter-bases resources (e.g., Blue Cut Fire, Canyon 2 Fire, Odessa disturbances) have demonstrated that ~~IBR's~~inverter-based resource's response to a normally cleared few cycle fault is undesirable and poses risk to system reliability. All these disturbance analyses have identified that inverter-based resources~~IBRs~~ involved did not have sufficient monitoring data to understand the plants' responses. The initiating event, e.g., a normally cleared transmission fault, was not a large-scale system disturbance; however, ~~IBR plant's~~inverter-based resource's undesirable response due to a system fault resulted in a larger system disturbance. Adequate monitoring data is required to understand ~~IBR plant's~~ inverter-based resource's performance. Most of the ~~IBRs~~inverter-based resources involved in these disturbances did not have and

[1] For the purpose of this standard, "inverter-based resources" refers to a collection of individual solar photovoltaic (PV), Type 3 and Type 4 wind turbines, battery energy storage system (BESS), or fuel cells that operate as a single plant/resource. In case of offshore wind plants connecting via a dedicated voltage source converter high voltage direct current (VSC HVDC) line, the inverter-based resource includes VSC HVDC line.~~Inverter-Based Resource as of 02/22/2024: A plant/facility that is connected to the electric system, consisting of one or more IBR Unit(s) operated as a single resource at a common point of interconnection. IBRs include, but are not limited to, solar photovoltaic (PV), Type 3 and Type 4 wind, battery energy storage system (BESS), and fuel cell.~~ ~~**(This footnote will be removed when IBR definition is finalized)**~~

~~[2] IBR Unit as of 02/23/2024: An individual device that uses a power electronic interface, such as an inverter or converter, capable of exporting Real Power from a primary energy source or energy storage system, and that connects at a single point on the collector system; or a grouping of multiple devices that uses a power electronic interface(s), such as an inverter or converter, capable of exporting Real Power from a primary energy source or energy storage system, and that connect together at a single point on the collector system.~~ ~~**(This footnote will be removed when IBR Unit definition is finalized)**~~

were not required to have adequate disturbance monitoring data. The lack of disturbance monitoring data available from these facilities led to difficulty in adequately assessing the events. Introducing ~~IBR~~inverter-based resource monitoring requirements to Reliability Standard PRC-002 may create unintended consequences to purpose of Reliability Standard PRC-002 and may lead to industry confusion. Hence, to address needs identified in the Standard Authorization Request (SAR) submitted by the Inverter-Based Resource Performance Task Force (IRPTF), a new standard for monitoring requirements for ~~IBRs~~inverter-based resources is created instead of revising the Reliability Standard PRC-002.

The Transmission Owners and Generator Owners, as applicable, will have the responsibility for ensuring that adequate data is available for applicable Elements at the applicable inverter-based resources~~IBRs generating facilities~~. This standard requires that sequence of events recording (SER), fault recording (FR), and dynamic disturbance recording (DDR) data is available from the applicable inverter-based resources~~IBRs generating facilities~~.

Rationale for Applicability Section

Functional Entities

The two functional entities that are responsible for implementing disturbance monitoring equipment and collecting recording data are: Generator Owner and Transmission Owner. The standard is only applicable to Transmission Owner in case where Transmission Owner owns equipment (e.g., circuit breaker(s), main step-up transformer, collector bus, dynamic reactive device, etc.) within the ~~IBR Plant~~inverter-based resource.

Applicable Facilities

The BES ~~I~~inverter-~~B~~based ~~R~~resources ~~and Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV~~ are in the scope of this standard.

~~Order No. 901 directed NERC to develop Reliability Standards "to require registered IBR generator owners to install disturbance monitoring equipment at their buses and elements, to require registered IBR generator owners to provide disturbance monitoring data to Bulk-Power System planners and operators for analyzing disturbances on the Bulk-Power System, and to require Bulk-Power System planners and operators to validate registered IBR models using disturbance monitoring data from installed registered IBR generator owners' disturbance monitoring equipment." Order No. 901 at P 85. FERC continued, "We further agree with the findings in NERC reports (e.g., a lack of high-speed data captured at the IBR or plant-level controller and low-resolution time stamping of inverter sequence of event recorder information has hindered event analysis) and direct NERC through its standard development process to address these findings."~~

~~In distinguishing among the different types of IBRs and their registration status that must be covered by the standards, FERC stated: "Where necessary to describe our directives, however, we differentiate between IBRs registered with NERC (or which will be registered pursuant to the Commission's directives in *Registration of Inverter-based Resources*, 181 FERC ¶ 61,124 (2022) (IBR Registration Order)) and therefore~~

~~subject to the Reliability Standards (i.e., registered IBR), IBRs connected directly to the Bulk-Power System but not registered with NERC and therefore not subject to the Reliability Standards (i.e., unregistered IBRs), and IBRs connected to the distribution system that in the aggregate have a material impact on the Bulk-Power System (i.e., IBR-DER)." Order No. 901 at n. 14.~~

~~In proposed PRC-028-1, the standard drafting team includes both categories of generation that would be registered under proposed changes to NERC Rules of Procedure consistent with Order No. 901. In February 2024, the NERC Board of Trustees approved revisions to the Rules of Procedure to expand the Generator Owners and Generator Operators registered with NERC for compliance purposes. In addition to owners and operators of generating Facilities, NERC will register owners and operators of sub-BES IBRs meeting the following criteria: non-BES inverter based generating resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV. More information on these changes, which are pending FERC approval, are available at: https://www.nerc.com/gov/bot/Agenda%20highlights%20and%20Mintues%202013/Board%20Open%20 Agenda%20Package%20-%20February%2022%202024_ATTENDEE.pdf [nerc.com]~~

~~The standard drafting team understands that NERC will initiate a separate *Glossary* revision effort to revise the definition of Generator Owner and Generator Operator consistent with the proposed Rules of Procedure definitions for registration. This effort will complete well in advance of the team's proposed [X] year implementation plan for Reliability Standard PRC-028-1.~~

The following Elements associated with ~~I~~inverter-~~B~~based ~~R~~resources noted above are in the scope of this standard:

- Circuit breaker(s)
- Main power transformer(s)
- Collector bus
- Shunt static or dynamic reactive device(s), including any filter banks
- AC-DC and DC-AC converters, if any, in case of VSC HVDC line with a dedicated connection to inverter-based resources
  - ~~At least one IBR Unit on any of the collector feeders that is connected at a distance ≥ 90% of the longest collector feeder from the collector bus~~

The following examples are provided to clarify applicability of the PRC-028 standard.

Example 1: Applicability of PRC-028

Figure 1 shows a typical single line diagram of an inverter-based resource~~IBR generating facility~~. The ~~IBR~~inverter-based resource ~~generating facility~~ is connected to the transmission system via a short tie-line. ~~The length of collector feeder #1, #2, and #3 is 3000 ft, 2500 ft, and 2800 ft respectively. IBR Units #6 and~~

~~#7 are connected to collector feeder #1 at 2800 ft and 3000 ft distance from the collector bus respectively. IBR Unit #18 is connected to collector feeder #3 at 2800 ft distance from the collector bus. In other words, these IBR Units #6, #7 and #18 are connected at a distance ≥ 90% of the longest collector feeder from the collector bus.~~ This ~~IBR~~inverter-based resource ~~generating facility~~ is equipped with a dynamic reactive device (e.g., synchronous condenser, static VAR compensator etc.) connected to the collector bus.

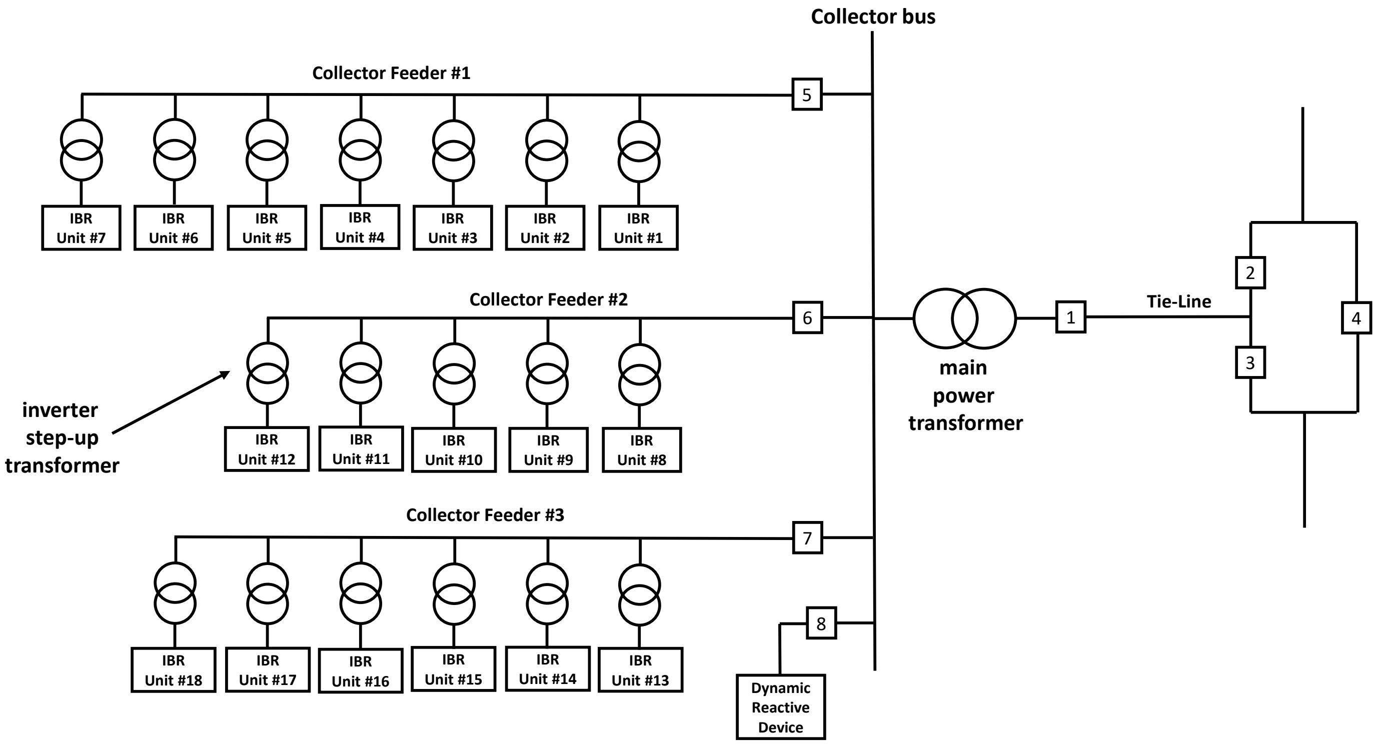

Figure 1: Typical ~~IBR~~inverter-based resource ~~Generating Facility~~ Single Line Diagram

SER Data: The SER data is required for circuits breaker 1, 5, 6, 7, and 8. Circuit breaker 1 is associated with the main power transformer. Circuit breakers 5, 6, 7, and 8 are associated with the collector bus. ~~The SER data for IBR Unit #6, #7, or #18 is required as these are connected at a distance ≥ 90% of the longest collector feeder from the collector bus.~~

FR Data: The FR data is required from high side terminals of the main power transformer. In this example, the ~~IBR plant~~inverter-based resource consists of only one main power transformer. If the inverter-based resource~~IBR plant~~ consists of more than one main power transformer, then FR data for each main power transformer is required. ~~The FR data for IBR Unit #6, #7, or #18 is required as these are connected at a distance ≥ 90% of the longest collector feeder from the collector bus.~~ As the inverter-based resource~~IBR plant~~ is equipped with the dynamic reactive device, the FR data for it also required.

DDR Data: The DDR data is required from high side terminals of the main power transformer. If the inverter-based resource~~IBR plant~~ consists of more than one main power transformer, then DDR data for each main power transformer is required. ~~The DDR data from individual IBR Units is not required.~~

Example 2: Applicability of PRC-028 (Facility with two collector buses and main power transformers)

Figure 2 shows a single line diagram of an inverter-based resource~~IBR generating facility~~ with two collector buses and main power transformers. The inverter-based resource~~IBR generating facility~~ is connected to the transmission system via a short tie-line. The collector feeders #1 and #2 are connected to collector bus #1. The collector feeders #3 and #4 are connected to collector bus #2. ~~The length of collector feeder #1, #2, #3, and #4 is 3000 ft, 2500 ft, 2800 ft, and 2600 ft respectively. The collector feeder #1 is the longer of two collector feeders connected to collector bus #1. IBR Units #6 and #7 are connected to collector feeder #1 at 2800 ft and 3000 ft distance from the collector bus #1 respectively. IBR Unit #12 is connected to collector feeder #2 at 2500 ft from the collector bus #1. The IBR Units #6 and #7 are connected at a distance ≥ 90% of the longest collector feeder from the collector bus #1. The collector feeder #3 is the longer of two collector feeders connected to collector bus #2. IBR Units #17 and #18 are connected to collector feeder #3 at 2600 ft and 2800 ft distance from the collector bus #2 respectively. IBR Unit #23 is connected to collector feeder #4 at 2600 ft from the collector bus #2. The IBR Units #17, #18, and #23 are connected at a distance ≥ 90% of the longest collector feeder from the collector bus #2.~~

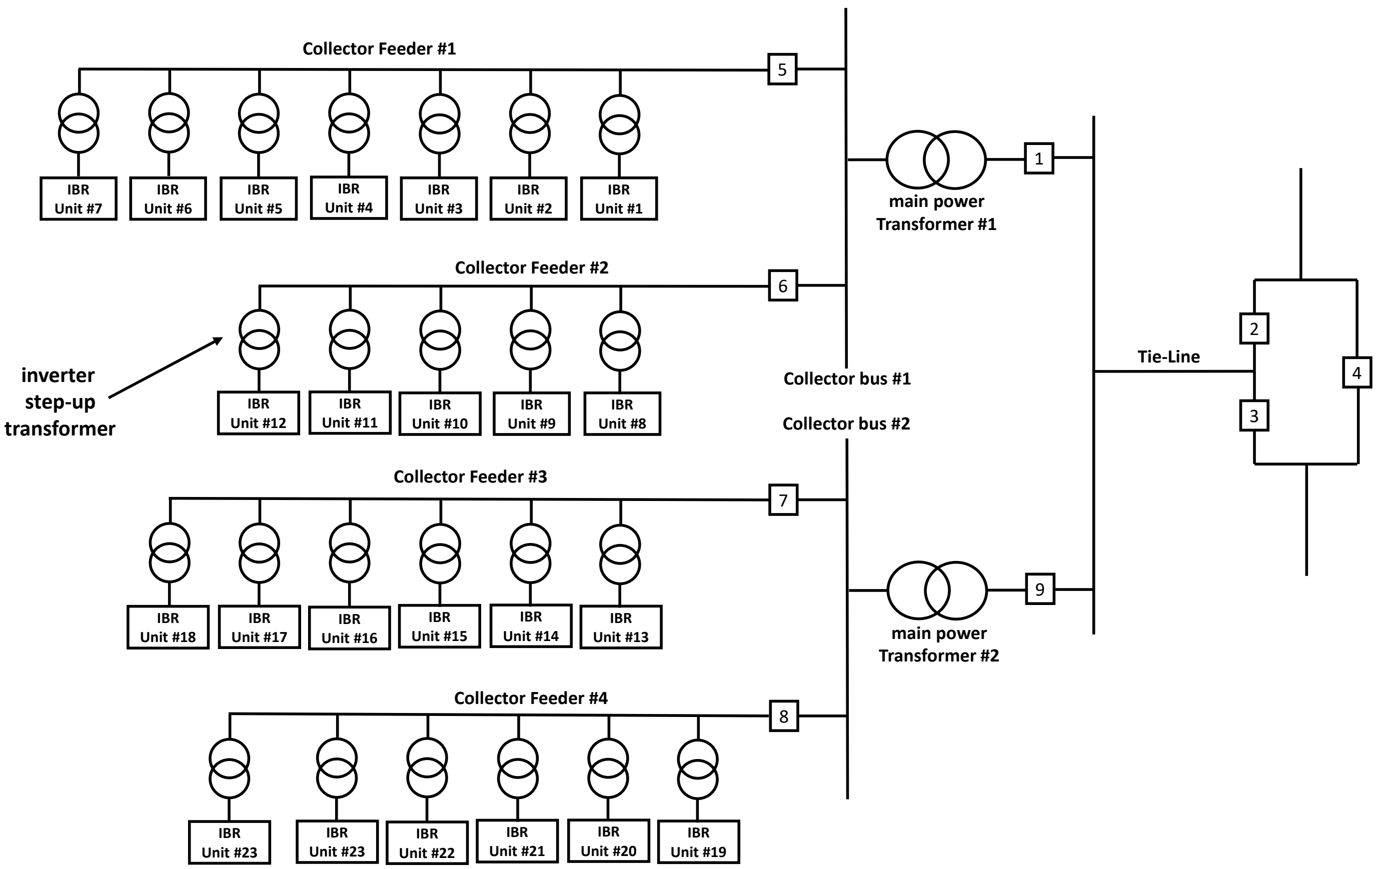

Figure 2: Typical inverter-based resource~~IBR Generating Facility~~ with two collector buses and main power transformers

SER Data: The SER data is required for circuits breaker 1, 5, 6, 7, 8 and 9. Circuit breakers 1 and 9 are associated with main power transformers. Circuit breakers 5, 6, 7, and 8 are associated with collector buses #1 and #2. ~~The SER data for IBR Unit #6 or #7 is required as these are connected at a distance ≥ 90% of the~~

~~longest collector feeder from the collector bus #1. The SER data for IBR Unit #17, #18, or #23 is required as these are connected at a distance ≥ 90% of the longest collector feeder from the collector bus #2.~~

FR Data: The FR data is required from high side terminals of both main power transformers. ~~The SER data for IBR Unit #6 or #7 is required as these are connected at a distance ≥ 90% of the longest collector feeder from the collector bus #1. The SER data for IBR Unit #17, #18, or #23 is required as these are connected at a distance ≥ 90% of the longest collector feeder from the collector bus #2.~~

DDR Data: The DDR data is required from high side terminals of both main power transformers.

Example 3: Applicability of PRC-028 (VSC HVDC system with a dedicated connection to inverter-based resources)

Figure 3 shows an example of dedicated VSC HVDC system connecting the inverter-based resource. Transformers on both sides of the HVDC system are considered main power transformer.

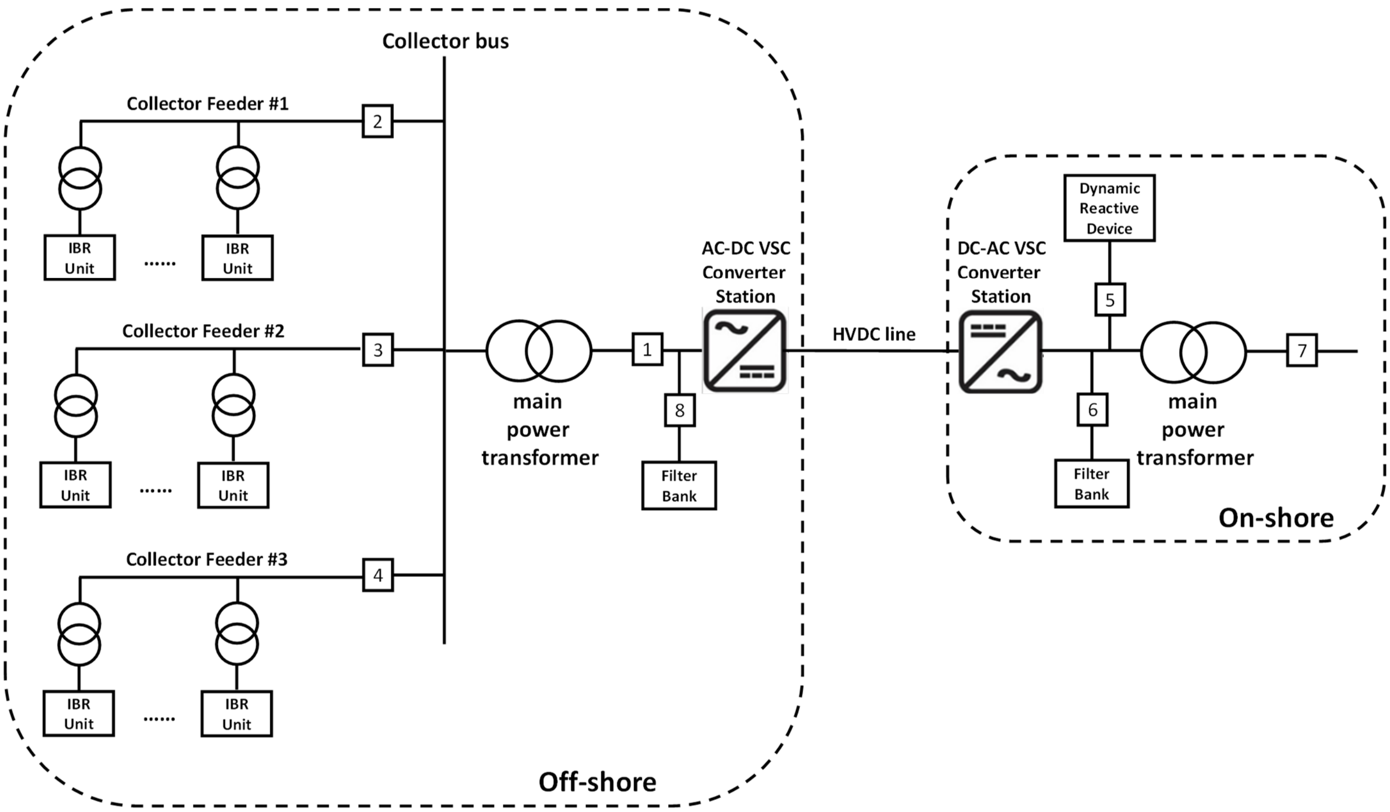

Figure 3: Typical inverter-based resource connected via dedicated VSC HVDC

SER Data: The SER data is required for circuits breaker 1, 2, 3, 4, 5, 6, 7 and 8. Circuit breakers 1 and 7 are associated with main power transformers. Circuit breakers 2, 3, and 4 are associated with the collector bus. Circuit breakers 6 and 8 are associated with filter banks and circuit breaker 5 is associated with shunt dynamic reactive device.

FR Data: The FR data is required from high side terminals of both main power transformers.

DDR Data: The DDR data is required from high side terminals of both main power transformers.

Example ~~3~~4: Applicability of PRC-002 versus PRC-028

Figure ~~3~~ 4 shows an example of inverter-based resource~~IBR~~ interconnection to the transmission system via Line 34. The BES bus in substation Wu is the identified BES bus per methodology in Attachment 1 of the Reliability Standard PRC-002. The SER and FR data requirements for the identified BES bus are per the requirements in the Reliability Standard PRC-002. ~~The IBR generating facility in this example meets the criteria set by inclusion I2 of the BES definition. Hence, ~~T~~t~~he Reliability Standard PRC-028 is applicable to the inverter-based resource~~IBR generating facility~~.

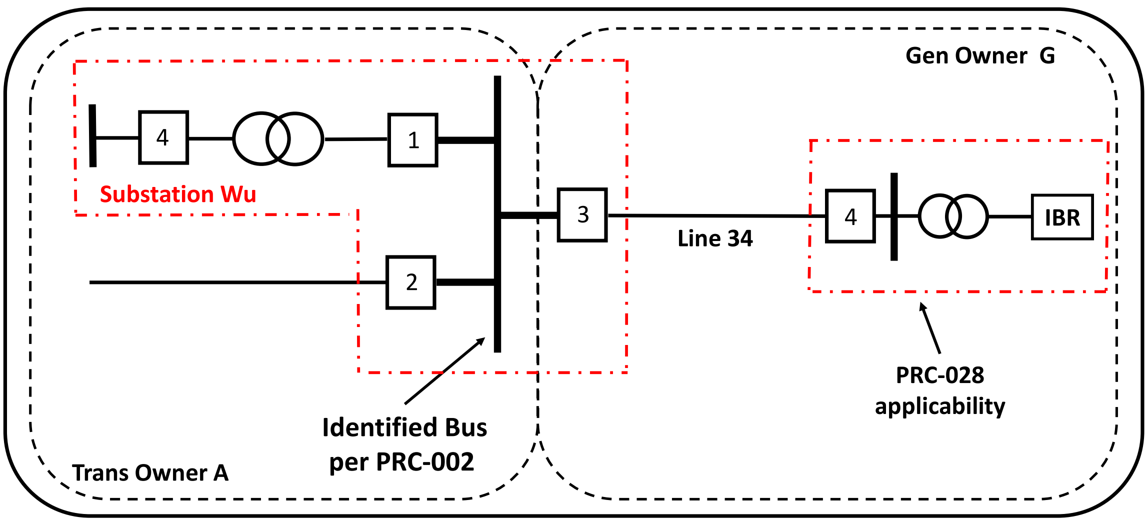

Figure ~~3~~4: Inverter-based resource~~IBR~~ Interconnection – Applicability of PRC-002 versus PRC-028

Example ~~4~~5: Transmission Owner owned Equipment within the ~~I~~inverter-~~B~~based ~~R~~resource~~IBR generating facility~~

Figure ~~4~~5 shows an example of an inverter-based resource~~IBR~~ interconnection where Transmission Owner A owns circuit breaker 3 associated with an inverter-based resource~~IBR generating facility~~. In this case, Transmission Owner A is responsible for SER data for circuit breaker 3. It is not common for Transmission Owner to own the main power transformer and/or portions of collector system associated with an inverter-based resource~~IBR generating facility~~. However, in cases where this is true, Transmission Owner is responsible for SER, FR, and DDR data, as applicable, required by the Reliability Standard PRC-028.

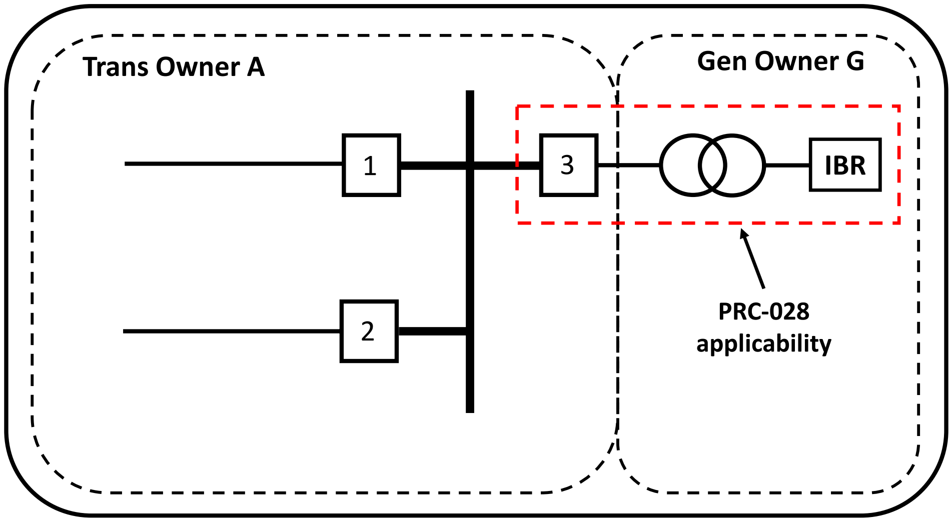

Figure ~~4~~5: Transmission Owner owned Equipment within an inverter-based resource~~IBR Plant~~

Rationale for Requirement R1

The standard requires to capture SER data from circuit breakers ~~and IBR Units~~ within the inverter-based resource~~IBR generating facility~~ associated with:~~. At least one IBR Unit, per collector bus, connected at a distance ≥ 90% of the longest collector feeder from the collector bus must have the data specified in R1, Part 1.2 and Part 1.3.~~

- Main power transformer(s)
- Collector bus(es), including collector feeder breakers
- Shunt static or dynamic reactive device(s), including any filter banks
- AC-DC and DC-AC converters, if any, in case of VSC HVDC system with a dedicated connection to inverter-based resources.

Change of state of circuit breaker position~~ and IBR Unit data~~, time stamped according to Requirement R7 to a time synchronized clock, provides the basis for assembling the detailed sequence of events timeline of ~~IBR's~~ inverter-based resource's ~~generating facility's~~ response during a power System disturbance. Analyses of system disturbances often begin by evaluation of SERs to help determine the initiating event(s) and follow the disturbance propagation. Recording of breaker operations helps determine the interruption of flows during the disturbances. ~~Recording of at least one IBR Unit, per collector bus, connected at a distance ≥ 90% of the longest collector feeder from the collector bus helps analysis of IBR Unit performance during BES disturbances that do not operate the interconnecting circuit breaker. One IBR Unit, per collector bus, connected at a distance ≥ 90% of the longest collector feeder from the collector bus is specified because it may be the most challenging location for IBR Unit to continue to ride-through during BES disturbance. For IBR Unit in commercial operation prior to the effective date of this standard, SER is data is required, if IBR Unit is capable of recording.~~

Rationale for Requirement R2

The intent is to capture sufficient FR data for Elements at each inverter-based resource~~IBR generating facility~~ to analyze the overall response of the inverter-based resource~~IBR generating facility~~ to a system disturbance. Analyses of disturbances involving widespread reduction of power output from inverter-based resource~~IBR~~s in recent years has shown that expansion of monitoring at inverter-based resource~~IBR~~ sites is necessary. The required electrical quantities may either be directly measured or determinable if sufficient FR data is captured (e.g. residual or neutral current if the phase currents are directly measured).

The plant level FR measurements, i.e., measured on high-side terminals of the main power transformer, specified in Requirement R2, Part 2.1 provide data at the inverter-based resource~~IBR~~ ~~generating facility~~ interconnection to the bulk power system. To cover all possible fault types, phase-to-neutral voltage recording for each phase is required to be determinable. Each phase current and residual current are required to distinguish between phase faults and ground faults. This data also facilitates determination of the fault location and cause of relay operation. The measurements of active and reactive power provide data on the overall generating facility's response to the system disturbance.

~~Analyses of system disturbances involving widespread reduction of real power output from IBRs in recent years have shown that all individual IBR Units within the IBR generating facility do not react to the disturbance identically because of their wide geographic distribution. Requirement R2, Part 2.2, requires monitoring of at least one IBR Unit, per collector bus, connected at a distance ≥ 90% of the longest collector feeder from the collector bus, ensuring that FR data is available to analyze individual IBR Unit response. It may be challenging to record/determine specified electrical quantities from IBR Unit terminals for existing installations. As such, the standard allows for recording/determining specified electrical quantities on high-side of IBR Unit transformer.~~

In some cases, the dynamic reactive device is used within the inverter-based resource~~IBR~~ ~~generating facility~~ and often connected to medium voltage collector bus. Regardless of where dynamic reactive device is connected, the output of it during system disturbances is important to understand overall performance of the plant during a disturbance. The measured or determined electrical quantities for dynamic reactive device are same as those specified to be measured/determined from high-side of main power transformer.

Recording of Electrical Quantities

For effective fault analysis, it is necessary to know values of all phase and neutral currents and all phase-to-neutral voltages. Based on such FR data, it is possible to determine all fault types. FR data also augments SERs in evaluating circuit breaker operation. FR also shows generator output response to a system disturbance.

Current Recordings

The required electrical quantities are normally directly measured. Certain quantities can be derived if sufficient data is measured, for example residual or neutral currents. Since a Transmission System is generally well balanced, with phase currents having essentially similar magnitudes and phase angle differences of 120 degrees, during normal conditions there is negligible neutral (residual) current. In case of a ground fault, the resulting phase current imbalance produces residual current that can be either measured or calculated.

Neutral current, also known as ground or residual current Ir, is calculated as a sum of vectors of three phase currents:

$\mathbf{I}_r = 3 \bullet \mathbf{I}_0 = \mathbf{I}_A + \mathbf{I}_B + \mathbf{I}_C$

$\mathbf{I}_0$ - Zero-sequence current

$\mathbf{I}_A$, $\mathbf{I}_B$, $\mathbf{I}_C$ - Phase current (vectors)

Voltage Recordings
Voltages are to be recorded or accurately determined at applicable Elements as outlined in Requirement R2.

Rationale for Requirement R3
Time stamped pre- and post-trigger FR data aid in the analysis of power system operations and determination if operations were as intended.

The "Odessa Disturbance" report from September 2021 recommended high resolution oscillography data at the point of interconnection~~ and on individual IBR Units~~. The minimum recording rate of 64 samples per cycle is specified recognizing state-of-the-art for DME including storage any storage capability limitations and provides sufficient data to recreate accurate response of the inverter-based resource~~IBR~~ ~~generating facility~~ to system disturbances. ~~This higher sampling rate is particularly important for capturing transient events at the individual IBR Units.~~

Pre- and post-trigger fault data along with the SER data, all time stamped to a common clock, aid in the analysis of Protection System operations after a fault to determine if a Protection System operated as designed. Additionally, inverter-based resource~~IBR~~s ~~Units~~ employ fast acting control systems (with built in protection functions) dictating ~~IBR~~inverter-based resource's ~~generating facility's~~ response to system disturbance. ~~The FR data from IBR Units time stamped to a common clock is necessary to analyze IBR Unit and generating facilities response to system disturbances.~~ Generally speaking, BES faults persist for a very short time period, approximately 1 to 30 cycles. To capture the full response of inverter-based resource~~IBR generating facility~~ spread over a large geographic area, a 2 second total minimum record length synchronized to a common clock is necessary for FR data. Multiple records allow for legacy microprocessor relays which, when time synchronized to a common clock, can provide adequate fault data but are not capable of providing fault data in a single record with 120 ~~contiguous~~ continuous cycles total.

FR triggers can be set so that when the monitored value on the recording device goes above or below the trigger value, data is recorded. Requirement R3, Part 3.1.3.1 specifies a neutral (residual) overcurrent trigger for ground faults. Requirement R3, sub-Part 3.1.3.2 specifies a phase overvoltage or undervoltage trigger during voltage ride-through events. ~~For IBR Unit FR data triggers, Requirement R3, Part 3.2.3.1 specifies a phase overvoltage and undervoltage. Requirement R3, sub-Part 3.2.3.2 specifies a trigger for overfrequency and underfrequency to record response during frequency ride-through events.~~

The triggers specified in Requirement R3, Part 3.3 for dynamic reactive device FR data are similar to ones specified in Requirement R3, Part 3.1 for plant level FR data measured or determined on high-side of the main power transformer.

Rationale for Requirement R4

Large scale system disturbances generally are an evolving sequence of events that occur over an extended period of time, making DDR data essential for event analysis. Data available pre- and post-contingency helps identify the causes and ~~IBR~~inverter-based resource's ~~generating facility's~~ response to large scale system disturbances. Therefore, continuous recording and storage are necessary to ensure sufficient data is available for the entire event. The state-of-the-art DDR equipment is capable of continuous recording.

DDR data contains the dynamic response of the inverter-based resource~~IBR~~ ~~generating facility~~ to a system disturbance and is used for analyzing complex power system events. This recording is typically used to capture short-term and long-term disturbances. Since the data of interest is changing over time, DDR data is normally stored in the form of RMS values or phasor values, as opposed to directly sampled data as found in FR data.

DDR is used to measure transient response to system disturbances during a relatively balanced post-fault condition. Therefore, it is sufficient to provide a single phase-to-neutral voltage or positive sequence voltage and current from the same phase or positive sequence for each applicable main power transformer for analysis. It is also sufficient to provide a single frequency for any of the provided voltages since all main power transformers within a inverter-based resource~~IBR~~ ~~generating facility~~ are at the same frequency. Recording of all three phases of voltage/current is not required, although this may be used to compute and record the positive sequence value(s). The electrical quantities for Real Power and Reactive Power on a three-phase basis can be measured/recorded or determined (calculated, derived, etc.).

The data requirements for PRC-028-1 are based on a system configuration assuming all normally closed circuit breakers on a BES bus are closed.

A crucial part of disturbance analysis is understanding the dynamic response of generating resources. Therefore, it is necessary to have DDR on high-side of the main power transformer(s) measuring the specified electrical quantities to adequately capture ~~IBR~~inverter-based resource's ~~generating facility's~~ response.

The Requirement R4, Part 4.1 requires either one phase-to-neutral or positive sequence voltage. However, the phase-to-phase voltage recording is acceptable. Since the BES operates under a relatively balanced operating condition and, if needed, phase-to-neutral quantities can be derived from phase-to-phase quantities.

Rationale for Requirement R5

An input sampling rate of at least 960 samples per second, which corresponds to 16 samples per cycle on the input side of the DDR equipment, ensures adequate accuracy for calculation of recorded measurements such as complex voltages and frequency. The input sampling rate specified is same as one specified in the Reliability Standard PRC-002.

An output recording rate of electrical quantities of at least 60 times per second refers to the recording rate of the device. Recorded measurements of at least 60 times per second provide adequate recording speed to monitor the ~~IBR~~inverter-based resource's ~~generating facility's~~ response during power system disturbances. Since control system associated with ~~IBR~~inverter-based resources is fast acting, higher frequency recording is necessary to accurately reconstruct events. An output recording rate of 60 times per second provides this higher frequency recording while not greatly increasing data storage requirements.

Rationale for Requirement R6

Time synchronization of disturbance monitoring data is essential for time alignment of large volumes of geographically dispersed records from diverse recording sources. Coordinated Universal Time (UTC) is a recognized time standard that utilizes atomic clocks for generating precision time measurements. All data must be provided in UTC formatted time either with or without the local time offset, expressed as a negative number (the difference between UTC and the local time zone where the measurements are recorded).

Accuracy of time synchronization applies only to the clock used for synchronizing the monitoring equipment. The equipment used to measure the electrical quantities must be time synchronized to ± 1 millisecond accuracy; however, accuracy of the application of this time stamp and therefore, the accuracy of the data itself is not mandated. This is because of inherent delays associated with measuring the electrical quantities and events such as breaker closing, measurement transport delays, algorithm and measurement calculation techniques, etc.

Ensuring that the monitoring devices internal clocks are within ± 1 millisecond accuracy will suffice with respect to providing time synchronized data. Accuracy of time synchronization applies only to the clock used for synchronizing the monitoring equipment. Note that the recently published IEEE Std 2800 requires the DME recording plant level data be synchronized to the clock with accuracy of ± 1 microsecond accuracy; however, the accuracy requirement is set to ± 1 millisecond to strike a balance between need of accuracy and practical limitations of equipment necessary to achieve the stated accuracy.

The ~~IBR~~inverter-based resources, which are not affected by inertial time constants, make changes in power production very rapidly. To understand and analyze control decisions during system disturbances and the reasons behind them over dozens of plants ~~with possibly 100's of IBR Units~~ requires a high level of accurate time synchronization. Following provide some examples of ~~IBR~~inverter-based resource's fast response:

- Typical 90% response to a three-phase fault is <40 ms.
- Central power plant controllers issue updated commands in as little as 40 ms upon detection of change in system conditions.
- Standard closed loop voltage control response can be <200 ms.
- Instantaneous Inverter protective trip decisions such as AC or DC overvoltage or reverse DC current can be made in less than 10 ms.

Rationale for Requirement R7

Requirement R7, Part 7.1 specifies a minimum time period of 20 calendar days inclusive of the day the data was recorded for which the data to be retrievable. Data hold requests are usually initiated the same or next day following a major event, however, it takes a longer time to determine which data from which generating facility needs to be retrieved for event analysis. A 20 calendar day time period provides enough time for communication between various Entities regarding the event and need for data retrieval from DME at various generating facilities. The requestor of data has to be aware of 20 calendar day retrievability limit to ensure timely data hold requests. Requiring data retention for a longer period of time is expensive and unnecessary.

With the state-of-the-art equipment, having the data retrievable for the 20 calendar days is realistic and doable. It is important to note that applicable entities should account for any expected delays in retrieving data and this may require devices to have data available for more than 20 days. To clarify the 20 calendar day time frame, let's assume that event occurs on Day 1. If a request for data is made on Day 6, then that data has to be provided to the requestor within 20 calendar days after a request or a granted time extension. However, if a request for the data is made on Day 21, that is outside the 20 calendar days specified in the requirement, and an entity would not be out of compliance if it did not have the data.

This requirement directs the applicable entities, upon requests from the Reliability Coordinator, Regional Entity or NERC, to provide SER, FR and DDR data for generating facilities as per the applicability. To facilitate the analysis of system disturbances, it is important that the data is provided to the requestor within a reasonable time. Providing the data within ~~30~~15 calendar days (or the granted extension time), subject to Requirement R7, Part 7.2, allows for reasonable time to collect the data and perform any necessary computations or formatting. An entity may request an extension of the ~~30~~15 calendar days submission requirement. If granted by the requestor, the entity must submit the data within the approved extended time.

Disturbance analysis includes reviewing data recording from many devices and entities. Standardized formatting and naming conventions of these files significantly improves timely analysis. The formatting and naming convention requirements for SER, FR, and DDR are consistent with same requirements in the Reliability Standard PRC-002.

SER data: Requirement R7, Part 7.3 specifies a simple ASCII Comma Separated Value (CSV) format according to Attachment 1. It is necessary to establish a standard format as it allows data submitted by one entity or facility to be incorporated with same data provided by other entities or facilities to develop a detailed sequence of events timeline of a power system disturbance.

FR ~~and DDR~~ data: Requirement R7, Part 7.4 specifies ~~either CSV format or~~ the IEEE C37.111 Standard for Common Format for Transient Data Exchange (COMTRADE) format for the FR ~~and DDR~~ data. The IEEE C37.111 is well established in the industry. Exchanging data in a standard format helps in analysis of a power system disturbance, especially considering multiple data submission from many sources. ~~The 2013 revision of the IEEE C37.111 includes an annex describing the application of the COMTRADE standard to synchrophasor data.~~

DDR data: Requirement R7, Part 7.5 specifies either CSV format with appropriate headers or the IEEE C37.111 Standard for Common Format for Transient Data Exchange (COMTRADE) format for the DDR data. The IEEE C37.111 is well established in the industry. Exchanging data in a standard format helps in analysis of a power system disturbance, especially considering multiple data submission from many sources. The

2013 revision of the IEEE C37.111 includes an annex describing the application of the COMTRADE standard to synchrophasor data.

Requirement R7, Part 7.6~~5~~ specifies the IEEE C37.232 Standard for Common Format for Naming Time Sequence Data Files (COMNAME) format for naming the SER, FR and DDR data files. The lack of a common naming practice seriously hinders the event analysis and investigation process.

Rationale for Requirement R8

The standard requires that Entity restore the recording capability for SER, FR, or DDR data within 90 calendar days of the discovery of a failure. The 90 calendar day time period permitted in this requirement strikes a balance between reasonable time needed to restore capability while ensuring that recording capability is not out of service for an extended duration. If the recording capability cannot be restored within 90 calendar days due to limitations such as budget cycle, service crews, vendors, needed outages, etc., the entity is required to submit a Corrective Action Plan for restoring the recording capability to the Regional Entity and implement it. It is treated as a failure if the recording capability is out of service for maintenance and/or testing for greater than 90 calendar days. An outage of the monitored Element does not constitute a failure of the disturbance monitoring capability.

~~**Rationale for Requirement R9**~~

~~For Facilities in commercial operation on or before the effective date of PRC-028-1, the Implementation Plan requires applicable Entities to be fully compliant at 50% of their Facilities within three (3) calendar years of the effective date of PRC-028-1 and fully compliant at 100% of Facilities prior to January 1st, 2030. The Implementation Plan recognizes Federal Energy Regulatory Commission's directive, under Order No. 901[3], to have this standard effective and enforceable before 2030. The Reliability Standard PRC-028-1 is expected to have a wide-ranging impact on Entities as many existing Facilities would be required to have disturbance monitoring equipment. Considering time needed to procure equipment, complete design, schedule outages, and install equipment, technical or supply chain constraints may prevent Entities from being fully compliant in a timeframe stated in the Implementation Plan. Requirement R9 allows Entities of an applicable Facility in commercial operation before the effective date of Reliability Standard PRC-028-1 that is not able to install disturbance monitoring equipment per Requirements R1 through R7 to develop, maintain, and implement a Corrective Action Plan. Requirement R9, Parts 9.1 through 9.5 outlines details to be included in the Corrective Action Plan.~~

UPDATED

Standards Announcement

Project 2021-04 Modifications to PRC-002 – Phase II

Formal Comment Period Extended, Now Open through June 17, 2024

Now Available

The formal comment period for **Project 2021-04 Modifications to PRC-002- Phase** II has been extended and is now open through **8 p.m. Eastern, Monday, June 17, 2024** for the following standards and implementation plan:

- PRC-002-5 – Disturbance Monitoring and Reporting Requirements
- PRC-028-1 – Disturbance Monitoring and Reporting Requirements for Inverter-Based Resources
- Implementation Plan

The standard drafting team's considerations of the responses received from the previous comment period are reflected in this draft of the standard.

Reminder Regarding Corporate RBB Memberships

Under the NERC Rules of Procedure, each entity and its affiliates is collectively permitted one voting membership per Registered Ballot Body Segment. Each entity that undergoes a change in corporate structure (such as a merger or acquisition) that results in the entity or affiliated entities having more than the one permitted representative in a particular Segment must withdraw the duplicate membership(s) prior to joining new ballot pools or voting on anything as part of an existing ballot pool. Contact ballotadmin@nerc.net to assist with the removal of any duplicate registrations.

Commenting

Use the Standards Balloting and Commenting System (SBS) to submit comments. An unofficial Word version of the comment form is posted on the project page.

- *Contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern) for problems regarding accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out.*
- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*

- *Please be mindful of ballot and comment period closing dates. We ask to **allow at least 48 hours** for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts **prior to the last day** of a comment/ballot period.*

Next Steps

Additional ballots for the standards and implementation plan, as well as the non-binding polls of the associated Violation Risk Factors and Violation Severity Levels have been extended and will now be conducted **June 5 – 17, 2024**.

For more information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Senior Standards Developer**,** Ben Wu (via email) or at 470-542-6882. Subscribe to this project's observer mailing list by selecting "NERC Email Distribution Lists" from the "Service" drop-down menu and specify “Project 2021-04 Modifications to PRC-002 observer list” in the Description Box.

Standards Announcement

Project 2021-04 Modifications to PRC-002 – Phase II

Formal Comment Period Open through June 14, 2024

Now Available

A 15-day formal comment period for **Project 2021-04 Modifications to PRC-002- Phase II** is open through **8 p.m. Eastern, Friday, June 14, 2024** for the following standards and implementation plan:

- PRC-002-5 – Disturbance Monitoring and Reporting Requirements
- PRC-028-1 – Disturbance Monitoring and Reporting Requirements for Inverter-Based Resources
- Implementation Plan

The standard drafting team's considerations of the responses received from the previous comment period are reflected in this draft of the standard.

Reminder Regarding Corporate RBB Memberships

Under the NERC Rules of Procedure, each entity and its affiliates is collectively permitted one voting membership per Registered Ballot Body Segment. Each entity that undergoes a change in corporate structure (such as a merger or acquisition) that results in the entity or affiliated entities having more than the one permitted representative in a particular Segment must withdraw the duplicate membership(s) prior to joining new ballot pools or voting on anything as part of an existing ballot pool. Contact **ballotadmin@nerc.net** to assist with the removal of any duplicate registrations.

There were 61 sets of responses, including comments from approximately 144 different people from approximately 92 companies representing 10 of the Industry Segments as shown in the table on the following pages.

Questions

1. Do you agree with the modification in “Applicability, Section 4.2. Facilities” in PRC-028-1 to remove “Non-BES Inverter Based Resources …”?

2. Do you agree with removing “Inverter Based Resources” and “IBR Unit” under Term(s) for Reliability Standards PRC-002-5 and PRC-028-1?

3. Do you agree with the standard drafting team removing Requirement R9 in Reliability Standard PRC-028-1 and adding it to the Implementation Plan since it is more like a process, not a Requirement?

4. Do you agree with the Implementation Plan for revised PRC-002-5 and new Standard PRC-028-1?

5. Do you agree the modifications made in PRC-002-5 and new Standard PRC-028-1 are cost effective?

6. Provide any additional comments for the standard drafting team to consider, if desired.

1. Do you agree with the modification in "Applicability, Section 4.2. Facilities" in PRC-028-1 to remove "Non-BES Inverter Based Resources …"?

Robert Follini - Avista - Avista Corporation - 3

Answer	No
Document Name	

Comment

Industry comments show that the exact definition of Inverter Based Resource should be used, not the uncapitalized version that is currently in the PRC-028 draft, which is not bounded by the official definition. The footnote in the proposed standard is also an expansion of the NERC approved definition.

FE supports EEI Comments which state:

EEI does not support the modifications to the Applicability Section. The definition for Inverter Based Resource (IBR) was approved by industry in April under Project 2020-06. We also do not agree with inserting the uncapitalized version of IBR into this section because it is unbounded and insufficient to identify the Facilities applicable to this Standard, as required in the Rules of Procedure (Appendix 3a, Standard Processes Manual). Moreover, the footnote included in the Purpose statement has the effect of expanding the meaning of the recently approved definition of IBR outside of the

Applicability Section of this Standard. EEI notes that the Standards Processes Manual states that the "Applicability: Identifies the specific Functional Entities and Facilities to which the Reliability Standard applies." and "Purpose: The reliability outcome achieved through compliance with the Requirements of the Reliability Standard." The Purpose statement is not intended to define or expand which facilities are to be applicable to a NERC Reliability Standard. To address this issue the Applicability Section of PRC-028 should be changed back to the capitalized version of Inverter Based Resources.

We also note that Voltage Source Converters – High-voltage Direct Current (VSC-HVDC) were included in Requirement R1, subpart 1.4 but not specifically identified in the Applicability Section of PRC-028 or the approved SAR. EEI further notes that this project was approved to address issues surrounding the changing resource mix and the increased penetration of IBRs. If VSC-HVDC systems are subject to the same risks and concerns as IBRs, then the SAR should be modified and resubmitted with a technical justification clarifying why those resources need to be included in this Reliability Standard, in alignment with the Standard Processes Manual (Appendix 3a). While there is some information contained in the Technical Rationale, EEI does not believe this is sufficient to allow these resources to be added to this Standard.

No. Non-BES IBRs should be applicable to this standard, as it aligns with the FERC order activities and the on-going NERC Registration efforts to incorporate the non-registered BPS-connected IBRs that are owned/operated by the newly proposed Category 2 GO and GOP entities. Exclusion of these BPS-connected IBRs would significantly limit the ability to ensure that all BPS-connected IBRs have adequate data for performance evaluation/analysis during BPS/BES disturbances and data for BPS-connected IBR model validation.

USV agrees with comments proposed by NPCC. The purpose of the project is to create a clear understanding of Non-BES and BES inverter-based resources and address gaps that exist in the current standards. With the proposed language, we foresee a lot of interpretation when it comes to inverter-based resources and note inconsistency between the three PRC standards. Suggest coordination between the three PRC standards that are currently open and progressively work towards the same or similar goal.

It is imperative that the standard drafting teams for this project as well as the 2020-02 (PRC-024 and PRC-029) and 2023-02 (PRC-030 vs PRC-004) assure a coherent way of addressing the inclusion and exclusion of IBRs in current and upcoming standards. Furthermore, this modification no longer addresses the purpose or goal of the IRPTF SAR as approved by the Standards Committee: “This SAR proposes to revise PRC-002-2 or create a new standard to address gaps within the existing standard. The goal is to ensure adequate data is available and periodically assessed to facilitate the analysis of BES disturbances, **including in areas of the Bulk Power System (BPS) that may not be covered by the existing requirements**. Nor do these modifications address the recommendations of the IRPTF in the IRPTF Review of NERC Reliability Standards White Paper where “The IRPTF recommends **that a SAR(s) be developed** to address each of the issues identified. IRPTF recommends that this be made a priority by the NERC Standards Committee, **due to the continued growth of BPS-connected inverter-based resources**”.

Comment
The ISO/RTO Council (IRC) Standards Review Committee (SRC) is concerned with the removal of non-BES inverter-based resources (IBRs) from Applicability, Section 4.2, particularly if non-BES IBRs will need to be added later. Although NERC has authority over the BPS, to the extent proposed PRC-028, Section 4.2 explicitly applies to BES IBRs only, then PRC-028 would not apply to BPS resources (i.e. registered non-BES IBRs). Several other NERC standards are relying on PRC-028 for monitoring. If PRC-028 doesn't require IBR monitoring as a foundational element, then the other IBR performance standards relying on PRC-028 will likely be less effective too. Therefore, the Applicability of PRC-028 should be expanded to apply to both BES IBRs and non-BES IBRs. Ultimately, adequate data must be available from IBRs to evaluate IBR ride-through performance during BES Disturbances and to provide data for IBR model validation.

AEPC signed on to ACES comments:

ACES is very appreciative of the effort put forth by the SDT to listen to industry comments and revise PRC-028-1 accordingly. It is the opinion of ACES that removing "Non-BES Inverter Based Resources" is the correct approach for this draft; however, we do not completely agree with language chosen by the SDT for Section 4.2. We recommend the following language:

4.2.1 For the purposes of this standard, "inverter-based resources" refers to a collection of 1 (one) or more of any of the following facility types that operate as a single plant/resource:

4.2 Facilities: Elements associated with inverter-based resources meeting the criteria of Inclusion I4 of the BES definition.

4.2.1.1 Individual solar photovoltaic (PV)

4.2.1.2 Type 3 and Type 4 wind turbines

4.2.1.2 In the case of offshore wind plants connecting via a dedicated voltage source converter high voltage direct current (VSC HVDC) line, the inverter-based resource includes the VSC HVDC line.

4.2.1.3 Battery energy storage system (BESS), or

4.2.1.4 Fuel cells

Answer	Yes
Document Name	

Comment	
SMUD agrees with the SDT's decision to remove "Non-BES Inverter Based Resources" from the applicable facilities in this new version of PRC-028-1; however, we are concerned that this may be a short-term fix since FERC Order 901 directs NERC to "submit, by November 4, 2024, new or modified Reliability Standards that require disturbance monitoring data sharing and post-event performance validation for **registered IBRs** [emphasis added]." The term "registered IBRs" in FERC Order 901 includes BES IBRs registered with NERC and IBRs which will be registered according to FERC's IBR Registration Order. Once FERC approves the registration criteria proposed in NERC's rules of procedure changes submitted to FERC on March 19, 2024, the SDT will be required to modify PRC-028-1 again to include the non-BES IBRs that will be registered. This future change that would be required to PRC-028-1 is inefficient.

EEI does not support the modifications to the Applicability Section. The definition for Inverter Based Resource (IBR) was approved by industry in April under Project 2020-06. We also do not agree with inserting the uncapitalized version of IBR into this section because it is unbounded and insufficient to identify the Facilities applicable to this Standard, as required in the Rules of Procedure (Appendix 3a, Standard Processes Manual). Moreover, the footnote included in the Purpose statement has the effect of expanding the meaning of the recently approved definition of IBR outside of the Applicability Section of this Standard. EEI notes that the Standards Processes Manual states that the "Applicability: Identifies the specific Functional Entities and Facilities to which the Reliability Standard applies." and "Purpose: The reliability outcome achieved through compliance with the Requirements of the Reliability Standard." The Purpose statement is not intended to define or expand which facilities are to be applicable to a NERC	

Reliability Standard. To address this issue the Applicability Section of PRC-028 should be changed back to the capitalized version of Inverter Based Resources.

We also note that Voltage Source Converters – High-voltage Direct Current (VSC-HVDC) were included in Requirement R1, subpart 1.4 but not specifically identified in the Applicability Section of PRC-028 or the approved SAR. EEI further notes that this project was approved to address issues surrounding the changing resource mix and the increased penetration of IBRs. If VSC-HVDC systems are subject to the same risks and concerns as IBRs, then the SAR should be modified and resubmitted with a technical justification clarifying why those resources need to be included in this Reliability Standard, in alignment with the Standard Processes Manual (Appendix 3a). While there is some information contained in the Technical Rationale, EEI does not believe this is sufficient to allow these resources to be added to this Standard.

Answer	Yes
Document Name	
Comment	

Southern Indiana Gas and Electric Company d/b/a CenterPoint Energy Indiana South (SIGE) agrees with the removal of Non-BES Inverter Based Resources. SIGE is concerned that the intention behind removing Non-BES Inverter Based Resources is only a short-term allowance until the Rules of Procedure changes are approved.

While SIGE recognizes the challenges the Drafting Teams are facing; the parallel development of IBR-focused Standards and IBR definitions/rules of procedure may result in ‘temporary’ Standards that may not be fully aligned across their Applicability and Facilities sections. Meaning, it seems the current open drafts are being written as stop gaps until the IBR definitions and Rules of Procedure are approved rather than pausing to focus on the definitions and Rules of Procedure first then revise the Standards.

Texas RE is concerned removing “Non-BES Inverter Based Resources” from the Applicability Section 4.2 will eliminate all solar facilities with less than 75 MW of aggregated generation capacity from complying with this standard. In addition, storage facilities with less than 75 MW aggregated generation capacity would be excluded from this standard. This data is needed to have adequate data available from inverter-based resources to evaluate ride-through performance during BES Disturbances. Texas RE recommends the following verbiage (in bold):

4.2. Facilities

4.2.1 BES inverter-based resources

4.2.2 Non-BES inverter-based resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

This change would also facilitate the new GADS reporting for Solar facilities, which requires generating plants with a Plant Total Installed Capacity of 20 MW or greater per plant to submit the data.

Charles Yeung - Southwest Power Pool, Inc. (RTO) - 2 - MRO,WECC, Group Name SRC 2024	
Answer	No
Document Name	
Comment	
The SRC disagrees with the removal of these terms from the standards. One of the benefits of developing formal definitions for IBR and IBR Unit in Project 2020-06 is that these terms, once finalized, will provide a consistent understanding of what constitutes an IBR and an IBR Unit for purposes of NERC Reliability Standards. However, developing IBR-focused standards that explicitly decline to use these standardized definitions undermines the benefits of developing Glossary-level definitions, and presents a risk that different standards will use different definitions of what constitutes an IBR, resulting in an inconsistent, difficult-to-comply-with patchwork of regulations rather than a consistent suite of IBR-related Reliability Standards. The draft 2 postings effectively explained the overlap with the work being done in Project 2020-06 so that entities could evaluate PRC-002 and PRC-028 in light of those definitions. The SRC recommends that the drafting team revise PRC-002 and PRC-028 to once again rely on the Project 2020-06 definitions of IBR and IBR Unit to help ensure consistency across IBR-related standards on the front end and avoid the need to make subsequent revisions to these standards once Project 2020-06 is complete. The SRC believes that a decision not to use the Project 2020-06 definitions should be supported by a compelling justification.

The voters in Project 2020-06, Inverter-based Resource Glossary Terms draft #2, approved the definition of IBR on April 8, 2024, which is different than the definition proposed in Footnote 1 of PRC-028-1. Using the term “inverter-based resources” and defining it with Footnote 1 is inefficient and would create two definitions for the same resource. The SDT of PRC-028-1 should coordinate with the SDT of Project 2020-06 and NERC staff to ensure the definition of IBR and new PRC-028-1 are submitted to FERC simultaneously thereby eliminating another ballot for PRC-028-1 to add the NERC Glossary Term for IBR into the standard.

No. Removing these two Terms is not aligned with the other on-going IBR standard related work throughout NERC. By removing these two Terms, it appears to have forced the creation of a new definition of "inverter-based resources" under Footnote 1 of this draft of PRC-028-1. It seems counter productive to have a unique definition of IBRs and IBR units under each different NERC standard. Having all standards aligned to the same core definitions/terms for IBRs will make all this standard development work, execution of the standards, and compliance activities more efficient for all entities involved.

Adrian Andreoiu - BC Hydro and Power Authority - 1, Group Name BC Hydro	
Answer	No
Document Name	
Comment	

BC Hydro appreciates the drafting team's efforts and opportunity to comment, and offers the following.

BC Hydro prefers that PRC-028-1 rely on an IBR definition, we understand the rationale for moving ahead while the definitions being drafted by the Project 2020-06 drafting team are being finalized.

BC Hydro requests that the drafting team clarify that the Footnote 1 is not intended to expand on the applicability scope of PRC-028-1, which does not include reactive power devices providing reactive support, such as STATCOMs as an example.

BC Hydro suggests that the Footnote 1 be (a) referenced within the Section 4.2 Facilities of PRC-028-1, and (b) revised to include a provision that IBRs are devices capable of exporting Real Power as follows.

Suggested revision to Footnote 1 – For the purpose of this standard, “inverter-based resources” refers to a collection of individual solar photovoltaic (PV), Type 3 and Type 4 wind turbines, battery energy storage system (BESS), or fuel cells that operate as a single plant/resource and can export Real Power from a primary energy source or energy storage system via a power electronics interface (such as an inverter or converter), and that is/are operated as a single resource connected to the electric power system at a common point of connection.

Tri-State agrees with the removal of unapproved defined terms in the standard. However, if the intention is that the definitions will be added at a later date when they are approved then the SDT should not include the footnote and wait until the definitions are approved through ballot. It seems like we are putting the "cart before the horse" by not having the IBR definitions approved first and working on the related standards just to meet a deadline. It will make it a duplicate process to have to come back to PRC-028 and comment/ballot again when the definitions are added.

Southern Company agrees to removing R9. However, Southern Company **does not agree** to requiring RE approval of an extension plan. Some criteria should be provided in the implementation plan which will permit extension in cases where the procurement and/or installation of designated additional DME is beyond the control of the entity required to install the DME.

NV Energy agrees with removing R9 and with the concept of placing the "Process for Seeking an Extension from Compliance Dates" in the implementation Plan. However, there should be no requirement for the GO or TO to seek approval from the Regional Entity. NV Energy recommends that the SDT create clear and auditable criteria that if met, allows for the extension of compliance dates. GOs and TOs would submit notification to the Regional Entity that they will require an extension to the compliance dates, based on the met criteria. The Regional Entities' role would be to ensure that the proper criteria are indicated by the GO or TO to allow for an extension of compliance dates, rather make subjective decisions on approval of requests. This would also eliminate concerns about differences between regions in allowing for extensions.

4. Do you agree with the Implementation Plan for revised PRC-002-5 and new Standard PRC-028-1?

Charles Yeung - Southwest Power Pool, Inc. (RTO) - 2 - MRO,WECC, Group Name SRC 2024

Answer	No
Document Name	

Comment

All IBRs that enter commercial operation after the effective date of the standard should be required to comply with the PRC-028 no later than 15 months after the effective date of the standard. IBRs that have a commercial operations date more than 15 months after the effective date of the standard should be required to be compliant on their first day of commercial operation. Such facilities should be constructed to meet the requirements of the standard, and should not be eligible to operate without being compliant for 15 months after they are in commercial operation. This should be clarified in the Implementation Plan as detailed below:

Compliance Date for PRC-028-1 Requirements R1-R7 (page 3)

"For inverter-based resources facilities entering commercial operation after the effective date: Entities shall comply with Requirements R1 through R7 within 15 calendar months following the effective date of the standard or by the commercial operation date, whichever is earlier later."

NIPSCO agrees with the majority of the implementation plan but still has concerns with the "15 calendar months following the effective date of the standard" requirement for inverter-based resources entering commercial operation after the effective date, and believes that more time is needed to properly budget, modify designs and procure equipment for projects already under development. NIPSCO proposes modifying the following language: For inverter-based resources entering commercial operation after the effective date: Entities shall comply with Requirements R1 through R7 within "36 calendar months following the effective date of the standard or by" the commercial operation date, whichever is later.

Comment	
NV Energy agrees with the proposed compliance dates; however, NV Energy does not agree with the proposed "Process for Seeking an Extension from Compliance Dates" (see response to question 3.) The implementation plan requires compliance 15 calendar months after the effective date or the commercial operation date whichever is later. The WebEx discussed that facilities in commercial operation beyond the 15 months after the effective date must be compliant on the first day of commercial operation. The language should be clarified since this is an important detail.

It is unclear if the implementation plan compliance due date for facilities reaching COD after the effective date of PRC-028 is meant to be absolutely 15 months after the effective date of PRC-028. Given that IBRs in commercial operation on or before the effective date is previously prescribed (50% within 3 calendar years and 100% by 1/1/2030), IBRs entering CO after the effective date should just be 15 calendar months and not include "whichever is later."

Six years would be a sufficient amount of time to plan and budget for the procurement and installation of the DDR equipment barring any supply chain complications or any other delays. USV recognizes the FERC directive mandating completion by 1/1/2030, however, due to many of the IBR sites having strict language when dealing with manufacturer's warranty and having to rely on third parties, it may result in additional complications that could delay the installation and setting up of this highly specialized equipment. We recommend that the implementation period be changed to 6 years from the effective date of the standard as opposed to targeting the date of January 1, 2030.

AES CE believes that the new implementation plan language for PRC-028 around requiring compliance 15 calendar months after the effective date or the commercial operation date, whichever is later, needs to be revised. During the Webinar the SDT discussed that facilities in commercial operation beyond the 15 months after the effective date must be compliant on the first day of commercial operation. The language should be updated to clearly reflect this intention.

Texas RE recommends maintaining the previous verbiage of the implantation plan for the Compliance Date for PRC-028-1 Requirements R1 – R7: “Entities shall comply with Requirements R1 through R7 at 50% of **their generating plants/Facilities** within three calendar years of the effective date…” If it is changed to inverter-based resources, it is unclear how to comply with 50%. The description of inverter-based resource in Footnote 1 in PRC-028-1 appears to contradict the language of R1. The footnote description of IBR is at the collector level while Requirement R1 refers to the Point of Interconnection (POI). The implementation plan should be at the Point of Interconnection to be clear what is needed to comply with R1. Additionally, Texas RE recommends the header on page 3 say “Process for **Requesting** an Extension to Compliance Dates.” Instead of “Process for Seeking an Extension from Compliance Dates.”

WECC aggrees with the majority of the implementation plan but still has two concerns that were voiced in our prior comments.	

First: the use of the term "beyond control" is ambiguous. Who gets to determine what is "beyond control?" Second: It is unclear if a Regional Entity has the authority to grant a compliance waiver. Clarification is necessary.

5. Do you agree the modifications made in PRC-002-5 and new Standard PRC-028-1 are cost effective?

Donna Wood - Tri-State G and T Association, Inc. - 1

Answer	No
Document Name	
Comment	

PRC-028 will result in costs that were not previously budgeted for.   There will be a large cost to retrofit legacy equipment for monitoring and also costs for the new communications. You will also have to bring on new staff to monitor, track and maintain.

AEPC signed on to ACES comments: It is ACES' opinion that the proposed changes to PRC-002 are minimal and therefore should have little to no cost to implement. As for the proposed PRC-028-1, we agree with the approach taken by the SDT to create a new Standard to specifically address inverter-based resources; however, we disagree with making this new standard inclusive of all BES inverter-based resources regardless of risk to the BES. In the opinion of ACES, a blanket approach requiring every BES inverter-based resource to install SER, FR, and/or DDR capabilities is overly gratuitous. We believe that the industry's finite resources would best be spent by first ascertaining which inverter-based resources pose the biggest risk to the BES, and where disturbance monitoring and reporting would provide the most benefit to the BES, **before selectively** adding such capabilities. In summary, it is our recommendation that PRC-028-1 take a similar *risk-based approach as is done in PRC-002-5.*

Comment	
No. The standard requires IBR owners to have a robust compliance program implemented as well as event data collection process in place. However, this version of the standard removed the requirement for any IBR Unit to have SER, FR, or DDR data in an entire IBR plant. This will not help any event analysis process as it will not allow adequate analysis of an IBR facility's abnormal performance. At a minimum, fault codes should be available from every single IBR Unit within the facility. Lack of comprehensive data has significantly affected the ERO Enterprise's ability to conduct event analysis at many facilities over the past 7 years, as reported in numerous disturbance reports. The proposed standard would lead to inadequate data available at the inverter-level to do any useful event analysis and model validation, possibly leading to ongoing inconclusive root cause analyses. This would therefore not be cost effective for the industry. In addition, new IBRs being installed today and going forward will have all the SER, FR, and DDR data capabilities included in their inverters already, which means if the standard doesn't require this data set for these inverters/resources it could result in significant underutilization of the full capabilities of this equipment to ensure they operate reliably on the BPS.

AES CE believes this is not a cost effective approach to meet FERC Order 901. The requirements should be based on some study criteria similar to PRC-002 to identify specific generators that impacts reliability and therefore must invest this capital in order to ensure the reliability of the BES. AES CE recommends that the SDT leverage the expertise of Project Finance SMEs at the entities to understand the feasibility of implementing this new Standard, and the potential impacts to reliability that these additional costs could incur.

The modifications to the present version of PRC-028-1 are less costly than the previous version; however, PRC-028-1 overall is not cost-effective. PRC-002 methodology for selecting BES buses that require (SER) and (FR) Data would be more appropriate and cost-effective than the present method for PRC-028. Requiring the TO and RC to identify areas that are susceptible to disturbances or have a large concentration of IBRs would benefit from DME capabilities. This would target the investment in the areas that need it most. Alison Mackellar on behalf of Constellation Segments 5 and 6

Under the applicability of PRC-002, there is a process to identify the need to have FR, SER, and/or DDR capabilities. However, PRC-028 requires any GO/TO with BES inverter-based resources to have similar if not more stringent requirements for all BES inverter-based resources. For PRC-002, it is the responsibility of TOs and RCs to identify which BES elements are required to have this recording capability. Why should PRC-028, which is meant to be similar in purpose to PRC-002, be any different. We would like to understand the reliability benefit of including all BES IBR's rather than using a qualifying process like PRC-002 does with Attachment 1.

PRC-028-1 will result in costs that were not previously required. These costs are not simply for the design and implementation of the monitoring but also for new communications infrastructure for legacy locations or compliance related staff to monitor, track and maintain compliance where it was not required before. For those owners that stream PMU data this standard could add significant communications costs to upgrade older facilities.

These following two comments relate to possible greatly increased costs for benefits that are not necessarily effective:

A) requiring SER on breaker positions on the GSU, collector buses and feeders, shunt devices, and AC-DC/DC-AC converters seems excessive. This quantity of monitored elements could require multiple DDRs depending on location and wiring.

B) Typically, fault recording is put on either the high side or low side of the GSU, not both. Requiring both could require multiple DDRs depending on location and wiring.

We suggest that the SDT consider requiring the DME on new (future) IBR facilities rather than applying this requirement retroactively. Including this data collection at the inverter level (for some of the inverters at the IBR facility) may prove to be beneficial for analyzing reactions of IBR facilities to transmission system disturbances. Provisioning the facility to include this data collection is much easier to accomplish during the design and construction phase of the facility.

SPP has a concern that the drafting team didn't provide any viable evidence in reference to cost effectiveness. The implementation Plan mentions the various stages of implementing the requirements for PRC-028, however, there are no actual numbers to support the effort and/or determine if either standard address cost effectiveness or not. SPP recommends that the drafting team provides some type of cost analysis to support their efforts to determine if both standards address cost effectiveness.

6. Provide any additional comments for the standard drafting team to consider, if desired.

Rhonda Jones - Invenergy LLC - 5,6	
Answer	
Document Name	
Comment	

Invenergy thanks the drafting team for their work and the opportunity to provide comments.

Invenergy has concerns regarding R7.1. and the 20 calendar day data retention requirement for SER, FR, and DDR data. The Technical Rationale for PRC-028-1 states that, "With the state-of-the-art equipment, having the data retrievable for the 20 calendar days is realistic and doable." However, PRC-028-1 will apply to many existing inverter-based resources, some of which have been operational for decades and may possess legacy equipment incapable of storing data for such an extended period of time. Invenergy proposes the below modifications to R7.1.:

7.1. Data shall be retrievable for the period of 20 calendar days, inclusive of the day the data was recorded.

7.1.1. If the recording equipment is incapable of storing 20 calendar days of data due to storage constraints, then data shall be retrievable for the maximum allowable period supported by the storage capabilities of the recording equipment, but not less than 10 calendar days.

Leslie Hamby - Southern Indiana Gas and Electric Co. - 3,5,6 - RF	
Answer	
Document Name	
Comment	

Southern Indiana Gas and Electric Company d/b/a CenterPoint Energy Indiana South (SIGE) is providing the following additional comments:

Purpose Statement comments: SIGE does not support the use of Footnote 1 in the Purpose Statement. If the "inverter-based resource" definition/Footnote 1 referenced in the Purpose Statement is intended to be specific to PRC-028, then a Standard definition section should be included in PRC-028 and the "inverter-based resource" definition/Footnote 1 should be moved to the definition section (see PRC-005-6 for reference).

R1.2 comments: SIGE requests removal of "including collector feeder breakers" from R1.2 as the inclusion of collector feeder breakers has the potential to include non-BES elements.

Charles Yeung - Southwest Power Pool, Inc. (RTO) - 2 - MRO,WECC, Group Name SRC 2024	
Answer	
Document Name	
Comment	

The SRC submit four additional comments/requests:

1) Reinstate the language “at least one IBR unit” in the PRC-028 requirements.

2) Reinstate inverter-level requirements in PRC-028 and to all future IBR installations

3) Update the associated Technical Rationale with justification for not including past recommendations into PRC-028

4) Continuing concern from last comment period regarding DDR coverage

The SRC disagrees with the modifications made to remove the “at least one IBR Unit” language from the PRC-028 requirements.

Based on NERC’s Reliability Guideline entitled, *BPS-Connected Inverter-Based Resource Performance,* our understanding is that having IBR Unit level data is critical when investigating events. This recommendation was later reiterated in a 2nd NERC Reliability Guideline entitled, *Improvements to Interconnection Requirements for BPS-Connected Inverter-Based Resources*.Therefore, we see the removal of this requirement as problematic. We would like to see the “at least one IBR Unit” language added back in all applicable requirements, i.e., Parts 1.2, 1.3, 2.2. and 3.2.

The SRC requests inverter-level requirements be reinstated in PRC-028 and applied to all future IBR installations, at a minimum.

In September 2018, following unexpected performance of several large IBR plants during disturbances, NERC issued a Reliability Guideline entitled, *BPS-Connected Inverter-Based Resource Performance.*

{C}o This guideline contains a section (Chapter 6) dedicated to measurement data and performance monitoring. Within this section are “individual inverter level data” functional requirements.

{C}o The NERC guidance considers the need for inverter-level data to diagnose performance under certain types of events. For instance, the SRC understands partial tripping of plants, where only certain inverters persistently trip during events, to be a common issue.

In September 2019, NERC issued a second Reliability Guideline that again highlighted the need for inverter-level data, stating: “Data should be available from multiple sources to provide sufficient clarity as to any abnormal response or behavior within the plant. This includes plant control settings and static values, plant supervisory control and data acquisition data, sequence of events recording data, dynamic disturbance recorder data, and inverter fault codes and inverter-level dynamic recordings.”

At least one ISO/RTO has modified its Generator Interconnection Agreement (GIA) to require inverter-level data (see current version of MISO’s tariff

However, now that PRC-028 is diverging from prior NERC guidance and lowering the bar on monitoring requirements, the latest draft of PRC-028 appears to be inconsistent with NERC recommendations and reliability needs. Therefore, the SRC requests the SDT reinstate IBR Unit level requirements in PRC-028 to align with NERC Reliability Guideline recommendations.

Moreover, PRC-028 provides the foundation for monitoring performance that will be relied upon across NERC standards to validate models and identify performance issues.

To the extent PRC-028 standard does not establish an adequate foundation, other standards that rely on operational visibility are also likely to be weakened.

A mismatch between reliability needs and NERC standards will lead to fractured adoption of monitoring across the U.S. as it will require individual ISOs/RTOs and TOs to take independent action. This is already underway, given the lack of existing national standards, common in other countries.

Deferring requirements that mandate the monitoring of IBR performance may contribute to the ongoing trend of IBR performance issues.

Barriers to collecting inverter-level data for existing IBR plants should not prevent the development of inverter-level data requirements for future IBR plants needed for post-event analysis.

The PRC-028 drafting process has demonstrated challenges with retroactively applying inverter-level data requirements. Foregoing development of appropriate ‘forward-looking” standards that require inverter-level data for future IBR plants will only exacerbate this problem.

Update the Technical Rationale

The Technical Rationale should include the justification for not including inverter-level requirements as recommended by NERC Reliability Guidelines published in 2018 and 2019.

Continued concern over minimum DDR installation requirements

The SRC notes that in its previous comments, it requested clarification as to whether any or all or none of the DDRs required by PRC-028-1 Requirement R4 are required (or allowed) to be included in the minimum DDR coverage under PRC-002-5 Requirement R5 Part 5.2. The SDT’s response indicates that “PRC-002-5 does not apply to IBRs, so the DDR requirements in PRC-028 do not count toward PRC-002. No elements should be covered under both standards as this would set up a double jeopardy situation.” The SRC is concerned that as IBR penetration increases, PRC-002-5 Requirement R5 Part 5.2 may put the RC in the position of having to specify additional (and potentially unnecessary) DDR locations simply to satisfy the minimum coverage requirement, despite PRC-028-1 requiring a DDR at each main power transformer of every IBR (meaning that there will likely be enough DDR associated with IBRs to satisfy the minimum coverage requirement within the RC footprint). The SRC recommends that either the coverage requirement be eliminated, or that the coverage calculation be revised to include DDRs associated with IBRs.

Colin Chilcoat - Invenergy LLC - 5,6

Answer	
Document Name	

Comment

Invenergy thanks the drafting team for their work and the opportunity to provide comments.

Invenergy has concerns regarding R7.1. and the 20 calendar day data retention requirement for SER, FR, and DDR data. The Technical Rationale for PRC-028-1 states that, "With the state-of-the-art equipment, having the data retrievable for the 20 calendar days is realistic and doable." However, PRC-028-1 will apply to many existing inverter-based resources, some of which have been operational for decades and may possess legacy equipment incapable of storing data for such an extended period of time. Invenergy proposes the below modifications to R7.1.:

7.1. Data shall be retrievable for the period of 20 calendar days, inclusive of the day the data was recorded.

7.1.1. If the recording equipment is incapable of storing 20 calendar days of data due to storage constraints, then data shall be retrievable for the maximum allowable period supported by the storage capabilities of the recording equipment, but not less than 10 calendar days.

Comment

NextEra supports EEI's comments:

EEI offer the following additional Comments:

PRC-028-1 Comments:

Purpose Statement Comments: EEI does not support the addition of Footnote 1 to the Purpose Statement because it inappropriately changes the applicability of PRC-028, outside of the Applicability Section.

Applicability Section Comments: EEI does not support the Applicability section because it uses the uncapitalized version of IBR and could unintentionally broaden the scope and create confusion in expectations.

Requirement R1 Comments:

Subpart 1.1: EEI does not support footnote 2 because it identifies facility scope that is not identified in the Applicability Section and appears to go beyond what was allowed in the approved SAR.

Subpart 1.4: EEI does not support the addition of VSC HVDC equipment because it was not included in the industry approved definition of IBR or this SAR. While EEI is not opposed to including VSC-HVDC equipment to this Reliability Standard if that equipment is in fact creating reliability concerns, no technical justification has been provided to clarify why this is necessary. To address our concern, we ask that that the SAR be revised to include this equipment and submit a technical justification document, as required by the Rules of Procedure (see Standard Processes Manual, Appendix 3a).

Requirement R7 Comments and associated VSLs:

Subpart 7.1: EEI suggests aligning Requirement R7, Subpart 7.1 with PRC-002, Requirement R11, subpart 11.1. Making the data requirements different in the two standards may cause entities that own both synchronous generators and IBRs to inadvertently make compliance errors.

Subpart 7.2: This requirement seems to parallel Requirement R11, Subpart 11.2 yet the obligation for IBR owners to provide data has been reduced from 30 days to 15 days, while synchronous generator owners are afforded 30 days. EEI does not support this difference and believes these requirements should be harmonized.

VSL for R7: EEI suggests aligning the VSLs for Requirement R7 to what was provided for PRC-002, Requirement R11.

PRC-002-5 Comments:

Applicability Section comments: EEI does not support the Applicability section because it uses the uncapitalized version of IBR. The definition of Inverter Based Resource was approved by the industry during the last posting of that definition and therefore should be capitalized. Additionally, footnote 1 is unnecessary.

Footnote 2: EEI finds footnote 2 to be confusing and potentially in conflict with the Applicability Section. In the Applicability Section it states that IBRs are excluded from the scope of PRC-002 yet footnote 2 states "For the purposes of this standard, "directly connected" BES Elements are BES Elements connected at the same voltage level within the same physical location sharing a common ground grid with the BES bus identified under Attachment 1." We note that certain IBRs are BES Elements, but the Applicability Section stated inverter based resources (undefined in this standard) are not included. Yet footnote 2 seems to imply BES IBRs connected to a common bus at the same voltage level within the same physical location are to be included in PRC-002. Therefore, if this is the case, then certain IBRs are part of PRC-002. Please clarify what is intended by this footnote or delete it.

Comment

PRC-028-1

1. Section B: What is the purpose of removing the need for recording data at the inverter level? It seems like this data is important to record and monitor.

PRC-002-5

1. This document states *"Disturbance monitoring and reporting requirements for inverter-based resources are addressed in PRC-028."*, however, PRC-028-1 draft has removed the requirement for IBR monitoring/reporting.

A general comment: IEEE 2800 does a great job addressing IBRs and could be referenced when making these types of updates for IBRs.

Comment	

The standard specific definition for inverter-based resource found in PRC-028 footnote 1 should be placed into item #6 of the **"A. Introduction"** section, as can be seen was done for PRC-005-6 rather than being defined in the footnote.

Unless the power level of a collection system feeder breaker is > 75 MVA, the collection system feeder breaker specified in Section 1.2 of the proposed PRC-028 overreaches the BES definition for inverter-based resource.

Southern Company does not agree with the language in PRC-028, R8 requiring a Corrective Action Plan to be submitted to the **Regional Entity**. If at any time a Regional Entity desires to review a TO's or GO's Corrective Action Plans, they have the authority to request them. Simply requiring the Corrective Action Plans to be submitted to the Regional Entity with no requirement for the Regional Entity to do something with them is purely administrative and does nothing to improve the reliability of the Bulk Electric System. Further, the timely development and implementation of a Corrective Action Plan needed to repair equipment can be thoroughly examined during an audit engagement. This same reasoning applies to PRC-002, R12 and is also recommended to be removed.

Some provision in PRC-028, R7 is needed for an exception to the data delivery requirements for DME equipment that is being repaired as permitted by PRC-028, R8.

Comment	

Texas RE recommends including a timeframe for implementing the CAPs in both PRC-002-5 Requirement R12 and PRC-028-1 Requirement R8.

In PRC-002-5, Requirement 12 there seems to be an open-ended timeframe for implementing the corrective action plan. Texas RE suggests the following for R12 second bullet:

- Submit a Corrective Action Plan (CAP) and the specific implementation schedule to the Regional Entity within 90 calendar days and implement the CAP according to the timeline specified. The timeline for implementing the CAP shall be within 9 months of the discovery, unless specific reasons for not meeting the timeline is approved by the Regional Entity.

In PRC-028-1, Requirement 8 there seems to be an open-ended timeframe for implementing the corrective action plan. Texas RE suggests the following for R8 second bullet:

- Submit a Corrective Action Plan (CAP) and the specific implementation schedule to the Regional Entity within 90 calendar days and implement the CAP according to the timeline specified. The timeline for implementing the CAP shall be within 9 months of the discovery, unless specific reasons for not meeting the timeline is approved by the Regional Entity.

Synchronous Condensers are dynamic reactive power compensation devices that are becoming essential for stabilizing the grid with the rapid additions of IBRs. Disturbance data from these devices will be valuable when evaluating the BPS disturbances.

Texas RE suggests that the SDT clearly state that the SER data for circuit breakers associated with standalone synchronous condensers and synchronous condensers co-located at the IBR facility(ies) are included in the PRC-028-1 Requirement R1.

Texas RE recommends the following verbiage (in bold):

R1, 1.3 Shunt static or dynamic reactive device(s), **including any filter banks and synchronous condensers.**

Texas RE notes that the redline version does not match the clean version. Please verify that the Draft 3, "redline to last posted" document matches with the draft 3, "clean" version of PRC-028-1 document.

Comment	

The NAGF provides the following additional comments for consideration:

a. General Comments:

i. The NAGF does not agree with requiring that electronic files be provided only in a format that is established by an outside organization. While NAGF acknowledges that C37.111 is the format most used presently, there must still be an option to provide data in a format not controlled by an outside standard as dictated by NERC Rules of Procedure Section 302.6 "Completeness — Reliability Standards shall be complete and self-contained. The Reliability Standards shall not depend on external information to determine the required level of performance." Therefore, the NAGF recommends that the proposed PRC-002-5 sub-Requirement 11.4 and PRC-028-1 sub-Requirement 7.4 keep the option for providing data in CSV format.

b. PRC-028-1:

i. Requirement 1.1- Please explicitly clarify for offshore wind connected VSC-HVDC plants if the main power transformer includes only the inverter (onshore) transformer or it includes the offshore (rectifier) converter transformer. Note that, for a VSC-HVDC connected offshore wind, the rectifier side reactive power device status will have little impact on the onshore grid and bulk electric system reliability.

ii. Requirement 1.2:

1) the individual feeder buses are not considered BES elements per the NERC BES Definition Reference Document Volume 2, April 2014. It is unclear if the individual feeder-collector bus breakers, which connect to the collector bus, are considered BES. The NAGF requests clarification from the DT on this matter.

2) The NAGF requests clarification for recording of the collector system CB and protection system status for the offshore wind AC system

iii. Requirement 1.3:

1) The NAGF notes that the proposed narrative has the potential to apply to low voltage auxiliary equipment that is not considered BES. Recommend revising the narrative accordingly.

2) Is the synchronous condenser within the IBR plant also considered a part of "dynamic reactive power device(s)"? Note that in most IBR plant designs the synchronous condenser may not provide reactive power compensation; its purpose is to strengthen the grid at the IBR plant POI.

iv. The NAGF requests the DT to consider revising Requirement R1.1 – R1.3 language to clarify the rectifier side data monitoring requirements for VSC-HVDC connected offshore wind facilities.

v. Page 3, footnotes 1 and 2 – recommend moving the footnotes under the Introduction Section – Definitions Used in this Standard (similar to PRC-005-6).

vi. Requirement R7 – Recommend that the narrative be modified to include an exception for missing data that is associated with Corrective Action Plan activities.

vii. Requirement R8 – The NAGF does not see the value of submitting the CorrectiveA ction Plan to the Regional Entity and recommends deleting the associated bullet. This would also apply to PRC-002-5 Requirement R12.

Testing and demonstrating performance could be a challenge without further guidance on expectations.

· Many existing devices used for fault recording (SEL-351 for example) cannot meet the 2.0 second duration in R3.1.1. A duration of 1.0 second would better align with equipment capabilities. Perhaps the clause could be written that all new equipment should have the 2.0 second duration capability while existing equipment has requirements in-line with the capabilities of the equipment installed over the past few years.

Comment

This latest draft of PRC-028-1 continues to diverge further from the IEEE 2800-2022 standard, which is the de facto standard for IBR plants interconnecting with electric transmission systems. This PRC-028-1 standard and other NERC IBR-focused standards should be conforming to/matching the IEEE 2800 standard unless there is excessively strong and clear risk evidence that there is a need to go beyond the requirements in IEEE 2800. Any NERC IBR-focused standard that creates requirements that are less than those in IEEE 2800 is incorrect and faulty.

A lot of the SER/FR/DDR capabilities may not be available in existing IBR plants already connected and operating on the grid. Creating a NERC standard for both existing IBR plants and new/future IBR plants is a difficult task, but creating a standard that is the least common denominator of the capabilities of existing and new facilities would result in a watered-down standard that would not be effective, not be cost effective, and not be valuable in achieving the reliable interconnection and operation of these IBR plants going forward. New IBR plants will most likely be designed to the IEEE 2800 standard going forward, and all these SER/FR/DDR data capture and recording capabilities are therefore all available today and a new NERC standard for these IBRs should be made to utilize these data capabilities for reliable BPS operations. The SER/FR/DDR data sampling rates and data retention rates for IBR units at existing IBR plants would add cost and would require adequate timeframe to implement (as already identified in the draft Implementation Plan for PRC-028-1), but removing these requirements from new/future IBR plants to account for limitations of existing IBR resources seems to go in a negative direction and should have a technically backed justification if it is to remain in the standard as it will set back the industry by significantly underutilizing the full capabilities of new inverters being connected to the grid now and into the future.

Further highlighting the point above, the 2021 Odessa Disturbance report and the NERC IBR Reliability Guideline document both give a recommendation to include SER data for all IBR units (i.e. all inverters) and to include FR/DDR data on some IBR units on the collector busses at IBR plants. These documents point to this Project 2021-04 and recommends including these recommendations as requirements in the updated standard(s).

Related to the 2021 Odessa Disturbance report, in the updated PRC-028-1 Technical Rationale document, page 10 gives reference to the 2021 Odessa Disturbance report. However, in this lasted PRC-028-1 Technical Rational document update there is a redline removal of the report's recommendation of high-resolution oscillography data for individual IBR units. This redline removal should not have occurred as it removes a key recommendation from the 2021 Odessa report that is specifically important to Project 2021-04 and the new draft PRC-028-1 standard. This redline removal should be added back into the technical rational document and the IBR unit level SER/FR/DDR requirements should be added back into the draft PRC-028-1 standard.

In continuing the topic of IBR-related NERC Standards not adopting the IEEE 2800-2022 standard, the PRC-002 and the new PRC-028-1 standard both put into place requirements that adopt/require the use of the IEEE C37.111 COMTRADE standard and the IEEE C37.232 COMNAME standard. The language in the PRC-002 and PRC-028 Technical Rational documents highlight that requiring these IEEE industry standards helps the industry with the analysis and other work that is required from these standards. It is exactly that same reason why these updated NERC standards should adopt the IEEE 2800-2022 standard requirements; this would give the industry consistency and clarity on all technical requirements going forward for BPS-connected IBRs. This continued inconsistency regarding NERC's approach and opinion in this area of IEEE 2800 standard adoption should be addressed.

We have had no disturbances since the implementation of PRC-002 monitoring. Installation of additional monitoring equipment at all IBR sites will increase capital and operational costs for a very low likelihood event and is not a cost effective approach to protecting the grid. If there are specific regions with a higher risk (history) of disturbance, perhaps the PRC-028 applicability could be amended to include a geographic/regional filter

Regarding proposed EOP-002-5 R12 changes, the updated language does not address updates to the CAP and its timeline and could lead to a PNC if an entity is unable to meet the target dates originally provided to the Regional Entity.

Would recommend revising the language to one of the following options for the second bullet under R12:

"Submit a Corrective Action Plan (CAP) to the Regional Entity (RE) within 90 calendar days and then implement it in accordance with the most up to date CAP timeline submitted to the RE."

OR

"Submit a Corrective Action Plan (CAP) to the Regional Entity (RE) within 90 calendar days and then implement it according to CAP timeline or submit an updated CAP to the RE prior to the CAP timeline target."

Requirement 2.2 “shunt dynamic reactive device data” could be replaced with FACTS. MOD-025/-026 project uses FACTS to refer to these devices and capture Synchronous Condensers, STATCOMS, SVCS, etc. This DT should do the same, so the intent of which devices are intended are the same. Uniformity across standards and standard families is critical for ensuring compliance with the requirements and equipment.

General Comments:

(From NAGF) We do not agree with requiring that electronic files be provided only in a format that is established by an outside organization. Although C37.111 is the format most used currently, there must still be an option to provide data in a format not controlled by an outside standard as dictated by NERC Rules of Procedure Section 302.6 “Completeness — Reliability Standards shall be complete and self-contained. The Reliability Standards shall not depend on external information to determine the required level of performance.”

PRC-028-1:

i. (From NAGF) Requirement 1.2 - the individual collector buses are not considered BES elements per the NERC BES Definition Reference Document Volume 2, April 2014. Recommend revising the narrative accordingly.

ii. (From NAGF) Requirement 1.3 – the proposed narrative has the potential to apply to low voltage auxiliary equipment that is not considered BES. Recommend revising the narrative accordingly.

iii. (From NAGF) Requirement R7 – Recommend that the narrative be modified to include an exception for missing data that is associated with Corrective Action Plan activities.

iv. (From EEI) Should align Requirement R7, Subpart 7.1 with PRC-002, Requirement R11, subpart 11.1. Making the data requirements different in the two standards may cause entities that own both synchronous generators and IBRs to inadvertently make compliance errors.

v. (From EEI) Subpart 7.2: This requirement seems to parallel Requirement R11, Subpart 11.2 yet the obligation for IBR owners to provide data has been reduced from 30 days to 15 days, while synchronous generator owners are afforded 30 days. Requirements should be the same.

vi. (From EEI) VSL for R7: Align the VSLs for Requirement R7 to what was provided for PRC-002, Requirement R11.

vii. (From NAGF) Requirement R8 – Do not see the value of submitting the Corrective

Action Plan to the Regional Entity and recommends deleting the associated bullet.

PRC-002:

(From EEI) Footnote 2: In the Applicability Section it states that IBRs are excluded from the scope of PRC-002 yet footnote 2 states “For the purposes of this standard, “directly connected” BES Elements are BES Elements connected at the same voltage level within the same physical location sharing a common ground grid with the BES bus identified under Attachment 1.” We note that certain IBRs are BES Elements, but the Applicability Section stated inverter based resources (undefined in this standard) are not included. Yet footnote 2 seems to imply BES IBRs connected to a common bus at the

same voltage level within the same physical location are to be included in PRC-002. Therefore, if this is the case, then certain IBRs are part of PRC-002. Please clarify what is intended by this footnote or delete it.

Comment
1. Requirement R7 as drafted seems to imply that in case a failure to record data that is discovered while responding to a data request from an applicable entity, that would constitute a violation of R7. BC Hydro recommends that R7 be revised to clarify that a recording equipment failure would not constitute a compliance violation to R7. 2. The PRC-028-1 Technical Rationale states on page 13 (Rationale for Requirement R7 section) that, unless an extension is granted, “data has to be provided to the requestor within 20 calendar days after a request”. This appears to be in conflict with R7 Part 7.2, which states that “Data subject to Part 7.1 shall be provided within 15 calendar days of a request”. Please clarify and revise accordingly. 3. The VSL Table for PRC-028-1 R7 does not seem to set a severity level in case an extension is granted per R7 Part 7.2., e.g. a delay in providing data per the extended deadline does not factor in. Specifically, if an entity were granted an extension to 30 calendar days and provided the required data any number of days past Day 30 could not be assessed a severity level.

Comment
We appreciate some significant improvements in the draft Standard in response to previous comments, particularly removing the requirement for Sequence of Event Recording (SER) and Fault Recording (FR) at individual Inverter-Based Resource (IBR) units, and increasing the plant size threshold for PRC-028 compliance from 20 MVA to Bulk Electric System (BES) resources, which are generally 75 MVA and greater. These improvements, which are noted at the end of our comments, are important and should be retained in the final Standard.

However, concerns expressed by Leeward Renewables in the most recent comment period, Pine Gate Renewables in the initial comment period, and others have not been fully addressed. These concerns include the cost and burden of 1. Retroactively applying the standard to existing plants and 2. Applying the requirements to smaller plants.{C}[MG1]{C}

We believe the costs and benefits of the proposed standard can be better balanced by 1. Only applying the data collection requirements to plants that sign an interconnection agreement after the effective date of the standard, and 2. Only requiring data collection at IBR generating plants larger than 500 MVA. These changes would greatly reduce the compliance cost and burden while optimizing reliability benefits, as explained below. These changes are also necessary to reduce the disparity between the strict requirements on IBRs in PRC-028 relative to the requirements on synchronous generators in PRC-002, which could result in undue discrimination against IBRs.

1. The Standard's requirements should only apply prospectively, not retroactively to existing plants

Applying the PRC-028 requirements retroactively to existing generators, as the current draft proposes, greatly exacerbates the cost and burden on generators with minimal benefit. Applying PRC-028 prospectively and not retroactively would avoid the highly costly retrofit of existing facilities, costs that in most cases cannot be recovered by plant owners because existing IBR generators typically sell their output at a fixed price under a long-term power purchase agreement. As noted below, PRC-029 and PRC-030, as well as other modeling and validation Standards revisions that are underway, apply to both existing and new resources. As a result, any concerns about the reliability performance of existing resources will be addressed through those Standards, and thus need not be addressed with PRC-030.

In the initial draft, the requirement to install SER at IBR units in part 1.2 of R1 had an exemption that "IBR units installed prior to the effective date of this standard and are not capable of recording this data are excluded," but that was removed. In the current draft, all requirements apply to all existing and new IBR resources. The retroactive requirement to install SER at IBR units may be particularly challenging in cases in which the OEM that manufactured the inverter is no longer in business, as the records produced by some inverter models are proprietary and require OEM intervention to provide in readable format to the generator owner.

The cost and implementation burden for retrofits is typically much higher than if the data collection equipment were planned and installed as part of initial plant construction. For example, in many cases new data communication wires may have to be run across existing wires, suitable locations must be found to add data collection, storage, and transmission equipment and deliver power to that equipment, and other changes that would be far less costly if they were planned during initial plant design. Adding this equipment also adds ongoing operations and maintenance and compliance costs for that equipment.

Retroactive requirements also impose a much greater financial burden on the generator as those costs cannot typically be recovered once a power purchase agreement has been signed. These unexpected and unrecoverable costs are far more concerning to lenders and other generation project financiers as they were not accounted for during the project's financing. As a result, retroactive requirements set a bad precedent by introducing regulatory uncertainty that makes future generation investment more uncertain and risky, and likely more costly by forcing financiers to charge higher risk premiums.

2. The Standard should only apply to large generators[MG2]

Only applying the requirements to larger IBR plants will greatly reduce the total cost and burden of compliance. The large fixed costs associated with installing and operating the required data collection, storage, and transmission equipment make up a larger share of the total cost of smaller plants. Only applying PRC-028 to larger plants will also make it more comparable to the PRC-002 companion standard for synchronous generators, avoiding undue discrimination against IBRs. As noted below, PRC-029 and PRC-030, as well as other modeling and validation Standards revisions that are underway, would apply to small IBR resources under NERC's IBR registration proposal. As a result, any concerns about the reliability performance of smaller IBR resources will be addressed through those Standards, and thus need not be addressed with PRC-030.

To make the cost of PRC-028 more reasonable while preserving the value of the proposed data collection, as well as avoiding undue discrimination against IBRs relative to synchronous generators, we suggest that data collection in PRC-028 only be required at plants that are 500 MVA and greater. This is the plant size threshold at which synchronous generator dynamic disturbance data collection is required in the PRC-002 standard. If the TO or RC/PC can compellingly demonstrate that smaller new plants should be required to comply with PRC-028's data collection requirements due to local reliability concerns, such as weak grid issues or high penetrations of IBRs in a local area, then that should be allowed. That would avoid an unnecessary cost burden for many smaller plants.

IBR wind, solar, and storage plants are highly modular, so larger IBR plants typically contain the same equipment as smaller plants, just in a larger aggregation (*e.g.,* more collector feeders). Because larger IBR plants are typically just larger aggregations of the equipment in smaller plants, it should be possible to infer the detailed behavior of smaller plants during a disturbance based on the performance of larger plants that are nearby and use similar equipment.

Other Standards and FERC Orders address the reliability concerns addressed by PRC-028, particularly for existing or small IBRs

Regarding potential reliability benefits of the proposed standard, we agree that ride-through issues at some IBRs have presented a legitimate reliability concern. However, the ride-through concerns PRC-028 is primarily attempting to understand have already been addressed by Federal Energy Regulatory Commission (FERC) Order 2023, the draft PRC-029 and PRC-030 Standards that are currently out for comment and balloting, as well as ongoing Standards revisions to require IBR plant modeling and validation of those models. In particular, reliability concerns about smaller and existing plants are being addressed by these Standards, and thus need not be addressed through PRC-030.

The draft PRC-029 Standard requires all existing and new generators to meet the standard, though existing generators can file for an equipment limitation exemption. Obtaining an exemption requires the owner of the existing generator to document and communicate to the Planning Coordinator "**6.1.2.** Which aspects of voltage ride-through requirements that the IBR would be unable to meet" and "**6.1.3** Identify the specific piece(s) of equipment causing the limitation," so it will be known which existing plants are unable to ride through and why. PRC-030 provides an even more open-ended tool for identifying and addressing unexpected losses of IBR generation, including from both new and existing generators.

In addition, the recent adoption of FERC Order 2023 directly addresses many of the concerns PRC-28 is attempting to address, as it imposes mandatory requirements to fully ride-through grid disturbances and to accurately validate models of plant performance at the sub-second transient timescale. Prior to the adoption of Order 2023 and the development of other NERC Standards, the proposed requirements of PRC-028 may have provided a significant reliability benefit by improving understanding of the ride-through performance of IBRs, and thus helping to identify solutions to any concerns. However, now that FERC Order 2023 and the other NERC Standards have solved many of those concerns by requiring ride-through performance and accurate modeling of sub-second plant performance, it is not clear what reliability benefit PRC-028 might provide.

To the extent the value of PRC-028 was to gather information to help craft improved ride-through requirements through PRC-029, PRC-030, and FERC Order 2023, the window for that opportunity is closing this year, or in the case of FERC Order 2023, has already closed. Data collection equipment installed by the year 2030 pursuant to PRC-028 will not help with designing those standards.

Improvements since the previous draft of PRC-028

As noted above, we appreciate some significant improvements in the draft Standard in response to previous comments. These improvements are important and should be retained in the final Standard:

-Sequence of Event Recording and Fault Recording at individual IBR units is no longer required

-Increasing the plant size threshold for PRC-028 compliance from 20 MVA to BES resources, which are generally 75 MVA and greater

However, concerns about the cost and burden of retroactive application and the application to smaller plants remain, as noted above. Even with the above improvements, the cost and burden of compliance is still significant.

The drafting team even noted the burden at pages 125-126 in the Consideration of Comments document for the initial comment period by saying "The Reliability Standard PRC-028-1 is expected to have a wide-ranging impact on Entities as many existing Facilities would be required to have disturbance monitoring equipment. Considering time needed to procure equipment, complete design, schedule outages, and install equipment, technical or supply chain constraints may prevent Entities from being fully compliant in a timeframe stated in the Implementation Plan. Requirement R9 allows Entities of an applicable Facility in commercial operation before the effective date of Reliability Standard PRC-028-1 that is not able to install disturbance monitoring equipment per Requirements R1 through R7 to develop, maintain, and implement a Corrective Action Plan."

There are also significant concerns about the disparity between the strict requirements on IBRs in PRC-028 relative to the requirements on synchronous generators in PRC-002, which could result in undue discrimination against IBRs. For example, R3 in PRC-028 requires IBRs to have FR for 2 seconds (120 cycles) following a disturbance, versus a requirement in PRC-002 for synchronous generators to only record for 30 cycles following a disturbance. IBR behavior is not inherently different enough to justify this difference, and the duration of disturbances faced by IBRs and synchronous generators are identical. There are technical hurdles and cost burdens associated with longer event reports, as they can start to fill up the device working memories and can inadvertently erase older records as those fill up. This is especially challenging when retroactively applying this requirement to sites with legacy data acquisition and storage. Similar concerns are caused by the requirement in PRC-028 R5 for IBRs to have dynamic disturbance recording at a rate of 60 times per second, versus 30 times per second for non-IBRs in PRC-002. As a final example, the synchronization requirement in R6 in PRC-028 is 1 millisecond, versus 2 milliseconds in PRC-002.

Given that there are finite resources for complying with all NERC requirements, we are concerned that PRC-028 as proposed could actually undermine reliability by distracting from more pressing reliability needs. We believe the revisions we have proposed to exempt existing and smaller plants and better align the requirements with those imposed on synchronous generators in PRC-002 will result in a Standard that better balances the cost of complying with the Standard with its reliability benefit.

Comment

AZPS supports the following comments that were submitted by EEI on behalf of its members regarding PRC-028 Requirement 7:

Subpart 7.1: EEI suggests aligning Requirement R7, Subpart 7.1 with PRC-002, Requirement R11, subpart 11.1. Making the data requirements different in the two standards may cause entities that own both synchronous generators and IBRs to inadvertently make compliance errors.

Subpart 7.2: This requirement seems to parallel Requirement R11, Subpart 11.2 yet the obligation for IBR owners to provide data has been reduced from 30 days to 15 days, while synchronous generator owners are afforded 30 days. EEI does not support this difference and believes these requirements should be harmonized.

AZPS requested that 30 days be used for both synchronous generators and IBRS.

VSL for R7: EEI suggests aligning the VSLs for Requirement R7 to what was provided for PRC-002, Requirement R11.

AZPS supports the following comments that were submitted by EEI on behalf of their members in regards to PRC-002:

Applicability Section comments: EEI does not support the Applicability section because it uses the uncapitalized version of IBR. The definition of Inverter Based Resource was approved by the industry during the last posting of that definition and therefore should be capitalized. Additionally, footnote 1 is unnecessary.

Footnote 2: EEI finds footnote 2 to be confusing and potentially in conflict with the Applicability Section. In the Applicability Section it states that IBRs are excluded from the scope of PRC-002 yet footnote 2 states “For the purposes of this standard, “directly connected” BES Elements are BES Elements connected at the same voltage level within the same physical location sharing a common ground grid with the BES bus identified under Attachment 1.” We note that certain IBRs are BES Elements, but the Applicability Section stated inverter based resources (undefined in this standard) are not included. Yet footnote 2 seems to imply BES IBRs connected to a common bus at the same voltage level within the same physical location are to be included in PRC-002. Therefore, if this is the case, then certain IBRs are part of PRC-002. Please clarify what is intended by this footnote or delete it.

Response

Richard Jackson - U.S. Bureau of Reclamation - 1

Answer	
Document Name	

Comment

Reclamation does not agree with the modifications to the wording of BES Elements in R6 and R7 in the “Violation Severity Levels” section. ‘Element’ is sufficiently defined in the NERC Glossary of terms and ‘BES Element’ encompasses the required equipment (elements) for Disturbance Monitoring. Reclamation recommends keeping the original wording “for all applicable BES Elements”.

Reclamation concurs that all IBR resources should have and maintain their own separate standards.

Comment

FE supports EEI's comments which offers the following suggestions:

PRC-028-1 Comments:

Purpose Statement Comments: EEI does not support the addition of Footnote 1 to the Purpose Statement because it inappropriately changes the applicability of PRC-028, outside of the Applicability Section.

Applicability Section Comments: EEI does not support the Applicability section because it uses the uncapitalized version of IBR and could unintentionally broaden the scope and create confusion in expectations.

Requirement R1 Comments:

Subpart 1.1: EEI does not support footnote 2 because it identifies facility scope that is not identified in the Applicability Section and appears to go beyond what was allowed in the approved SAR.

Subpart 1.4: EEI does not support the addition of VSC HVDC equipment because it was not included in the industry approved definition of IBR or this SAR. While EEI is not opposed to including VSC-HVDC equipment to this Reliability Standard if that equipment is in fact creating reliability concerns, no technical justification has been provided to clarify why this is necessary. To address our concern, we ask that that the SAR be revised to include this equipment and submit a technical justification document, as required by the Rules of Procedure (see Standard Processes Manual, Appendix 3a).

Requirement R7 Comments and associated VSLs:

Subpart 7.1: EEI suggests aligning Requirement R7, Subpart 7.1 with PRC-002, Requirement R11, subpart 11.1. Making the data requirements different in the two standards may cause entities that own both synchronous generators and IBRs to inadvertently make compliance errors.

Subpart 7.2: This requirement seems to parallel Requirement R11, Subpart 11.2 yet the obligation for IBR owners to provide data has been reduced from 30 days to 15 days, while synchronous generator owners are afforded 30 days. EEI does not support this difference and believes these requirements should be harmonized.

VSL for R7: EEI suggests aligning the VSLs for Requirement R7 to what was provided for PRC-002, Requirement R11.

PRC-002-5 Comments:
Applicability Section comments: EEI does not support the Applicability section because it uses the uncapitalized version of IBR. The definition of Inverter Based Resource was approved by the industry during the last posting of that definition and therefore should be capitalized. Additionally, footnote 1 is unnecessary.
Footnote 2: EEI finds footnote 2 to be confusing and potentially in conflict with the Applicability Section. In the Applicability Section it states that IBRs are excluded from the scope of PRC-002 yet footnote 2 states "For the purposes of this standard, "directly connected" BES Elements are BES Elements connected at the same voltage level within the same physical location sharing a common ground grid with the BES bus identified under Attachment 1." We note that certain IBRs are BES Elements, but the Applicability Section stated inverter based resources (undefined in this standard) are not included. Yet footnote 2 seems to imply BES IBRs connected to a common bus at the same voltage level within the same physical location are to be included in PRC-002. Therefore, if this is the case, then certain IBRs are part of PRC-002. Please clarify what is intended by this footnote or delete it.

Comment	
AEP applauds the efforts of the standards drafting team for their continued work on this project. We believe that the newest drafts of both standards are greatly improved as compared to their predecessors. AEP is concerned however by recent revisions to PRC-028 R7.2, where all data requested in R7 must be provided within 15 days, rather than the 30 days allowed in the previous draft. In some cases, it will be very difficult to obtain, quality check, and	

provide this data within a 15-day window. Indeed, extensions might even be necessary in these cases. AEP seeks clarity from the standards drafting team regarding the justification for this, as the current draft of the Technical Rationale document provides no insight. During the webinar on 6/4/2024, the question was asked if a synchronous condenser is to be considered a dynamic reactive device per this standard. AEP would agree with the SDT that a synchronous condenser at an IBR facility should be considered a dynamic reactive device and requiring the desired monitoring. However, AEP would not agree to requiring monitoring "all" synchronous condensers in the transmission system under this SDT effort, and requests this be made clear in the Technical Rationale document. Please note that ERCOT already requires PMU monitoring at new FACTS devices and new synchronous condensers connected to 100kV and above.

There were 61 sets of responses, including comments from approximately 144 different people from approximately 92 companies representing 10 of the Industry Segments as shown in the table on the following pages.

All comments submitted can be reviewed in their original format on the project page.

If you feel that your comment has been overlooked, let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, contact Vice President of Engineering and Standards, Soo Jin Kim (via email) or at (404) 446-9742.

Questions

1. Do you agree with the modification in “Applicability, Section 4.2. Facilities” in PRC-028-1 to remove “Non-BES Inverter Based Resources …”?

2. Do you agree with removing “Inverter Based Resources” and “IBR Unit” under Term(s) for Reliability Standards PRC-002-5 and PRC-028-1?

3. Do you agree with the standard drafting team removing Requirement R9 in Reliability Standard PRC-028-1 and adding it to the Implementation Plan since it is more like a process, not a Requirement?

4. Do you agree with the Implementation Plan for revised PRC-002-5 and new Standard PRC-028-1?

5. Do you agree the modifications made in PRC-002-5 and new Standard PRC-028-1 are cost effective?

6. Provide any additional comments for the standard drafting team to consider, if desired.

1. Do you agree with the modification in "Applicability, Section 4.2. Facilities" in PRC-028-1 to remove "Non-BES Inverter Based Resources …"?

Robert Follini - Avista - Avista Corporation - 3	
Answer	No
Document Name	
Comment	
Industry comments show that the exact definition of Inverter Based Resource should be used, not the uncapitalized version that is currently in the PRC-028 draft, which is not bounded by the official definition. The footnote in the proposed standard is also an expansion of the NERC approved definition.

FE supports EEI Comments which state:

EEI does not support the modifications to the Applicability Section. The definition for Inverter Based Resource (IBR) was approved by industry in April under Project 2020-06. We also do not agree with inserting the uncapitalized version of IBR into this section because it is unbounded and insufficient to identify the Facilities applicable to this Standard, as required in the Rules of Procedure (Appendix 3a, Standard Processes Manual). Moreover, the footnote included in the Purpose statement has the effect of expanding the meaning of the recently approved definition of IBR outside of the Applicability Section of this Standard. EEI notes that the Standards Processes Manual states that the "Applicability: Identifies the specific Functional Entities and Facilities to which the Reliability Standard applies." and "Purpose: The reliability outcome achieved through compliance with the Requirements of the Reliability Standard." The Purpose statement is not intended to define or expand which facilities are to be applicable to a NERC Reliability Standard. To address this issue the Applicability Section of PRC-028 should be changed back to the capitalized version of Inverter Based Resources.

We also note that Voltage Source Converters – High-voltage Direct Current (VSC-HVDC) were included in Requirement R1, subpart 1.4 but not specifically identified in the Applicability Section of PRC-028 or the approved SAR. EEI further notes that this project was approved to address issues surrounding the changing resource mix and the increased penetration of IBRs. If VSC-HVDC systems are subject to the same risks and concerns as IBRs, then the SAR should be modified and resubmitted with a technical justification clarifying why those resources need to be included in this Reliability Standard, in alignment with the Standard Processes Manual (Appendix 3a). While there is some information contained in the Technical Rationale, EEI does not believe this is sufficient to allow these resources to be added to this Standard.

No. Non-BES IBRs should be applicable to this standard, as it aligns with the FERC order activities and the on-going NERC Registration efforts to incorporate the non-registered BPS-connected IBRs that are owned/operated by the newly proposed Category 2 GO and GOP entities. Exclusion of these BPS-connected IBRs would significantly limit the ability to ensure that all BPS-connected IBRs have adequate data for performance evaluation/analysis during BPS/BES disturbances and data for BPS-connected IBR model validation.

USV agrees with comments proposed by NPCC. The purpose of the project is to create a clear understanding of Non-BES and BES inverter-based resources and address gaps that exist in the current standards. With the proposed language, we foresee a lot of interpretation when it comes to inverter-based resources and note inconsistency between the three PRC standards. Suggest coordination between the three PRC standards that are currently open and progressively work towards the same or similar goal.

It is imperative that the standard drafting teams for this project as well as the 2020-02 (PRC-024 and PRC-029) and 2023-02 (PRC-030 vs PRC-004) assure a coherent way of addressing the inclusion and exclusion of IBRs in current and upcoming standards. Furthermore, this modification no longer addresses the purpose or goal of the IRPTF SAR as approved by the Standards Committee: "This SAR proposes to revise PRC-002-2 or create a new standard to address gaps within the existing standard. The goal is to ensure adequate data is available and periodically assessed to facilitate the analysis of BES disturbances, **including in areas of the Bulk Power System (BPS) that may**	

not be covered by the existing requirements. Nor do these modifications address the recommendations of the IRPTF in the IRPTF Review of NERC Reliability Standards White Paper where "The IRPTF recommends **that a SAR(s) be developed** to address each of the issues identified. IRPTF recommends that this be made a priority by the NERC Standards Committee, **due to the continued growth of BPS-connected inverter-based resources**".

The ISO/RTO Council (IRC) Standards Review Committee (SRC) is concerned with the removal of non-BES inverter-based resources (IBRs) from Applicability, Section 4.2, particularly if non-BES IBRs will need to be added later. Although NERC has authority over the BPS, to the extent proposed PRC-028, Section 4.2 explicitly applies to BES IBRs only, then PRC-028 would not apply to BPS resources (i.e. registered non-BES IBRs). Several other NERC standards are relying on PRC-028 for monitoring. If PRC-028 doesn't require IBR monitoring as a foundational element, then the other IBR performance standards relying on PRC-028 will likely be less effective too. Therefore, the Applicability of PRC-028 should be expanded to apply to both BES IBRs and non-BES IBRs. Ultimately, adequate data must be available from IBRs to evaluate IBR ride-through performance during BES Disturbances and to provide data for IBR model validation.

AEPC signed on to ACES comments:	

ACES is very appreciative of the effort put forth by the SDT to listen to industry comments and revise PRC-028-1 accordingly. It is the opinion of ACES that removing “Non-BES Inverter Based Resources” is the correct approach for this draft; however, we do not completely agree with language chosen by the SDT for Section 4.2. We recommend the following language:

4.2.1 For the purposes of this standard, “inverter-based resources” refers to a collection of 1 (one) or more of any of the following facility types that operate as a single plant/resource:

4.2 Facilities: Elements associated with inverter-based resources meeting the criteria of Inclusion I4 of the BES definition.

4.2.1.1 Individual solar photovoltaic (PV)

4.2.1.2 Type 3 and Type 4 wind turbines

4.2.1.2 In the case of offshore wind plants connecting via a dedicated voltage source converter high voltage direct current (VSC HVDC) line, the inverter-based resource includes the VSC HVDC line.

4.2.1.3 Battery energy storage system (BESS), or

4.2.1.4 Fuel cells

Answer	Yes
Document Name	

Comment

SMUD agrees with the SDT's decision to remove "Non-BES Inverter Based Resources" from the applicable facilities in this new version of PRC-028-1; however, we are concerned that this may be a short-term fix since FERC Order 901 directs NERC to "submit, by November 4, 2024, new or modified Reliability Standards that require disturbance monitoring data sharing and post-event performance validation for **registered IBRs** [emphasis added]."

The term "registered IBRs" in FERC Order 901 includes BES IBRs registered with NERC and IBRs which will be registered according to FERC's IBR Registration Order. Once FERC approves the registration criteria proposed in NERC's rules of procedure changes submitted to FERC on March 19, 2024, the SDT will be required to modify PRC-028-1 again to include the non-BES IBRs that will be registered. This future change that would be required to PRC-028-1 is inefficient.

Comment	
EEI does not support the modifications to the Applicability Section. The definition for Inverter Based Resource (IBR) was approved by industry in April under Project 2020-06. We also do not agree with inserting the uncapitalized version of IBR into this section because it is unbounded and insufficient to identify the Facilities applicable to this Standard, as required in the Rules of Procedure (Appendix 3a, Standard Processes Manual). Moreover, the footnote included in the Purpose statement has the effect of expanding the meaning of the recently approved definition of IBR outside of the Applicability Section of this Standard. EEI notes that the Standards Processes Manual states that the "Applicability: Identifies the specific Functional Entities and Facilities to which the Reliability Standard applies." and "Purpose: The reliability outcome achieved through compliance with the Requirements of the Reliability Standard." The Purpose statement is not intended to define	

or expand which facilities are to be applicable to a NERC Reliability Standard. To address this issue the Applicability Section of PRC-028 should be changed back to the capitalized version of Inverter Based Resources. We also note that Voltage Source Converters – High-voltage Direct Current (VSC-HVDC) were included in Requirement R1, subpart 1.4 but not specifically identified in the Applicability Section of PRC-028 or the approved SAR. EEI further notes that this project was approved to address issues surrounding the changing resource mix and the increased penetration of IBRs. If VSC-HVDC systems are subject to the same risks and concerns as IBRs, then the SAR should be modified and resubmitted with a technical justification clarifying why those resources need to be included in this Reliability Standard, in alignment with the Standard Processes Manual (Appendix 3a). While there is some information contained in the Technical Rationale, EEI does not believe this is sufficient to allow these resources to be added to this Standard.

ACES is very appreciative of the effort put forth by the SDT to listen to industry comments and revise PRC-028-1 accordingly. It is the opinion of ACES that removing "Non-BES Inverter Based Resources" is the correct approach for this draft; however, we do not completely agree with language chosen by the SDT for Section 4.2. We recommend the following language: 4.2 Facilities: Elements associated with inverter-based resources meeting the criteria of Inclusion I4 of the BES definition. 4.2.1 For the purposes of this standard, "inverter-based resources" refers to a collection of 1 (one) or more of any of the following facility types that operate as a single plant/resource:	

4.2.1.1 Individual solar photovoltaic (PV) 4.2.1.2 Type 3 and Type 4 wind turbines 4.2.1.2 In the case of offshore wind plants connecting via a dedicated voltage source converter high voltage direct current (VSC HVDC) line, the inverter-based resource includes the VSC HVDC line. 4.2.1.3 Battery energy storage system (BESS), or 4.2.1.4 Fuel cells

Southern Indiana Gas and Electric Company d/b/a CenterPoint Energy Indiana South (SIGE) agrees with the removal of Non-BES Inverter Based Resources. SIGE is concerned that the intention behind removing Non-BES Inverter Based Resources is only a short-term allowance until the Rules of Procedure changes are approved. While SIGE recognizes the challenges the Drafting Teams are facing; the parallel development of IBR-focused Standards and IBR definitions/rules of procedure may result in 'temporary' Standards that may not be fully aligned across their Applicability and Facilities sections. Meaning, it seems the current open drafts are being written as stop gaps until the IBR definitions and Rules of Procedure are approved rather than pausing to focus on the definitions and Rules of Procedure first then revise the Standards.

Texas RE is concerned removing "Non-BES Inverter Based Resources" from the Applicability Section 4.2 will eliminate all solar facilities with less than 75 MW of aggregated generation capacity from complying with this standard. In addition, storage facilities with less than 75 MW aggregated generation capacity would be excluded from this standard. This data is needed to have adequate data available from inverter-based resources to evaluate ride-through performance during BES Disturbances. Texas RE recommends the following verbiage (in bold):

4.2. Facilities

4.2.1 BES inverter-based resources

4.2.2 Non-BES inverter-based resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

This change would also facilitate the new GADS reporting for Solar facilities, which requires generating plants with a Plant Total Installed Capacity of 20 MW or greater per plant to submit the data.

The SRC disagrees with the removal of these terms from the standards. One of the benefits of developing formal definitions for IBR and IBR Unit in Project 2020-06 is that these terms, once finalized, will provide a consistent understanding of what constitutes an IBR and an IBR Unit for purposes of NERC Reliability Standards. However, developing IBR-focused standards that explicitly decline to use these standardized definitions undermines the benefits of developing Glossary-level definitions, and presents a risk that different standards will use different definitions of what constitutes an IBR, resulting in an inconsistent, difficult-to-comply-with patchwork of regulations rather than a consistent suite of IBR-related Reliability Standards. The draft 2 postings effectively explained the overlap with the work being done in Project 2020-06	

so that entities could evaluate PRC-002 and PRC-028 in light of those definitions. The SRC recommends that the drafting team revise PRC-002 and PRC-028 to once again rely on the Project 2020-06 definitions of IBR and IBR Unit to help ensure consistency across IBR-related standards on the front end and avoid the need to make subsequent revisions to these standards once Project 2020-06 is complete. The SRC believes that a decision not to use the Project 2020-06 definitions should be supported by a compelling justification.

The voters in Project 2020-06, Inverter-based Resource Glossary Terms draft #2, approved the definition of IBR on April 8, 2024, which is different than the definition proposed in Footnote 1 of PRC-028-1. Using the term “inverter-based resources” and defining it with Footnote 1 is inefficient and would create two definitions for the same resource. The SDT of PRC-028-1 should coordinate with the SDT of Project 2020-06 and NERC staff to ensure the definition of IBR and new PRC-028-1 are submitted to FERC simultaneously thereby eliminating another ballot for PRC-028-1 to add the NERC Glossary Term for IBR into the standard.

No. Removing these two Terms is not aligned with the other on-going IBR standard related work throughout NERC. By removing these two Terms, it appears to have forced the creation of a new definition of “inverter-based resources” under Footnote 1 of this draft of PRC-028-1. It seems counter productive to have a unique definition of IBRs and IBR units under each different NERC standard. Having all standards aligned to the same core definitions/terms for IBRs will make all this standard development work, execution of the standards, and compliance activities more efficient for all entities involved.

BC Hydro appreciates the drafting team's efforts and opportunity to comment, and offers the following. BC Hydro prefers that PRC-028-1 rely on an IBR definition, we understand the rationale for moving ahead while the definitions being drafted by the Project 2020-06 drafting team are being finalized.	

BC Hydro requests that the drafting team clarify that the Footnote 1 is not intended to expand on the applicability scope of PRC-028-1, which does not include reactive power devices providing reactive support, such as STATCOMs as an example. BC Hydro suggests that the Footnote 1 be (a) referenced within the Section 4.2 Facilities of PRC-028-1, and (b) revised to include a provision that IBRs are devices capable of exporting Real Power as follows. Suggested revision to Footnote 1 – For the purpose of this standard, “inverter-based resources” refers to a collection of individual solar photovoltaic (PV), Type 3 and Type 4 wind turbines, battery energy storage system (BESS), or fuel cells that operate as a single plant/resource and can export Real Power from a primary energy source or energy storage system via a power electronics interface (such as an inverter or converter), and that is/are operated as a single resource connected to the electric power system at a common point of connection.

Until industry and NERC DTs pass definitions, they should not be used in other standards with a capital letter. If DT needs to use lower case inverter based resource they must stipulate which ones they mean, which this draft has a footnote doing.

Tri-State agrees with the removal of unapproved defined terms in the standard. However, if the intention is that the definitions will be added at a later date when they are approved then the SDT should not include the footnote and wait until the definitions are approved through ballot. It seems like we are putting the "cart before the horse" by not having the IBR definitions approved first and working on the related standards just to meet a deadline. It will make it a duplicate process to have to come back to PRC-028 and comment/ballot again when the definitions are added.

Pamela Hunter - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - SERC, Group Name Southern Company	
Answer	No
Document Name	
Comment	
Southern Company agrees to removing R9. However, Southern Company **does not agree** to requiring RE approval of an extension plan. Some criteria should be provided in the implementation plan which will permit extension in cases where the procurement and/or installation of designated additional DME is beyond the control of the entity required to install the DME.

Response	
Thanks for your comment. The extension of compliance date would be beyond timeline allowed by FERC directive. Hence, some oversight by compliance enforcement agency is necessary. Note that the "regional entity" is replaced with "compliance enforcement agency" along with some other clarifying revisions.

NV Energy agrees with removing R9 and with the concept of placing the "Process for Seeking an Extension from Compliance Dates" in the implementation Plan. However, there should be no requirement for the GO or TO to seek approval from the Regional Entity. NV Energy recommends that the SDT create clear and auditable criteria that if met, allows for the extension of compliance dates. GOs and TOs would submit notification to the Regional Entity that they will require an extension to the compliance dates, based on the met criteria. The Regional Entities' role would be to ensure that the proper criteria are indicated by the GO or TO to allow for an extension of compliance dates, rather make subjective decisions on approval of requests. This would also eliminate concerns about differences between regions in allowing for extensions.

All IBRs that enter commercial operation after the effective date of the standard should be required to comply with the PRC-028 no later than 15 months after the effective date of the standard. IBRs that have a commercial operations date more than 15 months after the effective date of the standard should be required to be compliant on their first day of commercial operation. Such facilities should be constructed to meet the requirements of the standard, and should not be eligible to operate without being compliant for 15 months after they are in commercial operation. This should be clarified in the Implementation Plan as detailed below:

Compliance Date for PRC-028-1 Requirements R1-R7 (page 3)

"For inverter-based resources facilities entering commercial operation after the effective date: Entities shall comply with Requirements R1 through R7 within 15 calendar months following the effective date of the standard or by the commercial operation date, whichever is earlier later."

NIPSCO agrees with the majority of the implementation plan but still has concerns with the "15 calendar months following the effective date of the standard" requirement for inverter-based resources entering commercial operation after the effective date, and believes that more	

time is needed to properly budget, modify designs and procure equipment for projects already under development. NIPSCO proposes modifying the following language: For inverter-based resources entering commercial operation after the effective date: Entities shall comply with Requirements R1 through R7 within “36 calendar months following the effective date of the standard or by" the commercial operation date, whichever is later.

Comment	
NV Energy agrees with the proposed compliance dates; however, NV Energy does not agree with the proposed “Process for Seeking an Extension from Compliance Dates” (see response to question 3.) The implementation plan requires compliance 15 calendar months after the effective date or the commercial operation date whichever is later. The WebEx discussed that facilities in commercial operation beyond the 15 months after the effective date must be compliant on the first day of commercial operation. The language should be clarified since this is an important detail.

It is unclear if the implementation plan compliance due date for facilities reaching COD after the effective date of PRC-028 is meant to be absolutely 15 months after the effective date of PRC-028. Given that IBRs in commercial operation on or before the effective date is previously prescribed (50% within 3 calendar years and 100% by 1/1/2030), IBRs entering CO after the effective date should just be 15 calendar months and not include "whichever is later."

Six years would be a sufficient amount of time to plan and budget for the procurement and installation of the DDR equipment barring any supply chain complications or any other delays. USV recognizes the FERC directive mandating completion by 1/1/2030, however, due to many of the IBR sites having strict language when dealing with manufacturer's warranty and having to rely on third parties, it may result in additional complications that could delay the installation and setting up of this highly specialized equipment. We recommend that the implementation period be changed to 6 years from the effective date of the standard as opposed to targeting the date of January 1, 2030.

Thank you for your comment. In Order No. 901, FERC directed the development of Reliability Standards to address IBR disturbance monitoring requirements by November 4, 2024. Further, FERC directed that all of the Reliability Standards developed under that order, including Reliability Standards to address IBR disturbance monitoring data, be “effective and enforceable well in advance of 2030.” Order No. 901 at P 226. Since the initial posting of proposed PRC-028-1 in August 2023, the drafting team recognized that the proposed standard is expected to have wide ranging impacts on entities as many will be installing disturbance monitoring equipment on their IBRs for the first time. The drafting team also considered stakeholder feedback regarding the challenges that entities may face in implementing the standard across an entire fleet. However, FERC’s direction in Order No. 901 is clear: all requirements that address directives from Order No. 901 must be implemented by 2030 at the latest. Further, a large majority of these requirements rely on installed and functioning IBR disturbance monitoring equipment. All delays implementing proposed PRC-028-1 will impact the ability to effectively comply with other Order No. 901 related requirements. The proposed compliance extension process is intended to provide a “relief valve” for entities in the event they are unable to comply with the standard’s requirements due to circumstances beyond their control. Under this process, entities would explain the circumstances precluding a timely implementation and would receive an extension from the compliance date, and the ERO would maintain its reliability oversight. In response to your comment and others, the drafting team has included further explanation of the circumstances that may warrant an extension from the compliance date. These circumstances may include supply chain delays associated with the procurement, engineering, installation, or commissioning of disturbance monitoring equipment, inability to secure scheduled outages, or other exceptional circumstances outside the entity’s control. The drafting team also replaced “Regional Entity” with “Compliance Enforcement Authority” to leave maximum flexibility. The drafting team expects that NERC (or authorities in non-U.S. jurisdictions) will provide more guidance on how/where to submit requests closer to the effective date.

AES CE believes that the new implementation plan language for PRC-028 around requiring compliance 15 calendar months after the effective date or the commercial operation date, whichever is later, needs to be revised. During the Webinar the SDT discussed that facilities in commercial operation beyond the 15 months after the effective date must be compliant on the first day of commercial operation. The language should be updated to clearly reflect this intention.

Texas RE recommends maintaining the previous verbiage of the implantation plan for the Compliance Date for PRC-028-1 Requirements R1 – R7: “Entities shall comply with Requirements R1 through R7 at 50% of **their generating plants/Facilities** within three calendar years of the effective date…” If it is changed to inverter-based resources, it is unclear how to comply with 50%. The description of inverter-based resource in Footnote 1 in PRC-028-1 appears to contradict the language of R1. The footnote description of IBR is at the collector level while Requirement R1 refers to	

the Point of Interconnection (POI). The implementation plan should be at the Point of Interconnection to be clear what is needed to comply with R1. Additionally, Texas RE recommends the header on page 3 say "Process for **Requesting** an Extension to Compliance Dates." Instead of "Process for Seeking an Extension from Compliance Dates."	
Likes 0	
Dislikes 0	
Response	
Thanks for your comment. Based on other industry comment, the standard refers to proposed definition of Inverter-Based Resource. Per definition, the IBR is a plant/facility. The header on Page 3 is revised as suggested.	
Steven Rueckert - Western Electricity Coordinating Council - 10, Group Name WECC	
Answer	
Document Name	
Comment	
WECC aggrees with the majority of the implementation plan but still has two concerns that were voiced in our prior comments. First: the use of the term "beyond control" is ambiguous. Who gets to determine what is "beyond control?" Second: It is unclear if a Regional Entity has the authority to grant a compliance waiver. Clarification is necessary.

Thank you for your comment. In Order No. 901, FERC directed the development of Reliability Standards to address IBR disturbance monitoring requirements by November 4, 2024. Further, FERC directed that all of the Reliability Standards developed under that order, including Reliability Standards to address IBR disturbance monitoring data, be “effective and enforceable well in advance of 2030.” Order No. 901 at P 226.

Since the initial posting of proposed PRC-028-1 in August 2023, the drafting team recognized that the proposed standard is expected to have wide ranging impacts on entities as many will be installing disturbance monitoring equipment on their IBRs for the first time. The drafting team also considered stakeholder feedback regarding the challenges that entities may face in implementing the standard across an entire fleet.

However, FERC’s direction in Order No. 901 is clear: all requirements that address directives from Order No. 901 must be implemented by 2030 at the latest. Further, a large majority of these requirements rely on installed and functioning IBR disturbance monitoring equipment. All delays implementing proposed PRC-028-1 will impact the ability to effectively comply with other Order No. 901 related requirements.

The proposed compliance extension process is intended to provide a “relief valve” for entities in the event they are unable to comply with the standard’s requirements due to circumstances beyond their control. Under this process, entities would explain the circumstances precluding a timely implementation and would receive an extension from the compliance date, and the ERO would maintain its reliability oversight.

In response to your comment and others, the drafting team has included further explanation of the circumstances that may warrant an extension from the compliance date. These circumstances may include supply chain delays associated with the procurement, engineering, installation, or commissioning of disturbance monitoring equipment, inability to secure scheduled outages, or other exceptional circumstances outside the entity’s control.

The drafting team also replaced “Regional Entity” with “Compliance Enforcement Authority” to leave maximum flexibility. The drafting team expects that NERC (or authorities in non-U.S. jurisdictions) will provide more guidance on how/where to submit requests closer to the effective date.

5. Do you agree the modifications made in PRC-002-5 and new Standard PRC-028-1 are cost effective?	
Donna Wood - Tri-State G and T Association, Inc. - 1	
Answer	No
Document Name	
Comment	
PRC-028 will result in costs that were not previously budgeted for. There will be a large cost to retrofit legacy equipment for monitoring and also costs for the new communications. You will also have to bring on new staff to monitor, track and maintain.

AEPC signed on to ACES comments: It is ACES' opinion that the proposed changes to PRC-002 are minimal and therefore should have little to no cost to implement. As for the proposed PRC-028-1, we agree with the approach taken by the SDT to create a new Standard to specifically address inverter-based resources; however, we disagree with making this new standard inclusive of all BES inverter-based resources regardless of risk to the BES. In the opinion of ACES, a blanket approach requiring every BES inverter-based resource to install SER, FR, and/or DDR capabilities is overly gratuitous. We believe that the industry's finite resources would best be spent by first ascertaining which inverter-based resources pose the biggest risk to the BES, and where disturbance monitoring and reporting would provide the most benefit to the BES, **before selectively** adding such capabilities. In summary, it is our recommendation that PRC-028-1 take a similar *risk-based approach as is done in PRC-002-5.*

Thanks for your comment. The SDT is aware of cost burden of implementing PRC-028. The proposed standard hopes to strike a balance between reliability needs, recommendations from various NERC disturbance reports, and FERC directive. Also, note that the purpose of PRC-028 is very different from PRC-002's purpose. The FR and DDR data collected at IBRs is expected to be used to show compliance with PRC-029 and for performance analysis under PRC-030.

Comment	
No. The standard requires IBR owners to have a robust compliance program implemented as well as event data collection process in place. However, this version of the standard removed the requirement for any IBR Unit to have SER, FR, or DDR data in an entire IBR plant. This will not help any event analysis process as it will not allow adequate analysis of an IBR facility's abnormal performance. At a minimum, fault codes should be available from every single IBR Unit within the facility. Lack of comprehensive data has significantly affected the ERO Enterprise's ability to conduct event analysis at many facilities over the past 7 years, as reported in numerous disturbance reports. The proposed standard would lead to inadequate data available at the inverter-level to do any useful event analysis and model validation, possibly leading to ongoing inconclusive root cause analyses. This would therefore not be cost effective for the industry. In addition, new IBRs being installed today and going forward will have all the SER, FR, and DDR data capabilities included in their inverters already, which means if the standard doesn't require this data set for these inverters/resources it could result in significant underutilization of the full capabilities of this equipment to ensure they operate reliably on the BPS.

AES CE believes this is not a cost effective approach to meet FERC Order 901. The requirements should be based on some study criteria similar to PRC-002 to identify specific generators that impacts reliability and therefore must invest this capital in order to ensure the reliability of the BES. AES CE recommends that the SDT leverage the expertise of Project Finance SMEs at the entities to understand the feasibility of implementing this new Standard, and the potential impacts to reliability that these additional costs could incur.

Under the applicability of PRC-002, there is a process to identify the need to have FR, SER, and/or DDR capabilities. However, PRC-028 requires any GO/TO with BES inverter-based resources to have similar if not more stringent requirements for all BES inverter-based resources.	

For PRC-002, it is the responsibility of TOs and RCs to identify which BES elements are required to have this recording capability. Why should PRC-028, which is meant to be similar in purpose to PRC-002, be any different. We would like to understand the reliability benefit of including all BES IBR's rather than using a qualifying process like PRC-002 does with Attachment 1.

PRC-028-1 will result in costs that were not previously required. These costs are not simply for the design and implementation of the monitoring but also for new communications infrastructure for legacy locations or compliance related staff to monitor, track and maintain compliance where it was not required before. For those owners that stream PMU data this standard could add significant communications costs to upgrade older facilities.

These following two comments relate to possible greatly increased costs for benefits that are not necessarily effective:

A) requiring SER on breaker positions on the GSU, collector buses and feeders, shunt devices, and AC-DC/DC-AC converters seems excessive. This quantity of monitored elements could require multiple DDRs depending on location and wiring.

B) Typically, fault recording is put on either the high side or low side of the GSU, not both. Requiring both could require multiple DDRs depending on location and wiring.

We suggest that the SDT consider requiring the DME on new (future) IBR facilities rather than applying this requirement retroactively. Including this data collection at the inverter level (for some of the inverters at the IBR facility) may prove to be beneficial for analyzing reactions of IBR facilities to transmission system disturbances. Provisioning the facility to include this data collection is much easier to accomplish during the design and construction phase of the facility.

Comment

SPP has a concern that the drafting team didn't provide any viable evidence in reference to cost effectiveness. The implementation Plan mentions the various stages of implementing the requirements for PRC-028, however, there are no actual numbers to support the effort and/or determine if either standard address cost effectiveness or not.

SPP recommends that the drafting team provides some type of cost analysis to support their efforts to determine if both standards address cost effectiveness.

6. Provide any additional comments for the standard drafting team to consider, if desired.	
Rhonda Jones - Invenergy LLC - 5,6	
Answer	
Document Name	
Comment	
Invenergy thanks the drafting team for their work and the opportunity to provide comments. Invenergy has concerns regarding R7.1. and the 20 calendar day data retention requirement for SER, FR, and DDR data. The Technical Rationale for PRC-028-1 states that, “With the state-of-the-art equipment, having the data retrievable for the 20 calendar days is realistic and doable.” However, PRC-028-1 will apply to many existing inverter-based resources, some of which have been operational for decades and may possess legacy equipment incapable of storing data for such an extended period of time. Invenergy proposes the below modifications to R7.1.: 7.1. Data shall be retrievable for the period of 20 calendar days, inclusive of the day the data was recorded. 7.1.1. If the recording equipment is incapable of storing 20 calendar days of data due to storage constraints, then data shall be retrievable for the maximum allowable period supported by the storage capabilities of the recording equipment, but not less than 10 calendar days.

Response	
Thanks for your comment. The SDT realized that in some cases, equipment at some existing IBRs, might need to be replaced to meet requirements of PRC-028. As such, the implementation plan allows appropriate time for existing IBRs. The justification for 20 calendar days retrievability is included in the technical rationale.

Comment	
Southern Indiana Gas and Electric Company d/b/a CenterPoint Energy Indiana South (SIGE) is providing the following additional comments: **Purpose Statement** comments: SIGE does not support the use of Footnote 1 in the Purpose Statement. If the "inverter-based resource" definition/Footnote 1 referenced in the Purpose Statement is intended to be specific to PRC-028, then a Standard definition section should be included in PRC-028 and the "inverter-based resource" definition/Footnote 1 should be moved to the definition section (see PRC-005-6 for reference). **R1.2 comments:** SIGE requests removal of "including collector feeder breakers" from R1.2 as the inclusion of collector feeder breakers has the potential to include non-BES elements.	
Likes 0	
Dislikes 0	
Response	
Thanks for your comment. The standard is revised and refers to proposed definition of Inverter-Based Resource that is being balloted concurrently with PRC-002/028 ballot. To understand IBR plant's performance during system disturbances, data from collector system is necessary. As such, SER data from IBR units and collector feeder breakers is required. In lieu of FR data from IBR units, FR data from collector feeder breakers is specified.

Charles Yeung - Southwest Power Pool, Inc. (RTO) - 2 - MRO,WECC, Group Name SRC 2024	
Answer	
Document Name	
Comment	

The SRC submit four additional comments/requests:

1) Reinstate the language "at least one IBR unit" in the PRC-028 requirements.

2) Reinstate inverter-level requirements in PRC-028 and to all future IBR installations

3) Update the associated Technical Rationale with justification for not including past recommendations into PRC-028

4) Continuing concern from last comment period regarding DDR coverage

The SRC disagrees with the modifications made to remove the "at least one IBR Unit" language from the PRC-028 requirements.

Based on NERC's Reliability Guideline entitled, *BPS-Connected Inverter-Based Resource Performance,* our understanding is that having IBR Unit level data is critical when investigating events. This recommendation was later reiterated in a 2nd NERC Reliability Guideline entitled, *Improvements to Interconnection Requirements for BPS-Connected Inverter-Based Resources*. Therefore, we see the removal of this requirement as problematic. We would like to see the "at least one IBR Unit" language added back in all applicable requirements, i.e., Parts 1.2, 1.3, 2.2. and 3.2.

The SRC requests inverter-level requirements be reinstated in PRC-028 and applied to all future IBR installations, at a minimum.

In September 2018, following unexpected performance of several large IBR plants during disturbances, NERC issued a Reliability Guideline entitled, *BPS-Connected Inverter-Based Resource Performance.*

{C}o This guideline contains a section (Chapter 6) dedicated to measurement data and performance monitoring. Within this section are "individual inverter level data" functional requirements.

{C}o The NERC guidance considers the need for inverter-level data to diagnose performance under certain types of events. For instance, the SRC understands partial tripping of plants, where only certain inverters persistently trip during events, to be a common issue.

In September 2019, NERC issued a second Reliability Guideline that again highlighted the need for inverter-level data, stating: "Data should be available from multiple sources to provide sufficient clarity as to any abnormal response or behavior within the plant. This includes plant control settings and static values, plant supervisory control and data acquisition data, sequence of events recording data, dynamic disturbance recorder data, and inverter fault codes and inverter-level dynamic recordings."

At least one ISO/RTO has modified its Generator Interconnection Agreement (GIA) to require inverter-level data (see current version of MISO's tariff

However, now that PRC-028 is diverging from prior NERC guidance and lowering the bar on monitoring requirements, the latest draft of PRC-028 appears to be inconsistent with NERC recommendations and reliability needs. Therefore, the SRC requests the SDT reinstate IBR Unit level requirements in PRC-028 to align with NERC Reliability Guideline recommendations.

Moreover, PRC-028 provides the foundation for monitoring performance that will be relied upon across NERC standards to validate models and identify performance issues.

To the extent PRC-028 standard does not establish an adequate foundation, other standards that rely on operational visibility are also likely to be weakened.

A mismatch between reliability needs and NERC standards will lead to fractured adoption of monitoring across the U.S. as it will require individual ISOs/RTOs and TOs to take independent action. This is already underway, given the lack of existing national standards, common in other countries.

Deferring requirements that mandate the monitoring of IBR performance may contribute to the ongoing trend of IBR performance issues.

Barriers to collecting inverter-level data for existing IBR plants should not prevent the development of inverter-level data requirements for future IBR plants needed for post-event analysis.

The PRC-028 drafting process has demonstrated challenges with retroactively applying inverter-level data requirements. Foregoing development of appropriate 'forward-looking" standards that require inverter-level data for future IBR plants will only exacerbate this problem.

Update the Technical Rationale

The Technical Rationale should include the justification for not including inverter-level requirements as recommended by NERC Reliability Guidelines published in 2018 and 2019.

Continued concern over minimum DDR installation requirements

The SRC notes that in its previous comments, it requested clarification as to whether any or all or none of the DDRs required by PRC-028-1 Requirement R4 are required (or allowed) to be included in the minimum DDR coverage under PRC-002-5 Requirement R5 Part 5.2. The SDT's response indicates that "PRC-002-5 does not apply to IBRs, so the DDR requirements in PRC-028 do not count toward PRC-002. No elements should be covered under both standards as this would set up a double jeopardy situation." The SRC is concerned that as IBR penetration increases, PRC-002-5 Requirement R5 Part 5.2 may put the RC in the position of having to specify additional (and potentially unnecessary) DDR locations simply to satisfy the minimum coverage requirement, despite PRC-028-1 requiring a DDR at each main power transformer of every IBR (meaning that there will likely be enough DDR associated with IBRs to satisfy the minimum coverage requirement within the RC footprint). The SRC recommends that either the coverage requirement be eliminated, or that the coverage calculation be revised to include DDRs associated with IBRs.

Response

Thanks for your comment.

The SDT recognizes that SER and FR data from IBR units are helpful in event analysis. The SDT reviewed data requirements from CA-ISO and MISO's tariff and concluded that neither actually requires oscillography data from IBR units. Considering various opposing opinions and to strike a balance between reliability needs, recommendations from various NERC disturbance reports, and cost burden, IBR unit SER data requirement is reintroduced, and SER data from all IBR units is required. However, in lieu of FR data from IBR units, same from collector feeder breakers is specified.

Regarding comment about minimum DDR installations requirements, even with increasing penetration of IBRs, it is very likely that for some operating conditions, system is synchronous machine dominated. For example, Southeast USA region may be solar rich but during cold winter mornings, most load is still expected to be served from synchronous machine-based resources. To ensure adequate coverage considering widely different and various operating conditions, it may not be appropriate to eliminate coverage requirement or revise coverage calculation. However, the SDT does recognize that based on learnings in future, this may be necessary.

Comment	
Invenergy thanks the drafting team for their work and the opportunity to provide comments. Invenergy has concerns regarding R7.1. and the 20 calendar day data retention requirement for SER, FR, and DDR data. The Technical Rationale for PRC-028-1 states that, "With the state-of-the-art equipment, having the data retrievable for the 20 calendar days is realistic and doable." However, PRC-028-1 will apply to many existing inverter-based resources, some of which have been operational for decades and may possess legacy equipment incapable of storing data for such an extended period of time. Invenergy proposes the below modifications to R7.1.: *7.1. Data shall be retrievable for the period of 20 calendar days, inclusive of the day the data was recorded.*	

7.1.1. If the recording equipment is incapable of storing 20 calendar days of data due to storage constraints, then data shall be retrievable for the maximum allowable period supported by the storage capabilities of the recording equipment, but not less than 10 calendar days.

Likes 0	
Dislikes 0	

Response

Thanks for your comment. The SDT realized that in some cases, equipment at some existing IBRs, might need to be replaced to meet requirements of PRC-028. As such, the implementation plan allows appropriate time for existing IBRs. The justification for 20 calendar days retrievability is included in the technical rationale.

Comment

NextEra supports EEI's comments:

EEI offer the following additional Comments:

PRC-028-1 Comments:

Purpose Statement Comments: EEI does not support the addition of Footnote 1 to the Purpose Statement because it inappropriately changes the applicability of PRC-028, outside of the Applicability Section.

Applicability Section Comments: EEI does not support the Applicability section because it uses the uncapitalized version of IBR and could unintentionally broaden the scope and create confusion in expectations.

Requirement R1 Comments:

Subpart 1.1: EEI does not support footnote 2 because it identifies facility scope that is not identified in the Applicability Section and appears to go beyond what was allowed in the approved SAR.

Subpart 1.4: EEI does not support the addition of VSC HVDC equipment because it was not included in the industry approved definition of IBR or this SAR. While EEI is not opposed to including VSC-HVDC equipment to this Reliability Standard if that equipment is in fact creating reliability concerns, no technical justification has been provided to clarify why this is necessary. To address our concern, we ask that that the SAR be revised to include this equipment and submit a technical justification document, as required by the Rules of Procedure (see Standard Processes Manual, Appendix 3a).

Requirement R7 Comments and associated VSLs:

Subpart 7.1: EEI suggests aligning Requirement R7, Subpart 7.1 with PRC-002, Requirement R11, subpart 11.1. Making the data requirements different in the two standards may cause entities that own both synchronous generators and IBRs to inadvertently make compliance errors.

Subpart 7.2: This requirement seems to parallel Requirement R11, Subpart 11.2 yet the obligation for IBR owners to provide data has been reduced from 30 days to 15 days, while synchronous generator owners are afforded 30 days. EEI does not support this difference and believes these requirements should be harmonized.

VSL for R7: EEI suggests aligning the VSLs for Requirement R7 to what was provided for PRC-002, Requirement R11.

PRC-002-5 Comments:

Applicability Section comments: EEI does not support the Applicability section because it uses the uncapitalized version of IBR. The definition of Inverter Based Resource was approved by the industry during the last posting of that definition and therefore should be capitalized. Additionally, footnote 1 is unnecessary.

Footnote 2: EEI finds footnote 2 to be confusing and potentially in conflict with the Applicability Section. In the Applicability Section it states that IBRs are excluded from the scope of PRC-002 yet footnote 2 states “For the purposes of this standard, “directly connected” BES Elements are BES Elements connected at the same voltage level within the same physical location sharing a common ground grid with the BES bus identified under Attachment 1.” We note that certain IBRs are BES Elements, but the Applicability Section stated inverter based resources (undefined in this standard) are not included. Yet footnote 2 seems to imply BES IBRs connected to a common bus at the same voltage level

within the same physical location are to be included in PRC-002. Therefore, if this is the case, then certain IBRs are part of PRC-002. Please clarify what is intended by this footnote or delete it.

Response	
Thanks for your comment. The standard is revised and refers to proposed definition of Inverter-Based Resource that is being balloted concurrently with PRC-002/028 ballot. The definition of the Inverter-Based Resource includes plants connected to ac transmission system via VSC-HVDC system. See IBR definition's technical rationale for more information. The requirement R7 in PRC-028 is intentionally a bit different from an equivalent requirement R11 in PRC-002. This difference is justified based on differences in "purpose" of both of these standards. Regarding Footnote 2 in PRC-002, the exclusion in 4.2 is applicable to entire standard. In case where a BES IBR is "directly connected" to the identified bus, that BES IBR is excluded from PRC-002 requirements because of exclusion in 4.2. See Figure 1 in PRC-002's technical rationale.

Comment	

PRC-028-1

1. Section B: What is the purpose of removing the need for recording data at the inverter level? It seems like this data is important to record and monitor.

PRC-002-5

1. This document states *"Disturbance monitoring and reporting requirements for inverter-based resources are addressed in PRC-028."*, however, PRC-028-1 draft has removed the requirement for IBR monitoring/reporting.

A general comment: IEEE 2800 does a great job addressing IBRs and could be referenced when making these types of updates for IBRs.

Dislikes 0	
Response	

Thanks for your comment. The inverter level SER data requirement is reintroduced. However, in lieu of inverter level FR data, the FR data from collector feeder breakers is required. This is a compromise considering various opposing views, reliability needs, recommendations from various NERC disturbance reports, and cost burden of implementation PRC-028 standard. During the development, the SDT considered IEEE 2800 requirements, along with comments from various OEMs.

Comment	
The standard specific definition for inverter-based resource found in PRC-028 footnote 1 should be placed into item #6 of the **"A. Introduction"** section, as can be seen was done for PRC-005-6 rather than being defined in the footnote. Unless the power level of a collection system feeder breaker is > 75 MVA, the collection system feeder breaker specified in Section 1.2 of the proposed PRC-028 overreaches the BES definition for inverter-based resource. Southern Company does not agree with the language in PRC-028, R8 requiring a Corrective Action Plan to be submitted to the **Regional Entity**. If at any time a Regional Entity desires to review a TO's or GO's Corrective Action Plans, they have the authority to request them. Simply requiring the Corrective Action Plans to be submitted to the Regional Entity with no requirement for the Regional Entity to do something with them is purely administrative and does nothing to improve the reliability of the Bulk Electric System. Further, the timely development and implementation of a Corrective Action Plan needed to repair equipment can be thoroughly examined during an audit engagement. This same reasoning applies to PRC-002, R12 and is also recommended to be removed. Some provision in PRC-028, R7 is needed for an exception to the data delivery requirements for DME equipment that is being repaired as permitted by PRC-028, R8.

Response	

Thanks for your comment. The standard is revised and refers to proposed definition of Inverter-Based Resource that is being balloted concurrently with PRC-002/028 ballot. The SDT recognizes that collector feeder may not be a BES element. However, the applicability of the standard now included non-BES IBRs given that NERC proposed registration criteria is not approved by FERC. Standard is not limited to monitoring of BES resources or elements only. The proposed compliance extension process is intended to provide a "relief valve" for entities in the event they are unable to comply with the standard's requirements due to circumstances beyond their control. Under this process, entities would explain the circumstances precluding a timely implementation and would receive an extension from the compliance date, and the ERO would maintain its reliability oversight. It is implied that when DME is non-operational as allowed by R8, then data delivery requirements in R7 does not apply.

Comment	

Texas RE recommends including a timeframe for implementing the CAPs in both PRC-002-5 Requirement R12 and PRC-028-1 Requirement R8.

In PRC-002-5, Requirement 12 there seems to be an open-ended timeframe for implementing the corrective action plan. Texas RE suggests the following for R12 second bullet:

- Submit a Corrective Action Plan (CAP) and the specific implementation schedule to the Regional Entity within 90 calendar days and implement the CAP according to the timeline specified. The timeline for implementing the CAP shall be within 9 months of the discovery, unless specific reasons for not meeting the timeline is approved by the Regional Entity.

In PRC-028-1, Requirement 8 there seems to be an open-ended timeframe for implementing the corrective action plan. Texas RE suggests the following for R8 second bullet:

- Submit a Corrective Action Plan (CAP) and the specific implementation schedule to the Regional Entity within 90 calendar days and implement the CAP according to the timeline specified. The timeline for implementing the CAP shall be within 9 months of the discovery, unless specific reasons for not meeting the timeline is approved by the Regional Entity.

Synchronous Condensers are dynamic reactive power compensation devices that are becoming essential for stabilizing the grid with the rapid additions of IBRs. Disturbance data from these devices will be valuable when evaluating the BPS disturbances.

Texas RE suggests that the SDT clearly state that the SER data for circuit breakers associated with standalone synchronous condensers and synchronous condensers co-located at the IBR facility(ies) are included in the PRC-028-1 Requirement R1.

Texas RE recommends the following verbiage (in bold):

R1, 1.3 Shunt static or dynamic reactive device(s), **including any filter banks and synchronous condensers.**

Texas RE notes that the redline version does not match the clean version. Please verify that the Draft 3, “redline to last posted” document matches with the draft 3, “clean” version of PRC-028-1 document.

Likes 0	
Dislikes 0	
Response	

Thanks for your comment. The SDT recognizes that timeline to implement CAP in PRC-002 - Requirement R11 and PRC-028 - Requirement R7 is open ended. However, failure of recording capability is rare and when occurs would be limited to very few sites on the system. There should be enough coverage of monitoring devices across the system to aid with event analysis during system disturbances. To allow entities some flexibility, it is not necessary to put a strict time line. The entity is required to submit a CAP (including a timeline) to the respective Regional Entity. Including disturbance monitoring requirement for standalone Synchronous Condensers is not in scope of this project. The technical rational includes a statement that synchronous condenser when installed within an IBR is considered a shunt dynamic reactive device. The SDT has reviewed new draft thoroughly, redline and clean versions should match.

The NAGF provides the following additional comments for consideration:

a. General Comments:

i. The NAGF does not agree with requiring that electronic files be provided only in a format that is established by an outside organization. While NAGF acknowledges that C37.111 is the format most used presently, there must still be an option to provide data in a format not controlled by an outside standard as dictated by NERC Rules of Procedure Section 302.6 "Completeness — Reliability Standards shall be complete and self-contained. The Reliability Standards shall not depend on external information to determine the required level of performance." Therefore, the NAGF recommends that the proposed PRC-002-5 sub-Requirement 11.4 and PRC-028-1 sub-Requirement 7.4 keep the option for providing data in CSV format.

b. PRC-028-1:

i. Requirement 1.1- Please explicitly clarify for offshore wind connected VSC-HVDC plants if the main power transformer includes only the inverter (onshore) transformer or it includes the offshore (rectifier) converter transformer. Note that, for a VSC-HVDC connected offshore wind, the rectifier side reactive power device status will have little impact on the onshore grid and bulk electric system reliability.

ii. Requirement 1.2:

1) the individual feeder buses are not considered BES elements per the NERC BES Definition Reference Document Volume 2, April 2014. It is unclear if the individual feeder-collector bus breakers, which connect to the collector bus, are considered BES. The NAGF requests clarification from the DT on this matter.

2) The NAGF requests clarification for recording of the collector system CB and protection system status for the offshore wind AC system

iii. Requirement 1.3:

1) The NAGF notes that the proposed narrative has the potential to apply to low voltage auxiliary equipment that is not considered BES. Recommend revising the narrative accordingly.

2) Is the synchronous condenser within the IBR plant also considered a part of "dynamic reactive power device(s)"? Note that in most IBR plant designs the synchronous condenser may not provide reactive power compensation; its purpose is to strengthen the grid at the IBR plant POI.

iv. The NAGF requests the DT to consider revising Requirement R1.1 – R1.3 language to clarify the rectifier side data monitoring requirements for VSC-HVDC connected offshore wind facilities.

v. Page 3, footnotes 1 and 2 – recommend moving the footnotes under the Introduction Section – Definitions Used in this Standard (similar to PRC-005-6).

vi. Requirement R7 – Recommend that the narrative be modified to include an exception for missing data that is associated with Corrective Action Plan activities.

vii. Requirement R8 – The NAGF does not see the value of submitting the Corrective Action Plan to the Regional Entity and recommends deleting the associated bullet. This would also apply to PRC-002-5 Requirement R12.

Testing and demonstrating performance could be a challenge without further guidance on expectations. · Many existing devices used for fault recording (SEL-351 for example) cannot meet the 2.0 second duration in R3.1.1. A duration of 1.0 second would better align with equipment capabilities. Perhaps the clause could be written that all new equipment should have the 2.0 second duration capability while existing equipment has requirements in-line with the capabilities of the equipment installed over the past few years.

This latest draft of PRC-028-1 continues to diverge further from the IEEE 2800-2022 standard, which is the de facto standard for IBR plants interconnecting with electric transmission systems. This PRC-028-1 standard and other NERC IBR-focused standards should be conforming to/matching the IEEE 2800 standard unless there is excessively strong and clear risk evidence that there is a need to go beyond the requirements in IEEE 2800. Any NERC IBR-focused standard that creates requirements that are less than those in IEEE 2800 is incorrect and faulty.

A lot of the SER/FR/DDR capabilities may not be available in existing IBR plants already connected and operating on the grid. Creating a NERC standard for both existing IBR plants and new/future IBR plants is a difficult task, but creating a standard that is the least common denominator of the capabilities of existing and new facilities would result in a watered-down standard that would not be effective, not be cost effective, and not be valuable in achieving the reliable interconnection and operation of these IBR plants going forward. New IBR plants will most likely be designed to the IEEE 2800 standard going forward, and all these SER/FR/DDR data capture and recording capabilities are therefore all available today and a new NERC standard for these IBRs should be made to utilize these data capabilities for reliable BPS operations. The SER/FR/DDR data sampling rates and data retention rates for IBR units at existing IBR plants would add cost and would require adequate timeframe to implement (as already identified in the draft Implementation Plan for PRC-028-1), but removing these requirements from new/future IBR plants to account for limitations of existing IBR resources seems to go in a negative direction and should have a technically backed justification if it is to remain in the standard as it will set back the industry by significantly underutilizing the full capabilities of new inverters being connected to the grid now and into the future.

Further highlighting the point above, the 2021 Odessa Disturbance report and the NERC IBR Reliability Guideline document both give a recommendation to include SER data for all IBR units (i.e. all inverters) and to include FR/DDR data on some IBR units on the collector busses at IBR plants. These documents point to this Project 2021-04 and recommends including these recommendations as requirements in the updated standard(s).

Related to the 2021 Odessa Disturbance report, in the updated PRC-028-1 Technical Rationale document, page 10 gives reference to the 2021 Odessa Disturbance report. However, in this lasted PRC-028-1 Technical Rational document update there is a redline removal of the report’s recommendation of high-resolution oscillography data for individual IBR units. This redline removal should not have occurred as it removes a key recommendation from the 2021 Odessa report that is specifically important to Project 2021-04 and the new draft PRC-028-1 standard.

This redline removal should be added back into the technical rational document and the IBR unit level SER/FR/DDR requirements should be added back into the draft PRC-028-1 standard.

In continuing the topic of IBR-related NERC Standards not adopting the IEEE 2800-2022 standard, the PRC-002 and the new PRC-028-1 standard both put into place requirements that adopt/require the use of the IEEE C37.111 COMTRADE standard and the IEEE C37.232 COMNAME standard. The language in the PRC-002 and PRC-028 Technical Rational documents highlight that requiring these IEEE industry standards helps the industry with the analysis and other work that is required from these standards. It is exactly that same reason why these updated NERC standards should adopt the IEEE 2800-2022 standard requirements; this would give the industry consistency and clarity on all technical requirements going forward for BPS-connected IBRs. This continued inconsistency regarding NERC's approach and opinion in this area of IEEE 2800 standard adoption should be addressed.

Response

Thanks for your comment. The standard drafting team has considered requirements in IEEE Std 2800 and recommendations from various NERC disturbance reports. The SDT also received input from two OEMs for inverters during the development process. The proposed standard aims to strike a balance between various opinions received from the industry. Considering comments received from the industry, the SER data requirement for IBR units is restored. In lieu of FR data from IBR units, the FR data from collector feeder breakers is required.

Jennifer Bray - Arizona Electric Power Cooperative, Inc. – 1

AEPC signed on to ACES comments:

It is the opinion of ACES that Section 4.2 should be comprehensive and stand-alone; therefore, we disagree with using footnotes to prescribe which inverter-based resources are applicable to this standard. We recommend creating an all-inclusive list as a sub-section of Section 4.2 as shown in our response to question 1.

Thank you for the opportunity to comment.

We have had no disturbances since the implementation of PRC-002 monitoring. Installation of additional monitoring equipment at all IBR sites will increase capital and operational costs for a very low likelihood event and is not a cost effective approach to protecting the grid. If there are specific regions with a higher risk (history) of disturbance, perhaps the PRC-028 applicability could be amended to include a geographic/regional filter

Regarding proposed EOP-002-5 R12 changes, the updated language does not address updates to the CAP and its timeline and could lead to a PNC if an entity is unable to meet the target dates originally provided to the Regional Entity.	

Would recommend revising the language to one of the following options for the second bullet under R12: "Submit a Corrective Action Plan (CAP) to the Regional Entity (RE) within 90 calendar days and then implement it in accordance with the most up to date CAP timeline submitted to the RE." OR "Submit a Corrective Action Plan (CAP) to the Regional Entity (RE) within 90 calendar days and then implement it according to CAP timeline or submit an updated CAP to the RE prior to the CAP timeline target."

Requirement 2.2 “shunt dynamic reactive device data” could be replaced with FACTS. MOD-025/-026 project uses FACTS to refer to these devices and capture Synchronous Condensers, STATCOMS, SVCS, etc. This DT should do the same, so the intent of which devices are intended are the same. Uniformity across standards and standard families is critical for ensuring compliance with the requirements and equipment.

General Comments: (From NAGF) We do not agree with requiring that electronic files be provided only in a format that is established by an outside organization. Although C37.111 is the format most used currently, there must still be an option to provide data in a format not controlled by an outside	

standard as dictated by NERC Rules of Procedure Section 302.6 “Completeness — Reliability Standards shall be complete and self-contained. The Reliability Standards shall not depend on external information to determine the required level of performance.”

PRC-028-1:

i. (From NAGF) Requirement 1.2 - the individual collector buses are not considered BES elements per the NERC BES Definition Reference Document Volume 2, April 2014. Recommend revising the narrative accordingly.

ii. (From NAGF) Requirement 1.3 – the proposed narrative has the potential to apply to low voltage auxiliary equipment that is not considered BES. Recommend revising the narrative accordingly.

iii. (From NAGF) Requirement R7 – Recommend that the narrative be modified to include an exception for missing data that is associated with Corrective Action Plan activities.

iv. (From EEI) Should align Requirement R7, Subpart 7.1 with PRC-002, Requirement R11, subpart 11.1. Making the data requirements different in the two standards may cause entities that own both synchronous generators and IBRs to inadvertently make compliance errors.

v. (From EEI) Subpart 7.2: This requirement seems to parallel Requirement R11, Subpart 11.2 yet the obligation for IBR owners to provide data has been reduced from 30 days to 15 days, while synchronous generator owners are afforded 30 days. Requirements should be the same.

vi. (From EEI) VSL for R7: Align the VSLs for Requirement R7 to what was provided for PRC-002, Requirement R11.

vii. (From NAGF) Requirement R8 – Do not see the value of submitting the Corrective

Action Plan to the Regional Entity and recommends deleting the associated bullet.

PRC-002:

(From EEI) Footnote 2: In the Applicability Section it states that IBRs are excluded from the scope of PRC-002 yet footnote 2 states “For the purposes of this standard, “directly connected” BES Elements are BES Elements connected at the same voltage level within the same physical location sharing a common ground grid with the BES bus identified under Attachment 1.” We note that certain IBRs are BES Elements, but the Applicability Section stated inverter based resources (undefined in this standard) are not included. Yet footnote 2 seems to imply BES

IBRs connected to a common bus at the same voltage level within the same physical location are to be included in PRC-002. Therefore, if this is the case, then certain IBRs are part of PRC-002. Please clarify what is intended by this footnote or delete it.

Response	
Thanks for your comment. PRC-002 and 028 now allows sharing of data in CSV format. Requirement R1.2 - The applicability of standard is revised and now applies to non-BES IBRs. Requirement R1.3 – The technical rationale document clearly shows an example of shunt reactive device. The SDT is unaware of a scenario where a dynamic reactive device could be a low voltage auxiliary equipment. Requirement R7 - The R8 clearly states “upon the discovery of a failure of the recording capability”. If the discovery occurs while gathering data under Requirement R7 then it is implied that data won’t be available. The Requirement R7 in PRC-028 deviates a bit from a similar requirement in PRC-002. This is intentional and aligns with scopes of each standard. Requirement R8 – This is similar to an equivalent requirement in PRC-002. PRC-002 excludes all IBRs, regardless of it being “directly connected” to identified bus or not. Technical rationale includes an example to convey this point.	
Adrian Andreoiu - BC Hydro and Power Authority - 1, Group Name BC Hydro	
Answer

Comment	
1. Requirement R7 as drafted seems to imply that in case a failure to record data that is discovered while responding to a data request from an applicable entity, that would constitute a violation of R7. BC Hydro recommends that R7 be revised to clarify that a recording equipment failure would not constitute a compliance violation to R7.	

2. The PRC-028-1 Technical Rationale states on page 13 (Rationale for Requirement R7 section) that, unless an extension is granted, "data has to be provided to the requestor within 20 calendar days after a request". This appears to be in conflict with R7 Part 7.2, which states that "Data subject to Part 7.1 shall be provided within 15 calendar days of a request". Please clarify and revise accordingly. 3. The VSL Table for PRC-028-1 R7 does not seem to set a severity level in case an extension is granted per R7 Part 7.2., e.g. a delay in providing data per the extended deadline does not factor in. Specifically, if an entity were granted an extension to 30 calendar days and provided the required data any number of days past Day 30 could not be assessed a severity level.

Response	
Thanks for your comment. The R8 clearly states "upon the discovery of a failure of the recording capability". If the discovery occurs while gathering data under Requirement R7 then it is implied that data won't be available. The technical rationale is revised, second paragraph in Rationale for Requirement R7, and should be consistent with Requirement R7, Part 7.2. The VSL for Requirement R7 is revised and addresses the raised concern.

We appreciate some significant improvements in the draft Standard in response to previous comments, particularly removing the requirement for Sequence of Event Recording (SER) and Fault Recording (FR) at individual Inverter-Based Resource (IBR) units, and increasing the plant size threshold for PRC-028 compliance from 20 MVA to Bulk Electric System (BES) resources, which are generally 75 MVA and greater. These improvements, which are noted at the end of our comments, are important and should be retained in the final Standard.	

However, concerns expressed by Leeward Renewables in the most recent comment period, Pine Gate Renewables in the initial comment period, and others have not been fully addressed. These concerns include the cost and burden of 1. Retroactively applying the standard to existing plants and 2. Applying the requirements to smaller plants.{C}[MG1]{C}

We believe the costs and benefits of the proposed standard can be better balanced by 1. Only applying the data collection requirements to plants that sign an interconnection agreement after the effective date of the standard, and 2. Only requiring data collection at IBR generating plants larger than 500 MVA. These changes would greatly reduce the compliance cost and burden while optimizing reliability benefits, as explained below. These changes are also necessary to reduce the disparity between the strict requirements on IBRs in PRC-028 relative to the requirements on synchronous generators in PRC-002, which could result in undue discrimination against IBRs.

1. The Standard’s requirements should only apply prospectively, not retroactively to existing plants

Applying the PRC-028 requirements retroactively to existing generators, as the current draft proposes, greatly exacerbates the cost and burden on generators with minimal benefit. Applying PRC-028 prospectively and not retroactively would avoid the highly costly retrofit of existing facilities, costs that in most cases cannot be recovered by plant owners because existing IBR generators typically sell their output at a fixed price under a long-term power purchase agreement. As noted below, PRC-029 and PRC-030, as well as other modeling and validation Standards revisions that are underway, apply to both existing and new resources. As a result, any concerns about the reliability performance of existing resources will be addressed through those Standards, and thus need not be addressed with PRC-030.

In the initial draft, the requirement to install SER at IBR units in part 1.2 of R1 had an exemption that “IBR units installed prior to the effective date of this standard and are not capable of recording this data are excluded,” but that was removed. In the current draft, all requirements apply to all existing and new IBR resources. The retroactive requirement to install SER at IBR units may be particularly challenging in cases in which the OEM that manufactured the inverter is no longer in business, as the records produced by some inverter models are proprietary and require OEM intervention to provide in readable format to the generator owner.

The cost and implementation burden for retrofits is typically much higher than if the data collection equipment were planned and installed as part of initial plant construction. For example, in many cases new data communication wires may have to be run across existing wires, suitable locations must be found to add data collection, storage, and transmission equipment and deliver power to that equipment, and other changes that would be far less costly if they were planned during initial plant design. Adding this equipment also adds ongoing operations and maintenance and compliance costs for that equipment.

Retroactive requirements also impose a much greater financial burden on the generator as those costs cannot typically be recovered once a power purchase agreement has been signed. These unexpected and unrecoverable costs are far more concerning to lenders and other generation project financiers as they were not accounted for during the project's financing. As a result, retroactive requirements set a bad precedent by introducing regulatory uncertainty that makes future generation investment more uncertain and risky, and likely more costly by forcing financiers to charge higher risk premiums.

2. The Standard should only apply to large generators[MG2]

Only applying the requirements to larger IBR plants will greatly reduce the total cost and burden of compliance. The large fixed costs associated with installing and operating the required data collection, storage, and transmission equipment make up a larger share of the total cost of smaller plants. Only applying PRC-028 to larger plants will also make it more comparable to the PRC-002 companion standard for synchronous generators, avoiding undue discrimination against IBRs. As noted below, PRC-029 and PRC-030, as well as other modeling and validation Standards revisions that are underway, would apply to small IBR resources under NERC's IBR registration proposal. As a result, any concerns about the reliability performance of smaller IBR resources will be addressed through those Standards, and thus need not be addressed with PRC-030.

To make the cost of PRC-028 more reasonable while preserving the value of the proposed data collection, as well as avoiding undue discrimination against IBRs relative to synchronous generators, we suggest that data collection in PRC-028 only be required at plants that are 500 MVA and greater. This is the plant size threshold at which synchronous generator dynamic disturbance data collection is required in the PRC-002 standard. If the TO or RC/PC can compellingly demonstrate that smaller new plants should be required to comply with PRC-028's data collection requirements due to local reliability concerns, such as weak grid issues or high penetrations of IBRs in a local area, then that should be allowed. That would avoid an unnecessary cost burden for many smaller plants.

IBR wind, solar, and storage plants are highly modular, so larger IBR plants typically contain the same equipment as smaller plants, just in a larger aggregation (*e.g.,* more collector feeders). Because larger IBR plants are typically just larger aggregations of the equipment in smaller plants, it should be possible to infer the detailed behavior of smaller plants during a disturbance based on the performance of larger plants that are nearby and use similar equipment.

Other Standards and FERC Orders address the reliability concerns addressed by PRC-028, particularly for existing or small IBRs

Regarding potential reliability benefits of the proposed standard, we agree that ride-through issues at some IBRs have presented a legitimate reliability concern. However, the ride-through concerns PRC-028 is primarily attempting to understand have already been addressed by

Federal Energy Regulatory Commission (FERC) Order 2023, the draft PRC-029 and PRC-030 Standards that are currently out for comment and balloting, as well as ongoing Standards revisions to require IBR plant modeling and validation of those models. In particular, reliability concerns about smaller and existing plants are being addressed by these Standards, and thus need not be addressed through PRC-030.

The draft PRC-029 Standard requires all existing and new generators to meet the standard, though existing generators can file for an equipment limitation exemption. Obtaining an exemption requires the owner of the existing generator to document and communicate to the Planning Coordinator "**6.1.2.** Which aspects of voltage ride-through requirements that the IBR would be unable to meet" and "**6.1.3** Identify the specific piece(s) of equipment causing the limitation," so it will be known which existing plants are unable to ride through and why. PRC-030 provides an even more open-ended tool for identifying and addressing unexpected losses of IBR generation, including from both new and existing generators.

In addition, the recent adoption of FERC Order 2023 directly addresses many of the concerns PRC-28 is attempting to address, as it imposes mandatory requirements to fully ride-through grid disturbances and to accurately validate models of plant performance at the sub-second transient timescale. Prior to the adoption of Order 2023 and the development of other NERC Standards, the proposed requirements of PRC-028 may have provided a significant reliability benefit by improving understanding of the ride-through performance of IBRs, and thus helping to identify solutions to any concerns. However, now that FERC Order 2023 and the other NERC Standards have solved many of those concerns by requiring ride-through performance and accurate modeling of sub-second plant performance, it is not clear what reliability benefit PRC-028 might provide.

To the extent the value of PRC-028 was to gather information to help craft improved ride-through requirements through PRC-029, PRC-030, and FERC Order 2023, the window for that opportunity is closing this year, or in the case of FERC Order 2023, has already closed. Data collection equipment installed by the year 2030 pursuant to PRC-028 will not help with designing those standards.

Improvements since the previous draft of PRC-028

As noted above, we appreciate some significant improvements in the draft Standard in response to previous comments. These improvements are important and should be retained in the final Standard:

-Sequence of Event Recording and Fault Recording at individual IBR units is no longer required

-Increasing the plant size threshold for PRC-028 compliance from 20 MVA to BES resources, which are generally 75 MVA and greater

However, concerns about the cost and burden of retroactive application and the application to smaller plants remain, as noted above. Even with the above improvements, the cost and burden of compliance is still significant. The drafting team even noted the burden at pages 125-126 in the Consideration of Comments document for the initial comment period by saying “The Reliability Standard PRC-028-1 is expected to have a wide-ranging impact on Entities as many existing Facilities would be required to have disturbance monitoring equipment. Considering time needed to procure equipment, complete design, schedule outages, and install equipment, technical or supply chain constraints may prevent Entities from being fully compliant in a timeframe stated in the Implementation Plan. Requirement R9 allows Entities of an applicable Facility in commercial operation before the effective date of Reliability Standard PRC-028-1 that is not able to install disturbance monitoring equipment per Requirements R1 through R7 to develop, maintain, and implement a Corrective Action Plan.” There are also significant concerns about the disparity between the strict requirements on IBRs in PRC-028 relative to the requirements on synchronous generators in PRC-002, which could result in undue discrimination against IBRs. For example, R3 in PRC-028 requires IBRs to have FR for 2 seconds (120 cycles) following a disturbance, versus a requirement in PRC-002 for synchronous generators to only record for 30 cycles following a disturbance. IBR behavior is not inherently different enough to justify this difference, and the duration of disturbances faced by IBRs and synchronous generators are identical. There are technical hurdles and cost burdens associated with longer event reports, as they can start to fill up the device working memories and can inadvertently erase older records as those fill up. This is especially challenging when retroactively applying this requirement to sites with legacy data acquisition and storage. Similar concerns are caused by the requirement in PRC-028 R5 for IBRs to have dynamic disturbance recording at a rate of 60 times per second, versus 30 times per second for non-IBRs in PRC-002. As a final example, the synchronization requirement in R6 in PRC-028 is 1 millisecond, versus 2 milliseconds in PRC-002. Given that there are finite resources for complying with all NERC requirements, we are concerned that PRC-028 as proposed could actually undermine reliability by distracting from more pressing reliability needs. We believe the revisions we have proposed to exempt existing and smaller plants and better align the requirements with those imposed on synchronous generators in PRC-002 will result in a Standard that better balances the cost of complying with the Standard with its reliability benefit.

Response	
Thank you for your comments.	

Considering other comments received, the recording of SER data from IBR units is reintroduced. However, in lieu of IBR unit FR data, FR data from collector feeder breakers is proposed.

FERC recently approved the NERC proposed IBR registration criteria. Given that, the applicability of PRC-028 now includes non-BES IBRs.

The purpose of PRC-028 is to have adequate data available from Inverter-Based Resources to evaluate Inverter-Based Resource ride-through performance during Bulk Electric System (BES) Disturbances and to provide data for Inverter-Based Resource model validation. This is applicable to all IBRs, not just large IBRs or new IBRs. Hence, the standard applies to all IBRs. The implementation plan provides time for installation of disturbance monitoring equipment at existing plants. The data recorded under PRC-028 is to be used to show compliance with PRC-029 (ride-through requirements) and PRC-030 (analysis and mitigation of IBR performance issues).

The differences in requirements for IBRs in PRC-028 compared to PRC-002 are justified based on IBR's fast response during system disturbances, observation of IBR performance over last few years, and recent advancement in monitoring technology. Also note that purpose of these standards is very different.

Comment

AZPS supports the following comments that were submitted by EEI on behalf of its members regarding PRC-028 Requirement 7:

Subpart 7.1: EEI suggests aligning Requirement R7, Subpart 7.1 with PRC-002, Requirement R11, subpart 11.1. Making the data requirements different in the two standards may cause entities that own both synchronous generators and IBRs to inadvertently make compliance errors.

Subpart 7.2: This requirement seems to parallel Requirement R11, Subpart 11.2 yet the obligation for IBR owners to provide data has been reduced from 30 days to 15 days, while synchronous generator owners are afforded 30 days. EEI does not support this difference and believes these requirements should be harmonized.

AZPS requested that 30 days be used for both synchronous generators and IBRS.

VSL for R7: EEI suggests aligning the VSLs for Requirement R7 to what was provided for PRC-002, Requirement R11.

AZPS supports the following comments that were submitted by EEI on behalf of their members in regards to PRC-002: **Applicability Section comments:** EEI does not support the Applicability section because it uses the uncapitalized version of IBR. The definition of Inverter Based Resource was approved by the industry during the last posting of that definition and therefore should be capitalized. Additionally, footnote 1 is unnecessary. **Footnote 2:** EEI finds footnote 2 to be confusing and potentially in conflict with the Applicability Section. In the Applicability Section it states that IBRs are excluded from the scope of PRC-002 yet footnote 2 states "For the purposes of this standard, "directly connected" BES Elements are BES Elements connected at the same voltage level within the same physical location sharing a common ground grid with the BES bus identified under Attachment 1." We note that certain IBRs are BES Elements, but the Applicability Section stated inverter based resources (undefined in this standard) are not included. Yet footnote 2 seems to imply BES IBRs connected to a common bus at the same voltage level within the same physical location are to be included in PRC-002. Therefore, if this is the case, then certain IBRs are part of PRC-002. Please clarify what is intended by this footnote or delete it.

Thanks for your comment. The standard is revised and refers to proposed definition of Inverter-Based Resource that is being balloted concurrently with PRC-002/028 ballot. The definition of the Inverter-Based Resource includes plants connected to ac transmission system via VSC-HVDC system. See IBR definition's technical rationale for more information. The requirement R7 in PRC-028 is intentionally a bit different from an equivalent requirement R11 in PRC-002. This difference is justified based on differences in "purpose" of both of these standards. Regarding Footnote 2 in PRC-002, the exclusion in 4.2 is applicable to entire standard. In case where a BES IBR is "directly connected" to the identified bus, that BES IBR is excluded from PRC-002 requirements because of exclusion in 4.2. See Figure 1 in PRC-002's technical rationale.	
Richard Jackson - U.S. Bureau of Reclamation - 1	
Answer	

Document Name	
Comment	
Reclamation does not agree with the modifications to the wording of BES Elements in R6 and R7 in the "Violation Severity Levels" section. 'Element' is sufficiently defined in the NERC Glossary of terms and 'BES Element' encompasses the required equipment (elements) for Disturbance Monitoring. Reclamation recommends keeping the original wording "for all applicable BES Elements". Reclamation concurs that all IBR resources should have and maintain their own separate standards.

Comment	
FE supports EEI's comments which offers the following suggestions: PRC-028-1 Comments: Purpose Statement Comments: EEI does not support the addition of Footnote 1 to the Purpose Statement because it inappropriately changes the applicability of PRC-028, outside of the Applicability Section.	

Applicability Section Comments: EEI does not support the Applicability section because it uses the uncapitalized version of IBR and could unintentionally broaden the scope and create confusion in expectations.

Requirement R1 Comments:

Subpart 1.1: EEI does not support footnote 2 because it identifies facility scope that is not identified in the Applicability Section and appears to go beyond what was allowed in the approved SAR.

Subpart 1.4: EEI does not support the addition of VSC HVDC equipment because it was not included in the industry approved definition of IBR or this SAR. While EEI is not opposed to including VSC-HVDC equipment to this Reliability Standard if that equipment is in fact creating reliability concerns, no technical justification has been provided to clarify why this is necessary. To address our concern, we ask that that the SAR be revised to include this equipment and submit a technical justification document, as required by the Rules of Procedure (see Standard Processes Manual, Appendix 3a).

Requirement R7 Comments and associated VSLs:

Subpart 7.1: EEI suggests aligning Requirement R7, Subpart 7.1 with PRC-002, Requirement R11, subpart 11.1. Making the data requirements different in the two standards may cause entities that own both synchronous generators and IBRs to inadvertently make compliance errors.

Subpart 7.2: This requirement seems to parallel Requirement R11, Subpart 11.2 yet the obligation for IBR owners to provide data has been reduced from 30 days to 15 days, while synchronous generator owners are afforded 30 days. EEI does not support this difference and believes these requirements should be harmonized.

VSL for R7: EEI suggests aligning the VSLs for Requirement R7 to what was provided for PRC-002, Requirement R11.

PRC-002-5 Comments:
Applicability Section comments: EEI does not support the Applicability section because it uses the uncapitalized version of IBR. The definition of Inverter Based Resource was approved by the industry during the last posting of that definition and therefore should be capitalized. Additionally, footnote 1 is unnecessary.
Footnote 2: EEI finds footnote 2 to be confusing and potentially in conflict with the Applicability Section. In the Applicability Section it states that IBRs are excluded from the scope of PRC-002 yet footnote 2 states “For the purposes of this standard, “directly connected” BES Elements are BES Elements connected at the same voltage level within the same physical location sharing a common ground grid with the BES bus identified under Attachment 1.” We note that certain IBRs are BES Elements, but the Applicability Section stated inverter based resources

(undefined in this standard) are not included. Yet footnote 2 seems to imply BES IBRs connected to a common bus at the same voltage level within the same physical location are to be included in PRC-002. Therefore, if this is the case, then certain IBRs are part of PRC-002. Please clarify what is intended by this footnote or delete it.

TEPC agrees with EEI's comments regarding both PEC-002 and PRC-028:

PRC-002-5 - EEI does not support the Applicability section because it uses the uncapitalized version of IBR. The definition of Inverter Based Resource was approved by the industry during the last posting of that definition and therefore should be capitalized. Additionally, footnote 1 is unnecessary.

PRC-028-1 - EEI does not support the Applicability section because it uses the uncapitalized version of IBR and could unintentionally broaden the scope and create confusion in expectations.

Response	
Thanks for your comment. See response to EEI's comments. The applicability section is revised and refers to proposed definition of Inverter-Based Resource being balloted concurrently with PRC-002/028 ballot.

Comment	
AEP applauds the efforts of the standards drafting team for their continued work on this project. We believe that the newest drafts of both standards are greatly improved as compared to their predecessors. AEP is concerned however by recent revisions to PRC-028 R7.2, where all data requested in R7 must be provided within 15 days, rather than the 30 days allowed in the previous draft. In some cases, it will be very difficult to obtain, quality check, and provide this data within a 15-day window. Indeed, extensions might even be necessary in these cases. AEP seeks clarity from the standards drafting team regarding the justification for this, as the current draft of the Technical Rationale document provides no insight. During the webinar on 6/4/2024, the question was asked if a synchronous condenser is to be considered a dynamic reactive device per this standard. AEP would agree with the SDT that a synchronous condenser at an IBR facility should be considered a dynamic reactive device and requiring the desired monitoring. However, AEP would not agree to requiring monitoring "all" synchronous condensers in the transmission system under this SDT effort, and requests this be made clear in the Technical Rationale document. Please note that ERCOT already requires PMU monitoring at new FACTS devices and new synchronous condensers connected to 100kV and above.

Response

Thanks for your comment.

The time period of 15 calendar days strikes a compromise or balance between opposing opinions recommending shorter or longer time duration. The entity has a flexibility to request extension when more time is necessary to gather and quality check data before providing to the requester.

The PRC-028 applies to Inverter-Based Resources only. The synchronous condensers connected directly to transmission system and not part of Inverter-Based Resources are not in purview of the standard. If the synchronous condenser is installed within the IBR plant to provide dynamic reactive support, then only synchronous condenser to be monitored per requirements applicable to dynamic reactive device.

Comment

Protection relays and most disturbance monitoring equipment does not record power quantities in the FR Comtrade records. The sequence, power, and frequency values can be calculated from the analog values that are recorded in 2.1.1 and 2.1.2. Will it be acceptable to provide a comtrade file with only the individual phase analog values which can be used to calculate the real and reactive power values?

Likes 0	
Dislikes 0	

Response

Thanks for your comment. PRC-002/028 require recorded data to “determine” specified quantities. It is understood that some specified quantities are recorded while others are derived from recorded quantities. For example, active and reactive power is determined based on voltage and current recordings.

Standards Announcement

Project 2021-04 Modifications to PRC-002 - Phase II

Additional Ballots and Non-binding Polls Open through June 14, 2024

Now Available

Additional ballots for **Project 2021-04 Modifications to PRC-002 - Phase II** and non-binding polls of the associated Violation Risk Factors and Violation Severity Levels are open through **8 p.m. Eastern, Friday, June 14, 2024** for the following standards and implementation plan:

- PRC-002-5 – Disturbance Monitoring and Reporting Requirements
- PRC-028-1 – Disturbance Monitoring and Reporting Requirements for Inverter-Based Resources
- Implementation Plan

The standard drafting team's considerations of the responses received from the last comment period are reflected in this draft of the standard.

Reminder Regarding Corporate RBB Memberships

Under the NERC Rules of Procedure, each entity and its affiliates is collectively permitted one voting membership per Registered Ballot Body Segment. Each entity that undergoes a change in corporate structure (such as a merger or acquisition) that results in the entity or affiliated entities having more than the one permitted representative in a particular Segment must withdraw the duplicate membership(s) prior to joining new ballot pools or voting on anything as part of an existing ballot pool. Contact ballotadmin@nerc.net to assist with the removal of any duplicate registrations.

Balloting

Members of the ballot pools associated with this project can log in and submit their votes by accessing the Standards Balloting and Commenting System (SBS) here.

Note: Votes cast in previous ballots will not carry over to additional ballots. It is the responsibility of the registered voter in the ballot pools to place votes again. To ensure a quorum is reached, if you do not want to vote affirmative or negative, cast an abstention.

- *Contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern) for problems regarding accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out.*
- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*

- *Please be mindful of ballot and comment period closing dates. We ask to* ***allow at least 48 hours*** *for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts* ***prior to the last day*** *of a comment/ballot period.*

Next Steps
The ballot results will be announced and posted on the project page. The drafting team will review all responses received during the comment period and determine the next steps of the project.

For information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Senior Standards Developer, Ben Wu (via email) or at 470-542-6882. Subscribe to this project's observer mailing list by selecting "NERC Email Distribution Lists" from the "Service" drop-down menu and specify “Project 2021-04 Modifications to PRC-002 observer list” in the Description Box.

Standards Announcement

Project 2021-04 Modifications to PRC-002 – Phase II

Formal Comment Period Extended, Now Open through June 17, 2024

Now Available

The formal comment period for **Project 2021-04 Modifications to PRC-002- Phase** II has been extended and is now open through **8 p.m. Eastern, Monday, June 17, 2024** for the following standards and implementation plan:

- PRC-002-5 – Disturbance Monitoring and Reporting Requirements
- PRC-028-1 – Disturbance Monitoring and Reporting Requirements for Inverter-Based Resources
- Implementation Plan

The standard drafting team's considerations of the responses received from the previous comment period are reflected in this draft of the standard.

Reminder Regarding Corporate RBB Memberships

Under the NERC Rules of Procedure, each entity and its affiliates is collectively permitted one voting membership per Registered Ballot Body Segment. Each entity that undergoes a change in corporate structure (such as a merger or acquisition) that results in the entity or affiliated entities having more than the one permitted representative in a particular Segment must withdraw the duplicate membership(s) prior to joining new ballot pools or voting on anything as part of an existing ballot pool. Contact **ballotadmin@nerc.net** to assist with the removal of any duplicate registrations.

Commenting

Use the Standards Balloting and Commenting System (SBS) to submit comments. An unofficial Word version of the comment form is posted on the project page.

- *Contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern) for problems regarding accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out.*

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

PRC-028-1 is posted for a formal comment period with additional ballot.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	January 20, 2021
SAR posted for comment	June 14, 2021 – July 13, 2021

Anticipated Actions	Date
45-day formal comment period with ballot	August 1, 2023 – September 14, 2023
25-day formal or informal comment period with additional ballot	March 18, 2024 – April 11, 2024
15-day formal or informal comment period with additional ballot	May 31, 2024 – June 17, 2024
22-day formal or informal comment period with additional ballot	July 22, 2024 – August 12, 2024
10-day final ballot	September 15, 2024 – September 24, 2024
Board adoption	October 15, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be **removed**.

Term(s):

The terms Inverter-Based Resource (IBR) refer to proposed definitions being developed under the Project 2020-06 Verifications of Models and Data for Generators. As of this posting, the proposed definition of Inverter-Based Resource is:

Inverter-Based Resource (IBR): A plant/facility consisting of individual devices that are capable of exporting Real Power through a power electronic interface(s) such as inverter or converter, and that are operated together as a single resource at a common point of interconnection to the electric system. IBRs include, but are not limited to, plants/facilities with solar photovoltaic (PV), Type 3 and Type 4 wind, battery energy storage system (BESS), and fuel cell devices.

A. Introduction

1. **Title:** Disturbance Monitoring and Reporting Requirements for Inverter-Based Resources

2. **Number:** PRC-028-1

3. **Purpose:** To have adequate data available from Inverter-Based Resources to evaluate Inverter-Based Resource ride-through performance during System Disturbances and to provide data for Inverter-Based Resource model validation.

4. **Applicability:**

   4.1. Functional Entities:

   4.1.1. Generator Owner that owns equipment as identified in section 4.2

   4.2. Facilities:

   4.2.1 BES Inverter-Based Resources

   4.2.2 Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV

5. **Effective Date:** See Implementation Plan

B. Requirements and Measures

R1. Each Generator Owner shall have sequence of event recording (SER) data for the following Elements that it owns: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

1.1. Circuit breaker position (open/close) for circuit breakers associated with the main power transformer(s)[1], collector bus(es), shunt static and dynamic reactive device(s), and AC-DC and DC-AC converters, if any, in case of VSC HVDC system with a dedicated connection to Inverter-Based Resource.

1.2. For IBR units[2] in commercial operation after the effective date of this standard, the following data shall be recorded when triggered by ride-through operation or tripping of an IBR unit.

1.2.1. All fault codes.

[1] For the purpose of this standard, the main power transformer is the power transformer that steps up voltage from the collection system voltage to the nominal transmission/interconnecting system voltage for Inverter-Based Resources. In case of dedicated VSC HVDC system connecting to an Inverter-Based Resource, a transformer isolating the DC-AC converter from the transmission system is also considered a main power transformer.

[2] IBR unit includes the inverter, converter, wind turbine generator, or high voltage direct current converter connecting generating resource to alternating current Transmission network.

1.2.2. All fault alarms.

1.2.3. High and low voltage ride-through mode status.

1.2.4. High and low frequency ride-through mode status.

1.3. For IBR units in commercial operation before the effective date of this standard, the following data shall be recorded, if capable, when triggered by ride-through operation or tripping of an IBR unit.

1.3.1. All fault codes.

1.3.2. All fault alarms.

1.3.3. High and low voltage ride-through mode status.

1.3.4. High and low frequency ride-through mode status.

M1. The Generator Owner has evidence (electronic or hard copy) of data, as applicable, as specified in Requirement R1. Evidence may include, but is not limited to: (1) actual data recordings; or (2) documents describing the device interconnections and configurations which may include a single design standard as representative for common installations; or (3) station or equipment drawings.

R2. Each Generator Owner shall have triggered fault recording (FR) data to determine the following electrical quantities for Elements that it owns: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

2.1. High-side of the main power transformer FR data:

2.1.1. Phase-to-neutral voltage for each phase.

2.1.2. Each phase current and the residual or neutral current.

2.1.3. Real and Reactive Power expressed on a three-phase basis.

2.2. Collector feeder breaker FR data:

2.2.1. Phase-to-neutral voltage for each phase.

2.2.2. Each phase current and the residual or neutral current.

2.2.3. Real and Reactive Power expressed on a three-phase basis.

2.3. Shunt dynamic reactive device FR data:

2.3.1. Phase-to-neutral voltage for each phase.

2.3.2. Each phase current and the residual or neutral current.

2.3.3. Reactive Power output expressed on a three-phase basis.

M2. The Generator Owner has evidence (electronic or hard copy) of FR data that is sufficient to determine electrical quantities as specified in Requirement R2. Evidence may include, but is not limited to: (1) actual data recordings or derivations; or (2) documents describing the device specifications and configurations which may include a single design standard as representative for common installations; or (3) station or equipment drawings.

R3. Each Generator Owner shall have FR data as specified in Requirement R2 that meets the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

3.1. High-side of the main power transformer FR data:

3.1.1. A single record or multiple records that include a pre-trigger record length of at least two cycles and a total record length of at least 2.0 seconds for the same trigger point.

3.1.2. A minimum recording rate of 64 samples per cycle.

3.1.3. Trigger settings for at least the following:

3.1.3.1. Neutral (residual) overcurrent.

3.1.3.2. AC phase overvoltage and undervoltage.

3.1.3.3. Overfrequency and underfrequency

3.2. Collector feeder breaker FR data:

3.2.1. A single record or multiple records that include a pre-trigger record length of at least two cycles and a total record length of at least 2.0 seconds for the same trigger point.

3.2.2. A minimum recording rate of 64 samples per cycle.

3.2.3. Trigger settings for at least the following:

3.2.3.1. Neutral (residual) overcurrent, if applicable.

3.2.3.2. AC phase overvoltage and undervoltage.

3.2.3.3. Overfrequency and underfrequency.

3.3. Shunt dynamic reactive device FR data:

3.3.1. A single record or multiple records that include a pre-trigger record length of at least two cycles and a total record length of at least 2.0 seconds for the same trigger point.

3.3.2. A minimum recording rate of 64 samples per cycle.

3.3.3. Trigger settings for at least the following:

3.3.3.1. Neutral (residual) overcurrent.

3.3.3.2. AC phase overvoltage and undervoltage.

M3. The Generator Owner has evidence (electronic or hard copy) that FR data meets Requirement R3. Evidence may include, but is not limited to: (1) actual data recordings or derivations, or (2) documents describing the device specification and device configuration or settings.

R4. Each Generator Owner shall have continuous dynamic disturbance recording (DDR) data and storage to determine the following electrical quantities for each main power transformer(s) it owns: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

4.1. One phase-to-neutral or positive sequence voltage on high-side of the main power transformer(s).

4.2. The phase current for the same phase at the same voltage corresponding to the voltage in Requirement R4, Part 4.1, or the positive sequence current.

4.3. Real Power and Reactive Power flows expressed on a three-phase basis corresponding to each main power transformer(s) where current measurements are required.

4.4. Frequency of any one of the voltage(s) in Requirement R4, Part 4.1.

M4. The Generator Owner has evidence (electronic or hard copy) of continuous DDR data recording and storage to determine electrical quantities as specified in Requirement R4. Evidence may include, but is not limited to: (1) actual data recordings or derivations; or (2) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (3) station drawings.

R5. Each Generator Owner responsible for DDR data for the electrical quantities identified in Requirement R4 shall have DDR data that meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

5.1. Input sampling rate of at least 960 samples per second.

5.2. Output recording rate of electrical quantities of at least 60 times per second.

M5. The Generator Owner has evidence (electronic or hard copy) that DDR data meets Requirement R5. Evidence may include, but is not limited to: (1) documents describing the device specification, device configuration, or settings (R5, Part 5.1; R5, Part 5.2); or (2) actual data recordings (R5, Part 5.2).

R6. Each Generator Owner shall time synchronize all SER, FR, and DDR data to meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

6.1. Synchronization to Coordinated Universal Time (UTC) with or without a local time offset.

6.2. Synchronized device clock accuracy within ± 1 milliseconds of UTC. The IBR units shall have synchronized device clock accuracy within ± 100 milliseconds of UTC.

M6. The Generator Owner has evidence (electronic or hard copy) of time synchronization described in Requirement R6. Evidence may include, but is not limited to: (1) documents describing the device specification, configuration, or setting; (2) time synchronization indication or status; or 3) station drawings.

R7. Each Generator Owner shall provide all requested SER, FR, and DDR data to its Transmission Planner, Planning Coordinator, Transmission Operator, Balancing Authority, Reliability Coordinator, Regional Entity, or NERC in accordance with the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

7.1. Data shall be retrievable for the period of 20 calendar days, inclusive of the day the data was recorded.

7.2. Data subject to Part 7.1 shall be provided within 15 calendar days of a request unless an extension is granted by the requestor.

7.3. SER data shall be provided in ASCII[3] Comma Separated Value (CSV) format following Attachment 1.

7.4. FR data shall be provided either in CSV format with appropriate headers or in electronic files that are formatted in conformance with C37.111, IEEE Standard Common Format for Transient Data Exchange (COMTRADE), revision C37.111-1999 or later.

7.5. DDR data shall be provided either in CSV format with appropriate headers or in electronic files that are formatted in conformance with C37.111, IEEE Standard Common Format for Transient Data Exchange (COMTRADE), revision C37.111-1999 or later.

7.6. Data files shall be named in conformance with C37.232, IEEE Standard for Common Format for Naming Time Sequence Data Files (COMNAME), revision C37.232-2011 or later.

M7. The Generator Owner has evidence (electronic or hard copy) that data was submitted upon request in accordance with Requirement R7. Evidence may include, but is not limited to: (1) actual data recordings; (2) dated transmittals to the requesting entity with formatted records; or (3) documents describing data storage capability, device specification, configuration, or settings.

R8. Each Generator Owner shall, upon the discovery of a failure of the recording capability for the SER, FR, or DDR data: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

- Restore the recording capability within 90 calendar days, or
- Submit a Corrective Action Plan (CAP) to the Regional Entity within 90 calendar days and then implement it according to CAP timeline.

M8. The Generator Owner has dated evidence (electronic or hard copy) that meets Requirement R8. Evidence may include, but is not limited to: (1) dated reports of the discovery of a failure, (2) documentation noting the date the data recording was restored, (3) SCADA records, or (4) dated Corrective Action Plan transmittals to the Regional Entity and evidence of Corrective Action Plan implementation.

C. Compliance

1. **Compliance Monitoring Process**

   1.1. **Compliance Enforcement Authority:** “Compliance Enforcement Authority” means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

   1.2. **Evidence Retention:**

   The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

   The Generator Owner shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

   The Generator Owner shall retain evidence, as per Requirements R1 through R8, for three calendar years.

   If a Generator Owner is found non-compliant, it shall keep information related to the non-compliance until mitigation is completed and approved or for the time specified above, whichever is longer.

   The Compliance Enforcement Authority shall keep the last audit records, and all requested and submitted subsequent audit records.

   1.3. **Compliance Monitoring and Enforcement Program:** As defined in the NERC Rules of Procedure, “Compliance Monitoring and Enforcement Program” refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	Each Generator Owner as directed by Requirement R1 to have the required SER data had more than 80 percent, but less than 100 percent of the circuit breaker(s) identified in Requirement R1.	Each Generator Owner as directed by Requirement R1 to have the required SER data had more than 70 percent, but less than or equal to 80 percent of the circuit breaker(s) identified in Requirement R1.	Each Generator Owner as directed by Requirement R1 to have the required SER data had more than 60 percent, but less than or equal to 70 percent of the circuit breaker(s) identified in Requirement R1.	Each Generator Owner as directed by Requirement R1 to have the required SER data had less than or equal to 60 percent of the circuit breaker(s) identified in Requirement R1.
R2	The Generator Owner had FR data as directed by Requirement R2, Parts 2.1, 2.2, and 2.3 that covers more than 80 percent, but less than 100 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The Generator Owner had FR data as directed by Requirement R2, Parts 2.1, 2.2, and 2.3 that covers more than 70 percent, but less than or equal to 80 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The Generator Owner had FR data as directed by Requirement R2, Parts 2.1, 2.2, and 2.3 that covers more than 60 percent, but less than or equal to 70 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The Generator Owner had FR data as directed by Requirement R2, Parts 2.1, 2.2, and 2.3 that covers less than or equal to 60 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.
R3	The Generator Owner had FR data that meets more	The Generator Owner had FR data that meets more	The Generator Owner had FR data that meets more	The Generator Owner had FR data that meets less

	than 80 percent, but less than 100 percent of the total recording parameters as specified in Requirement R3.	than 70 percent, but less than or equal to 80 percent of the total recording parameters as specified in Requirement R3.	than 60 percent, but less than or equal to 70 percent of the total recording parameters as specified in Requirement R3.	than or equal to 60 percent of the total recording parameters as specified in Requirement R3.
R4	The Generator Owner had DDR data as directed by Requirement R4, Parts 4.1 through 4.4 that covered more than 80 percent, but less than 100 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The Generator Owner had DDR data as directed by Requirement R4, Parts 4.1 through 4.4 for more than 70 percent, but less than or equal to 80 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The Generator Owner had DDR data as directed by Requirement R4, Parts 4.1 through 4.4 for more than 60 percent, but less than or equal to 70 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The Generator Owner had DDR data as directed by Requirement R4, Parts 4.1 through 4.4 for less than or equal to 60 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.
R5	The Generator Owner had DDR data that meets more than 80 percent, but less than 100 percent of the total recording parameters as specified in Requirement R5.	The Generator Owner had DDR data that meets more than 70 percent, but less than or equal to 80 percent of the total recording properties as specified in Requirement R5.	The Generator Owner had DDR data that meets more than 60 percent, but less than or equal to 70 percent of the total recording properties as specified in Requirement R5.	The Generator Owner had DDR data that meets less than or equal to 60 percent of the total recording properties as specified in Requirement R5.

R6	The Generator Owner had time synchronized SER, FR, or DDR data per Requirement R6, Parts 6.1 and 6.2 for more than 90 percent, but less than 100 percent of the Elements.	The Generator Owner had time synchronized SER, FR, or DDR data per Requirement R6, Parts 6.1 and 6.2 for more than 80 percent, but less than or equal to 90 percent of the Elements.	The Generator Owner had time synchronized SER, FR, or DDR data per Requirement R6, Parts 6.1 and 6.2 for more than 70 percent, but less than or equal to 80 percent of the Elements.	The Generator Owner failed to have time synchronized SER, FR, or DDR data per Requirement R6, Parts 6.1 and 6.2 for less than or equal to 70 percent of the Elements.
R7	The Generator Owner as directed by Requirement R7 provided more than 90 percent, but less than 100 percent of the requested data. OR The Generator Owner as directed by Requirement R7, Part 7.2 provided the requested data one to 10 calendar days late. OR The Generator Owner as directed by Requirement R7, Parts 7.3 through 7.6 provided more than 90 percent of the data, but less than 100 percent of	The Generator Owner as directed by Requirement R7 provided more than 80 percent, but less than or equal to 90 percent of the requested data. OR The Generator Owner as directed by Requirement R7, Part 7.2 provided the requested data 11 to 20 calendar days late. Attachment 1

Sequence of Events Recording (SER) Data Format

(Requirement R7, Part 7.3)

Date, Time, Local Time Code, Plant Name, Device[4], State[5]

08/27/23, 23:58:57.110, -5, Plant name 1, Breaker 1, Close

08/27/23, 23:58:57.082, -5, Plant name 2, Breaker 2, Close

08/27/23, 23:58:57.217, -5, Plant name 1, IBR unit 1, undervoltage ride-through mode

08/27/23, 23:58:57.214, -5, Plant name 2, IBR unit 2, dc overcurrent trip

[4] Device name may include specific names of breakers or IBR units as appropriate.

[5] Breaker status and any other terminology such as TRIP, TRIP TO LOCKOUT, RECLOSE, etc. is acceptable. For IBR unit level data, fault codes, alarms, change in operating mode etc., are also acceptable.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

PRC-028-1 is posted for a formal comment period with additional ballot.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	January 20, 2021
SAR posted for comment	June 14, 2021 – July 13, 2021

Anticipated Actions	Date
45-day formal comment period with ballot	August 1, 2023 – September 14, 2023
25-day formal or informal comment period with additional ballot	March 18, 2024 – April 11, 2024
15-day formal or informal comment period with additional ballot	May 31, 2024 – June 17, 2024
22-day formal or informal comment period with additional ballot	July 22, 2024 – August 12, 2024
10-day final ballot	September 15, 2024 – September 24, 2024
Board adoption	October 15, 2024

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be **removed**.

Term(s):

The terms Inverter-Based Resource (IBR) refer to proposed definitions being developed under the Project 2020-06 Verifications of Models and Data for Generators. As of this posting, the proposed definition of Inverter-Based Resource is:

~~N/A~~ **Inverter-Based Resource (IBR):** A plant/facility consisting of individual devices that are capable of exporting Real Power through a power electronic interface(s) such as inverter or converter, and that are operated together as a single resource at a common point of interconnection to the electric system. IBRs include, but are not limited to, plants/facilities with solar photovoltaic (PV), Type 3 and Type 4 wind, battery energy storage system (BESS), and fuel cell devices.

A. Introduction

1. **Title:** Disturbance Monitoring and Reporting Requirements for Inverter-Based Resources

2. **Number:** PRC-028-1

3. **Purpose:** To have adequate data available from ~~i~~Inverter-~~b~~Based ~~r~~Resources~~[1]~~ to evaluate ~~i~~Inverter-~~b~~Based ~~r~~Resource ride-through performance during ~~Bulk Electric~~ System ~~(BES)~~ Disturbances and to provide data for ~~i~~Inverter-~~b~~Based ~~r~~Resource model validation.

4. **Applicability:**

   4.1. Functional Entities:

   ~~4.1.1. Transmission Owner that owns equipment as identified in section 4.2~~

   ~~4.1.2.~~4.1.1. Generator Owner that owns equipment as identified in section 4.2

   4.2. Facilities:

   4.2.1 BES ~~i~~Inverter-~~b~~Based ~~r~~Resources

   ~~4.1.1~~4.2.2 Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV

5. **Effective Date:** See Implementation Plan

B. Requirements and Measures

R1. Each ~~Transmission Owner and~~ Generator Owner shall have ~~circuit breaker position (open/close)~~ sequence of event recording (SER) data for the following Elements~~circuit breakers~~ that it owns~~associated with~~: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

~~1.1.~~ Circuit breaker position (open/close) for circuit breakers associated with the ~~Main~~ main power transformer(s)[2], collector bus(es), shunt static and dynamic reactive device(s), and AC-DC and DC-AC converters, if any, in case of VSC HVDC system with a dedicated connection to Inverter-Based Resource.

~~[1] For the purpose of this standard, "inverter-based resources" refers to a collection of individual solar photovoltaic (PV), Type 3 and Type 4 wind turbines, battery energy storage system (BESS), or fuel cells that operate as a single plant/resource. In case of offshore wind plants connecting via a dedicated voltage source converter high voltage direct current (VSC HVDC) line, the inverter-based resource includes VSC HVDC line.~~

[2] For the purpose of this standard, the main power transformer is the power transformer that steps up voltage from the collection system voltage to the nominal transmission/interconnecting system voltage for ~~i~~Inverter-~~b~~Based ~~r~~Resources. In case of dedicated VSC HVDC system connecting to an ~~i~~Inverter-~~b~~Based ~~r~~Resource, a transformer isolating the DC-AC converter from the transmission system is also considered a main power transformer.

~~**1.2.** Collector bus(es), including collector feeder breakers.~~

~~**1.3.** Shunt static or dynamic reactive device(s).~~

1.1. ~~AC-DC and DC-AC converters, if any, in case of VSC HVDC system with a dedicated connection to inverter-based resource.~~

1.2. For IBR units[3] in commercial operation after the effective date of this standard, the following data shall be recorded when triggered by ride-through operation or tripping of an IBR unit.

1.2.1. All fault codes.

1.2.2. All fault alarms.

1.2.3. High and low voltage ride-through mode status.

1.2.4. High and low frequency ride-through mode status.

1.3. For IBR units in commercial operation before the effective date of this standard, the following data shall be recorded, if capable, when triggered by ride-through operation or tripping of an IBR unit.

1.3.1. All fault codes.

1.3.2. All fault alarms.

1.3.3. High and low voltage ride-through mode status.

~~**1.3.1.**~~**1.3.4.** High and low frequency ride-through mode status.

M1. The ~~Transmission Owner or~~ Generator Owner has evidence (electronic or hard copy) of data, as applicable, as specified in Requirement R1. Evidence may include, but is not limited to: (1) actual data recordings; or (2) documents describing the device interconnections and configurations which may include a single design standard as representative for common installations; or (3) station or equipment drawings.

R2. Each ~~Transmission Owner and~~ Generator Owner shall have triggered fault recording (FR) data to determine the following electrical quantities for Elements that it owns: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

2.1. High-side of the main power transformer FR data:

2.1.1. Phase-to-neutral voltage for each phase.

2.1.2. Each phase current and the residual or neutral current.

2.1.3. Real and R~~r~~eactive ~~p~~Power expressed on a three-phase basis.

2.2. Collector feeder breaker FR data:

2.2.1. Phase-to-neutral voltage for each phase.

[3] IBR unit includes the inverter, converter, wind turbine generator, or high voltage direct current converter connecting generating resource to alternating current Transmission network.

2.2.2. Each phase current and the residual or neutral current.

~~2.1.3.~~2.2.3. Real and Reactive Power expressed on a three-phase basis.

~~2.2.~~2.3. Shunt dynamic reactive device FR data:

~~2.2.1.~~2.3.1. Phase-to-neutral voltage for each phase.

~~2.2.2.~~2.3.2. Each phase current and the residual or neutral current.

~~2.2.3.~~2.3.3. Reactive P~~p~~ower output expressed on a three-phase basis.

M2. The ~~Transmission Owner or~~ Generator Owner has evidence (electronic or hard copy) of FR data that is sufficient to determine electrical quantities as specified in Requirement R2. Evidence may include, but is not limited to: (1) actual data recordings or derivations; or (2) documents describing the device specifications and configurations which may include a single design standard as representative for common installations; or (3) station or equipment drawings.

R3. Each ~~Transmission Owner and~~ Generator Owner shall have FR data as specified in Requirement R2 that meets the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

3.1. High-side of the main power transformer FR data:

3.1.1. A single record or multiple records that include a pre-trigger record length of at least two cycles and a total record length of at least 2.0 seconds for the same trigger point.

3.1.2. A minimum recording rate of 64 samples per cycle.

3.1.3. Trigger settings for at least the following:

3.1.3.1. Neutral (residual) overcurrent.

3.1.3.2. AC phase overvoltage and undervoltage.

~~3.1.3.2.~~3.1.3.3. Overfrequency and underfrequency

3.2. Collector feeder breaker FR data:

3.2.1. A single record or multiple records that include a pre-trigger record length of at least two cycles and a total record length of at least 2.0 seconds for the same trigger point.

3.2.2. A minimum recording rate of 64 samples per cycle.

3.2.3. Trigger settings for at least the following:

3.2.3.1. Neutral (residual) overcurrent, if applicable.

3.2.3.2. AC phase overvoltage and undervoltage.

3.2.3.3. Overfrequency and underfrequency.

~~3.2.~~3.3. Shunt dynamic reactive device FR data:

~~3.2.1.~~3.3.1. A single record or multiple records that include a pre-trigger record length of at least two cycles and a total record length of at least 2.0 seconds for the same trigger point.

~~3.2.2.~~3.3.2. A minimum recording rate of 64 samples per cycle.

~~3.2.3.~~3.3.3. Trigger settings for at least the following:

~~3.2.3.1.~~3.3.3.1. Neutral (residual) overcurrent.

~~3.2.3.2.~~3.3.3.2. AC phase overvoltage and undervoltage.

M3. The ~~Transmission Owner or~~ Generator Owner has evidence (electronic or hard copy) that FR data meets Requirement R3. Evidence may include, but is not limited to: (1) actual data recordings or derivations, or (2) documents describing the device specification and device configuration or settings.

R4. Each Generator Owner ~~and Transmission Owner~~ shall have continuous dynamic disturbance recording (DDR) data and storage to determine the following electrical quantities for each main power transformer(s) it owns: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

4.1. One phase-to-neutral or positive sequence voltage on high-side of the main power transformer(s).

4.2. The phase current for the same phase at the same voltage corresponding to the voltage in Requirement R4, Part 4.1, or the positive sequence current.

4.3. Real Power and Reactive Power flows expressed on a three-phase basis corresponding to each main power transformer(s) where current measurements are required.

4.4. Frequency of any one of the voltage(s) in Requirement R4, Part 4.1.

M4. The Generator Owner ~~or Transmission Owner~~ has evidence (electronic or hard copy) of continuous DDR data recording and storage to determine electrical quantities as specified in Requirement R4. Evidence may include, but is not limited to: (1) actual data recordings or derivations; or (2) documents describing the device specifications and configurations, which may include a single design standard as representative for common installations; or (3) station drawings.

R5. Each ~~Transmission Owner and~~ Generator Owner responsible for DDR data for the electrical quantities identified in Requirement R4 shall have DDR data that meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

5.1. Input sampling rate of at least 960 samples per second.

5.2. Output recording rate of electrical quantities of at least 60 times per second.

M5. The ~~Transmission Owner or~~ Generator Owner has evidence (electronic or hard copy) that DDR data meets Requirement R5. Evidence may include, but is not limited to: (1) documents describing the device specification, device configuration, or settings (R5, Part 5.1; R5, Part 5.2); or (2) actual data recordings (R5, Part 5.2).

R6. Each ~~Transmission Owner and~~ Generator Owner shall time synchronize all SER, FR, and DDR data to meet the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

6.1. Synchronization to Coordinated Universal Time (UTC) with or without a local time offset.

6.2. Synchronized device clock accuracy within ± 1 milliseconds of UTC. The IBR units shall have synchronized device clock accuracy within ± 100 milliseconds of UTC.

M6. The ~~Transmission Owner or~~ Generator Owner has evidence (electronic or hard copy) of time synchronization described in Requirement R6. Evidence may include, but is not limited to: (1) documents describing the device specification, configuration, or setting; (2) time synchronization indication or status; or 3) station drawings.

R7. Each ~~Transmission Owner and~~ Generator Owner shall provide all requested SER, FR, and DDR data to its Transmission Planner, Planning Coordinator, Transmission Operator, Balancing Authority, Reliability Coordinator, Regional Entity, or NERC in accordance with the following: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

7.1. Data shall be retrievable for the period of 20 calendar days, inclusive of the day the data was recorded.

7.2. Data subject to Part 7.1 shall be provided within 15 calendar days of a request unless an extension is granted by the requestor.

7.3. SER data shall be provided in ASCII[4] Comma Separated Value (CSV) format following Attachment 1.

7.4. FR data shall be provided either in CSV format with appropriate headers or in electronic files that are formatted in conformance with C37.111, IEEE Standard Common Format for Transient Data Exchange (COMTRADE), revision C37.111-1999 or later.

7.5. DDR data shall be provided either in CSV format with appropriate headers or in electronic files that are formatted in conformance with C37.111, IEEE Standard Common Format for Transient Data Exchange (COMTRADE), revision C37.111-1999 or later.

7.6. Data files shall be named in conformance with C37.232, IEEE Standard for Common Format for Naming Time Sequence Data Files (COMNAME), revision C37.232-2011 or later.

M7. The ~~Transmission Owner or~~ Generator Owner has evidence (electronic or hard copy) that data was submitted upon request in accordance with Requirement R7. Evidence may include, but is not limited to: (1) actual data recordings; (2) dated transmittals to

[4] American Standard Code for Information Exchange

the requesting entity with formatted records; or (3) documents describing data storage capability, device specification, configuration, or settings.

R8. Each ~~Transmission Owner and~~ Generator Owner shall, upon the discovery of a failure of the recording capability for the SER, FR, or DDR data: *[Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

- Restore the recording capability within 90 calendar days, or
- Submit a Corrective Action Plan (CAP) to the Regional Entity within 90 calendar days and then implement it according to CAP timeline.

M8. The ~~Transmission Owner or~~ Generator Owner has dated evidence (electronic or hard copy) that meets Requirement R8. Evidence may include, but is not limited to: (1) dated reports of the discovery of a failure, (2) documentation noting the date the data recording was restored, (3) SCADA records, or (4) dated Corrective Action Plan transmittals to the Regional Entity and evidence of Corrective Action Plan implementation.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: “Compliance Enforcement Authority” means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention:

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The ~~Transmission Owner and~~ Generator Owner shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

The ~~Transmission Owner and~~ Generator Owner shall retain evidence, as per Requirements R1 through R8, for three calendar years.

If a ~~Transmission Owner or~~ Generator Owner is found non-compliant, it shall keep information related to the non-compliance until mitigation is completed and approved or for the time specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records, and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	Each ~~Transmission Owner or~~ Generator Owner as directed by Requirement R1 to have the required SER data had more than 80 percent, but less than 100 percent of the circuit breaker(s) identified in Requirement R1.	Each ~~Transmission Owner or~~ Generator Owner as directed by Requirement R1 to have the required SER data had more than 70 percent, but less than or equal to 80 percent of the circuit breaker(s) identified in Requirement R1.	Each ~~Transmission Owner or~~ Generator Owner as directed by Requirement R1 to have the required SER data had more than 60 percent, but less than or equal to 70 percent of the circuit breaker(s) identified in Requirement R1.	Each ~~Transmission Owner or~~ Generator Owner as directed by Requirement R1 to have the required SER data had less than or equal to 60 percent of the circuit breaker(s) identified in Requirement R1.
R2	The ~~Transmission Owner or~~ Generator Owner had FR data as directed by Requirement R2, Parts 2.1, 2.2, and 2.3 that covers more than 80 percent, but less than 100 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The ~~Transmission Owner or~~ Generator Owner had FR data as directed by Requirement R2, Parts 2.1, 2.2, and 2.3 that covers more than 70 percent, but less than or equal to 80 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The ~~Transmission Owner or~~ Generator Owner had FR data as directed by Requirement R2, Parts 2.1, 2.2, and 2.3 that covers more than 60 percent, but less than or equal to 70 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The ~~Transmission Owner or~~ Generator Owner had FR data as directed by Requirement R2, Parts 2.1, 2.2, and 2.3 that covers less than or equal to 60 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.

R3	The ~~Transmission Owner or~~ Generator Owner had FR data that meets more than 80 percent, but less than 100 percent of the total recording parameters as specified in Requirement R3.	The ~~Transmission Owner or~~ Generator Owner had FR data that meets more than 70 percent, but less than or equal to 80 percent of the total recording parameters as specified in Requirement R3.	The ~~Transmission Owner or~~ Generator Owner had FR data that meets more than 60 percent, but less than or equal to 70 percent of the total recording parameters as specified in Requirement R3.	The ~~Transmission Owner or~~ Generator Owner had FR data that meets less than or equal to 60 percent of the total recording parameters as specified in Requirement R3.
R4	The ~~Transmission Owner or~~ Generator Owner had DDR data as directed by Requirement R4, Parts 4.1 through 4.4 that covered more than 80 percent, but less than 100 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The ~~Transmission Owner or~~ Generator Owner had DDR data as directed by Requirement R4, Parts 4.1 through 4.4 for more than 70 percent, but less than or equal to 80 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The ~~Transmission Owner or~~ Generator Owner had DDR data as directed by Requirement R4, Parts 4.1 through 4.4 for more than 60 percent, but less than or equal to 70 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	The ~~Transmission Owner or~~ Generator Owner had DDR data as directed by Requirement R4, Parts 4.1 through 4.4 for less than or equal to 60 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.
R5	The ~~Transmission Owner or~~ Generator Owner had DDR data that meets more than 80 percent, but less than 100 percent of the	The ~~Transmission Owner or~~ Generator Owner had DDR data that meets more than 70 percent, but less than or equal to 80 percent of the	The ~~Transmission Owner or~~ Generator Owner had DDR data that meets more than 60 percent, but less than or equal to 70	The ~~Transmission Owner or~~ Generator Owner had DDR data that meets less than or equal to 60 percent of the total

	total recording parameters as specified in Requirement R5.	total recording properties as specified in Requirement R5.	percent of the total recording properties as specified in Requirement R5.	recording properties as specified in Requirement R5.
R6	The ~~Transmission Owner or~~ Generator Owner had time synchronized SER, FR, or DDR data per Requirement R6, Parts 6.1 and 6.2 for more than 90 percent, but less than 100 percent of the Elements.	The ~~Transmission Owner or~~ Generator Owner had time synchronized SER, FR, or DDR data per Requirement R6, Parts 6.1 and 6.2 for more than 80 percent, but less than or equal to 90 percent of the Elements.	The ~~Transmission Owner or~~ Generator Owner had time synchronized SER, FR, or DDR data per Requirement R6, Parts 6.1 and 6.2 for more than 70 percent, but less than or equal to 80 percent of the Elements.	The ~~Transmission Owner or~~ Generator Owner failed to have time synchronized SER, FR, or DDR data per Requirement R6, Parts 6.1 and 6.2 for less than or equal to 70 percent of the Elements.
R7	The ~~Transmission Owner or~~ Generator Owner as directed by Requirement R7 provided more than 90 percent, but less than 100 percent of the requested data. OR The ~~Transmission Owner or~~ Generator Owner as directed by Requirement R7, Part 7.2 provided the requested data one to 10 calendar days late~~more than 15 calendar days, but less than or equal to 25~~	The ~~Transmission Owner or~~ Generator Owner as directed by Requirement R7 provided more than 80 percent, but less than or equal to 90 percent of the requested data. OR The ~~Transmission Owner or~~ Generator Owner as directed by Requirement R7, Part 7.2 provided the requested data 21 to 30 calendar days late~~more than 35 calendar days, but less than or equal to 45~~	The ~~Transmission Owner or~~ Generator Owner as directed by Requirement R7 failed to provide less than or equal to 70 percent of the requested data. OR The ~~Transmission Owner or~~ Generator Owner as directed by Requirement R7, Part 7.2 provided the requested data more than 30~~45~~ calendar days late~~after the request,~~

	~~calendar days after the request, unless an extension was granted by the requestor~~. OR The ~~Transmission Owner or~~ Generator Owner as directed by Requirement R7, Parts 7.3 through 7.6 provided more than 90 percent of the data, but less than 100 percent of the data in the proper data format.	~~the request, unless an extension was granted by the requestor~~. OR The ~~Transmission Owner or~~ Generator Owner as directed by Requirement R7, Parts 7.3 through 7.6 provided more than 80 percent of the data, but less than or equal to 90 percent of the data in the proper data format.	~~calendar days after the request, unless an extension was granted by the requestor~~. OR The ~~Transmission Owner or~~ Generator Owner as directed by Requirement R7, Parts 7.3 through 7.6 provided more than 70 percent of the data, but less than or equal to 80 percent of the data in the proper data format.	~~unless an extension was granted by the requestor~~. OR The ~~Transmission Owner or~~ Generator Owner as directed by Requirement R7, Parts 7.3 through 7.6 provided less than or equal to 70 percent of the data in the proper data format.
R8	The ~~Transmission Owner or~~ Generator Owner as directed by Requirement R8 was unable to restore recording capability within 90 calendar days and provided a Corrective Action Plan to the Regional Entity more than 90 calendar days, but less than or equal to 100 calendar days after discovery of the failure.	The ~~Transmission Owner or~~ Generator Owner as directed by Requirement R8 was unable to restore recording capability within 90 calendar days and provided a Corrective Action Plan to the Regional Entity more than 100 calendar days, but less than or equal to 110 calendar days after discovery of the failure.	The ~~Transmission Owner or~~ Generator Owner as directed by Requirement R8 was unable to restore recording capability within 90 calendar days and provided a Corrective Action Plan to the Regional Entity more than 110 calendar days, but less than or equal to 120 calendar days after discovery of the failure. OR	The ~~Transmission Owner or~~ Generator Owner as directed by Requirement R8 was unable to restore recording capability within 90 calendar days and provided a Corrective Action Plan to the Regional Entity more than 120 calendar days after discovery of the failure. OR ~~Transmission Owner or~~ Generator Owner as directed by Requirement

			The ~~Transmission Owner or~~ Generator Owner as directed by Requirement R8 submitted a Corrective Action Plan to the Regional Entity but failed to implement it.	R8 failed to restore the recording capability within 90 calendar days and failed to submit a Corrective Action Plan to the Regional Entity.

Attachment 1

Sequence of Events Recording (SER) Data Format

(Requirement R7, Part 7.3)

Date, Time, Local Time Code, Plant Name, Device[5], State[6]

08/27/23, 23:58:57.110, -5, Plant name 1, Breaker 1, Close

08/27/23, 23:58:57.082, -5, Plant name 2, Breaker 2, Close

08/27/23, 23:58:57.217, -5, Plant name 1, IBR unit 1, undervoltage ride-through mode

08/27/23, 23:58:57.214, -5, Plant name 2, IBR unit 2, dc overcurrent trip

[5] Device name may include specific names of breakers or IBR units as appropriate.

[6] Breaker status and any other terminology such as TRIP, TRIP TO LOCKOUT, RECLOSE, etc. is acceptable. For IBR unit level data, fault codes, alarms, change in operating mode etc., are also acceptable.

Implementation Plan

Project 2021-04
Reliability Standards PRC-002-5 and PRC-028-1

Applicable Standard(s)

- PRC-002-5 Disturbance Monitoring and Reporting Requirements
- PRC-028-1 Disturbance Monitoring and Reporting Requirements for Inverter-Based Resources

Requested Retirement(s)

- PRC-002-4 – Disturbance Monitoring and Reporting Requirements

Applicable Entities

- Reliability Coordinator
- Transmission Owner (TO)
- Generator Owner (GO)

General Considerations

Additional time to implement Reliability Standard PRC-002-5 is not provided because the revisions are clarifying in nature to exclude Inverter-Based Resources (or "IBRs) from PRC-002 applicability as they are included in PRC-028. The revision to PRC-002 does not require any additional procurement or installation of Disturbance Monitoring Equipment.

Reliability Standard PRC-028-1 is expected to have wide ranging impact on GOs, as many existing and new facilities would be required to have Disturbance Monitoring Equipment. A graduated approach to implementation recognizes that progress will be made while attempting to minimize any potential significant impact to the entities. The implementation plan takes into account scheduling outages needed to implement sequence of events recording, fault recording, and dynamic disturbance recording capability. The implementation plan accounts for any increase in requests to vendors for this technology or capability that could impact implementation timelines for the respective entities.

The ERO enterprise acknowledges that Generator Owners and Generator Operators owning or operating Bulk-Power System connected IBRs that do not meet NERC's current definition of Bulk Electric System ("BES") will be registered no later than May 2026 in accordance with the IBR Registration proceeding in FERC Docket No. RR24-2. To ensure an orderly registration and compliance process for these entities, as well as fairness and consistency in the standard's application among similar asset types, this implementation plan provides additional time for both new and existing registered entities to come into compliance with Reliability Standard PRC-028-1 for their applicable Inverter-Based Resources not meeting BES definition. In so doing, this implementation plan advances an orderly process for new registrants while allowing existing entities to focus their immediate efforts on their assets posing the highest risk to the reliable operation of the Bulk-Power System.

The implementation plan recognizes the Federal Energy Regulatory Commission's directive to have this standard effective and enforceable before 2030.[1]

Effective Date of PRC-002-5

Where approval by an Applicable Governmental Authority is required, Reliability Standard PRC-002-5 shall become effective on the first day of the first calendar quarter after the effective date of the Applicable Governmental Authority's order approving the standard or as otherwise provided for by the Applicable Governmental Authority.

Where approval by an Applicable Governmental Authority is not required, Reliability Standard PRC-002-5 shall become effective the first day of the first calendar quarter after the date the standard is adopted by the NERC Board of Trustees or as otherwise provided for in that jurisdiction.

Effective Date of PRC-028-1 and Phased-in Compliance Dates

The effective date for proposed Reliability Standard PRC-028-1 is provided below. Where the standard drafting team identified the need for a longer implementation period for compliance with a particular section of a proposed Reliability Standard (i.e., an entire Requirement or a portion thereof), the additional time for compliance with that section is specified below. The phased-in compliance date for those particular sections represents the date that entities must begin to comply with that particular section of the Reliability Standard, even where the Reliability Standard goes into effect at an earlier date.

Reliability Standard PRC-028-1

Where approval by an Applicable Governmental Authority is required, Reliability Standard PRC-028-1 shall become effective on the first day of the first calendar quarter after the effective date of the Applicable Governmental Authority's order approving the standard or as otherwise provided for by the Applicable Governmental Authority.

Where approval by an Applicable Governmental Authority is not required, Reliability Standard PRC-028-1 shall become effective on the first day of the first calendar quarter after the date the standard is adopted by the NERC Board of Trustees or as otherwise provided for in that jurisdiction.

BES Inverter-Based Resources

Compliance Date for PRC-028-1 Requirements R1-R7

[1] See Order No. 901 at P226.

For BES Inverter-Based Resources in commercial operation on or before the effective date: Entities shall comply with Requirements R1 through R7 at 50% of their BES Inverter-Based Resources within three (3) calendar years of the effective date of PRC-028-1 and 100% of their BES Inverter-Based Resources by January 1, 2030.

Entities that are required to monitor only one (1) BES Inverter-Based Resource shall comply with Requirements R1 through R7 within three (3) calendar years of the effective date of Reliability Standard PRC-028-1.

For BES Inverter-Based Resources entering commercial operation after the effective date: Entities shall comply with Requirements R1 through R7 within 15 calendar months following the effective date of the standard or the commercial operation date, whichever is later. As an example: Assume the effective date of the PRC-028-1 is July 1, 2025:

- For BES IBRs entering commercial operation after July 1, 2025, but on or before October 1, 2026, entities shall comply with Requirements R1 through R7 by October 1, 2026.
- For BES IBRs entering commercial operation after October 1, 2026, entities shall comply with Requirements R1 through R7 on the commercial operation date.

Compliance Date for PRC-028-1 Requirement R8

Entities shall comply with Requirement R8 by no later than nine (9) months after the effective date of Reliability Standard PRC-028-1.

Non-BES Inverter-Based Resources

The “Non-BES Inverter-Based Resources” are those that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

Compliance Date for PRC-028-1 Requirements R1-R7

For non-BES Inverter-Based Resources in commercial operation on or before May 2026: Entities shall comply with Requirements R1 through R7 at 100% of their non-BES Inverter-Based Resources by January 1, 2030.

For non-BES Inverter-Based Resources in commercial operation after May 2026: Entities shall comply with Requirements R1 through R7 within 15 calendar months following the effective date of the standard or the commercial operation date, whichever is later.

Compliance Date for PRC-028-1 Requirement R8

Entities shall comply with Requirement R8 by no later than April 1, 2027.

Process for Requesting an Extension from Compliance Dates

Each GO that owns one or more applicable Inverter-Based Resources that are in commercial operation before the effective date of Reliability Standard PRC-028-1 may request an extension from the above-listed compliance dates if circumstances beyond its control prevent the installation of Disturbance Monitoring Equipment on one or more of its Inverter-Based Resources.

To request an extension, the entity shall develop and submit to its Compliance Enforcement Authority[2] a request for extension that contains at a minimum the following information:

1.1. Identification of the Inverter-Based Resource(s) for which the entity requests the extension;

1.2. A plan for installing the Disturbance Monitoring Equipment and a timetable for completion;

1.3. A description of the circumstances precluding the timely installation of Disturbance Monitoring Equipment and how those circumstances are beyond the control of the entity; and

1.4. Any other information the entity deems relevant to the Compliance Enforcement Authority's consideration of its request.

Circumstances beyond the entity's control may include supply chain delays associated with the procurement, engineering, installation, or commissioning of disturbance monitoring equipment, inability to secure scheduled outages, or other exceptional circumstances outside the entity's control.

The entity shall provide any information requested by the Compliance Enforcement Authority to validate the information provided above, including any information specified by the Compliance Enforcement Authority in a supporting process document. If the extension request is granted, the entity shall implement the plan in accordance with the provided timetable. Should additional time be required, the entity shall submit an updated request to its Compliance Enforcement Authority.

Requests should be submitted as soon as the entity identifies circumstances impeding the timely implementation of Reliability Standard PRC-028-1, but no later than three months prior to the compliance date for which the entity requests an extension.

[2] The extension requests for a non-US Registered Entity should be implemented in a manner that is consistent with, or under the direction of, the applicable governmental authority or its agency in the non-US jurisdiction.

Retirement Date

Reliability Standard PRC-002-4 shall be retired immediately prior to the effective date of Reliability Standard PRC-002-5 in the particular jurisdiction in which the revised standard is becoming effective.

Implementation Plan

Project 2021-04
Reliability Standards PRC-002-5 and PRC-028-1

Applicable Standard(s)

- PRC-002-5 Disturbance Monitoring and Reporting Requirements
- PRC-028-1 Disturbance Monitoring and Reporting Requirements for ~~i~~Inverter-~~b~~Based ~~r~~Resources

Requested Retirement(s)

- PRC-002-4 – Disturbance Monitoring and Reporting Requirements

Applicable Entities

- Reliability Coordinator
- Transmission Owner (TO)
- Generator Owner (GO)

General Considerations

Additional time to implement Reliability Standard PRC-002-5 is not provided because the revisions are clarifying in nature to exclude ~~i~~Inverter-~~b~~Based ~~r~~Resources (or "IBRs) from PRC-002 applicability as they are included in PRC-028. The revision to PRC-002 does not require any additional procurement or installation of Disturbance Monitoring Equipment.

~~The~~ Reliability Standard PRC-028-1 is expected to have wide ranging impact on ~~TOs and~~ GOs, as many existing and new facilities would be required to have Disturbance Monitoring Equipment. A graduated approach to implementation recognizes that progress will be made while attempting to minimize any potential significant impact to the entities. The ~~I~~implementation ~~P~~plan takes into account scheduling outages needed to implement sequence of events recording, fault recording, and dynamic disturbance recording capability. ~~An entity owning only one (1) identified inverter-based resource is allowed three (3) calendar years for implementation to accommodate normal outage schedules.~~ The ~~I~~implementation ~~P~~plan accounts for any increase in requests to vendors for this technology or capability that could impact implementation timelines for the respective entities.

The ERO enterprise acknowledges that Generator Owners and Generator~~s~~ Operators owning or operating Bulk-Power System connected IBRs that do not meet NERC's current definition of Bulk Electric System ("BES") will be registered no later than May 2026 in accordance with the IBR Registration proceeding in FERC Docket No. RR24-2. To ensure an orderly registration and compliance process for these entities, as well as fairness and consistency in the standard's application among similar asset types, this implementation plan provides additional time for both new and existing registered entities to come into compliance with Reliability Standard PRC-028-1 for their applicable Inverter-Based Resources not meeting BES definition. In so doing, this implementation plan advances an orderly process for new registrants while allowing existing entities to focus their immediate efforts on their assets posing the highest risk to the reliable operation of the Bulk-Power System.

The ~~I~~implementation ~~P~~plan recognizes the Federal Energy Regulatory Commission's directive to have this standard effective and enforceable before 2030.[1]

Effective Date of PRC-002-5

Where approval by an Applicable Governmental Authority is required, Reliability Standard PRC-002-5 shall become effective on the first day of the first calendar quarter after the effective date of the Applicable Governmental Authority's order approving the standard or as otherwise provided for by the Applicable Governmental Authority.

Where approval by an Applicable Governmental Authority is not required, Reliability Standard PRC-002-5 shall become effective the first day of the first calendar quarter after the date the standard is adopted by the NERC Board of Trustees or as otherwise provided for in that jurisdiction.

Effective Date of PRC-028-1 and Phased-in Compliance Dates

The effective date for proposed Reliability Standard PRC-028-1 is provided below. Where the standard drafting team identified the need for a longer implementation period for compliance with a particular section of a proposed Reliability Standard (i.e., an entire Requirement or a portion thereof), the additional time for compliance with that section is specified below. The phased-in compliance date for those particular sections represents the date that entities must begin to comply with that particular section of the Reliability Standard, even where the Reliability Standard goes into effect at an earlier date.

Reliability Standard PRC-028-1

Where approval by an Applicable Governmental Authority is required, Reliability Standard PRC-028-1 shall become effective on the first day of the first calendar quarter after the effective date of the Applicable Governmental Authority's order approving the standard or as otherwise provided for by the Applicable Governmental Authority.

Where approval by an Applicable Governmental Authority is not required, Reliability Standard PRC-028-1 shall become effective on the first day of the first calendar quarter after the date the standard is adopted by the NERC Board of Trustees or as otherwise provided for in that jurisdiction.

[1] See Order No. 901 at P226.

BES Inverter-Based Resources

Compliance Date for PRC-028-1 Requirements R1-R7

For BES ~~i~~Inverter-~~b~~Based ~~r~~Resources in commercial operation on or before the effective date:
Entities shall comply with Requirements R1 through R7 at 50% of their BES ~~i~~Inverter-~~b~~Based ~~r~~Resources within three (3) calendar years of the effective date of PRC-028-1 and 100% of their BES ~~i~~Inverter-~~b~~Based ~~r~~Resources by January 1, 2030.

Entities that are required to monitor only one (1) BES ~~i~~Inverter-~~b~~Based ~~r~~Resource shall comply with Requirements R1 through R7 within three (3) calendar years of the effective date of Reliability Standard PRC-028-1.

For BES ~~i~~Inverter-~~b~~Based ~~r~~Resources entering commercial operation after the effective date: Entities shall comply with Requirements R1 through R7 within 15 calendar months following the effective date of the standard or the commercial operation date, whichever is later. As an example: Assume the effective date of the PRC-028-1 is July 1, 2025:

- For BES IBRs entering commercial operation after July 1, 2025, but on or before October 1, 2026, entities shall comply with Requirements R1 through R7 by October 1, 2026.
- For BES IBRs entering commercial operation after October 1, 2026, entities shall comply with Requirements R1 through R7 on the commercial operation date.

Compliance Date for PRC-028-1 Requirement R8

Entities shall comply with Requirement R8 by no later than nine (9) months after the effective date of Reliability Standard PRC-028-1.

Non-BES Inverter-Based Resources

The "Non-BES Inverter-Based Resources" are those that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

Compliance Date for PRC-028-1 Requirements R1-R7

For non-BES Inverter-Based Resources in commercial operation on or before May 2026:
Entities shall comply with Requirements R1 through R7 at 100% of their non-BES Inverter-Based Resources by January 1, 2030.

For non-BES Inverter-Based Resources in commercial operation after May 2026:
Entities shall comply with Requirements R1 through R7 within 15 calendar months following the effective date of the standard or the commercial operation date, whichever is later.

Compliance Date for PRC-028-1 Requirement R8

Entities shall comply with Requirement R8 by no later than April 1, 2027.

Process for Requesting~~Seeking~~ an Extension from Compliance Dates

Each GO ~~and TO~~ that owns one or more applicable ~~i~~Inverter-~~b~~Based ~~r~~Resources that are in commercial operation before the effective date of Reliability Standard PRC-028-1 may ~~seek~~request an extension from the above-listed compliance dates if circumstances beyond its control prevent the installation of Disturbance Monitoring Equipment on one or more of its ~~i~~Inverter-~~b~~Based ~~r~~Resources.

To request~~seek~~ an extension, the entity shall develop and submit to its ~~Regional Entity~~Compliance Enforcement Authority[2]~~[3]~~ a request for extension that contains at a minimum the following information:

1.1. Identification of the ~~i~~Inverter-~~b~~Based ~~r~~Resource(s) for which the entity requests~~seeks~~ the extension;

1.2. A plan for installing the Disturbance Monitoring Equipment and a timetable for completion;

1.3. A description of the circumstances precluding the timely installation of Disturbance Monitoring Equipment and how those circumstances are beyond the control of the entity; and

1.4. Any other information the entity deems relevant to the Compliance Enforcement Authority~~Regional Entity~~'s consideration of its request.

Circumstances beyond the entity's control may include supply chain delays associated with the procurement, engineering, installation, or commissioning of disturbance monitoring equipment, inability to secure scheduled outages, or other exceptional circumstances outside the entity's control.

The entity shall provide any information requested by the ~~Regional Entity~~ Compliance Enforcement Authority to validate the information provided above~~in connection with its request~~, including any information specified by the Compliance Enforcement Authority in a supporting process document. If the extension request is granted, the entity shall implement the plan in accordance with the

[2] The extension requests for a non-US Registered Entity should be implemented in a manner that is consistent with, or under the direction of, the applicable governmental authority or its agency in the non-US jurisdiction.
~~[3] This is the Regional Entity that will receive any Corrective Action Plans developed in accordance with Requirement R8.~~

provided timetable. Should additional time be required, the entity shall submit an updated request to its Compliance Enforcement Authority~~Regional Entity~~.

Requests should be submitted as soon as the entity identifies circumstances impeding~~prescribing~~ the timely implementation of Reliability Standard PRC-028-1, but no later than three months prior to the compliance date for which the entity ~~seek~~requests an extension.

Retirement Date

Reliability Standard PRC-002-4 shall be retired immediately prior to the effective date of Reliability Standard PRC-002-5 in the particular jurisdiction in which the revised standard is becoming effective.

Unofficial Comment Form

Project 2021-04 Modifications to PRC-002 – Phase II

Do not use this form for submitting comments. Use the Standards Balloting and Commenting System (SBS) to submit comments on **PRC-028-1 – Disturbance Monitoring and Reporting Requirements for Inverter-Based Resources** by **8 p.m. Eastern, Monday, August 12, 2024.**

Additional information is available on the project page. If you have questions, contact Senior Standards Developer, Ben Wu (via email), or at 470-542-6882.

Background Information

This project will be completed in two phases. The first phase addressed the scope regarding notifications relative to the sequence of events recording (SER) and fault recording (FR) data, and to clearly identify the BES Element owners that need to have SER and FR data for transformers and transmission lines with the associated identified bus in the Glencoe Light and Power Standard Authorization Request.

The second phase will address gaps the Inverter-based Resource Performance Task Force identified within the PRC-002. The goal is to modify the requirements to ensure adequate data is available and periodically assessed to facilitate the analysis of BES disturbances, including in areas of the Bulk Power System that may not be covered by the existing requirements.

Questions

1. Do you agree with the modification made in PRC-028-1?

   ☐ Yes
   ☐ No

   Comments:

2. Do you agree with the Implementation Plan for revised PRC-028-1?

   ☐ Yes
   ☐ No

   Comments:

3. Do you agree the modifications made in PRC-028-1 are cost effective at unit level cost versus plant level cost compared to the benefit to reliability?

   ☐ Yes
   ☐ No

   Comments:

4. Provide any additional comments for the standard drafting team to consider, if desired.

   Comments:

Violation Risk Factor and Violation Severity Level Justifications

Project 2021-04 Modifications to PRC-002 – Phase II
(PRC-028-1)

This document provides the standard drafting team's (SDT's) justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-028-1. Each requirement is assigned a VRF and a VSL. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the Electric Reliability Organizations (ERO) Sanction Guidelines. The SDT applied the following NERC criteria and FERC Guidelines when developing the VRFs and VSLs for the requirements.

NERC Criteria for Violation Risk Factors

High Risk Requirement
A requirement that, if violated, could directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures, or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures, or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement
A requirement that, if violated, could directly affect the electrical state or the capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System. However, violation of a medium risk requirement is unlikely to lead to Bulk Electric System instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to Bulk Electric System instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System.

FERC Guidelines for Violation Risk Factors

Guideline (1) – Consistency with the Conclusions of the Final Blackout Report

FERC seeks to ensure that VRFs assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System. In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief.

Guideline (2) – Consistency within a Reliability Standard
FERC expects a rational connection between the sub-Requirement VRF assignments and the main Requirement VRF assignment.

Guideline (3) – Consistency among Reliability Standards
FERC expects the assignment of VRFs corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) – Consistency with NERC's Definition of the Violation Risk Factor Level
Guideline (4) was developed to evaluate whether the assignment of a particular VRF level conforms to NERC's definition of that risk level.

Guideline (5) – Treatment of Requirements that Co-mingle More Than One Obligation
Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

NERC Criteria for Violation Severity Levels

VSLs define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple “degrees” of noncompliant performance and may have only one, two, or three VSLs.

VSLs should be based on NERC’s overarching criteria shown in the table below:

Lower VSL	Moderate VSL	High VSL	Severe VSL
The performance or product measured almost meets the full intent of the requirement.	The performance or product measured meets the majority of the intent of the requirement.	The performance or product measured does not meet the majority of the intent of the requirement, but does meet some of the intent.	The performance or product measured does not substantively meet the intent of the requirement.

FERC Order of Violation Severity Levels

The FERC VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in the standard meet the FERC Guidelines for assessing VSLs:

Guideline (1) – Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline (2) – Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a “binary” type requirement must be a “Severe” VSL.

Do not use ambiguous terms such as “minor” and “significant” to describe noncompliant performance.

Guideline (3) – Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline (4) – Violation Severity Level Assignment Should Be Based on a Single Violation, Not on a Cumulative Number of Violations

Unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

PRC-028-1

VRF Justifications for PRC-028-1, Requirement R1	
Proposed VRF	**Lower**
NERC VRF Discussion	A VRF of Lower is appropriate due to this Requirement is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System; or a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System. Therefore, it is consistent with the definition of a Lower VRF.
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is consistent with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The VRF for Requirement R1 is consistent with those connections between the sub-Requirement VRF assignments and the main Requirement VRF assignment.
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	This VRF is consistent with other VRFs that address similar reliability goals in different Reliability Standards.
FERC VRF G4 Discussion Guideline 4- Consistency with NERC Definitions of VRFs	This VRF is consistent with the definition of a lower VRF requirement per the criteria filed with FERC as part of the ERO's Sanctions Guidelines.

VRF Justifications for PRC-028-1, Requirement R1	
Proposed VRF	**Lower**
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not mingle a higher risk reliability objective and a lesser risk reliability objective. Therefore, the VRF reflects the risk of the whole requirement.

VSLs for PRC-028-1, Requirement R1			
Lower	**Moderate**	**High**	**Severe**
Each Generator Owner as directed by Requirement R1 to have the required SER data had more than 80 percent, but less than 100 percent of the circuit breaker(s) identified in Requirement R1.	Each Generator Owner as directed by Requirement R1 to have the required SER data had more than 70 percent, but less than or equal to 80 percent of the circuit breaker(s) identified in Requirement R1.	Each Generator Owner as directed by Requirement R1 to have the required SER data had more than 60 percent, but less than or equal to 70 percent of the circuit breaker(s) identified in Requirement R1.	Each Generator Owner as directed by Requirement R1 to have the required SER data had less than or equal to 60 percent of the circuit breaker(s) identified in Requirement R1.

VSL Justifications for PRC-028-1, Requirement R1	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement is new. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of	The proposed VSLs are not binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VSL Justifications for PRC-028-1, Requirement R1	
Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

VRF Justifications for PRC-028-1, Requirement R2	
Proposed VRF	**Lower**
NERC VRF Discussion	A VRF of Lower is appropriate due to this Requirement is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System; or a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System. Therefore, it is consistent with the definition of a Lower VRF.

VRF Justifications for PRC-028-1, Requirement R2	
Proposed VRF	**Lower**
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is consistent with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The VRF for Requirement R1 is consistent with those connections between the sub-Requirement VRF assignments and the main Requirement VRF assignment
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	This VRF is consistent with other VRFs that address similar reliability goals in different Reliability Standards.
FERC VRF G4 Discussion Guideline 4- Consistency with NERC Definitions of VRFs	This VRF is consistent with the definition of a lower VRF requirement per the criteria filed with FERC as part of the ERO's Sanctions Guidelines.
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not mingle a higher risk reliability objective and a lesser risk reliability objective. Therefore, the VRF reflects the risk of the whole requirement.

VSLs for PRC-028-1, Requirement R2			
Lower	**Moderate**	**High**	**Severe**
The Generator Owner had FR data as directed by Requirement R2, Parts 2.1 and 2.2 that covers more than 80 percent, but less than 100	The Generator Owner had FR data as directed by Requirement R2, Parts 2.1 and 2.2 that covers more than 70 percent, but less than or	The Generator Owner had FR data as directed by Requirement R2, Parts 2.1 and 2.2 that covers more than 60 percent, but less than or	The Generator Owner had FR data as directed by Requirement R2, Parts 2.1 and 2.2 that covers less than or equal to 60 percent of the

percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	equal to 80 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	equal to 70 percent of the total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.	total required electrical quantities, which is the product of the total number of monitored Elements and the number of specified electrical quantities for each Element.

VSL Justifications for PRC-028-1, Requirement R2	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement is new. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	The proposed VSLs are not binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.

VSL Justifications for PRC-028-1, Requirement R2	
Corresponding Requirement	
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

VRF Justifications for PRC-028-1, Requirement R3	
Proposed VRF	**Lower**
NERC VRF Discussion	A VRF of Lower is appropriate due to this Requirement is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System; or a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System. Therefore, it is consistent with the definition of a Lower VRF.
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is consistent with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The VRF for Requirement R1 is consistent with those connections between the sub-Requirement VRF assignments and the main Requirement VRF assignment.
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	This VRF is consistent with other VRFs that address similar reliability goals in different Reliability Standards.

VRF Justifications for PRC-028-1, Requirement R3	
Proposed VRF	**Lower**
FERC VRF G4 Discussion Guideline 4- Consistency with NERC Definitions of VRFs	This VRF is consistent with the definition of a lower VRF requirement per the criteria filed with FERC as part of the ERO's Sanctions Guidelines.
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not mingle a higher risk reliability objective and a lesser risk reliability objective. Therefore, the VRF reflects the risk of the whole requirement.

VSLs for PRC-028-1, Requirement R3			
Lower	**Moderate**	**High**	**Severe**
The Generator Owner had FR data that meets more than 80 percent, but less than 100 percent of the total recording parameters as specified in Requirement R3.	The Generator Owner had FR data that meets more than 70 percent, but less than or equal to 80 percent of the total recording parameters as specified in Requirement R3.	The Generator Owner had FR data that meets more than 60 percent, but less than or equal to 70 percent of the total recording parameters as specified in Requirement R3.	The Generator Owner had FR data that meets less than or equal to 60 percent of the total recording parameters as specified in Requirement R3.

VSL Justifications for PRC-028-1, Requirement R3	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement is new. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2	The proposed VSLs are not binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VSL Justifications for PRC-028-1, Requirement R3	
Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

VRF Justifications for PRC-028-1, Requirement R4	
Proposed VRF	**Lower**

Violation Risk Factor and Violation Severity Level Justifications

Project 2021-04 Modifications to PRC-002 – Phase II (PRC-028-1)

This document provides the standard drafting team's (SDT's) justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-028-1. Each requirement is assigned a VRF and a VSL. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the Electric Reliability Organizations (ERO) Sanction Guidelines. The SDT applied the following NERC criteria and FERC Guidelines when developing the VRFs and VSLs for the requirements.

NERC Criteria for Violation Risk Factors

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures, or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures, or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System. However, violation of a medium risk requirement is unlikely to lead to Bulk Electric System instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to Bulk Electric System instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement
A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System.

FERC Guidelines for Violation Risk Factors

Guideline (1) – Consistency with the Conclusions of the Final Blackout Report
FERC seeks to ensure that VRFs assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System. In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief.

Guideline (2) – Consistency within a Reliability Standard
FERC expects a rational connection between the sub-Requirement VRF assignments and the main Requirement VRF assignment.

Guideline (3) – Consistency among Reliability Standards
FERC expects the assignment of VRFs corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) – Consistency with NERC's Definition of the Violation Risk Factor Level
Guideline (4) was developed to evaluate whether the assignment of a particular VRF level conforms to NERC's definition of that risk level.

Guideline (5) – Treatment of Requirements that Co-mingle More Than One Obligation
Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

NERC Criteria for Violation Severity Levels

VSLs define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple "degrees" of noncompliant performance and may have only one, two, or three VSLs.

VSLs should be based on NERC's overarching criteria shown in the table below:

Lower VSL	Moderate VSL	High VSL	Severe VSL
The performance or product measured almost meets the full intent of the requirement.	The performance or product measured meets the majority of the intent of the requirement.	The performance or product measured does not meet the majority of the intent of the requirement, but does meet some of the intent.	The performance or product measured does not substantively meet the intent of the requirement.

FERC Order of Violation Severity Levels

The FERC VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in the standard meet the FERC Guidelines for assessing VSLs:

Guideline (1) – Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline (2) – Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a "binary" type requirement must be a "Severe" VSL.

Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline (3) – Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline (4) – Violation Severity Level Assignment Should Be Based on a Single Violation, Not on a Cumulative Number of Violations

Unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

PRC-028-1

VRF Justifications for PRC-028-1, Requirement R1	
Proposed VRF	**Lower**
NERC VRF Discussion	A VRF of Lower is appropriate due to this Requirement is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System; or a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System. Therefore, it is consistent with the definition of a Lower VRF.
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is consistent with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The VRF for Requirement R1 is consistent with those connections between the sub-Requirement VRF assignments and the main Requirement VRF assignment.
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	This VRF is consistent with other VRFs that address similar reliability goals in different Reliability Standards.
FERC VRF G4 Discussion Guideline 4- Consistency with NERC Definitions of VRFs	This VRF is consistent with the definition of a lower VRF requirement per the criteria filed with FERC as part of the ERO's Sanctions Guidelines.

VRF Justifications for PRC-028-1, Requirement R1	
Proposed VRF	**Lower**
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not mingle a higher risk reliability objective and a lesser risk reliability objective. Therefore, the VRF reflects the risk of the whole requirement.

VSLs for PRC-028-1, Requirement R1			
Lower	**Moderate**	**High**	**Severe**

Each ~~Transmission Owner or~~ Generator Owner as directed by Requirement R1 to have the required SER data had more than 70 percent, but less than or equal to 80 percent of the circuit breaker(s) identified in Requirement R1.	Each ~~Transmission Owner or~~ Generator Owner as directed by Requirement R1 to have the required SER data had more than 60 percent, but less than or equal to 70 percent of the circuit breaker(s) identified in Requirement R1.	Each ~~Transmission Owner or~~ Generator Owner as directed by Requirement R1 to have the required SER data had less than or equal to 60 percent of the circuit breaker(s) identified in Requirement R1.

VSL Justifications for PRC-028-1, Requirement R1	
FERC VSL G1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	The requirement is new. Therefore, the proposed VSLs do not have the unintended consequence of lowering the level of compliance.
FERC VSL G2 Violation Severity Level Assignments Should Ensure Uniformity and	The proposed VSLs are not binary and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VSL Justifications for PRC-028-1, Requirement R1	
Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	
FERC VSL G3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSLs use the same terminology as used in the associated requirement and are, therefore, consistent with the requirement.
FERC VSL G4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	Each VSL is based on a single violation and not cumulative violations.

VRF Justifications for PRC-028-1, Requirement R2	
Proposed VRF	**Lower**
NERC VRF Discussion	A VRF of Lower is appropriate due to this Requirement is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System; or a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System. Therefore, it is consistent with the definition of a Lower VRF.

VRF Justifications for PRC-028-1, Requirement R2	
Proposed VRF	**Lower**
FERC VRF G1 Discussion Guideline 1- Consistency with Blackout Report	This VRF is consistent with the identified areas from the FERC list of critical areas in the Final Blackout Report.
FERC VRF G2 Discussion Guideline 2- Consistency within a Reliability Standard	The VRF for Requirement R1 is consistent with those connections between the sub-Requirement VRF assignments and the main Requirement VRF assignment
FERC VRF G3 Discussion Guideline 3- Consistency among Reliability Standards	This VRF is consistent with other VRFs that address similar reliability goals in different Reliability Standards.
FERC VRF G4 Discussion Guideline 4- Consistency with NERC Definitions of VRFs	This VRF is consistent with the definition of a lower VRF requirement per the criteria filed with FERC as part of the ERO's Sanctions Guidelines.
FERC VRF G5 Discussion Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation	This requirement does not mingle a higher risk reliability objective and a lesser risk reliability objective. Therefore, the VRF reflects the risk of the whole requirement.

Technical Rationale for Reliability Standard PRC-028-1

July 2024

PRC-028-1 – Disturbance Monitoring and Reporting Requirements for Inverter Based Resources

The recent disturbance reports (e.g., Blue Cut Fire, Canyon 2 Fire, Odessa disturbances) have identified a need for disturbance monitoring for Inverter-Based Resources to aid with event analysis, performance monitoring, and disturbance-based Inverter-Based Resource model validation. These disturbance reports are recommended to install disturbance monitoring equipment (DME) at wind and solar photovoltaic (PV) resources to ensure adequate data is available for event analysis, performance monitoring, and validating Inverter-Based Resource models. The recommendation included plant-level high resolution oscillography data, plant SCADA data with a resolution of one second, and inverter level of sequence of events recording data that include all fault codes and high resolution oscillography data. In a first version of this standard, only SER data at inverter level data is required. For the purposes of this standard, the inverter, converter, wind turbine generator, or high voltage direct current converter connecting generating resource to alternating current Transmission network is referred to as an IBR unit.

The purpose of Reliability Standard PRC-002 is to capture event data to understand large scale system disturbances occurring on the Bulk Electric System (BES). Even with changing resource mix, the Reliability Standard PRC-002 serves the purpose. The recent disturbance analyses of events involving inverter-bases resources (e.g., Blue Cut Fire, Canyon 2 Fire, Odessa disturbances) have demonstrated that Inverter-Based Resource's response to a normally cleared few cycle fault is undesirable and poses risk to system reliability. All these disturbance analyses have identified that Inverter-Based Resources involved did not have sufficient monitoring data to understand the plants' responses. The initiating event, e.g., a normally cleared transmission fault, was not a large-scale system disturbance; however, Inverter-Based Resource's undesirable response due to a system fault resulted in a larger system disturbance. Adequate monitoring data is required to understand Inverter-Based Resource's performance. Most of the Inverter-Based Resources involved in these disturbances did not have and were not required to have adequate disturbance monitoring data. The lack of disturbance monitoring data available from these facilities led to difficulty in adequately assessing the events. Introducing Inverter-Based Resource monitoring requirements to Reliability Standard PRC-002 may create unintended consequences to purpose of Reliability Standard PRC-002 and may lead to industry confusion. Hence, to address needs identified in the Standard Authorization Request (SAR) submitted by the Inverter-Based Resource Performance Task Force (IRPTF), a new standard for monitoring requirements for Inverter-Based Resources is created instead of revising the Reliability Standard PRC-002.

The Generator Owners, as applicable, will have the responsibility for ensuring that adequate data is available for applicable Elements at the applicable Inverter-Based Resources. This standard requires that sequence of events recording (SER), fault recording (FR), and dynamic disturbance recording (DDR) data is available from the applicable Inverter-Based Resources.

Rationale for Applicability Section
Functional Entities
The functional entity that is responsible for implementing disturbance monitoring equipment and collecting recording data is Generator Owner.

Applicable Facilities
The BES Inverter-Based Resources and Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV, are in the scope of this standard.

Order No. 901 directed NERC to develop Reliability Standards “to require registered IBR generator owners to install disturbance monitoring equipment at their buses and elements, to require registered IBR generator owners to provide disturbance monitoring data to Bulk-Power System planners and operators for analyzing disturbances on the Bulk-Power System, and to require Bulk-Power System planners and operators to validate registered IBR models using disturbance monitoring data from installed registered IBR generator owners’ disturbance monitoring equipment.” Order No. 901 at P 85. FERC continued, “We further agree with the findings in NERC reports (e.g., a lack of high-speed data captured at the IBR or plant-level controller and low-resolution time stamping of inverter sequence of event recorder information has hindered event analysis) and direct NERC through its standard development process to address these findings.”

In distinguishing among the different types of IBRs and their registration status that must be covered by the standards, FERC stated: “Where necessary to describe our directives, however, we differentiate between IBRs registered with NERC (or which will be registered pursuant to the Commission’s directives in Registration of Inverter-based Resources, 181 FERC ¶ 61,124 (2022) (IBR Registration Order)) and therefore subject to the Reliability Standards (i.e., registered IBR), IBRs connected directly to the Bulk-Power System but not registered with NERC and therefore not subject to the Reliability Standards (i.e., unregistered IBRs), and IBRs connected to the distribution system that in the aggregate have a material impact on the Bulk Power System (i.e., IBR-DER).” Order No. 901 at n. 14.

In proposed PRC-028-1, the standard drafting team includes both categories of generation that would be registered under proposed changes to NERC Rules of Procedure consistent with Order No. 901. In February 2024, the NERC Board of Trustees approved revisions to the Rules of Procedure to expand the Generator Owners and Generator Operators registered with NERC for compliance purposes. In addition to owners and operators of generating Facilities, NERC will register owners and operators of sub-BES IBRs meeting the following criteria: non-BES inverter based generating resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV. On June 27, 2024, FERC issued an order approving NERC's proposed revisions to its Rules of Procedure, subject to NERC submitting a compliance filing, under section 215 of the Federal Power Act.

The following Elements associated with Inverter-Based Resources noted above are in the scope of this standard:

- Circuit breaker(s) (or interrupting devices)
- Main power transformer(s)
- Collector bus
- Shunt static or dynamic reactive device(s)[1], including any filter banks,
- AC-DC and DC-AC converters, if any, in case of VSC HVDC line with a dedicated connection to Inverter-Based Resource

The following examples are provided to clarify applicability of the PRC-028 standard.

Example 1: Applicability of PRC-028

Figure 1 shows a typical single line diagram of an Inverter-Based Resource. The Inverter-Based Resource is connected to the transmission system via a short tie-line. This Inverter-Based Resource is equipped with a dynamic reactive device (e.g., synchronous condenser, static VAR compensator etc.) connected to the collector bus.

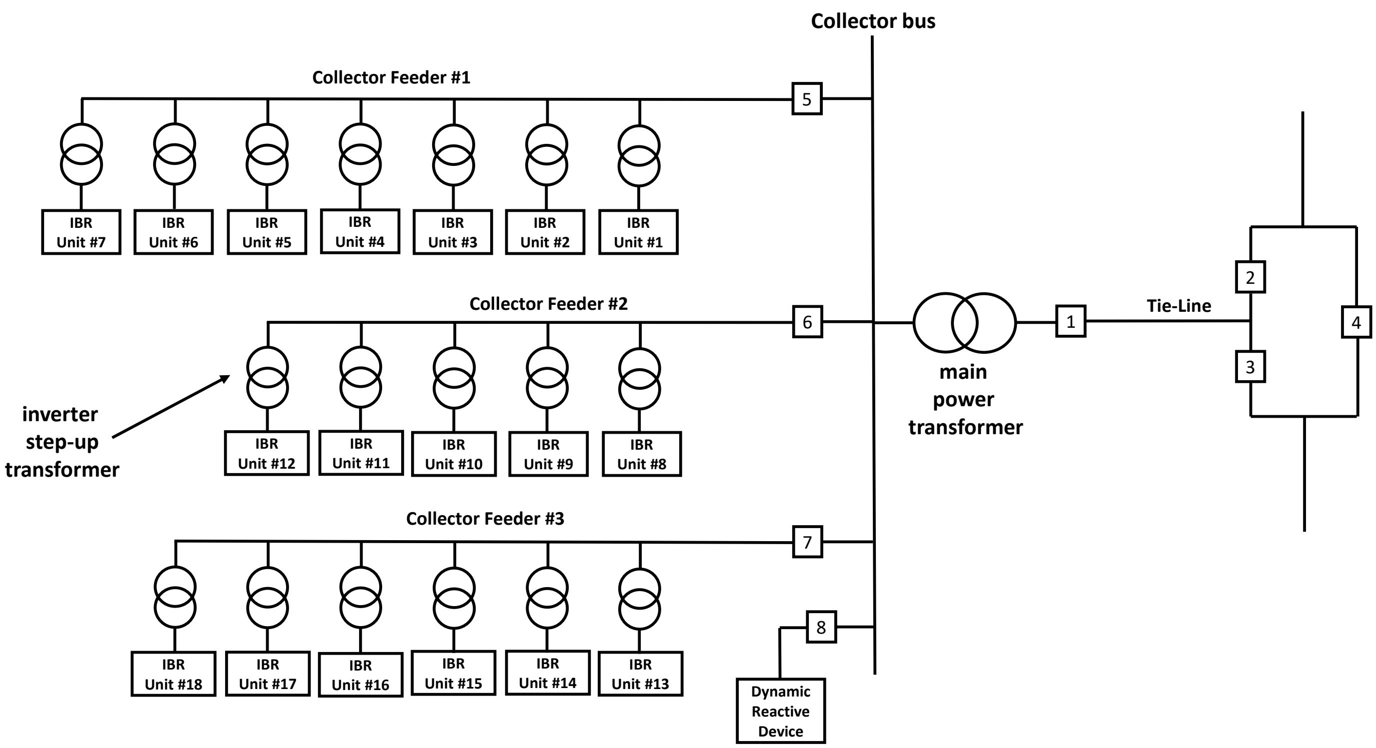

Figure 1: Typical Inverter-Based Resource Single Line Diagram

[1] Synchronous condensers when installed within the Inverter-Based Resource are considered shunt dynamic reactive devices.

SER Data: The SER data is required for circuit breakers 1, 5, 6, 7, and 8. Circuit breaker 1 is associated with the main power transformer. Circuit breakers 5, 6, 7, and 8 are associated with the collector bus. The SER data from all IBR units is required.

FR Data: The FR data is required from high side terminals of the main power transformer. In this example, the Inverter-Based Resource consists of only one main power transformer. If the Inverter-Based Resource consists of more than one main power transformer, then FR data for each main power transformer is required. As the Inverter-Based Resource is equipped with the dynamic reactive device, the FR data for it is also required. The FR data from collector feeder circuit breakers 5, 6, and 7 is also required.

DDR Data: The DDR data is required from high side terminals of the main power transformer. If the Inverter-Based Resource consists of more than one main power transformer, then DDR data for each main power transformer is required.

Example 2: Applicability of PRC-028 (Facility with two collector buses and main power transformers)

Figure 2 shows a single line diagram of an Inverter-Based Resource with two collector buses and main power transformers. The Inverter-Based Resource is connected to the transmission system via a short tie-line. The collector feeders #1 and #2 are connected to collector bus #1. The collector feeders #3 and #4 are connected to collector bus #2.

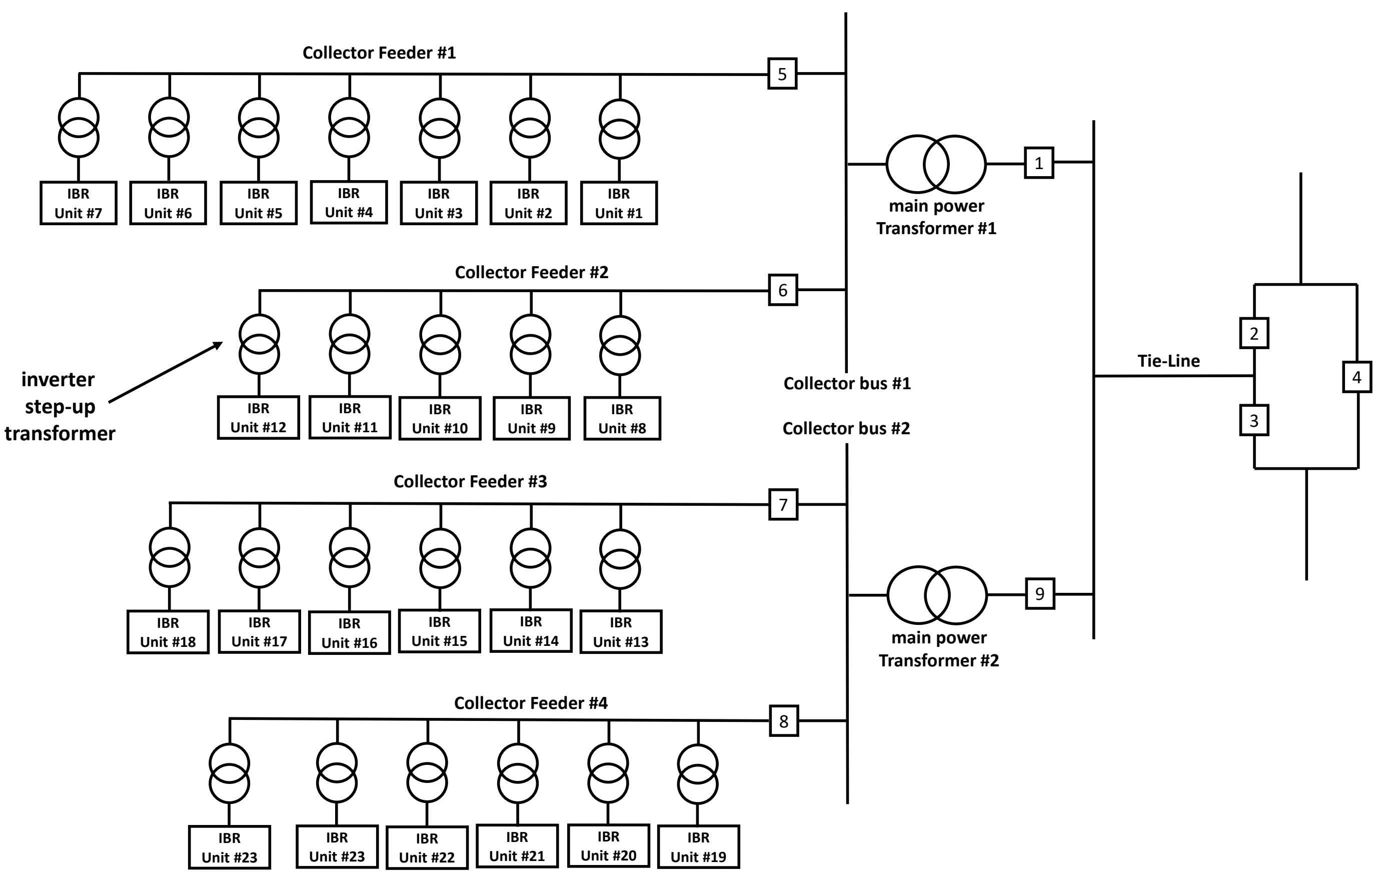

Figure 2: Typical Inverter-Based Resource with two collector buses and main power transformers

SER Data: The SER data is required for circuit breakers 1, 5, 6, 7, 8, and 9. Circuit breakers 1 and 9 are associated with main power transformers. Circuit breakers 5, 6, 7, and 8 are associated with collector buses #1 and #2. The SER data from all IBR units is required.

FR Data: The FR data is required from high side terminals of both main power transformers. The FR data from collector feeder circuit breakers 5, 6, 7, and 8 is also required.

DDR Data: The DDR data is required from high side terminals of both main power transformers.

Example 3: Applicability of PRC-028 (VSC HVDC system with a dedicated connection to Inverter-Based Resources)

Figure 3 shows an example of dedicated VSC HVDC system connecting the Inverter-Based Resource[2]. Transformers on both sides of the HVDC system are considered main power transformer.

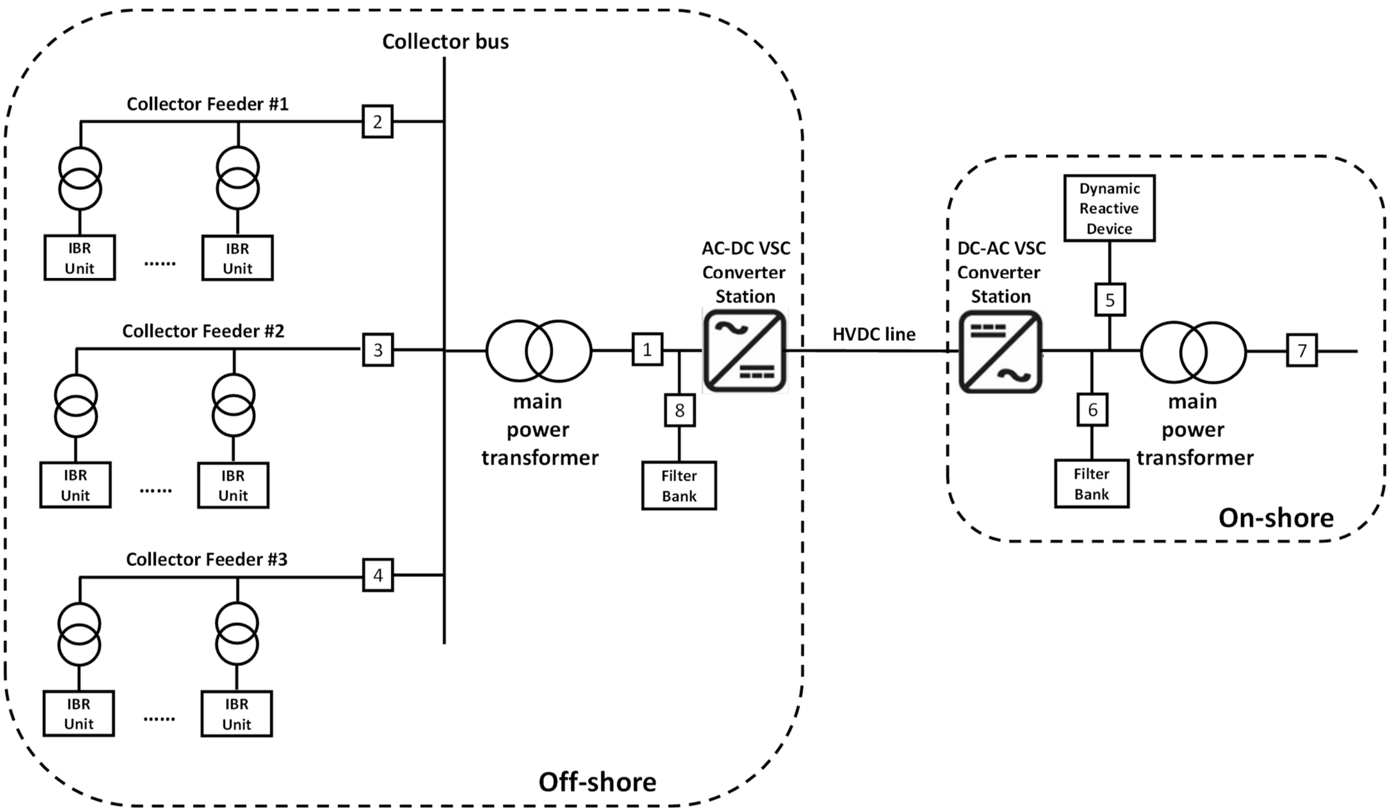

Figure 3: Typical Inverter-Based Resource connected via dedicated VSC HVDC

[2] Refer to Technical Rationale Project 2020-06 Verification of Models and Data for Generators Inverter-based Resource Definition available at: https://www.nerc.com/pa/Stand/Project_2020_06_Verifications_of_Models_and_Data_f/2020-06_IBR_Definition_Technical_Rationale_Clean_07122024.pdf.

SER Data: The SER data is required for circuit breakers 1, 2, 3, 4, 5, 6, 7, and 8. Circuit breakers 1 and 7 are associated with main power transformers. Circuit breakers 2, 3, and 4 are associated with the collector bus. Circuit breakers 6 and 8 are associated with filter banks and circuit breaker 5 is associated with shunt dynamic reactive device. The SER data from all IBR units is required.

FR Data: The FR data is required from high side terminals of both main power transformers. The FR data from collector feeder circuit breakers 2, 3, and 4 is also required.

DDR Data: The DDR data is required from high side terminals of both main power transformers.

Example 4: Applicability of PRC-002 versus PRC-028

Figure 4 shows an example of Inverter-Based Resource interconnection to the transmission system via Line 34. The BES bus in substation Wu is the identified BES bus per methodology in Attachment 1 of the Reliability Standard PRC-002. The SER and FR data requirements for the identified BES bus are per the requirements in the Reliability Standard PRC-002. The Reliability Standard PRC-028 is applicable to the Inverter-Based Resource.

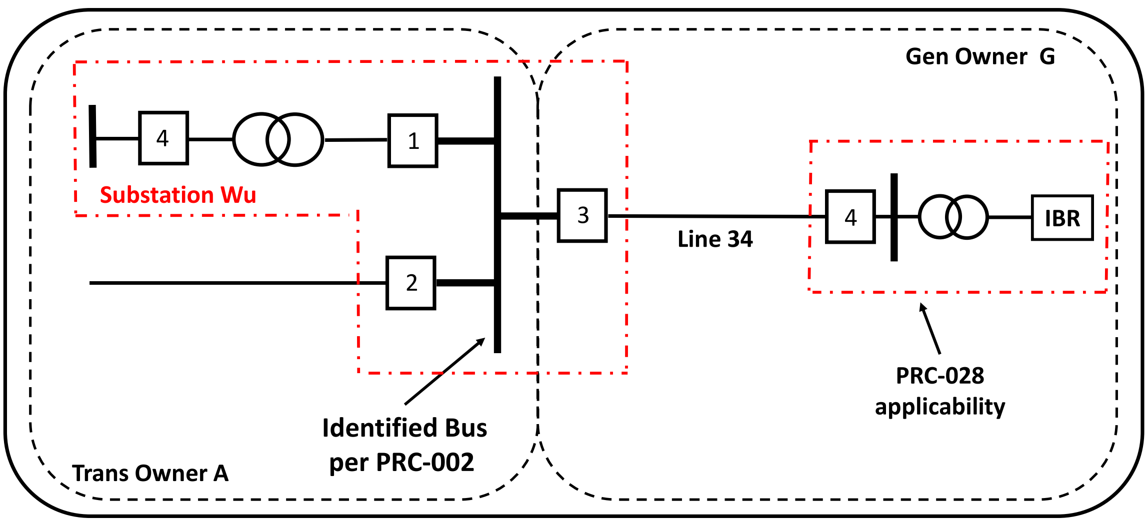

Figure 4: Inverter-Based Resource Interconnection – Applicability of PRC-002 versus PRC-028

Rationale for Requirement R1

The standard is required to capture SER data from circuit breakers within the Inverter-Based Resource associated with:

- Main power transformer(s)
- Collector bus(es), including collector feeder breakers
- Shunt static or dynamic reactive device(s), including any filter banks
- AC-DC and DC-AC converters, if any, in case of VSC HVDC system with a dedicated connection to Inverter-Based Resources.

The standard also requires capturing SER data from all IBR units. However, it is recognized that for IBR units in commercial operation before the effective date of this standard, IBR units may not be capable to capture SER data. If IBR unit is in commercial operation before the effective date of this standard and not capable to capture SER data then SER data is not required. The SER data required from IBR units are as follows: all fault codes and alarms, high and low voltage/frequency ride-through mode status.

Change of state of circuit breaker position and IBR unit SER data, time stamped according to Requirement R7 to a time synchronized clock, provides the basis for assembling the detailed sequence of events timeline of Inverter-Based Resource's response during a power System disturbance. Analyses of system disturbances often begin by evaluation of SERs to help determine the initiating event(s) and follow the disturbance propagation. Recording of breaker operations helps determine the interruption of flows during the disturbances.

Rationale for Requirement R2

The intent is to capture sufficient FR data for Elements at each Inverter-Based Resource to analyze the overall response of the Inverter-Based Resource to a system disturbance. Analyses of disturbances involving widespread reduction of power output from Inverter-Based Resources in recent years has shown that expansion of monitoring at Inverter-Based Resource sites is necessary. The required electrical quantities may either be directly measured or determinable if sufficient FR data is captured (e.g., residual or neutral current if the phase currents are directly measured).

The FR data captured from IBR units helps in understanding individual IBR unit's response during system disturbances. However, in lieu of requiring FR data from IBR units, standard requires FR data from collector feeder breakers. The FR data captured from collector feeder breakers provides information about collective response of IBR units on a given collector feeder during system disturbances.

The plant level FR measurements, i.e., measured on high-side terminals of the main power transformer, specified in Requirement R2, Part 2.1 provide data at the Inverter-Based Resource interconnection to the bulk power system. To cover all possible fault types, phase-to-neutral voltage recording for each phase is required to be determinable. Each phase current and residual current are required to distinguish between phase faults and ground faults. This data also facilitates determination of the fault location and cause of relay operation. The measurements of active and reactive power provide data on the overall generating facility's response to the system disturbance.

In some cases, the dynamic reactive device is used within the Inverter-Based Resource and often connected to medium voltage collector bus. Regardless of where dynamic reactive device is connected, the output of it during system disturbances is important to understand overall performance of the plant during a disturbance. The measured or determined electrical quantities for dynamic reactive device are same as those specified to be measured/determined from high-side of main power transformer.

<u>Recording of Electrical Quantities</u>

For effective fault analysis, it is necessary to know values of all phase and neutral currents and all phase-to-neutral voltages. Based on such FR data, it is possible to determine all fault types. FR data also augments

SERs in evaluating circuit breaker operation. FR also shows generator output response to a system disturbance.

Current Recordings

The required electrical quantities are normally directly measured. Certain quantities can be derived if sufficient data is measured, for example residual or neutral currents. Since a Transmission System is generally well balanced, with phase currents having essentially similar magnitudes and phase angle differences of 120 degrees, during normal conditions there is negligible neutral (residual) current. In case of a ground fault, the resulting phase current imbalance produces residual current that can be either measured or calculated.

Neutral current, also known as ground or residual current Ir, is calculated as a sum of vectors of three phase currents:

$$\mathbf{I}_r = 3 \bullet \mathbf{I}_0 = \mathbf{I}_A + \mathbf{I}_B + \mathbf{I}_C$$

$\mathbf{I}_0$ - Zero-sequence current

$\mathbf{I}_A$, $\mathbf{I}_B$, $\mathbf{I}_C$ - Phase current (vectors)

Voltage Recordings

Voltages are to be recorded or accurately determined at applicable Elements as outlined in Requirement R2.

Rationale for Requirement R3

Time stamped pre- and post-trigger FR data aid in the analysis of power system operations and determination if operations were as intended.

The “Odessa Disturbance” report from September 2021 recommended high resolution oscillography data at the point of interconnection. The minimum recording rate of 64 samples per cycle is specified recognizing state-of-the-art for DME including storage any storage capability limitations and provides sufficient data to recreate accurate response of the Inverter-Based Resource to system disturbances.

Pre- and post-trigger fault data along with the SER data, all time stamped to a common clock, aid in the analysis of Protection System operations after a fault to determine if a Protection System operated as designed. Additionally, Inverter-Based Resources employ fast acting control systems (with built in protection functions) dictating Inverter-Based Resource’s response to system disturbance. Generally speaking, BES faults persist for a very short time period, approximately 1 to 30 cycles. To capture the full response of Inverter-Based Resource spread over a large geographic area, a 2 second total minimum record length synchronized to a common clock is necessary for FR data. Multiple records allow for legacy microprocessor relays which, when time synchronized to a common clock, can provide adequate fault data but are not capable of providing fault data in a single record with 120 continuous cycles total.

FR triggers can be set so that when the monitored value on the recording device goes above or below the trigger value, data is recorded. Requirement R3, Part 3.1.3.1 specifies a neutral (residual) overcurrent trigger for ground faults. Requirement R3, sub-Part 3.1.3.2 specifies a phase overvoltage or undervoltage trigger during voltage ride-through events.

The triggers specified in Requirement R3, Part 3.3 for dynamic reactive device FR data are similar to ones specified in Requirement R3, Part 3.1 for plant level FR data measured or determined on high-side of the main power transformer.

Rationale for Requirement R4

Large scale system disturbances generally are an evolving sequence of events that occur over an extended period of time, making DDR data essential for event analysis. Data available pre- and post-contingency helps identify the causes and Inverter-Based Resource's response to large scale system disturbances. Therefore, continuous recording and storage are necessary to ensure sufficient data is available for the entire event. The state-of-the-art DDR equipment is capable of continuous recording.

DDR data contains the dynamic response of the Inverter-Based Resource to a system disturbance and is used for analyzing complex power system events. This recording is typically used to capture short-term and long-term disturbances. Since the data of interest is changing over time, DDR data is normally stored in the form of RMS values or phasor values, as opposed to directly sampled data as found in FR data.

DDR is used to measure transient response to system disturbances during a relatively balanced post-fault condition. Therefore, it is sufficient to provide a single phase-to-neutral voltage or positive sequence voltage and current from the same phase or positive sequence for each applicable main power transformer for analysis. It is also sufficient to provide a single frequency for any of the provided voltages since all main power transformers within an Inverter-Based Resource are at the same frequency. Recording of all three phases of voltage/current is not required, although this may be used to compute and record the positive sequence value(s). The electrical quantities for Real Power and Reactive Power on a three-phase basis can be measured/recorded or determined (calculated, derived, etc.).

The data requirements for PRC-028-1 are based on a system configuration assuming all normally closed circuit breakers on a BES bus are closed.

A crucial part of disturbance analysis is understanding the dynamic response of generating resources. Therefore, it is necessary to have DDR on high-side of the main power transformer(s) measuring the specified electrical quantities to adequately capture Inverter-Based Resource's response.

The Requirement R4, Part 4.1 requires either one phase-to-neutral or positive sequence voltage. However, the phase-to-phase voltage recording is acceptable. Since the BES operates under a relatively balanced operating condition and, if needed, phase-to-neutral quantities can be derived from phase-to-phase quantities.

Rationale for Requirement R5

An input sampling rate of at least 960 samples per second, which corresponds to 16 samples per cycle on the input side of the DDR equipment, ensures adequate accuracy for calculation of recorded measurements such as complex voltages and frequency. The input sampling rate specified is same as one specified in the Reliability Standard PRC-002.

An output recording rate of electrical quantities of at least 60 times per second refers to the recording rate of the device. Recorded measurements of at least 60 times per second provide adequate recording speed to monitor the Inverter-Based Resource's response during power system disturbances. Since control system associated with Inverter-Based Resources is fast acting, higher frequency recording is necessary to accurately reconstruct events. An output recording rate of 60 times per second provides this higher frequency recording while not greatly increasing data storage requirements.

Rationale for Requirement R6

Time synchronization of disturbance monitoring data is essential for time alignment of large volumes of geographically dispersed records from diverse recording sources. Coordinated Universal Time (UTC) is a recognized time standard that utilizes atomic clocks for generating precision time measurements. All data must be provided in UTC formatted time either with or without the local time offset, expressed as a negative number (the difference between UTC and the local time zone where the measurements are recorded).

Accuracy of time synchronization applies only to the clock used for synchronizing the monitoring equipment. The equipment used to measure the electrical quantities must be time synchronized to ± 1 millisecond accuracy; however, accuracy of the application of this time stamp and therefore, the accuracy of the data itself is not mandated. This is because of inherent delays associated with measuring the electrical quantities and events such as breaker closing, measurement transport delays, algorithm and measurement calculation techniques, etc.

Ensuring that the monitoring devices internal clocks are within ± 1 millisecond accuracy will suffice with respect to providing time synchronized data. Accuracy of time synchronization applies only to the clock used for synchronizing the monitoring equipment. Note that the recently published IEEE Std 2800 requires the DME recording plant level data be synchronized to the clock with accuracy of ± 1 microsecond accuracy; however, the accuracy requirement is set to ± 1 millisecond to strike a balance between need of accuracy and practical limitations of equipment necessary to achieve the stated accuracy. Recognizing challenges with distributing synchronizing clock signal to all IBR units with the Inverter-Based Resource, the IBR units (for capturing of SER data) are required to have synchronized device clock accuracy within ± 100 milliseconds of UTC.

The Inverter-Based Resources, which are not affected by inertial time constants, make changes in power production very rapidly. To understand and analyze control decisions during system disturbances and the reasons behind them over dozens of plants requires a high level of accurate time synchronization. The following provide some examples of Inverter-Based Resource's fast response:

- Typical 90% response to a three-phase fault is < 40 ms.
- Central power plant controllers issue updated commands in as little as 40 ms upon detection of change in system conditions.
- Standard closed loop voltage control response can be <200 ms.

- Instantaneous Inverter protective trip decisions such as AC or DC overvoltage or reverse DC current can be made in less than 10 ms.

Rationale for Requirement R7

Requirement R7, Part 7.1 specifies a minimum time period of 20 calendar days inclusive of the day the data was recorded for which the data is to be retrievable. Data hold requests are usually initiated the same or next day following a major event, however, it takes a longer time to determine which data from which generating facility needs to be retrieved for event analysis. A 20 calendar day time period provides enough time for communication between various Entities regarding the event and need for data retrieval from DME at various generating facilities. The requestor of data has to be aware of 20 calendar day retrievability limit to ensure timely data hold requests. Requiring data retention for a longer period of time is expensive and unnecessary.

With the state-of-the-art equipment, having the data retrievable for the 20 calendar days is realistic and doable. It is important to note that applicable entities should account for any expected delays in retrieving data and this may require devices to have data available for more than 20 days. To clarify the 20 calendar day time frame, let's assume that event occurs on Day 1. If a request for data is made on Day 6, then that data has to be provided to the requestor within 20 calendar days after a request or a granted time extension. However, if a request for the data is made on Day 21, that is outside the 20 calendar days specified in the requirement, and an entity would not be out of compliance if it did not have the data.

This requirement directs the applicable entities, upon requests from the Reliability Coordinator, Regional Entity or NERC, to provide SER, FR and DDR data for generating facilities as per the applicability. To facilitate the analysis of system disturbances, it is important that the data is provided to the requestor within a reasonable time. Providing the data within 15 calendar days (or the granted extension time), subject to Requirement R7, Part 7.2, allows for reasonable time to collect the data and perform any necessary computations or formatting. An entity may request an extension of the 15 calendar days submission requirement. If granted by the requestor, the entity must submit the data within the approved extended time.

Disturbance analysis includes reviewing data recording from many devices and entities. Standardized formatting and naming conventions of these files significantly improve timely analysis. The formatting and naming convention requirements for SER, FR, and DDR are consistent with same requirements in the Reliability Standard PRC-002.

SER data: Requirement R7, Part 7.3 specifies a simple ASCII Comma Separated Value (CSV) format according to Attachment 1. It is necessary to establish a standard format as it allows data submitted by one entity or facility to be incorporated with same data provided by other entities or facilities to develop a detailed sequence of events timeline of a power system disturbance.

FR data: Requirement R7, Part 7.4 specifies either CSV format with appropriate headers or the IEEE C37.111 Standard for Common Format for Transient Data Exchange (COMTRADE) format for the FR data. The IEEE C37.111 is well established in the industry. Exchanging data in a standard format helps in analysis of a power system disturbance, especially considering multiple data submission from many sources.

DDR data: Requirement R7, Part 7.5 specifies either CSV format with appropriate headers or the IEEE C37.111 Standard for Common Format for Transient Data Exchange (COMTRADE) format for the DDR data. The IEEE C37.111 is well established in the industry. Exchanging data in a standard format helps in analysis of a power system disturbance, especially considering multiple data submission from many sources.

The 2013 revision of the IEEE C37.111 includes an annex describing the application of the COMTRADE standard to synchrophasor data.

Requirement R7, Part 7.6 specifies the IEEE C37.232 Standard for Common Format for Naming Time Sequence Data Files (COMNAME) format for naming the SER, FR, and DDR data files. The lack of a common naming practice seriously hinders the event analysis and investigation process.

Rationale for Requirement R8

The standard requires that Entity restore the recording capability for SER, FR, or DDR data within 90 calendar days of the discovery of a failure. The 90 calendar day time period permitted in this requirement strikes a balance between reasonable time needed to restore capability while ensuring that recording capability is not out of service for an extended duration. If the recording capability cannot be restored within 90 calendar days due to limitations such as budget cycle, service crews, vendors, needed outages, etc., the entity is required to submit a Corrective Action Plan for restoring the recording capability to the Regional Entity and implement it. It is treated as a failure if the recording capability is out of service for maintenance and/or testing for greater than 90 calendar days. An outage of the monitored Element does not constitute a failure of the disturbance monitoring capability.

Technical Rationale for Reliability Standard PRC-028-1

July 2024

PRC-028-1 – Disturbance Monitoring and Reporting Requirements for Inverter Based Resources

The recent disturbance reports (e.g., Blue Cut Fire, Canyon 2 Fire, Odessa disturbances) have identified a need for disturbance monitoring for ~~inverter-based resource~~Inverter-Based Resources~~[1]~~ to aid with event analysis, performance monitoring, and disturbance-based ~~inverter-based resource~~Inverter-Based Resource model validation. These disturbance reports are recommended to install disturbance monitoring equipment (DME) at wind and solar photovoltaic (PV) resources to ensure adequate data is available for event analysis, performance monitoring, and validating ~~inverter-based resource~~Inverter-Based Resource models. The recommendation included plant-level high resolution oscillography data, plant SCADA data with a resolution of one second, and inverter level of sequence of events recording data that include all fault codes and high resolution oscillography data. ~~However, i~~In a first version of this standard, only SER data ~~recording of~~ at inverter level data is ~~not~~ required. For the purposes of this standard, the inverter, converter, wind turbine generator, or high voltage direct current converter connecting generating resource to alternating current Transmission network is referred to as an IBR unit.

The purpose of Reliability Standard PRC-002 is to capture event data to understand large scale system disturbances occurring on the Bulk Electric System (BES). Even with changing resource mix, the Reliability Standard PRC-002 serves the purpose. The recent disturbance analyses of events involving inverter-bases resources (e.g., Blue Cut Fire, Canyon 2 Fire, Odessa disturbances) have demonstrated that ~~inverter-based resource~~Inverter-Based Resource's response to a normally cleared few cycle fault is undesirable and poses risk to system reliability. All these disturbance analyses have identified that ~~inverter-based resource~~Inverter-Based Resources involved did not have sufficient monitoring data to understand the plants' responses. The initiating event, e.g., a normally cleared transmission fault, was not a large-scale system disturbance; however, ~~inverter-based resource~~Inverter-Based Resource's undesirable response due to a system fault resulted in a larger system disturbance. Adequate monitoring data is required to understand ~~inverter-based resource~~Inverter-Based Resource's performance. Most of the ~~inverter-based resource~~Inverter-Based Resources involved in these disturbances did not have and were not required to have adequate disturbance monitoring data. The lack of disturbance monitoring data available from these

~~[1] For the purpose of this standard, "inverter-based resource~~Inverter-Based Resources~~" refers to a collection of individual solar photovoltaic (PV), Type 3 and Type 4 wind turbines, battery energy storage system (BESS), or fuel cells that operate as a single plant/resource. In case of offshore wind plants connecting via a dedicated voltage source converter high voltage direct current (VSC HVDC) line, the inverter-based resource~~Inverter-Based Resource ~~includes VSC HVDC line.~~

facilities led to difficulty in adequately assessing the events. Introducing ~~inverter-based resource~~Inverter-Based Resource monitoring requirements to Reliability Standard PRC-002 may create unintended consequences to purpose of Reliability Standard PRC-002 and may lead to industry confusion. Hence, to address needs identified in the Standard Authorization Request (SAR) submitted by the ~~Inverter-Based Resource~~Inverter-Based Resource Performance Task Force (IRPTF), a new standard for monitoring requirements for ~~inverter-based resource~~Inverter-Based Resources is created instead of revising the Reliability Standard PRC-002.

The ~~Transmission Owners and~~ Generator Owners, as applicable, will have the responsibility for ensuring that adequate data is available for applicable Elements at the applicable ~~inverter-based resource~~Inverter-Based Resources. This standard requires that sequence of events recording (SER), fault recording (FR), and dynamic disturbance recording (DDR) data is available from the applicable ~~inverter-based resource~~Inverter-Based Resources.

Rationale for Applicability Section

Functional Entities

The ~~two~~ functional entity~~entities~~ that is~~are~~ responsible for implementing disturbance monitoring equipment and collecting recording data is~~are:~~ Generator Owner~~ and Transmission Owner~~. ~~The standard is only applicable to Transmission Owner in cases where Transmission Owner owns equipment (e.g., circuit breaker(s), main step-up transformer, collector bus, dynamic reactive device, etc.) within the inverter-based resourceInverter-Based Resource.~~

Applicable Facilities

~~The BES inverter-based resourceInverter-Based Resources are in the scope of this standard.~~

The BES Inverter-Based Resources and Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV, are in the scope of this standard.

Order No. 901 directed NERC to develop Reliability Standards "to require registered IBR generator owners to install disturbance monitoring equipment at their buses and elements, to require registered IBR generator owners to provide disturbance monitoring data to Bulk-Power System planners and operators for analyzing disturbances on the Bulk-Power System, and to require Bulk-Power System planners and operators to validate registered IBR models using disturbance monitoring data from installed registered IBR generator owners' disturbance monitoring equipment." Order No. 901 at P 85. FERC continued, "We further agree with the findings in NERC reports (e.g., a lack of high-speed data captured at the IBR or plant-level controller and low-resolution time stamping of inverter sequence of event recorder information has hindered event analysis) and direct NERC through its standard development process to address these findings."

In distinguishing among the different types of IBRs and their registration status that must be covered by the standards, FERC stated: "Where necessary to describe our directives, however, we differentiate between IBRs registered with NERC (or which will be registered pursuant to the Commission's directives in

Registration of Inverter-based Resources, 181 FERC ¶ 61,124 (2022) (IBR Registration Order)) and therefore subject to the Reliability Standards (i.e., registered IBR), IBRs connected directly to the Bulk-Power System but not registered with NERC and therefore not subject to the Reliability Standards (i.e., unregistered IBRs), and IBRs connected to the distribution system that in the aggregate have a material impact on the Bulk Power System (i.e., IBR-DER)." Order No. 901 at n. 14.

In proposed PRC-028-1, the standard drafting team includes both categories of generation that would be registered under proposed changes to NERC Rules of Procedure consistent with Order No. 901. In February 2024, the NERC Board of Trustees approved revisions to the Rules of Procedure to expand the Generator Owners and Generator Operators registered with NERC for compliance purposes. In addition to owners and operators of generating Facilities, NERC will register owners and operators of sub-BES IBRs meeting the following criteria: non-BES inverter based generating resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV. On June 27, 2024, FERC issued an order approving NERC's proposed revisions to its Rules of Procedure, subject to NERC submitting a compliance filing, under section 215 of the Federal Power Act.

The following Elements associated with ~~inverter-based resource~~Inverter-Based Resources noted above are in the scope of this standard:

- Circuit breaker(s) (or interrupting devices)
- Main power transformer(s)
- Collector bus
- Shunt static or dynamic reactive device(s)[2], including any filter banks,
- AC-DC and DC-AC converters, if any, in case of VSC HVDC line with a dedicated connection to ~~inverter-based resource~~Inverter-Based Resource~~s~~
-

The following examples are provided to clarify applicability of the PRC-028 standard.

Example 1: Applicability of PRC-028

Figure 1 shows a typical single line diagram of an ~~inverter-based resource~~Inverter-Based Resource. The ~~inverter-based resource~~Inverter-Based Resource is connected to the transmission system via a short tie-line. This ~~inverter-based resource~~Inverter-Based Resource is equipped with a dynamic reactive device (e.g., synchronous condenser, static VAR compensator etc.) connected to the collector bus.

[2] Synchronous condensers when installed within the Inverter-Based Resource are considered shunt dynamic reactive devices.

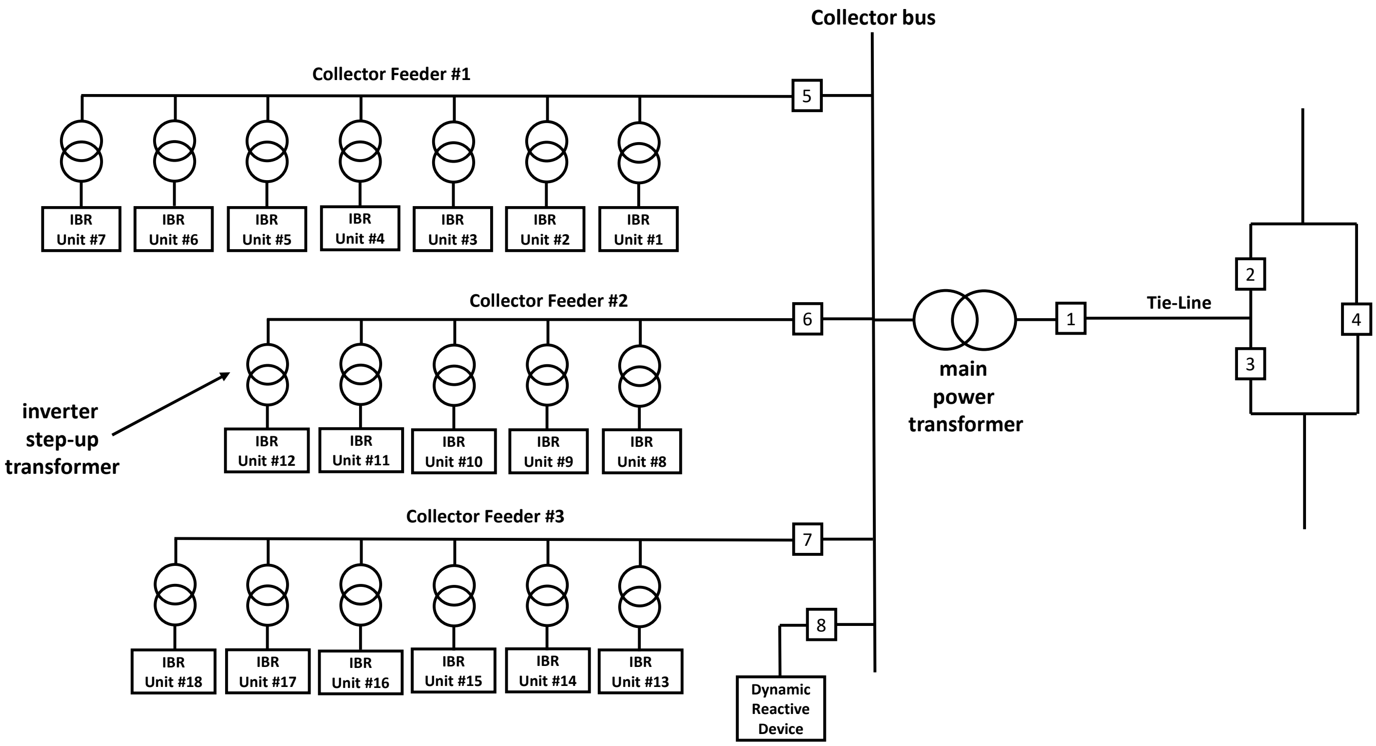

Figure 1: Typical ~~inverter-based resource~~Inverter-Based Resource Single Line Diagram

SER Data: The SER data is required for circuit~~s~~ breakers 1, 5, 6, 7, and 8. Circuit breaker 1 is associated with the main power transformer. Circuit breakers 5, 6, 7, and 8 are associated with the collector bus. The SER data from all IBR units is required.

FR Data: The FR data is required from high side terminals of the main power transformer. In this example, the ~~inverter-based resource~~Inverter-Based Resource consists of only one main power transformer. If the ~~inverter-based resource~~Inverter-Based Resource consists of more than one main power transformer, then FR data for each main power transformer is required. As the ~~inverter-based resource~~Inverter-Based Resource is equipped with the dynamic reactive device, the FR data for it is also required. The FR data from collector feeder circuit breakers 5, 6, and 7 is also required.

DDR Data: The DDR data is required from high side terminals of the main power transformer. If the ~~inverter-based resource~~Inverter-Based Resource consists of more than one main power transformer, then DDR data for each main power transformer is required.

Example 2: Applicability of PRC-028 (Facility with two collector buses and main power transformers)

Figure 2 shows a single line diagram of an ~~inverter-based resource~~Inverter-Based Resource with two collector buses and main power transformers. The ~~inverter-based resource~~Inverter-Based Resource is connected to the transmission system via a short tie-line. The collector feeders #1 and #2 are connected to collector bus #1. The collector feeders #3 and #4 are connected to collector bus #2.

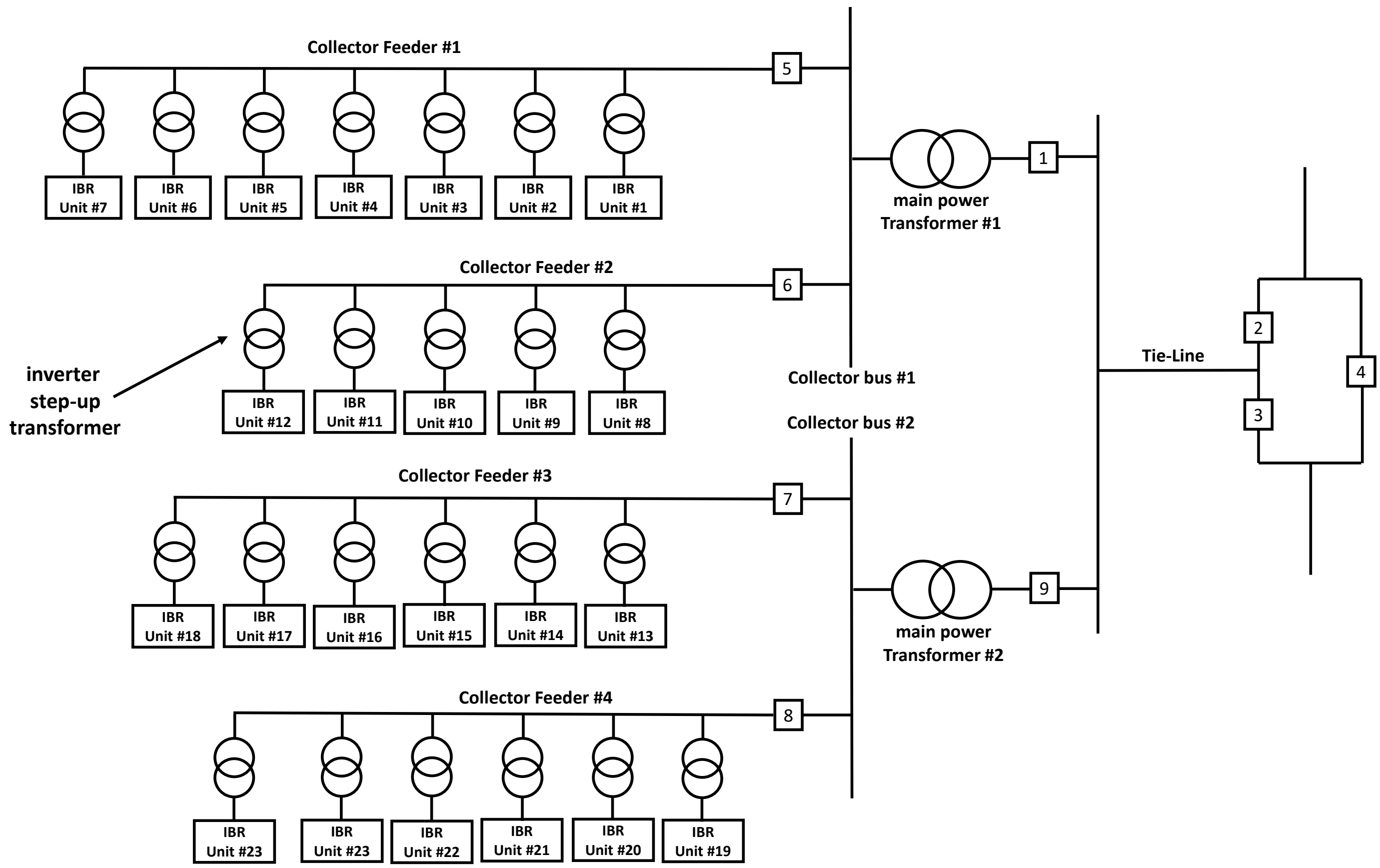

Figure 2: Typical ~~inverter-based resource~~Inverter-Based Resource with two collector buses and main power transformers

SER Data: The SER data is required for circuit~~s~~ breakers 1, 5, 6, 7, 8, and 9. Circuit breakers 1 and 9 are associated with main power transformers. Circuit breakers 5, 6, 7, and 8 are associated with collector buses #1 and #2. The SER data from all IBR units is required.

FR Data: The FR data is required from high side terminals of both main power transformers. The FR data from collector feeder circuit breakers 5, 6, 7, and 8 is also required.

DDR Data: The DDR data is required from high side terminals of both main power transformers.

Example 3: Applicability of PRC-028 (VSC HVDC system with a dedicated connection to ~~inverter-based resource~~Inverter-Based Resources)

Figure 3 shows an example of dedicated VSC HVDC system connecting the ~~inverter-based resource~~Inverter-Based Resource[3]. Transformers on both sides of the HVDC system are considered main power transformer.

[3] Refer to Technical Rationale Project 2020-06 Verification of Models and Data for Generators Inverter-based Resource Definition available at: https://www.nerc.com/pa/Stand/Project_2020_06_Verifications_of_Models_and_Data_f/2020-06_IBR_Definition_Technical_Rationale_Clean_07122024.pdf.

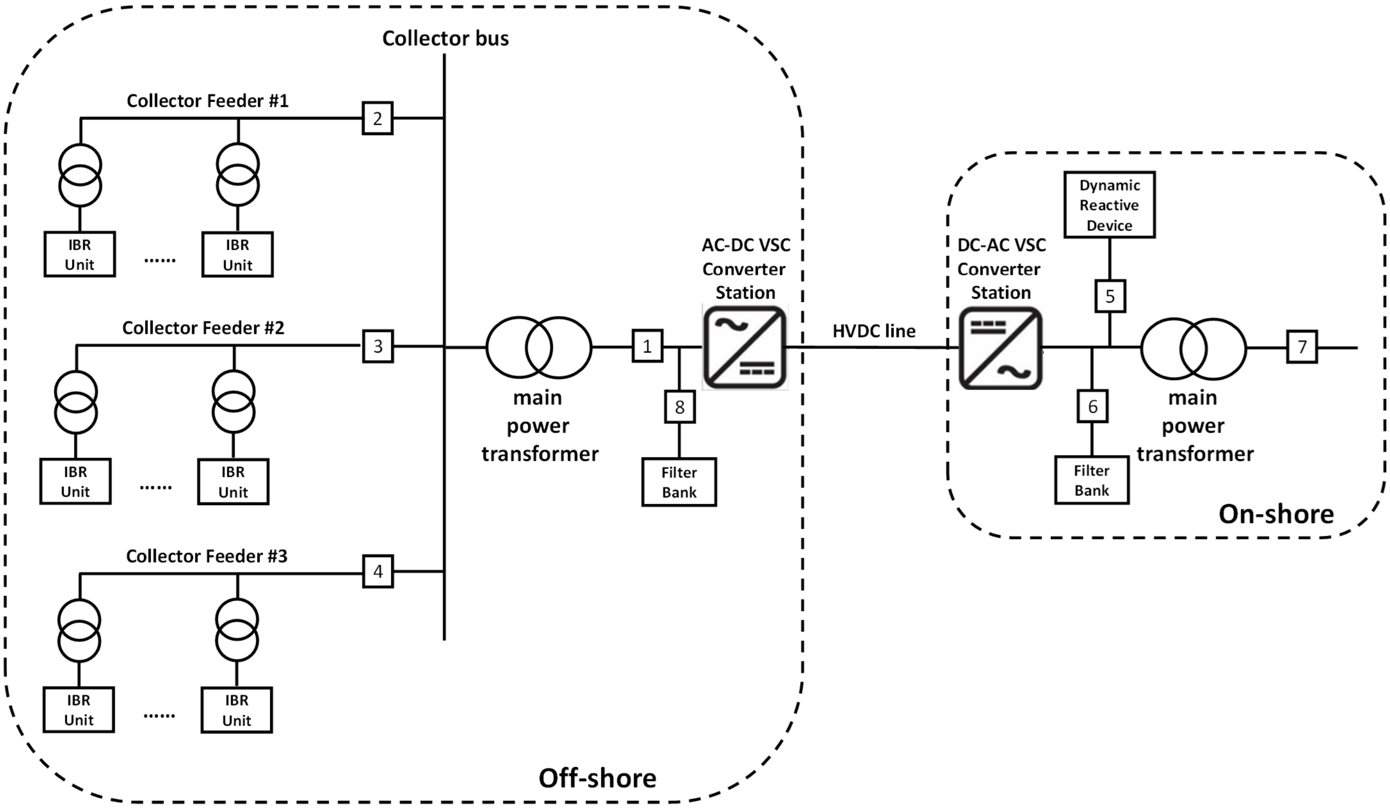

Figure 3: Typical ~~inverter-based resource~~Inverter-Based Resource connected via dedicated VSC HVDC

SER Data: The SER data is required for circuit~~s~~ breakers 1, 2, 3, 4, 5, 6, 7, and 8. Circuit breakers 1 and 7 are associated with main power transformers. Circuit breakers 2, 3, and 4 are associated with the collector bus. Circuit breakers 6 and 8 are associated with filter banks and circuit breaker 5 is associated with shunt dynamic reactive device. The SER data from all IBR units is required.

FR Data: The FR data is required from high side terminals of both main power transformers. The FR data from collector feeder circuit breakers 2, 3, and 4 is also required.

DDR Data: The DDR data is required from high side terminals of both main power transformers.

Example 4: Applicability of PRC-002 versus PRC-028

Figure 4 shows an example of ~~inverter-based resource~~Inverter-Based Resource interconnection to the transmission system via Line 34. The BES bus in substation Wu is the identified BES bus per methodology in Attachment 1 of the Reliability Standard PRC-002. The SER and FR data requirements for the identified BES bus are per the requirements in the Reliability Standard PRC-002. The Reliability Standard PRC-028 is applicable to the ~~inverter-based resource~~Inverter-Based Resource.

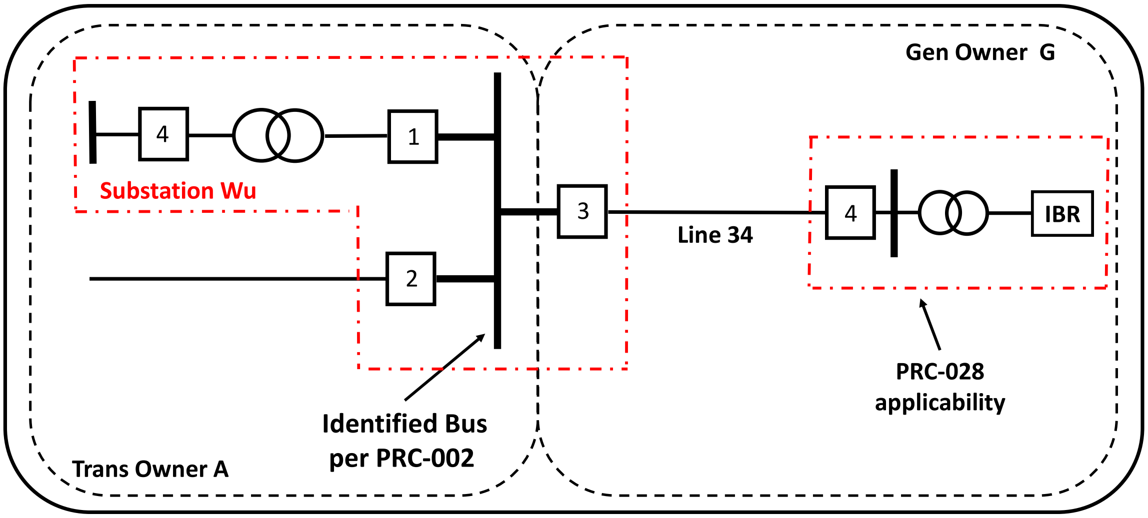

Figure 4: ~~Inverter-based resource~~Inverter-Based Resource Interconnection – Applicability of PRC-002 versus PRC-028

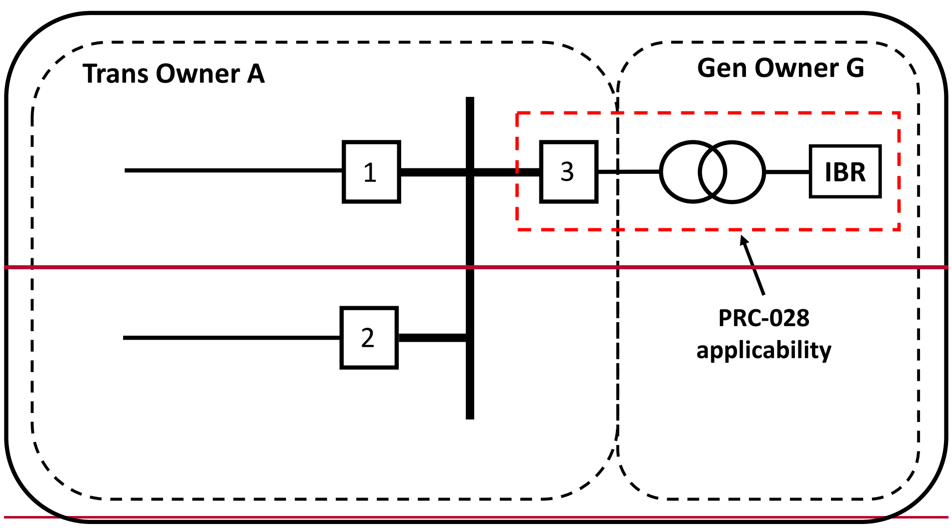
~~Example 5: Transmission Owner owned Equipment within the inverter-based resourceInverter-Based Resource~~

~~Figure 5 shows an example of an inverter-based resourceInverter-Based Resource interconnection where Transmission Owner A owns circuit breaker 3 associated with an inverter-based resourceInverter-Based Resource. In this case, Transmission Owner A is responsible for SER data for circuit breaker 3. It is not common for Transmission Owner to own the main power transformer and/or portions of collector system associated with an inverter-based resourceInverter-Based Resource. However, in cases where this is true, Transmission Owner is responsible for SER, FR, and DDR data, as applicable, required by the Reliability Standard PRC-028.~~



~~Figure 5: Transmission Owner owned Equipment within an inverter-based resourceInverter-Based Resource~~

Rationale for Requirement R1

The standard is requireds to capture SER data from circuit breakers within the ~~inverter-based resource~~Inverter-Based Resource associated with:

- Main power transformer(s)
- Collector bus(es), including collector feeder breakers
- Shunt static or dynamic reactive device(s), including any filter banks
- AC-DC and DC-AC converters, if any, in case of VSC HVDC system with a dedicated connection to ~~inverter-based resource~~Inverter-Based Resources.

The standard also requires capturing SER data from all IBR units. However, it is recognized that for IBR units in commercial operation before the effective date of this standard, IBR units may not be capable to capture SER data. If IBR unit is in commercial operation before the effective date of this standard and not capable to capture SER data then SER data is not required. The SER data required from IBR units are as follows: all fault codes and alarms, high and low voltage/frequency ride-through mode status.

Change of state of circuit breaker position and IBR unit SER data, time stamped according to Requirement R7 to a time synchronized clock, provides the basis for assembling the detailed sequence of events timeline of ~~inverter-based resource~~Inverter-Based Resource's response during a power System disturbance. Analyses of system disturbances often begin by evaluation of SERs to help determine the initiating event(s) and follow the disturbance propagation. Recording of breaker operations helps determine the interruption of flows during the disturbances.

Rationale for Requirement R2

The intent is to capture sufficient FR data for Elements at each ~~inverter-based resource~~Inverter-Based Resource to analyze the overall response of the ~~inverter-based resource~~Inverter-Based Resource to a system disturbance. Analyses of disturbances involving widespread reduction of power output from ~~inverter-based resource~~Inverter-Based Resources in recent years has shown that expansion of monitoring at ~~inverter-based resource~~Inverter-Based Resource sites is necessary. The required electrical quantities may either be directly measured or determinable if sufficient FR data is captured (e.g., residual or neutral current if the phase currents are directly measured).

The FR data captured from IBR units helps in understanding individual IBR unit's response during system disturbances. However, in lieu of requiring FR data from IBR units, standard requires FR data from collector feeder breakers. The FR data captured from collector feeder breakers provides information about collective response of IBR units on a given collector feeder during system disturbances.

The plant level FR measurements, i.e., measured on high-side terminals of the main power transformer, specified in Requirement R2, Part 2.1 provide data at the ~~inverter-based resource~~Inverter-Based Resource interconnection to the bulk power system. To cover all possible fault types, phase-to-neutral voltage recording for each phase is required to be determinable. Each phase current and residual current are required to distinguish between phase faults and ground faults. This data also facilitates determination of the fault location and cause of relay operation. The measurements of active and reactive power provide data on the overall generating facility's response to the system disturbance.

In some cases, the dynamic reactive device is used within the ~~inverter-based resource~~Inverter-Based Resource and often connected to medium voltage collector bus. Regardless of where dynamic reactive device is connected, the output of it during system disturbances is important to understand overall performance of the plant during a disturbance. The measured or determined electrical quantities for dynamic reactive device are same as those specified to be measured/determined from high-side of main power transformer.

Recording of Electrical Quantities

For effective fault analysis, it is necessary to know values of all phase and neutral currents and all phase-to-neutral voltages. Based on such FR data, it is possible to determine all fault types. FR data also augments SERs in evaluating circuit breaker operation. FR also shows generator output response to a system disturbance.

Current Recordings

The required electrical quantities are normally directly measured. Certain quantities can be derived if sufficient data is measured, for example residual or neutral currents. Since a Transmission System is generally well balanced, with phase currents having essentially similar magnitudes and phase angle differences of 120 degrees, during normal conditions there is negligible neutral (residual) current. In case of a ground fault, the resulting phase current imbalance produces residual current that can be either measured or calculated.

Neutral current, also known as ground or residual current Ir, is calculated as a sum of vectors of three phase currents:

$$\mathbf{I}_r = 3 \bullet \mathbf{I}_0 = \mathbf{I}_A + \mathbf{I}_B + \mathbf{I}_C$$

$\mathbf{I}_0$ - Zero-sequence current

$\mathbf{I}_A$, $\mathbf{I}_B$, $\mathbf{I}_C$ - Phase current (vectors)

Voltage Recordings

Voltages are to be recorded or accurately determined at applicable Elements as outlined in Requirement R2.

Rationale for Requirement R3

Time stamped pre- and post-trigger FR data aid in the analysis of power system operations and determination if operations were as intended.

The “Odessa Disturbance” report from September 2021 recommended high resolution oscillography data at the point of interconnection. The minimum recording rate of 64 samples per cycle is specified recognizing state-of-the-art for DME including storage any storage capability limitations and provides sufficient data to recreate accurate response of the ~~inverter-based resource~~Inverter-Based Resource to system disturbances.

Pre- and post-trigger fault data along with the SER data, all time stamped to a common clock, aid in the analysis of Protection System operations after a fault to determine if a Protection System operated as designed. Additionally, ~~inverter-based resource~~Inverter-Based Resources employ fast acting control systems (with built in protection functions) dictating ~~inverter-based resource~~Inverter-Based Resource's response to system disturbance. Generally speaking, BES faults persist for a very short time period, approximately 1 to 30 cycles. To capture the full response of ~~inverter-based resource~~Inverter-Based Resource spread over a large geographic area, a 2 second total minimum record length synchronized to a common clock is necessary for FR data. Multiple records allow for legacy microprocessor relays which, when time synchronized to a common clock, can provide adequate fault data but are not capable of providing fault data in a single record with 120 continuous cycles total.

FR triggers can be set so that when the monitored value on the recording device goes above or below the trigger value, data is recorded. Requirement R3, Part 3.1.3.1 specifies a neutral (residual) overcurrent trigger for ground faults. Requirement R3, sub-Part 3.1.3.2 specifies a phase overvoltage or undervoltage trigger during voltage ride-through events.

The triggers specified in Requirement R3, Part 3.3 for dynamic reactive device FR data are similar to ones specified in Requirement R3, Part 3.1 for plant level FR data measured or determined on high-side of the main power transformer.

Rationale for Requirement R4

Large scale system disturbances generally are an evolving sequence of events that occur over an extended period of time, making DDR data essential for event analysis. Data available pre- and post-contingency helps identify the causes and ~~inverter-based resource~~Inverter-Based Resource's response to large scale system disturbances. Therefore, continuous recording and storage are necessary to ensure sufficient data is available for the entire event. The state-of-the-art DDR equipment is capable of continuous recording.

DDR data contains the dynamic response of the ~~inverter-based resource~~Inverter-Based Resource to a system disturbance and is used for analyzing complex power system events. This recording is typically used to capture short-term and long-term disturbances. Since the data of interest is changing over time, DDR data is normally stored in the form of RMS values or phasor values, as opposed to directly sampled data as found in FR data.

DDR is used to measure transient response to system disturbances during a relatively balanced post-fault condition. Therefore, it is sufficient to provide a single phase-to-neutral voltage or positive sequence voltage and current from the same phase or positive sequence for each applicable main power transformer for analysis. It is also sufficient to provide a single frequency for any of the provided voltages since all main power transformers within an ~~inverter-based resource~~Inverter-Based Resource are at the same frequency. Recording of all three phases of voltage/current is not required, although this may be used to compute and record the positive sequence value(s). The electrical quantities for Real Power and Reactive Power on a three-phase basis can be measured/recorded or determined (calculated, derived, etc.).

The data requirements for PRC-028-1 are based on a system configuration assuming all normally closed circuit breakers on a BES bus are closed.

A crucial part of disturbance analysis is understanding the dynamic response of generating resources. Therefore, it is necessary to have DDR on high-side of the main power transformer(s) measuring the specified electrical quantities to adequately capture ~~inverter-based resource~~Inverter-Based Resource's response.

The Requirement R4, Part 4.1 requires either one phase-to-neutral or positive sequence voltage. However, the phase-to-phase voltage recording is acceptable. Since the BES operates under a relatively balanced operating condition and, if needed, phase-to-neutral quantities can be derived from phase-to-phase quantities.

Rationale for Requirement R5

An input sampling rate of at least 960 samples per second, which corresponds to 16 samples per cycle on the input side of the DDR equipment, ensures adequate accuracy for calculation of recorded measurements such as complex voltages and frequency. The input sampling rate specified is same as one specified in the Reliability Standard PRC-002.

An output recording rate of electrical quantities of at least 60 times per second refers to the recording rate of the device. Recorded measurements of at least 60 times per second provide adequate recording speed to monitor the ~~inverter-based resource~~Inverter-Based Resource's response during power system disturbances. Since control system associated with ~~inverter-based resource~~Inverter-Based Resources is fast acting, higher frequency recording is necessary to accurately reconstruct events. An output recording rate of 60 times per second provides this higher frequency recording while not greatly increasing data storage requirements.

Rationale for Requirement R6

Time synchronization of disturbance monitoring data is essential for time alignment of large volumes of geographically dispersed records from diverse recording sources. Coordinated Universal Time (UTC) is a recognized time standard that utilizes atomic clocks for generating precision time measurements. All data must be provided in UTC formatted time either with or without the local time offset, expressed as a negative number (the difference between UTC and the local time zone where the measurements are recorded).

Accuracy of time synchronization applies only to the clock used for synchronizing the monitoring equipment. The equipment used to measure the electrical quantities must be time synchronized to ± 1 millisecond accuracy; however, accuracy of the application of this time stamp and therefore, the accuracy of the data itself is not mandated. This is because of inherent delays associated with measuring the electrical quantities and events such as breaker closing, measurement transport delays, algorithm and measurement calculation techniques, etc.

Ensuring that the monitoring devices internal clocks are within ± 1 millisecond accuracy will suffice with respect to providing time synchronized data. Accuracy of time synchronization applies only to the clock used for synchronizing the monitoring equipment. Note that the recently published IEEE Std 2800 requires the DME recording plant level data be synchronized to the clock with accuracy of ± 1 microsecond accuracy;

however, the accuracy requirement is set to ± 1 millisecond to strike a balance between need of accuracy and practical limitations of equipment necessary to achieve the stated accuracy. Recognizing challenges with distributing synchronizing clock signal to all IBR units with the Inverter-Based Resource, the IBR units (for capturing of SER data) are required to have synchronized device clock accuracy within ± 100 milliseconds of UTC.

The ~~inverter-based resource~~Inverter-Based Resources, which are not affected by inertial time constants, make changes in power production very rapidly. To understand and analyze control decisions during system disturbances and the reasons behind them over dozens of plants requires a high level of accurate time synchronization. The f~~F~~ollowing provide some examples of ~~inverter-based resource~~Inverter-Based Resource's fast response:

- Typical 90% response to a three-phase fault is < 40 ms.
- Central power plant controllers issue updated commands in as little as 40 ms upon detection of change in system conditions.
- Standard closed loop voltage control response can be <200 ms.
- Instantaneous Inverter protective trip decisions such as AC or DC overvoltage or reverse DC current can be made in less than 10 ms.

Rationale for Requirement R7

Requirement R7, Part 7.1 specifies a minimum time period of 20 calendar days inclusive of the day the data was recorded for which the data is to be retrievable. Data hold requests are usually initiated the same or next day following a major event, however, it takes a longer time to determine which data from which generating facility needs to be retrieved for event analysis. A 20 calendar day time period provides enough time for communication between various Entities regarding the event and need for data retrieval from DME at various generating facilities. The requestor of data has to be aware of 20 calendar day retrievability limit to ensure timely data hold requests. Requiring data retention for a longer period of time is expensive and unnecessary.

With the state-of-the-art equipment, having the data retrievable for the 20 calendar days is realistic and doable. It is important to note that applicable entities should account for any expected delays in retrieving data and this may require devices to have data available for more than 20 days. To clarify the 20 calendar day time frame, let's assume that event occurs on Day 1. If a request for data is made on Day 6, then that data has to be provided to the requestor within 20 calendar days after a request or a granted time extension. However, if a request for the data is made on Day 21, that is outside the 20 calendar days specified in the requirement, and an entity would not be out of compliance if it did not have the data.

This requirement directs the applicable entities, upon requests from the Reliability Coordinator, Regional Entity or NERC, to provide SER, FR and DDR data for generating facilities as per the applicability. To facilitate the analysis of system disturbances, it is important that the data is provided to the requestor within a reasonable time. Providing the data within 15 calendar days (or the granted extension time), subject to Requirement R7, Part 7.2, allows for reasonable time to collect the data and perform any necessary computations or formatting. An entity may request an extension of the 15 calendar days submission requirement. If granted by the requestor, the entity must submit the data within the approved extended time.

Disturbance analysis includes reviewing data recording from many devices and entities. Standardized formatting and naming conventions of these files significantly improve~~s~~ timely analysis. The formatting and naming convention requirements for SER, FR, and DDR are consistent with same requirements in the Reliability Standard PRC-002.

<u>SER data:</u> Requirement R7, Part 7.3 specifies a simple ASCII Comma Separated Value (CSV) format according to Attachment 1. It is necessary to establish a standard format as it allows data submitted by one entity or facility to be incorporated with same data provided by other entities or facilities to develop a detailed sequence of events timeline of a power system disturbance.

<u>FR data:</u> Requirement R7, Part 7.4 specifies <u>either CSV format with appropriate headers or </u>the IEEE C37.111 Standard for Common Format for Transient Data Exchange (COMTRADE) format for the FR data. The IEEE C37.111 is well established in the industry. Exchanging data in a standard format helps in analysis of a power system disturbance, especially considering multiple data submission from many sources.

<u>DDR data:</u> Requirement R7, Part 7.5 specifies either CSV format with appropriate headers or the IEEE C37.111 Standard for Common Format for Transient Data Exchange (COMTRADE) format for the DDR data. The IEEE C37.111 is well established in the industry. Exchanging data in a standard format helps in analysis of a power system disturbance, especially considering multiple data submission from many sources.

The 2013 revision of the IEEE C37.111 includes an annex describing the application of the COMTRADE standard to synchrophasor data.

Requirement R7, Part 7.6 specifies the IEEE C37.232 Standard for Common Format for Naming Time Sequence Data Files (COMNAME) format for naming the SER, FR<u>,</u> and DDR data files. The lack of a common naming practice seriously hinders the event analysis and investigation process.

Rationale for Requirement R8

The standard requires that Entity restore the recording capability for SER, FR, or DDR data within 90 calendar days of the discovery of a failure. The 90 calendar day time period permitted in this requirement strikes a balance between reasonable time needed to restore capability while ensuring that recording capability is not out of service for an extended duration. If the recording capability cannot be restored within 90 calendar days due to limitations such as budget cycle, service crews, vendors, needed outages, etc., the entity is required to submit a Corrective Action Plan for restoring the recording capability to the Regional Entity and implement it. It is treated as a failure if the recording capability is out of service for maintenance and/or testing for greater than 90 calendar days. An outage of the monitored Element does not constitute a failure of the disturbance monitoring capability.

Considerations of FERC Order 901 Directives

Directive Language	Consideration of Directives
P 85: "Pursuant to section 215(d)(5) of the FPA, we adopt the NOPR proposal to direct NERC to include in the new or modified Reliability Standards technical criteria to require registered IBR generator owners to install disturbance monitoring equipment at their buses and elements, to require registered IBR generator owners to provide disturbance monitoring data to Bulk-Power System planners and operators for analyzing disturbances on the Bulk-Power System, and to require Bulk-Power System planners and operators to validate registered IBR models using disturbance monitoring data from installed registered IBR generator owners' disturbance monitoring equipment. We agree with NERC that updating Reliability Standard PRC-002-2 to apply to registered IBRs for disturbance monitoring data collection, including recording sequence of events, digital faults, synchronized phasor measurements, inverter oscillography, inverter and plant-level fault codes, and data retention, could be one way to accomplish this directive. We further agree with the findings in NERC reports (e.g., a lack of high-speed data captured at the IBR or plant-level controller and low-resolution time stamping of inverter sequence of event recorder information has hindered event analysis) and direct NERC through its standard development process to address these findings."	The directive is addressed by new Reliability Standard PRC-028-1 which applies to • BES IBRs – Inclusion I4 of BES definition • Non-BES IBRs - Either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV. The drafting team determined that introducing inverter-based resource monitoring requirements to Reliability Standard PRC-002 may create unintended consequences to purpose of Reliability Standard PRC-002 and may lead to industry confusion. Hence, a new Reliability Standard PRC-028-1 for monitoring requirements for Inverter-Based Resources is created instead of revising the Reliability Standard PRC-002. The Reliability Standard PRC-028-1, Requirements R1 through R6 obligates Transmission Owner and Generator Owner of Inverter-Based Resources to install Disturbance Monitoring Equipment to record sequence of event recording (SER), fault recording (FR), and dynamic disturbance recording (DDR) data at various places within the Inverter-Based Resource. The Reliability Standard PRC-028-1, Requirement R7 obligates Transmission Owner and Generator Owner of Inverter-Based Resources to share recorded data with Transmission Planner, Planning Coordinator, Transmission Operator, Balancing

	Authority, Reliability Coordinator, Regional Entity, or NERC upon request.
P 86: "As a general matter, we agree with ACP/SEIA regarding the need to balance the burden to generator owners of collecting and providing data collected by disturbance monitoring equipment with the benefit of that data to reliability. Thus, in developing the directed data collection requirements, we direct NERC to consider the burdens of generators collecting and providing data, while assuring that Bulk-Power System operators and planners have the data they need for accurate disturbance monitoring and analysis. Likewise, regarding CAISO's request that the Commission direct NERC to consider requiring registered IBRs to provide additional data, we agree that such data collections may be warranted, and direct NERC to consider through its standards development process whether additional IBR data points (e.g., telemetry collections or other automated platform integrations) are needed to further enhance real-time visibility of Bulk-Power System operations."	The directive is addressed in the Reliability Standard PRC-028-1 which strikes a balance between recommendations from various NERC disturbance reports, comments received from industry including two inverter OEMs, available data recording technology, cost burden, reliability need, as well as use of collected data to aid with event analysis, model validation etc.
Paragraph 226: Although we are not directing NERC to include implementation dates in its informational filing and are leaving determination of the proposed effective dates to the standards development process, we are concerned that the lack of a time limit for implementation could allow identified issues to remain unresolved for a significant and indefinite period. Therefore, we emphasize that industry has been aware of and alerted to the need to address the impacts of IBRs on the Bulk-Power System since at least 2016. The number of events, NERC Alerts, reports, whitepapers, guidelines, and ongoing standards projects more than demonstrate the need for the expeditious implementation of new or modified Reliability Standards addressing IBR data sharing, data and model validation, planning and operational studies, and performance requirements. Thus, in that light, the	The implementation plan addresses Reliability Standard PRC-028-1 becoming effective on the first day of first calendar quarter from the effective date of Commission order approving the PRC-028-1. In addition, a phased-in approach is provided for Inverter-Based Resources that are in commercial operation before the effective date of this standard, with all Inverter-Based Resources in commercial operation before the effective date of this standard are required to fully comply with Requirements R1 through R7 by January 1, 2030. Recognizing circumstances beyond Entity's control (e.g., supply chain delays associated with the procurement, engineering, installation, or commissioning of disturbance monitoring equipment, inability to secure scheduling outages) which may

Commission will consider the justness and reasonableness of each new or modified Reliability Standard's implementation plan when it is submitted for Commission approval. Further, we believe that there is a need to have all of the directed Reliability Standards effective and enforceable well in advance of 2030 and direct NERC to ensure that the associated implementation plans sequentially stagger the effective and enforceable dates to ensure an orderly industry transition for complying with the IBR directives in this final rule prior to that date.	prevent the installation of Disturbance Monitoring Equipment per the time allowed at Inverter-Based Resources that are in commercial operation before the effective date of PRC-028-1, the implementation plan includes a process for requesting an extension from compliance dates. Inverter-Based Resources entering commercial operation after the effective date of PRC-028-1, Entities are required to comply with Requirements R1 through R7 within 15 calendar months following the effective date of the standard or commercial operation date, whichever is later. For more details, see the PRC-028-1 Implementation Plan.

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

UPDATED

Standards Announcement

Project 2021-04 Modifications to PRC-002 – Phase II

Formal Comment Period Open through August 12, 2024

Now Available

A formal comment period for **PRC-028-1 – Disturbance Monitoring and Reporting Requirements for Inverter-based Resources** is open through **8 p.m. Eastern, Monday, August 12, 2024**. The drafting team decided to remove "**4.1.1. Transmission Owner that owns equipment as identified in section 4.2**" from the **Applicability** and all of the Transmission Owner referenced in the Requirements of Standard PRC-028-1.

This will be the last opportunity for NERC to ballot these projects through traditional mechanisms. The Board may take requisite action during the August 2024 Board of Trustees meeting to ensure directives are met.

The Standards Committee approved waivers to the Standard Processes Manual at their December 2023 meeting. These waivers were sought by NERC Standards staff for reduced formal comment and ballot periods. This will assist the drafting teams in expediting the standards development process due to firm timeline expectations set by FERC Order 901. *FERC Order 901 was issued under* Docket No. RM22-12-000 *on October 19, 2023.*

To assist industry in this upcoming comment and ballot period, NERC has released a Milestone 2 Summary that provides high-level overview of the current state of the associated projects and their interrelationships. The drafting team's considerations of the responses received from the previous comment period are reflected in this draft of the standard.

Note: PRC-002-5 passed the recent additional ballot (conducted June 5-15, 2024). The drafting team will be moving this standard to a final ballot when the PRC-028-1 ballots open (August 2-12, 2024) as only non-substantive revision(s) were made.

Reminder Regarding Corporate RBB Memberships

Under the NERC Rules of Procedure, each entity and its affiliates is collectively permitted one voting membership per Registered Ballot Body Segment. Each entity that undergoes a change in corporate structure (such as a merger or acquisition) that results in the entity or affiliated entities having more than the one permitted representative in a particular Segment must withdraw the duplicate membership(s) prior to joining new ballot pools or voting on anything as part of an existing ballot pool. Contact **ballotadmin@nerc.net** to assist with the removal of any duplicate registrations.

Commenting

Use the Standards Balloting and Commenting System (SBS) to submit comments. An unofficial Word version of the comment form is posted on the project page.

- *Contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern) for problems regarding accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out.*
- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*
- *Please be mindful of ballot and comment period closing dates. We ask to **allow at least 48 hours** for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts **prior to the last day** of a comment/ballot period.*

Next Steps

Additional ballots for the standards and implementation plan, as well as the non-binding polls of the associated Violation Risk Factors and Violation Severity Levels will be conducted **August 2 – 12, 2024**.

For more information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Senior Standards Developer**,** Ben Wu (via email) or at 470-542-6882. Subscribe to this project's observer mailing list by selecting "NERC Email Distribution Lists" from the "Service" drop-down menu and specify “Project 2021-04 Modifications to PRC-002 observer list” in the Description Box.

Comment Report

Project Name:	2021-04 Modifications to PRC-002 – Phase II | PRC-028-1
Comment Period Start Date:	7/22/2024
Comment Period End Date:	8/12/2024
Associated Ballots:	2021-04 Modifications to PRC-002 – Phase II Implementation Plan AB 4 OT 2021-04 Modifications to PRC-002 – Phase II PRC-028-1 AB 4 ST

There were 60 sets of responses, including comments from approximately 135 different people from approximately 91 companies representing 10 of the Industry Segments as shown in the table on the following pages.

Questions

1. Do you agree with the modifications made in PRC-028-1?

2. Do you agree with the Implementation Plan for revised PRC-028-1?

3. Do you agree the modifications made in PRC-028-1 are cost effective at unit level cost versus plant level cost compared to the benefit to reliability?

4. Provide any additional comments for the standard drafting team to consider, if desired.

1. Do you agree with the modifications made in PRC-028-1?	
Thomas Foltz - AEP - 5	
Answer	No
Document Name	
Comment	

While requiring recording all the fault codes and fault alarms as listed in R1.2 and R1.3 is certainly well-meaning, there may be disadvantages in requiring this breadth of data capturing and provision. Functional Entities (such as Transmission Planner, Planning Coordinator, Transmission Operator, Balancing Authority, Reliability Coordinator, and the Regional Entity) may not all equally benefit from receiving every fault code and fault alarm specified in R1.2 and R1.3. Fault codes and fault alarms differ across manufacturers and devices, and this is further complicated by the lack of standardization and consistent nomenclature in this area. Also, some entities may not be able to fully understand or draw proper conclusions from some of this data, which could lead to inconsistent and undesirable interpretation and application. Rather than requiring “all” the fault codes and alarms available, might it be worth considering for the standard to specify exactly which fault codes and alarms that the SDT believes would be beneficial?

AEP strongly recommends that the STD remove the requirement to capture all fault codes and alarms on IBR Units as SER data to +/- 100 millisecond from the standard and allow the GO to address IBR Unit performance issues as required under PRC-030.

PRC-029 requires the GO to ensure the design of IBR units meets the voltage and frequency ride through requirements or notify the applicable RC, BA and TO if the IBR is technically unable to meet those requirements. PRC-030 requires the GO to develop and execute a process to analyze Real Power change events including ride-through performance and implement corrective actions to address performance issues including applicable other GO IBR facilities.

Adding the requirement to capture all fault codes and alarms on IBR Units as SER data to +/- 100 millisecond back into this standard is unreasonable as it adds significant costs to the SER system and excessive administrative burden on the GO if an event occurs. Note that large IBR facilities have hundreds of IBR Units which would require the SER system to have thousands of SER data points. Is the intent of this requirement to have the TP, PC, TO, BA, RC, Regional Entity, or NERC determine the root cause of IBR Unit performance? If so, then why, as PRC-030 clearly holds the GO responsible for performing this analysis.

When an event occurs, the GO may be requested to submit DME data as proposed in PRC-028 while also having to address performance issues as required by PRC-030. Collecting SER data from every IBR Unit will be time consuming or require an expensive automated SER data collection system. The DME data for the MPT and collector bus should allow the TP, PC, TO, BA, RC, Regional Entity, or NERC to determine performance issues down to the IBR facility level and any corrective actions required on IBR Units would be address by the GO as required by PRC-030.

AEP disagrees with the mid-ballot period removal of Transmission Owner from the list of Functional Entities. The TO may in some cases be the owner of the MPT and high side breakers.

Comment

A) Duke Energy agrees with and supports the following NAGF comment:

1.b. Requirement R1.1:

i. NAGF members are still not certain that use of the term “collector bus(es)” includes feeder breakers and therefore are requesting that the requirement narrative be clarified to address this issue.

B) R1 Sections 1.2 & 1.3, 1.2.3 and 1.2.4, 1.3.3 & 1.3.4 require a mode status; this request is not a function of the recorders. In the technical rationale, please address this requirement or change standard to record voltage and frequency values instead of mode.

1. Based on the latest draft, the Standards Drafting Team (SDT) has removed the Transmission Owner from this Reliability Standard’s applicability. Part 1.1 of Requirement R1 states a Generator Owner is required to retain sequence of event recording (SER) data for the circuit breaker positions associated with main power transformers, collector buses, shunt static and dynamic reactive devices, and AC-DC and DC-AC converters, if any, in case of VSC HVDC systems. Following the removal of the Transmission Owner, we believe the inclusion of circuit breaker positions for AC-DC and DC-AC converters is now misplaced and should also be removed.
2. Requirement R1 will require a Generator Owner to retain SER data. When applied to Parts 1.2 and 1.3, a Generator Owner is then required to perform a second action, which is to retain data for each individual IBR unit. The concept of the individual IBR unit was recently abandoned by the SDT in the previously proposed draft. We believe this is a reversal in the direction for Generator Owners to adopt this Reliability Standard. Nonetheless, we propose removing the phrases “shall be recorded” and “all” in these parts for clarity. We instead recommend rephrasing these parts to “…the following recorded data when triggered by ride-through operation or tripping of an IBR unit: fault codes, fault alarms, high and low voltage ride-through mode statuses, and high and low frequency ride-through mode statuses.”
3. Part 1.3 allows for an exclusion to Generator Owners if the IBR Facility is incapable to record sequence of event data for each individual IBR unit. We believe the measure for this requirement should be expanded so Generator Owners can document this incapability as evidence.
4. Based on the latest draft, the SDT expanded the requirements of a Generator Owner to retain fault recording (FR) data for each collector feeder breaker. While data may exist, the purpose of the Protection Systems associated with each feeder breaker is to protect the collector bus from a Fault and the possibility of a failure within the feeder breaker. These Protection Systems use existing voltage and current sensing devices already on-site as Protection System Components. However, the SDT also proposes triggering the recording of FR data on each collector feeder breaker based on overfrequency and underfrequency events. The SDT assumes existing Protection Systems are capable of being reprogrammed to include this functionality. However, some microprocessor relays associated with each collector feeder breaker may not have such functionality available.
5. Part 3.2.3 identifies settings when fault recording devices are triggered to begin recording data. We believe each of the individual triggers currently listed should also have a statement identifying only if such capabilities exist. A similar statement should also be added to the measure for this requirement to support this as evidence.
6. Requirement R6 will require a Generator Owner to retain time synchronized data within a device clock accuracy of ± 1 milliseconds of Coordinated Universal Time (UTC). In this recently proposed draft, the SDT has added a requirement that each IBR unit’s device clock

accuracy must have its accuracy within ± 100 milliseconds of UTC. This new requirement was embedded within Part 6.2 as a separate sentence and suggests each IBR unit must be synchronized to a clock source. For existing facilities, this capability may not be possible. We further believe this approach opens a gap and data associated with IBR units would then be required to have a device clock accuracy of ± 1 milliseconds of UTC. We propose the following approach to revising this requirement. First, remove the phrase “all” in reference to SER, FR, and dynamic disturbance recording (DDR) data in Requirement R6. Second, revise Part 6.2 to “Synchronized device clock accuracy within ± 100 milliseconds of UTC when applied on IBR unit recorded data or within ± 1 milliseconds of UTC.”

The *NAGF provides the following comments for consideration:*

a. Applicability Section 4.2.2 – recommend that the term “Non-BES Inverter-Based Resources” be revised to “Non-BES Inverter-Based Resource(s)” to be consistent with other IBR standards.

b. Requirement R1.1:

i. NAGF members are still not certain that use of the term “collector bus(es)” includes feeder breakers and therefore are requesting that the requirement narrative be clarified to address this issue.

c. Requirement 3.2.1 – NAGF members have noted that existing IBR facilities do not have the capability to provide a fault recording data record length of 2 seconds as defined in this requirement.

d. *Requirement 6.2 – NAGF members have indicated that individual IBR units do not have the ability to meet the +- 100 millisecond accuracy threshold.*

R1.

For IBRs – the OEMs are responsible for **SER** data only. The question OEMs have been having is "*what is a ride through operation*", to define what triggers capturing a ride through event. Its an ambiguous term where p.u. parameters and time duration need to be explicitly defined to be set at the IBR.

{C}1.1   there is no clarity on data that needs to be collected. Do we collect all listed or a single source? This should be stated within the requirement.

Recommendation to remove 1.3 since the requirements are the same as 1.2 except for the timing of COD with respect to when the Standard becomes effective. Requirement 1.3 appears to be reactive in nature. This timing may be better addressed as part of the implementation plan.

R2

The standard does not provide clarity on if collector feeder data is needed from all units or specific units. It is important to note that information is only available on the high side, nothing on the low side.

Recommendation to remove footnote 3 as IBR unit is not a defined term found in the NERC Glossary of Terms.

R3

For DFRs in the substation – there was a change adding MV "collector breakers" to record fault reporting data. No project today or E&C best practices recommend 34.5KV fault reporting with 64 samples/cycle.

Need clarification on whether data should be only for high side, whether for anything that tripped, or for the entire event. Our recommendation would be to focus on the high side of GSU only.

R6

IBRs must be time synchronized to +/- 100milliseconds which implies PTP or installing a GPS clock at each inverter.

Recommend Footnote 4 revised to "interchange" not "exchange."

Comment

R1.3:

This requirement must be more specific with use of word “if capable”. Consider providing a clear exemption.

R2.1.3, R2.2.3, and R3.2.3

The protective devices with FR capabilities cannot capture Real and Reactive quantities. These quantities are typically calculated by using captured voltage and current quantities. SDT should clarify and state if calculated P and Q values are acceptable. If calculated P & Q values are not acceptable, then this requirement will have to be satisfied by installing dedicated fault recorders which can be a substantial burden on cost and implementation plan.

R3:

While WEC Energy Group fully supports triggering FR at proposed locations, WEC has a concern with 2 seconds recording requirement and 64 samples per cycle recording rate.

Most of the older microprocessor based protective relays do not have 2 seconds recording capabilities. The DT recognized this as well in the Technical Rationale document *(“Multiple records allow for legacy microprocessor relays which, when time synchronized to a common clock, can provide adequate fault data but are not capable of providing fault data in a single record with 120 continuous cycles total.”*). Note that microprocessor relays cannot record back to back events if the trigger is not active. This requirement, as currently written, will trigger costly upgrades. WEC suggest that SDT evaluates protective devices capabilities for most common relay manufacturers and reduces the recording requirement to 1 second.

Most of the older microprocessor based protective relays only have 4 or 8 samples/cycle sampling rate and do not have 64 samples per cycle recording rate capabilities. This requirement, as currently written, will trigger costly upgrades. WEC suggest that SDT evaluates protective devices capabilities for most common relay manufacturers and reduces the sampling rate below 64 samples per cycle.

These requirements seem to be more restrictive than PRC-002.

If recording and sampling requirement cannot be reduced, then existing FR equipment in commercial operation before the effective date of this standard should be exempted from 2 second recording requirement and 64 samples per cycle recording rate.

R3.1.3, R3.2.3, and R3.3.3:

SDT should determine pickups for the triggers. As currently written, entity could set pickups way too high or low and FR could never get recorded. For example, we can set 65Hz pickup for over-frequency. By the time we reach 65Hz, the event could be over.

R.6.2:

WEC Energy Group recommends that synchronized clock accuracy match PRC-002, which is +/- 2 milliseconds. An exception should be granted to IBR units in commercial operation before the effective date of this standard if synchronized signal at the IBR is not available or its accuracy cannot meet 100ms requirements.

R7:

WEC Energy Group suggests that R7 requirements match PRC-002 requirements.

R1.2 and R1.3 can involve hundreds of data points for a large facility if “all fault” and “all alarm” codes are included for every IBR unit on a site. Southern Company requests the SDT to consider adding verbiage to limit monitoring requirements to a sample of the IBR units within a facility. What (who) determines criteria of “if capable” in R1.3? Southern Company requests the SDT to consider updating M1 to include documentation explaining the IBR unit is not capable of providing the data for recording. Industry may require clarification of the term “ride through mode status” in R1.2 and R1.3. Southern Company requests the SDT to consider providing the necessary clarification. Southern Company believes R7.2 needs to be changed back to 30 days.

In response to many industry comments regarding the burdens and equipment limitations involved with previously proposed IBR Unit level monitoring requirements, the SDT responded in the Consideration of Comments issued on May 31, 2024, stating, "the SDT has reviewed the NERC disturbance reports, consulted with manufacturers, and considered the burden to industry. The data requirements are addressed in the PRC-028 Technical Rationale. All individual unit requirements have been removed from the latest draft, and meeting these requirements should be less of an issue with equipment used to monitor at the plant level." In Draft 4, not only have the IBR Unit level monitoring requirements been reinserted, but they have also been expanded to include monitoring at every IBR Unit. This sudden reversal of course runs counter to the previous three rounds of industry comment, and the SDT's own responses to those comments. Can the SDT provide additional justification or comment on the reasoning behind this change of course?

Charles Yeung - Southwest Power Pool, Inc. (RTO) - 2 - MRO,WECC,Texas RE,NPCC,SERC,RF, Group Name SRC 2024	
Answer	No
Document Name	
Comment	

In its June 14 comments, the ISO/RTO Council (IRC) Standards Review Committee (SRC) requested that inverter-level requirements be reinstated in PRC-028 and applied to all future IBR installations, at a minimum. The SRC provided numerous reasons for why the removal of these requirements is problematic and could impact reliability. The SRC understands from the SDT's consideration of this comment that the IBR unit SER data requirement was a compromise in lieu of the FR data. However, the SRC is still concerned that the FR data is limited to what the SER would provide as recommended in NERC's September 2019 guideline.

The SRC has noted since the initial draft that the DDR installation requirements proposed in PRC-028 should be considered in meeting DDR coverage requirements of PRC-002. Even though the SDT cites an example where there is not any overlap of DDR coverage between the 2 standards, the SRC believes the standard needs to allow for considerations of system topography in certain areas today where there is significant IBR penetration and possible DDR coverage overlap. The SRC believes the 2 standards need to be able to reconcile the possibility of overlapping coverage Footnote, ISO NE does not support this portion of the response to Q1.

Parts 2.2 and 3.2 are new and require a GO to have FR data for Collector Feeder breakers. Without a clear definition of "Collector Feeder" it is unclear whether this will be applicable only to generators that are configured to directly energize a Collector Feeder as part of a distribution network or whether R3.2 would include any non-BES distribution facilities (such as those located within a plant)?

The SRC also believes that Requirement R1, Parts 1.2 and 1.3 should also apply to broader impacts, including momentary cessation or any other abnormal behavior during events, and should therefore be revised to read as follows.

1.2. For IBR units in commercial operation after the effective date of this standard,

the following data shall be recorded when triggered by ride-through operation,

tripping, or longer-term disturbance response and recovery of an IBR unit including.

1.2.1. All fault codes.

1.2.2. All fault alarms.

1.2.3. High and low voltage ride-through mode status.

1.2.4. High and low frequency ride-through mode status.

1.2.5 Momentary cessation

1.2.6 Other abnormal behavior during events

1.3. For IBR units in commercial operation before the effective date of this standard,

the following data shall be recorded, if capable, when triggered by ride-through operation, tripping, or longer-term disturbance response and recovery of an IBR unit including.

1.3.1. All fault codes.

1.3.2. All fault alarms.

1.3.3. High and low voltage ride-through mode status.

1.3.4. High and low frequency ride-through mode status.

1.3.5 Momentary cessation

1.3.6 Other abnormal behavior during events

Because the “IBR Unit” definition will not be moving forward, it appears each standard seeking to acquire IBR unit information, such as Parts 1.2 and 1.3, will need to define what IBR unit means within the standard. In the case of PRC-028, the SRC understands that footnote 2 serves this purpose, and asks that the drafting team confirm whether the SRC’s understanding is correct.

The SRC supports Parts 2.2 and 3.2 primarily as a starting point for gathering collector feeder breaker FR data in this version of the standard. The SRC believes there is potential for future expansion of these requirements if they are found to be inadequate in the course of investigating the root causes of IBR performance issues.

Part 6.2 currently reads, “Synchronized device clock accuracy within ± 1 milliseconds of UTC. The IBR units shall have synchronized device clock accuracy within ± 100 milliseconds of UTC.”

The SRC seeks clarification from the SDT as to why 100 milliseconds was chosen for Part 6.2 when IEEE uses 100 microseconds. Currently, there are Generator Interconnection Agreements that require 1 millisecond time synchronization for plant- and unit-level device clock accuracy. Many entities are considering adopting the IEEE requirements, so an explanation for this difference is critical.

Additionally, the SRC recommends that PRC-028 be revised to require recording of inverter-level oscillography. As demonstrated throughout the 2022 Odessa Disturbance report, it is evident that inverter-level oscillography is readily available and critical to proper event analysis in cases where individual inverters trip offline even though frequency and voltage at the plant level remain in the must-ride-through zone. This is a known issue where terminal voltages and frequency measurements can vary greatly from the plant-level measurements due to the collector system and step-up transformer designs. In many cases this oscillography is available but just needs to be enabled and adequate storage made available. Table 19 in Section 11 of IEEE 2800 already requires recording of such information at the IBR unit level as well. Such a requirement could be applied to new units and to existing units that already have that capability available and simply need to enable it.

NERC recommended the following in the 2022 Odessa disturbance report for the SDT to consider (emphasis added).

“Monitoring Data ERCOT and the GOs in the Texas Interconnection ***have extensive data*** that is ***critical for root cause analysis***. This ***data includes*** plant-level high resolution oscillography data, plant SCADA data, and ***inverter-level*** sequence of events recording (e.g., fault codes) and ***oscillography data***. ***These types of measurements should be standard across industry for the purposes of event analysis and reducing the risk to plant performance***. The IRPS submitted a SAR, ***and Project 2021-04 is working on enhancements to PRC-002-2 to ensure this type of data is available at BES resources.”***

As written, Requirement R1 brings ambiguity with the use of “IBR unit” with the footnote definition. Additionally, what is a “ride-through operation”? For example- As written, the entity will need to record all aspect/Parts of R1.2 and R1.3 assuming the location failed the Ride-through definition or tripped offline. The discussion will be is it “all fault codes” of the inverter, converter, wind turbine generator, or high voltage direct current converter individually (as applicable)? Or something else? Requirement 1 Part 1.2 and Part 1.3 (including all sub Parts for both)- Capitalize “ride-through” as it is a defined term in another related Project.

AES CE does not agree that SER data at every IBR Unit is necessary to meet the objectives of the Standard. Past revisions contained more reasonable solutions such as SER data at the end of each feeder. We believe this middle solution will have a significant positive impact on system reliability, while adding this data at every single IBR Unit offers only an incremental improvement in ability to analyze system disturbances at a huge burden to GOs.

MISO supports the requirements (Parts 1.2 and 1.3) for IBR unit data. We also observe that, as the "IBR Unit" definition will not be moving forward, it appears each standard seeking to acquire IBR unit information, will need to define what IBR unit means within the standard. In the case of PRC-028, this is footnote 3. Is that correct? MISO supports Parts 2.2 and 3.2 as a starting point to gather collector feeder breaker FR data. That said, we also support the potential for future expansion of these requirements if they are found to be inadequate when investigating the root cause of IBR performance issues. **Part 6.2.** "Synchronized device clock accuracy within ± 1 milliseconds of UTC. The IBR units shall have synchronized device clock accuracy within ± ***100 milliseconds*** of UTC." Regarding Part 6.2., MISO is requesting clarification as to why the SDT chose 100 milliseconds when IEEE uses 100 microseconds. Currently, MISO's Generator Interconnection Agreement requires 1 millisecond time synchronization for plant and unit level device clock accuracy. As MISO is considering adopting the IEEE requirements, please explain the reason for the differential.

We do not disagree with modifications that have been made and we do not object to FERC order 901.

However, we do not believe this standard will improve reliability as the GO/GOP IBR entites would have to share data with (BAs, PAs, RCs, TOPs) only if they ask for said data. And those entities do not have any obligations to do anything with the data which GO/GOP IBRs would be required to provided them.

Consequently, we are unclear as to how GO/GOP IBRs that are required to procure and install a bunch of recording data and share recordings with entities, only if those entities ask for it, will do anything to improve reliability. As written this proposal looks like an expense to GO/GOPs with no reliability benefits.

All entities that GO/GOP IBRs are required to provide data to need to have requirements within this standard version detailing what they are to do with said data in order to improve reliability.

2. Do you agree with the Implementation Plan for revised PRC-028-1?

Steven Rueckert - Western Electricity Coordinating Council - 10	
Answer	No
Document Name	
Comment	

PRC-029 and PRC-030 hinge on the Implementation Plan (IP) for PRC-028. The inconsistent approach (“design”/”operation” aspects of Requirements in PRC-029/030 IPs) and use of “commercial operations date” in PRC-028 IP does not provide clarity. The DTs did not define what the design and operation aspects of PRC-030 are so compliance monitoring will be difficult if at all achievable until ALL parts of PRC-028 are applicable (essentially 2030). The use of commercial operation date is inconsistent with reliability and differs across the United States. There are no compliance evaluations that can be done for non-BES IBRs until after Jan 1, 2030.

For the following Implementation Plan requirement, the DT needs to be extremely clear that the 15 calendar months is ONLY applicable to the “effective date of the standard” portion of the phrase and not the “commercial operation date”:

“For non-BES Inverter-Based Resources in commercial operation after May 2026: Entities shall comply with Requirements R1 through R7 within 15 calendar months following the effective date of the standard or the commercial operation date, whichever is later. “

Does the DT confirm that interpretation of the phrase is correct? Effective date of standard plus 15 calendar months OR commercial operation date whichever is later is the correct way to read that phrase.

Most implemtation plans are effective on the first day of a quarter. If May is actually the desired month, the IP should not simply say “May 2026” it should be specivic such as May 1, May 15, or May 31, 2026.

Having a process for extension of compliance embedded within an Implementation Plan is not conducive or supportive to reliability. As written, this will be an administrative effort with NO defined timeline in sight and no process to support it. The ERO Enterprise should utilize the current processes in place. That is, if the entity, who has had years to be ready, is noncompliant they self-report the issue and follow the mitigation process. Putting this process in place requires a second set of books for compliance determination and status. The Implementation Plan (and the dependence of other Implementation Plans) does not set any expectation for IBRs to be compliant by any set date and does not support FERC’s intention of having Standards applied to IBRs no later than 2030. What happens if the entity does not provide information or provides information that is found to be incorrect and the CEA does not approve the extension? What happens if the entity does not supply the extension request in less time than “required” (i.e., “no later than three months prior to the compliance date”)? FERC recently ruled on cold weather standards regarding Corrective Action Plans being too long. The timing for these exemptions is non-existent and provides a compliance loophole that can be easily exploited by entities not addressing reliability in an effective manner. Those entities invested in reliability should be working towards implementation of these Requirements now. Unfortunately, the system is experiencing entities that are more interested in the bottom line versus reliability. Implementation Plans are not enforceable but set dates for enforcement based on the Standard Requirement language. No extension process should be considered. The electrical ecosystem has been experiencing IBR issues for a decade already and the risk this technology has exposed can not continue by allowing extensions. This again begs for a timeline diagram for the implementation of these 3 Standards (PRC-028/029/030) so that everyone knows the exact expectations for compliance dates.

Response

Steven Taddeucci - NiSource - Northern Indiana Public Service Co. - 3

Answer	No
Document Name	
Comment	

NIPSCO agrees with the majority of the implementation plan but still has concerns with the “15 calendar months following the effective date of the standard” requirement for inverter-based resources entering commercial operation after the effective date, and believes that more time is needed to properly budget, modify designs and procure equipment for projects already under development. NIPSCO proposes modifying the following language: For inverter-based resources entering commercial operation after the effective date: Entities shall comply with Requirements R1 through R7 within “36 calendar months following the effective date of the standard or by" the commercial operation date, whichever is later.

Although the PRC-028 Implementation Plan mirrors PRC-002-2 Implementation Plan, PRC-028 requires all BES IBRs and many non-BES IBRs to have DME installed. If the GO has a large IBR fleet, numerous DME installations would be required with a demanding project schedule. With the large amount of DME required to be installed per PRC-028, OEMs might not be able to provide GOs with a timely supply of DME equipment. Kimberly Turco on behalf of Constellation Energy Segments 5 and 6.

Richard Vendetti - NextEra Energy - 5	
Answer	No
Document Name	

Comment
For the implementation plan, we recommend focusing on those sites with a COD post the Standard becoming effective. Having an implementation for units with a COD prior to the Standard becoming effective does not appear consistent with implementation of other Standards, being retroactive, and will create undue burden to IBR owners who will need to perform rework on existing sites, as vendors have already indicated the equipment to meet compliance will not be available until 2026. In addition, we note the duration to implement has become an issue as the timeline has shifted by one year and the deadline to fully implement remains by 2030. NextEra recommends an implementation of 2032 to be fully compliant, providing reasonable time for the first 50% and the remainder of the sites. While we appreciate the Implementation Plan's note recognizing the potential supply chain issues and the potential for registered entities to address delays outside of their control, we do not think addressing these known issues as part of Compliance and Enforcement is the most effective for both industry and the ERO. As currently written, not only will we have further supply chain issues generated from the timeline reduction and the retroactive nature of requirement 1.3. but additional administrative burden post Standards development.

PRC-002 allowed ~6 years for implementation. It appears that PRC-028 will allow ~3.5 years for non-BES IBR owners to meet compliance following the registration deadline and ~4.5 years assuming an effective date of 7/1/25 for BES owners. If non-BES or BES owners have multiple existing facilities to update for compliance this may be difficult. Consider giving a similar time window of ~6 years to meet compliance. It seems larger facilities meeting this standard would be more beneficial than the numerous non-BES facilities.

1. We believe the Process for Requesting an Extension from Compliance Data has embedded inefficiencies that could place undue burdens on Generator Owners. As Generator Owners patiently await on an approval for an extension from their Compliance Enforcement Authority (CEA), even providing additional follow-up information requested from that CEA in a timely matter, the compliance burden still lies with the Generator Owner until such an extension is finally granted. Industry continues to see some CEAs struggle with addressing their backlogs for handling potential non-compliance of existing registered entities. Some of these registered entities have not even received a response from their CEA in years. We believe some accountable on the ERO Enterprise should be included within this Implementation Plan, whether under the Requesting an Extension Process or as a general consideration. This includes the development of a standard template that would be used across the ERO Enterprise for Generator Owners to complete when making an extension request. This template would identify all the information that is required to make the extension upfront. A completed template by the Generator Owners then would not impede the request because of

insufficient information. The process should also have some timeline constraints, such that a request is never left unanswered. This time could be reasonable to account for impacts on CEA resources, such as six months and at which time, the CEA is required to provide an update to the requesting Generator Owner on its review of the request. Failure to provide an update, or continuously extending this period for the CEA to process the request, would automatically imply the request for extension has been granted to the Generator Owner. NERC should also oversee the requesting process to ensure consistency is evenly applied by each CEA.

Thomas Foltz - AEP - 5	

Answer	No
Document Name	
Comment	

AEP supports the implementation schedule for R1-R7 for units in commercial operation prior to the effective date but requests the same implementation schedule be used for R8 as the DME system most likely will not have been installed by the effective date of R8. If the intent is to have a CAP to identify the targeted compliance date, this would create excessive administrative burden on the GO.

The example provided for compliance of IBR facilities entering commercial operation *after* the effective date does not make sense as stated. AEP recommends that the effective date for IBR facilities entering commercial operation after the effective date be required to comply with the standard within three (3) calendar years of the effective date of Reliability Standard PRC-028-1 to align with the requirements for existing IBR facilities.

For the reasons stated above, the compliance date for R8 for Non-BES IBR facilities should be the same as R1-R7.

3. Do you agree the modifications made in PRC-028-1 are cost effective at unit level cost versus plant level cost compared to the benefit to reliability?

Marty Hostler - Northern California Power Agency - 4	
Answer	No
Document Name	
Comment	
The SDT has not provided any cost or expected reliability indices improvement estimates. Consequently, it is impossible for entities to determine if this proposal is cost effective, or not; or to what extent, this proposal will improve reliability. Reliability standards should not be added or changed until the SDT provides said information so that Registered Entities can make educated determinations related to the cost and benefits of reliability standard modifications or new proposals. Basically, what we are being asked to do is to analyze the cost and reliability benefits this proposal would provide without any data. And, ironically GO/GOP IBR Entities are being asked to spend money to procure and install a bunch of devices to record data and/or to perform new activities that may, or may not, improve reliability. And if they do improve reliability, we don't have any idea if the reliability benefits are worth the cost. Electricity customers Nationwide will have the rates raised and there is no justification or hard evidence related to the improved reliability increase magnitude; i.e. no cost/benefit justification to provide customers as to why then rates will be increased.

This standard makes sense for new inverter-based resources (IBRs). However, for the legacy IBRs the reliability benefits do not justify the costs. The costs to design, purchase and install the required equipment for IBRs that are 10 years old or older, does not make sense if the facility has limited or no controls compared to the modern IBR equipment being installed today. PRC-028-1 provides a limited exemption in Requirement R1 for the data to be collected, but the data could be useless if the IBR's legacy controls place hard limitations on the ability of the IBR to actually ride-through a system disturbance.

PRC-028-1 will result in costs that are not in-line with the reliability benefits provided. These costs are not only for the design and implementation of the monitoring but also for new communications infrastructure for legacy locations or compliance related staff to monitor, track and maintain compliance where it was not required before. For those owners that stream PMU data this standard could add significant communications costs to upgrade older facilities. The reliability benefit of installing, maintaining, and operating monitoring capabilities on existing equipment does not justify the cost.

1. We believe the recent modifications to reintroduce the individual IBR unit to the proposed NERC Reliability Standard provide very little benefit to reliability. The information available at the IBR collector bus level and main power transformers are more than sufficient to determine how a IBR facility performed following a Disturbance. We question how operational entities would incorporate fault code and fault alarm data into their post-event analyses for improving BPS reliability. Generator Operators and Generator Owners, who are more familiar with fault codes and fault alarms, use such data for troubleshooting a localized issue detected within the IBR facility and to generate more immediate corrective actions in response.

Comment

AES CE believes this is not a cost effective approach to meet FERC Order 901. The requirement for SER data at every IBR Unit offers marginal benefit to reliability as compared to having SER data at the end of every feeder while incurring significant additional costs.

AES CE recommends that the SDT leverage the expertise of Project Finance SMEs at the entities to understand the feasibility of implementing this new Standard, and the potential impacts to reliability that these additional costs could incur.

There are concerns about cost effectiveness if the entity is required to purchase hardware in order to reach the level of data recording suggested. If the entity is only required to update software, then the suggested updates appear cost-effective. We recommend incorporating an exception process for smaller entities who do not have the ability to configure existing equipment to gather the requested level of data recording.

AEPC has signed on to ACES comments:

ACES agrees with the approach taken by the SDT to create a new Standard to specifically address inverter-based resources; however, we disagree with making this new standard inclusive of all BES inverter-based resources regardless of risk to the BPS.

In the opinion of ACES, a blanket approach requiring every IBR to install SER, FR, and/or DDR capabilities is overly gratuitous. We believe that the industry's finite resources would best be spent by first ascertaining which inverter-based resources pose the biggest risk to the BPS, and where disturbance monitoring and reporting would provide the most benefit to the BPS, before selectively adding such capabilities.

We believe that a risk-based approach is the best and only truly cost-effective option for all applicable IBRs, we believe that this is especially true for existing IBRs. In summary, it is our recommendation that PRC-028-1 take a similar risk-based approach for IBRs as is done in PRC-002-5 for synchronous generating resources.

4. Provide any additional comments for the standard drafting team to consider, if desired.

Kyle Thomas - Elevate Energy Consulting - NA - Not Applicable - NA - Not Applicable	
Answer	
Document Name	
Comment	

Elevate appreciates the opportunity to comment on the draft NERC standards, particularly those pertaining to future IBR NERC Reliability Standards, and FERC Order No. 901 directives.

Elevate continues to strongly encourage NERC to reconsider adoption of IEEE 2800-2022. The unwillingness to adopt IEEE 2800-2022 by NERC is leading to entirely duplicative efforts that are not serving any additional value as compared to the work conducted in the IEEE 2800-2022 developments. It does not appear that a holistic approach and strategy is being taken to meet the FERC Order No. 901 directives, which is leading to very low ballot scores, significant rework, and misalignment with industry recommended practices.

Elevate strongly recommends a single NERC standard that adopts IEEE 2800-2022 in a uniform and consistent manner. NERC can also issue a reliability guideline or implementation guidance that supports industry implementation of the standard. Rather than recreate parts of IEEE 2800-2022 inconsistently over multiple different standards, Elevate recommends a singular standard for BPS-connected IBR capability and performance requirements related to IEEE 2800-2022. Additional NERC standards can be developed where needed in situations where they are not covered directly with IEEE 2800-2022 (e.g., NERC PRC-030).

While improvements have been made in this latest draft of the NERC PRC-028 standard, this standard is duplicative with IEEE 2800-2022 Clause 11 yet the latest draft of the standard is still missing some of the monitoring aspects covered in the IEEE 2800 standard, including power quality monitoring data and IBR unit FR/DDR data (and additional fault code types). The 2021 Odessa Disturbance report and the NERC IBR Reliability Guideline document both give a recommendation to include FR/DDR data on some IBR units on the collector busses at IBR plants, but currently the draft PRC-028 standard has no FR/DDR requirement for IBR units. This PRC-028-1 standard and other NERC IBR-focused standards should be conforming to/matching the IEEE 2800 standard.

Steven Rueckert - Western Electricity Coordinating Council - 10	
Answer	
Document Name	
Comment	

PRC-028 R1 is using “IBR unit” versus IBR and provides a “definition” in the footnote 3 (only footnoted once but used several time in Requirement). Why complicate the issue with a definition in a footnote that would not be needed if using IBR only? That lacks consistency with PRC-029 and PRC-030 (which are inconsistent between each other as well). The use of commercial operation is ambiguous. Different entities may have a

different definition of "commercial operation." Suggest clarification of what commercial operation is. Suggest someting to the effect of IBRs must have these installed prior to first synch. Entities will have to maintain and provide ALL commercial operating dates for all IBRs. The VSLs as written will require an extent of condition (entity will have to supply ALL applicable "Elements" and /or electrical quantities to determine severity level if a single issue is found with a sample.)

Given the reliance on electronic communications for compliance such as the Secure Evidence Locker, the SRC notes that it seems inappropriate to allow for hard-copy documentation, e.g. M1:

The Generator Owner has evidence (electronic or hard copy) of data, as applicable, as specified in Requirement R1

This also seems contradictory to the more specific data format requirements contained elsewhere in the standard, such as in Parts 7.3 and 7.4, and the SRC requests that the SDT consider revising M1.

7.3. SER data shall be provided in ASCII Comma Separated Value (CSV) format

following Attachment 1.

7.4 FR data shall be provided either in CSV format with appropriate headers or in electronic files that are formatted…

R1.2.1, R1.2.2, R1.3.1, and **R1.3.2** are far too broad as currently drafted and must be amended to target specific categories of fault codes that the SDT deems relevant to the analysis of BES disturbances. Depending on the OEM, there may be thousands of fault codes, a vast majority of which would be entirely irrelevant to the purpose of analyzing BES disturbances.

R6.2 should be amended to include "if capable."

Invenergy thanks the drafting team for the opportunity to provide feedback.

Comment	

Southern Company does not agree with the language in PRC-028, R8 requiring a Corrective Action Plan to be submitted to the Regional Entity. If at any time a Regional Entity desires to review a TO's or GO's Corrective Action Plans, they have the authority to request them. Requiring the Corrective Action Plans to be submitted to the Regional Entity with no requirement for action by the Regional Entity is purely administrative and does nothing to improve the reliability of the Bulk Electric System. Further, the timely development and implementation of a Corrective Action Plan needed to repair equipment can be thoroughly examined during an audit engagement. This same reasoning applies to PRC-002, R12 and is also recommended to be removed.

1. Based on the purpose statement, this standard appears to be creating double jeopardy. If a non-compliance occurs with PRC-028, the entity is presumably non-compliant with Modeling standards in addition to PRC-029. However, it seems that the intent of the standard is similar to PRC-002: to capture adequate data to facilitate analysis of BES System Disturbances.

2. We recommend that the DT recreate the purpose statement of PRC-028 to align with the PRC-002 purpose statement. We believe the intent of the standard is to gather the necessary event data to analyze system disturbances. PRC-002 focuses on the TO (and some large generation facilities that meet the threshold in R5) gathering the appropriate data and doing it in a manner that is consistent so it can be analyzed in a more efficient manner when a large system disturbance occurs. PRC-028 suggests that IBR’s, regardless of size, have significant event recording capabilities. For the smaller IBR facilities that will inevitably be applicable to this standard, this data may not be useful at all. If this standard requires upgrades to hardware or additional hardware to meet the recording capabilities, this may not be commercially viable for these smaller entities that may not have any relevant data for analysis. Therefore, if care is not taken when further development of this standard occurs, the majority of these Requirements would end up being administrative in nature and not be beneficial for improved reliability of the BES.

3. In our entity’s review of this project, we are voting in the affirmative. We understand and appreciate that this project addresses important considerations for reliability and security responsiveness. However, we also recognize that this project in its current form presents compliance and

performance risks that remain unresolved. While affirmatively supporting this project to address the immediate regulatory assignments tied to FERC Order 901, NERC and the ERO must continue a constructive dialog with industry beyond this vote to truly optimize the impacts of this project on reliability, sustainability, and affordability. We encourage NERC to permit extending the SDT team and project to offer prospective enhancements or revisions to satisfy these compliance and performance risks.

Nick Leathers - Nick Leathers On Behalf of: David Jendras Sr, Ameren - Ameren Services, 3, 6, 1; - Nick Leathers

Answer	
Document Name	

Comment

Ameren agrees with and supports EEI's comments.

Ameren offers the following for consideration:

R1: Ameren recommends that the drafting team clarify what is meant by "fault codes" and "fault alarms" as applied to the standard for R1.

R2: The standards drafting team requires real and reactive power expressed on a three-phase basis. However, during a fault, these values would be zero. Ameren recommends that Volts and Amps are the only necessary data collected during a fault event.

R3, Ameren proposes 30 to 60 cycles per event with 2 cycles of pre-event data at 32 samples per cycle, which can be accomplished with most modern relays. The values for output recording rate and synchronized device clock accuracy should match PRC-002. Additionally, the number of days in R7.1 and R7.2 should also match PRC-002.

MRO NSRF is concerned about Regional Entities' ability to objectively and correctly evaluate requests for Seeking Extensions to Compliance Dates. MRO NSRF recommends that the SDT create clear and auditable criteria that if met, allow for the extension of compliance dates. GOs and TOs would submit notification to the Regional Entity that they will require an extension to the compliance dates, based on the met criteria. The Regional Entities' role would be to ensure that the proper criteria are indicated by the GO or TO to allow for an extension of compliance dates, rather than make subjective decisions on approval of requests. This would also eliminate concerns about differences between regions in allowing for extensions.

MRO NSRF does not agree with the language in R8 of PRC-028 and R12 of PRC-002, requiring a Corrective Action Plan to be submitted to the Regional Entity. If at any time a Regional Entity desires to review a TO's or GO's Corrective Action Plans, they have the authority to request them. Simply requiring the Corrective Action Plans to be submitted to the Regional Entity with no requirement for the Regional Entity to do something with them is purely and administrative and does nothing to improve the reliability of the Bulk Electric System.

While MRO NSRF supports much of this proposed standard, MRO NSRF does not agree with requiring the retrofitting of monitoring equipment on existing individual inverter based generating resources as included by I4, MRO NSRF does however believe that forward looking design standard addressing new installations would be reasonable.

TAL understands that the committee was following previous precedent of the 20MVA or greater facilities; however, we believe this standard will create undue hardship on utilities who will be required to meet this standard. 20MVA seems like a low threshold for the size of IBRs. TAL believes the impact of IBRs as small as 20 MVA seems minimal to the integrity of the BES.

1. Many existing devices used for fault recording (SEL-351 for example) cannot meet the 2.0 second duration in R3.1.1. A duration of 1.0 second would better align with equipment capabilities. Perhaps the clause could be written that all new equipment should have the 2.0 second duration capability while existing equipment has requirements in-line with the capabilities of the equipment installed over the past few years.

1. Purpose: we suggest harmonizing the usage of the term Inverter Based Resources and its acronym across the projects 2021-04, 202-02 and 2023-03. We suggest adding the acronym IBR in brackets after the capitalized term Inverter Based Resources, and to refer to IBR throughout the document.

2. We suggest that the drafting team modify section 4.2.2 to reflect the changes that were made to PRC-029-1 in Project 2020-02 and PRC-030-1 in project 2023-02. We suggest the following wording:

“The Elements associated with (1) Bulk Electric System (BES) IBRs and (2) Non-BES IBRs that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.”

Comment

The language in **Section 4, Applicability** does not match the language used in the latest proposed versions of PRC-029-1 and PRC-030-1.

The drafting team should remove the words “that owns equipment as identified in section 4.2” in Section 4.1.1. and ensure that the Section 4, Applicability language match the language in PRC-029-1 and PRC-030-1. The final, preferred language for Section 4, Applicability is shown below. This change is non-substantive and could be made in the final ballot.

The existing language in PRC-028-1 is as follows:

4.1. Functional Entities:

4.1.1. Generator Owner ***that owns equipment as identified in section 4.2***

4.2. Facilities:

4.2.1 BES Inverter-Based Resources

4.2.2 Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV

SMUD's preferred language in PRC-028-1 Section 4, Applicability is as follows:

4.1 Functional Entities:

4.1.1. Generator Owner

4.2. Facilities:

4.2.1 BES Inverter-Based Resources

4.2.2 Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

“There are concerns about reliably modeling IBRs on the grid. With the vast amount of intermittent capacity being added each year, we are affecting the system in ways that are currently unpredictable which reduces reliability. A contributing factor to this is the vast amount of data that is expected to be stored and analyzed. Can the Standards Drafting Team explain the reasoning behind the need to store a large amount of data that will likely go unused? Data Centers create a huge draw on the electric grid so the need to retain this amount of data seems counterintuitive to improving the reliability of the grid. Would it be possible to systematically study the effects before allowing more resources to be added instead of requiring a post-mortem review?”

Project Name:	2021-04 Modifications to PRC-002 – Phase II | PRC-028-1
Comment Period Start Date:	7/22/2024
Comment Period End Date:	8/12/2024
Associated Ballot(s):	2021-04 Modifications to PRC-002 – Phase II Implementation Plan AB 4 OT 2021-04 Modifications to PRC-002 – Phase II PRC-028-1 AB 4 ST

There were 60 sets of responses, including comments from approximately 135 different people from approximately 91 companies representing 10 of the Industry Segments as shown in the table on the following pages.

All comments submitted can be reviewed in their original format on the project page.

If you feel that your comment has been overlooked, let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, contact Manager of Standards Information, Nasheema Santos (via email) or at (404) 290-6796.

Questions

1. **Do you agree with the modifications made in PRC-028-1?**

2. **Do you agree with the Implementation Plan for revised PRC-028-1?**

3. **Do you agree the modifications made in PRC-028-1 are cost effective at unit level cost versus plant level cost compared to the benefit to reliability?**

4. **Provide any additional comments for the standard drafting team to consider, if desired.**

The Industry Segments are:

1 — Transmission Owners

2 — RTOs, ISOs

3 — Load-serving Entities

4 — Transmission-dependent Utilities

5 — Electric Generators

6 — Electricity Brokers, Aggregators, and Marketers

7 — Large Electricity End Users

8 — Small Electricity End Users

9 — Federal, State, Provincial Regulatory or other Government Entities

10 — Regional Reliability Organizations, Regional Entities

1. Do you agree with the modifications made in PRC-028-1?	
Thomas Foltz - AEP - 5	
Answer	No
Document Name	
Comment	

While requiring recording all the fault codes and fault alarms as listed in R1.2 and R1.3 is certainly well-meaning, there may be disadvantages in requiring this breadth of data capturing and provision. Functional Entities (such as Transmission Planner, Planning Coordinator, Transmission Operator, Balancing Authority, Reliability Coordinator, and the Regional Entity) may not all equally benefit from receiving every fault code and fault alarm specified in R1.2 and R1.3. Fault codes and fault alarms differ across manufacturers and devices, and this is further complicated by the lack of standardization and consistent nomenclature in this area. Also, some entities may not be able to fully understand or draw proper conclusions from some of this data, which could lead to inconsistent and undesirable interpretation and application. Rather than requiring "all" the fault codes and alarms available, might it be worth considering for the standard to specify exactly which fault codes and alarms that the SDT believes would be beneficial?

AEP strongly recommends that the STD remove the requirement to capture all fault codes and alarms on IBR Units as SER data to +/- 100 millisecond from the standard and allow the GO to address IBR Unit performance issues as required under PRC-030.

PRC-029 requires the GO to ensure the design of IBR units meets the voltage and frequency ride through requirements or notify the applicable RC, BA and TO if the IBR is technically unable to meet those requirements. PRC-030 requires the GO to develop and execute a process to analyze Real Power change events including ride-through performance and implement corrective actions to address performance issues including applicable other GO IBR facilities.

Adding the requirement to capture all fault codes and alarms on IBR Units as SER data to +/- 100 millisecond back into this standard is unreasonable as it adds significant costs to the SER system and excessive administrative burden on the GO if an event occurs. Note that large IBR facilities have hundreds of IBR Units which would require the SER system to have thousands of SER data points. Is the intent of this requirement to have the TP, PC, TO, BA, RC, Regional Entity, or NERC determine the root cause of IBR Unit performance? If so, then why, as

PRC-030 clearly holds the GO responsible for performing this analysis. When an event occurs, the GO may be requested to submit DME data as proposed in PRC-028 while also having to address performance issues as required by PRC-030. Collecting SER data from every IBR Unit will be time consuming or require an expensive automated SER data collection system. The DME data for the MPT and collector bus should allow the TP, PC, TO, BA, RC, Regional Entity, or NERC to determine performance issues down to the IBR facility level and any corrective actions required on IBR Units would be address by the GO as required by PRC-030. AEP disagrees with the mid-ballot period removal of Transmission Owner from the list of Functional Entities. The TO may in some cases be the owner of the MPT and high side breakers.

Dislikes 0	

Response
Thanks for your comment. It is understood that fault codes and alarms from IBR units may not be requested by the TP/PC/BA etc. However, availability of this data may help OEM and GO engineers to understand the event. There is also no standardization of fault codes/alarms at the IBR unit level across all OEMs and hence specific codes and alarms are not listed in the standard. Adding a requirement to record SER data for IBR units is a compromise that the SDT reached considering opposing views from many stakeholders. The SDT recognizes the cost burden of this standard. To evaluate IBR's performance during system disturbances, some data from IBR units is necessary. As the FR data requirement is moved to collector feeder breakers, the SER data requirement from IBR units was reintroduced in the last draft. Also note that IBR units should already be capable to record the SER data required by this standard. No additional disturbance monitoring equipment should be necessary to record SER data from IBR units. The TO was removed from the list of functional entities to align with PRC-029 and PRC-030 standards. As industry learns more about TO's role and ownership of equipment within IBRs, these standards could be revisited and modified as necessary.
Andy Thomas - Duke Energy - 1,3,5,6 - SERC,RF

Answer	No
Document Name	
Comment	

A) Duke Energy agrees with and supports the following NAGF comment:

1.b. Requirement R1.1:

i. NAGF members are still not certain that use of the term "collector bus(es)" includes feeder breakers and therefore are requesting that the requirement narrative be clarified to address this issue.

B) R1 Sections 1.2 & 1.3, 1.2.3 and 1.2.4, 1.3.3 & 1.3.4 require a mode status; this request is not a function of the recorders. In the technical rationale, please address this requirement or change standard to record voltage and frequency values instead of mode.

Likes 0	
Dislikes 0	
Response	

Thanks for your comment.

The collector bus itself does not include circuit breakers and any other equipment connected to it. Hence, R1 states that "circuit breakers associated with the main power transformer(s), collector bus(es), shunt static and dynamic reactive device(s),….."

The technical rationale includes additional information regarding fault codes, alarms, and ride-through mode status.

Brian Van Gheem - Radian Generation - NA - Not Applicable - NA - Not Applicable

Answer	No
Document Name	
Comment	

1. Based on the latest draft, the Standards Drafting Team (SDT) has removed the Transmission Owner from this Reliability Standard's applicability. Part 1.1 of Requirement R1 states a Generator Owner is required to retain sequence of event recording (SER) data for the circuit breaker positions associated with main power transformers, collector buses, shunt static and dynamic reactive devices, and AC-DC and DC-AC converters, if any, in case of VSC HVDC systems. Following the removal of the Transmission Owner, we believe the inclusion of circuit breaker positions for AC-DC and DC-AC converters is now misplaced and should also be removed.
2. Requirement R1 will require a Generator Owner to retain SER data. When applied to Parts 1.2 and 1.3, a Generator Owner is then required to perform a second action, which is to retain data for each individual IBR unit. The concept of the individual IBR unit was recently abandoned by the SDT in the previously proposed draft. We believe this is a reversal in the direction for Generator Owners to adopt this Reliability Standard. Nonetheless, we propose removing the phrases "shall be recorded" and "all" in these parts for clarity. We instead recommend rephrasing these parts to "…the following recorded data when triggered by ride-through operation or tripping of an IBR unit: fault codes, fault alarms, high and low voltage ride-through mode statuses, and high and low frequency ride-through mode statuses."
3. Part 1.3 allows for an exclusion to Generator Owners if the IBR Facility is incapable to record sequence of event data for each individual IBR unit. We believe the measure for this requirement should be expanded so Generator Owners can document this incapability as evidence.
4. Based on the latest draft, the SDT expanded the requirements of a Generator Owner to retain fault recording (FR) data for each collector feeder breaker. While data may exist, the purpose of the Protection Systems associated with each feeder breaker is to protect the collector bus from a Fault and the possibility of a failure within the feeder breaker. These Protection Systems use existing voltage and current sensing devices already on-site as Protection System Components. However, the SDT also proposes triggering the recording of FR data on each collector feeder breaker based on overfrequency and underfrequency events. The SDT assumes existing Protection Systems are capable of being reprogrammed to include this functionality. However, some microprocessor relays associated with each collector feeder breaker may not have such functionality available.
5. Part 3.2.3 identifies settings when fault recording devices are triggered to begin recording data. We believe each of the individual triggers currently listed should also have a statement identifying only if such capabilities exist. A similar statement should also be added to the measure for this requirement to support this as evidence.
6. Requirement R6 will require a Generator Owner to retain time synchronized data within a device clock accuracy of ± 1 milliseconds of Coordinated Universal Time (UTC). In this recently proposed draft, the SDT has added a requirement that each IBR unit's device clock accuracy must have its accuracy within ± 100 milliseconds of UTC. This new requirement was embedded within Part 6.2 as a separate sentence and suggests each IBR unit must be synchronized to a clock source. For existing facilities, this capability may not be possible. We further believe this approach opens a gap and data associated with IBR units would then be required to have a device clock accuracy of ± 1 milliseconds of UTC. We propose the following approach to revising this requirement. First, remove the phrase "all" in

reference to SER, FR, and dynamic disturbance recording (DDR) data in Requirement R6. Second, revise Part 6.2 to "Synchronized device clock accuracy within ± 100 milliseconds of UTC when applied on IBR unit recorded data or within ± 1 milliseconds of UTC."

Response

Thanks for your comment.

The TO was removed to align with PRC-029 and PRC-030 standards. In case of offshore wind plants connected to ac transmission lines and per the IBR definition, the IBR includes HVDC line as well as AC-DC and DC-AC converter stations. Hence, monitoring of circuit breakers associated of as such is still required. As industry learns more about TO's role and ownership of equipment within IBRs, these standards could be revisited and modified as necessary.

Adding a requirement to record SER data for IBR units is a compromise that the SDT reached considering opposing views from many stakeholders. The SDT recognizes the cost burden of this standard. To evaluate IBR's performance during system disturbances, some data from IBR units is necessary. As the FR data requirement is moved to collector feeder breakers, the SER data requirement from IBR units was reintroduced in the last draft. Also note that IBR units should already be capable to record the SER data required by this standard. No additional disturbance monitoring equipment should be necessary to record SER data from IBR units.

The measure for R1 is expanded to allow GOs to document incapability of IBR units to record SER data.

The SDT recognizes that upgrading of equipment may be necessary in some cases to record FR and DDR data as required by this standard.

It is not the intent to require IBR units to have a device clock accuracy of ± 1 milliseconds of UTC. Minor revisions are made to R6, Part 6.2 to clarify this.

Thanks for your comment.

The collector bus itself does not include circuit breakers and any other equipment connected to it. Hence, R1 states that "circuit breakers associated with the main power transformer(s), collector bus(es), shunt static and dynamic reactive device(s),….."

The SDT recognizes that upgrading of or new equipment may be necessary to be able to record data as specified in this standard.

R1.

For IBRs – the OEMs are responsible for **SER** data only. The question OEMs have been having is "*what is a ride through operation*", to define what triggers capturing a ride through event. Its an ambiguous term where p.u. parameters and time duration need to be explicitly defined to be set at the IBR.

{C}1.1   there is no clarity on data that needs to be collected. Do we collect all listed or a single source? This should be stated within the requirement.

Recommendation to remove 1.3 since the requirements are the same as 1.2 except for the timing of COD with respect to when the Standard becomes effective. Requirement 1.3 appears to be reactive in nature. This timing may be better addressed as part of the implementation plan.

R2

The standard does not provide clarity on if collector feeder data is needed from all units or specific units. It is important to note that information is only available on the high side, nothing on the low side.

Recommendation to remove footnote 3 as IBR unit is not a defined term found in the NERC Glossary of Terms.

R3

For DFRs in the substation – there was a change adding MV "collector breakers" to record fault reporting data. No project today or E&C best practices recommend 34.5KV fault reporting with 64 samples/cycle.

Need clarification on whether data should be only for high side, whether for anything that tripped, or for the entire event. Our recommendation would be to focus on the high side of GSU only. R6 IBRs must be time synchronized to +/- 100milliseconds which implies PTP or installing a GPS clock at each inverter. Recommend Footnote 4 revised to “interchange” not “exchange.”

Thanks for your comment. Additional content is added in the Technical Rationale document which may help in understanding context of IBR unit SER data requirement. The SDT, along with feedback from NERC staff, believes that R1.3 is appropriate to be part of a standard instead of incorporating it in the implementation plan. The standard requires FR data from each collector feeder breaker. In lieu of requiring FR data from IBR units, the FR data from collector feeder breakers is required. The SDT reached this compromise considering opposing views of various stakeholders. An effort was made to define IBR unit by the Project 2020-06 SDT, but the team moved forward with IBR definition only as it was anticipated that IBR unit definition may not be used by many standards. Hence, for the purposes of PRC-028 only, this SDT added a footnote to clarify this term. The SDT recognizes that in some cases upgrading of or new equipment may be necessary to meet the data recording requirements of this standard. Footnote 4 is revised as suggested.

R1.3:

This requirement must be more specific with use of word “if capable”. Consider providing a clear exemption.

R2.1.3, R2.2.3, and R3.2.3

The protective devices with FR capabilities cannot capture Real and Reactive quantities. These quantities are typically calculated by using captured voltage and current quantities. SDT should clarify and state if calculated P and Q values are acceptable. If calculated P & Q values are not acceptable, then this requirement will have to be satisfied by installing dedicated fault recorders which can be a substantial burden on cost and implementation plan.

R3:

While WEC Energy Group fully supports triggering FR at proposed locations, WEC has a concern with 2 seconds recording requirement and 64 samples per cycle recording rate.

Most of the older microprocessor based protective relays do not have 2 seconds recording capabilities. The DT recognized this as well in the Technical Rationale document *(“Multiple records allow for legacy microprocessor relays which, when time synchronized to a common clock, can provide adequate fault data but are not capable of providing fault data in a single record with 120 continuous cycles total.”*). Note that microprocessor relays cannot record back to back events if the trigger is not active. This requirement, as currently written, will trigger costly upgrades. WEC suggest that SDT evaluates protective devices capabilities for most common relay manufacturers and reduces the recording requirement to 1 second.

Most of the older microprocessor based protective relays only have 4 or 8 samples/cycle sampling rate and do not have 64 samples per cycle recording rate capabilities. This requirement, as currently written, will trigger costly upgrades. WEC suggest that SDT evaluates protective devices capabilities for most common relay manufacturers and reduces the sampling rate below 64 samples per cycle.

These requirements seem to be more restrictive than PRC-002.

If recording and sampling requirement cannot be reduced, then existing FR equipment in commercial operation before the effective date of this standard should be exempted from 2 second recording requirement and 64 samples per cycle recording rate.

R3.1.3, R3.2.3, and R3.3.3:

SDT should determine pickups for the triggers. As currently written, entity could set pickups way too high or low and FR could never get recorded. For example, we can set 65Hz pickup for over-frequency. By the time we reach 65Hz, the event could be over.

R.6.2:

WEC Energy Group recommends that synchronized clock accuracy match PRC-002, which is +/- 2 milliseconds. An exception should be granted to IBR units in commercial operation before the effective date of this standard if synchronized signal at the IBR is not available or its accuracy cannot meet 100ms requirements. R7: WEC Energy Group suggests that R7 requirements match PRC-002 requirements.

Thanks for your comment. The technical rationale includes additional detail regarding R1, Part 1.2 and 1.3, including some clarification for IBR units that are in commercial operation and meaning of "if capable" to record SER data. The Requirement R2 states "fault recording (FR) data to ***determine*** the following electrical quantities". The "determine" implies "calculated quantities are acceptable." The duration of FR recording is justified to capture IBR's response over few seconds after a fault is cleared. The SDT recognizes that in some cases upgrading of equipment or new equipment may be necessary to be able to record data as specified in this standard. The trigger pickups are intentionally not specified. This is consistent with PRC-002. The triggers may vary based on site location and interconnection. Synchronized clock accuracy requirement for plant level data is +/- 1 millisecond and reflects advances in technology since the publication of PRC-002. Considering challenges in achieving clock accuracy requirement, the higher tolerance is allowed for IBR units. The R7 is based on lengthy discussion among SDT members considering comments received from many stakeholders during previous ballots.	

Note that purpose of PRC-028 is very different from purpose of PRC-002.

Please consider the following: Define the term IBR Unit - rather than in footnotes	

Following the removal of the Transmission Owner, we believe the inclusion of circuit breaker positions for AC-DC and DC-AC converters is now misplaced and should also be removed. Clarifying the term “collector bus(es)” to include feeder breakers. Many IBR units do not have the ability to meet the +- 100 millisecond accuracy threshold, considerably higher than PRC-002.

Thanks for your comment. An effort was made to define IBR unit by the Project 2020-06 SDT, but the team moved forward with IBR definition only as it was anticipated that IBR unit definition may not be used by many standards. Hence, for the purposes of PRC-028 only, this SDT added a footnote to clarify this term. Based on IBR definition, the HVDC line and associated AC-DC and DC-AC converters are part of IBR. Hence, recording of circuit breaker positions for AC-DC and DC-AC converters is required. The collector bus itself does not include circuit breakers and any other equipment connected to it. Hence, R1 states that “circuit breakers associated with the main power transformer(s)[1], collector bus(es), shunt static and dynamic reactive device(s),…..” Regarding synchronized device clock accuracy, the higher number means less accuracy. The plant level measurements are required to have accuracy within +/- 1 millisecond but recognizing challenges with IBR unit, the accuracy requirement is relaxed to within +/- 100 milliseconds.

[1] For the purpose of this standard, the main power transformer is the power transformer that steps up voltage from the collection system voltage to the nominal transmission/interconnecting system voltage for Inverter-Based Resources. In case of dedicated VSC HVDC system connecting to an Inverter-Based Resource, a transformer isolating the DC-AC converter from the transmission system is also considered a main power transformer.

R1.2 and R1.3 can involve hundreds of data points for a large facility if “all fault” and “all alarm” codes are included for every IBR unit on a site. Southern Company requests the SDT to consider adding verbiage to limit monitoring requirements to a sample of the IBR units within a facility. What (who) determines criteria of “if capable” in R1.3? Southern Company requests the SDT to consider updating M1 to include documentation explaining the IBR unit is not capable of providing the data for recording. Industry may require clarification of the term “ride through mode status” in R1.2 and R1.3. Southern Company requests the SDT to consider providing the necessary clarification. Southern Company believes R7.2 needs to be changed back to 30 days.

Comment

In its June 14 comments, the ISO/RTO Council (IRC) Standards Review Committee (SRC) requested that inverter-level requirements be reinstated in PRC-028 and applied to all future IBR installations, at a minimum. The SRC provided numerous reasons for why the removal of these requirements is problematic and could impact reliability. The SRC understands from the SDT's consideration of this comment that the

IBR unit SER data requirement was a compromise in lieu of the FR data. However, the SRC is still concerned that the FR data is limited to what the SER would provide as recommended in NERC's September 2019 guideline.

The SRC has noted since the initial draft that the DDR installation requirements proposed in PRC-028 should be considered in meeting DDR coverage requirements of PRC-002. Even though the SDT cites an example where there is not any overlap of DDR coverage between the 2 standards, the SRC believes the standard needs to allow for considerations of system topography in certain areas today where there is significant IBR penetration and possible DDR coverage overlap. The SRC believes the 2 standards need to be able to reconcile the possibility of overlapping coverage Footnote, ISO NE does not support this portion of the response to Q1.

Parts 2.2 and 3.2 are new and require a GO to have FR data for Collector Feeder breakers. Without a clear definition of "Collector Feeder" it is unclear whether this will be applicable only to generators that are configured to directly energize a Collector Feeder as part of a distribution network or whether R3.2 would include any non-BES distribution facilities (such as those located within a plant)?

The SRC also believes that Requirement R1, Parts 1.2 and 1.3 should also apply to broader impacts, including momentary cessation or any other abnormal behavior during events, and should therefore be revised to read as follows.

1.2. For IBR units in commercial operation after the effective date of this standard,

the following data shall be recorded when triggered by ride-through operation,

tripping, or longer-term disturbance response and recovery of an IBR unit including.

1.2.1. All fault codes.

1.2.2. All fault alarms.

1.2.3. High and low voltage ride-through mode status.

1.2.4. High and low frequency ride-through mode status.

1.2.5 Momentary cessation

1.2.6 Other abnormal behavior during events

1.3. For IBR units in commercial operation before the effective date of this standard,

the following data shall be recorded, if capable, when triggered by ride-through operation, tripping, or longer-term disturbance response and recovery of an IBR unit including.

1.3.1. All fault codes.

1.3.2. All fault alarms.

1.3.3. High and low voltage ride-through mode status.

1.3.4. High and low frequency ride-through mode status.

1.3.5 Momentary cessation

1.3.6 Other abnormal behavior during events

Because the “IBR Unit” definition will not be moving forward, it appears each standard seeking to acquire IBR unit information, such as Parts 1.2 and 1.3, will need to define what IBR unit means within the standard. In the case of PRC-028, the SRC understands that footnote 2 serves this purpose, and asks that the drafting team confirm whether the SRC’s understanding is correct.

The SRC supports Parts 2.2 and 3.2 primarily as a starting point for gathering collector feeder breaker FR data in this version of the standard. The SRC believes there is potential for future expansion of these requirements if they are found to be inadequate in the course of investigating the root causes of IBR performance issues.

Part 6.2 currently reads, “Synchronized device clock accuracy within ± 1 milliseconds of UTC. The IBR units shall have synchronized device clock accuracy within ± 100 milliseconds of UTC.”

The SRC seeks clarification from the SDT as to why 100 milliseconds was chosen for Part 6.2 when IEEE uses 100 microseconds. Currently, there are Generator Interconnection Agreements that require 1 millisecond time synchronization for plant- and unit-level device clock accuracy. Many entities are considering adopting the IEEE requirements, so an explanation for this difference is critical.

Additionally, the SRC recommends that PRC-028 be revised to require recording of inverter-level oscillography. As demonstrated throughout the 2022 Odessa Disturbance report, it is evident that inverter-level oscillography is readily available and critical to proper event analysis in cases where individual inverters trip offline even though frequency and voltage at the plant level remain in the must-ride-through zone. This is a known issue where terminal voltages and frequency measurements can vary greatly from the plant-level measurements due to the collector system and step-up transformer designs. In many cases this oscillography is available but just needs to be enabled and adequate storage made available. Table 19 in Section 11 of IEEE 2800 already requires recording of such information at the IBR unit level as well. Such a requirement could be applied to new units and to existing units that already have that capability available and simply need to enable it.

NERC recommended the following in the 2022 Odessa disturbance report for the SDT to consider (emphasis added).

"Monitoring Data ERCOT and the GOs in the Texas Interconnection ***have extensive data*** that is ***critical for root cause analysis***. This ***data includes*** plant-level high resolution oscillography data, plant SCADA data, and ***inverter-level*** sequence of events recording (e.g., fault codes) and ***oscillography data***. ***These types of measurements should be standard across industry for the purposes of event analysis and reducing the risk to plant performance***. The IRPS submitted a SAR, ***and Project 2021-04 is working on enhancements to PRC-002-2 to ensure this type of data is available at BES resources."***

Footnote: MISO is a party to these comments but does not support the comments in response to Q1.

Response

Thanks for your comment.

The SDT reached a compromise considering opposing views from various stakeholders and required SER data from all IBR units. In lieu of requiring FR data from sample of or all IBR units, the standard required FR data from all collector feeder breakers.

The collector Feeder is a feeder that connects one or more IBR unit step-up transformer with the collector bus. The technical rationale provides some examples. As industry learns more about IBRs and their configuration, the standard could be revisited and modified as necessary based on future learnings.

Note that momentary cessation is inherently a part of ride-through mode. Clarify statement is added in the technical rationale.

An effort was made to define IBR unit by the Project 2020-06 SDT, but the team moved forward with IBR definition only as it was anticipated that IBR unit definition may not be used by many standards. Hence, for the purposes of PRC-028 only, this SDT added a footnote to clarify this term.

The SDT has heard from many stakeholders regarding the time synchronization accuracy requirement. The GPS clock typically exists at the plant level and signal of this GPS clock is shared with various equipment within the facility. Recognizing the latency and ability of commonly used protocol to transmit signal from plant level GPS clock to many IBR units within the plant, the SDT increased tolerance for time synchronization accuracy to ± 100 milliseconds. The recordings synchronized to higher time accuracy makes it easy to align data from various sources to perform event analysis, however, data not synchronized to higher time accuracy is still useful and is expected to serve the purpose.

The SDT recognizes that IBR unit level FR data might be more valuable than FR data recorded at the collector feeder breaker. However, considering opposing views of various stakeholders, cost burden, project timeline, etc., a compromise is made and in this first version of the standard, the collector feeder breaker FR data is required. Based on future learnings with implementation of this standard, future events, etc., the standard could be revised as necessary.

As written, Requirement R1 brings ambiguity with the use of "IBR unit" with the footnote definition. Additionally, what is a "ride-through operation"? For example- As written, the entity will need to record all aspect/Parts of R1.2 and R1.3 assuming the location failed the Ride-through definition or tripped offline. The discussion will be is it "all fault codes" of the inverter, converter, wind turbine generator, or high voltage direct current converter individually (as applicable)? Or something else? Requirement 1 Part 1.2 and Part 1.3 (including all sub Parts for both)- Capitalize "ride-through" as it is a defined term in another related Project.

Response	
Thanks for your comment. The definition of IBR unit for inclusion in NERC glossary is not moving forward, hence, the SDT decided to include footnote 3 to clarify IBR unit for purposes of this standard.	

The “ride-through operation” is when voltage or frequency deviates from nominal beyond certain threshold. Thresholds for voltage and frequency are set in inverter that declares ride-through operation. This is well understood in the industry and IBR unit OEMs. The requirement is to record whenever IBR unit enters a ride-through operation and not only when it fails to ride-through system disturbance. Additional explanation is added to the Technical Rationale document. The “ride-through” definition is not approved yet, hence, not included in this standard at this time.

AES CE does not agree that SER data at every IBR Unit is necessary to meet the objectives of the Standard. Past revisions contained more reasonable solutions such as SER data at the end of each feeder. We believe this middle solution will have a significant positive impact on	

system reliability, while adding this data at every single IBR Unit offers only an incremental improvement in ability to analyze system disturbances at a huge burden to GOs.	
Likes 0	
Dislikes 0	
Response	
Adding a requirement to record SER data for IBR units is a compromise that the SDT reached considering opposing views from many stakeholders. The SDT recognizes the cost burden of this standard. To evaluate IBR's performance during system disturbances, some data from IBR units is necessary. As the FR data requirement is moved to collector feeder breakers, the SER data requirement from IBR units was reintroduced in the last draft.

MISO supports the requirements (Parts 1.2 and 1.3) for IBR unit data. We also observe that, as the "IBR Unit" definition will not be moving forward, it appears each standard seeking to acquire IBR unit information, will need to define what IBR unit means within the standard. In the case of PRC-028, this is footnote 3. Is that correct?

MISO supports Parts 2.2 and 3.2 as a starting point to gather collector feeder breaker FR data. That said, we also support the potential for future expansion of these requirements if they are found to be inadequate when investigating the root cause of IBR performance issues.

Part 6.2. “Synchronized device clock accuracy within ± 1 milliseconds of UTC. The IBR units shall have synchronized device clock accuracy within ± ***100 milliseconds*** of UTC.”

Regarding Part 6.2., MISO is requesting clarification as to why the SDT chose 100 milliseconds when IEEE uses 100 microseconds. Currently, MISO’s Generator Interconnection Agreement requires 1 millisecond time synchronization for plant and unit level device clock accuracy. As MISO is considering adopting the IEEE requirements, please explain the reason for the differential.

Response

Thanks for your comment.

Correct, the IBR unit definition for inclusion in NERC Glossary is not moving forward currently. Because the PRC-028 requires IBR unit level SER data to be recorded, the footnote 3 is added to clarify IBR unit for purposes of this standard.

Thanks for your support for collector feeder level data in lieu of IBR unit level data.

The SDT has heard from many stakeholders regarding the time synchronization accuracy requirement. The GPS clock typically exists at the plant level and signal of this GPS clock is shared with various equipment within the facility. Recognizing the latency and ability of commonly used protocol to transmit signal from plant level GPS clock to many IBR units within the plant, the SDT increased tolerance for time synchronization accuracy to ± 100 milliseconds. The recordings synchronized to higher time accuracy makes it easy to align data from various sources to perform event analysis, however, data not synchronized to higher time accuracy is still useful and is expected to serve the purpose.

We do not disagree with modifications that have been made and we do not object to FERC order 901. However, we do not believe this standard will improve reliability as the GO/GOP IBR entites would have to share data with (BAs, PAs, RCs, TOPs) only if they ask for said data. And those entities do not have any obligations to do anything with the data which GO/GOP IBRs would be required to provided them. Consequently, we are unclear as to how GO/GOP IBRs that are required to procure and install a bunch of recording data and share recordings with entities, only if those entities ask for it, will do anything to improve reliability. As written this proposal looks like an expense to GO/GOPs with no reliability benefits. All entities that GO/GOP IBRs are required to provide data to need to have requirements within this standard version detailing what they are to do with said data in order to improve reliability.

Thanks for your comment. Various NERC disturbance reports published over last five years have suggested that there is a lack of data to analyze system disturbances. It is expected entities on Transmission side will be involved in data gathering from IBRs when performing event analysis. The data recorded as required by this standard is expected to serve as evidence for upcoming IBR ride-through standard PRC-029. One of the purposes of this standard is to record data that may be used for model validation, standards for which are expected to come along in near future.

2. Do you agree with the Implementation Plan for revised PRC-028-1?	
Steven Rueckert - Western Electricity Coordinating Council - 10	
Answer	No
Document Name	
Comment	

PRC-029 and PRC-030 hinge on the Implementation Plan (IP) for PRC-028. The inconsistent approach (“design”/”operation” aspects of Requirements in PRC-029/030 IPs) and use of “commercial operations date” in PRC-028 IP does not provide clarity. The DTs did not define what the design and operation aspects of PRC-030 are so compliance monitoring will be difficult if at all achievable until ALL parts of PRC-028 are applicable (essentially 2030). The use of commercial operation date is inconsistent with reliability and differs across the United States. There are no compliance evaluations that can be done for non-BES IBRs until after Jan 1, 2030.

For the following Implementation Plan requirement, the DT needs to be extremely clear that the 15 calendar months is ONLY applicable to the “effective date of the standard” portion of the phrase and not the “commercial operation date”:

“For non-BES Inverter-Based Resources in commercial operation after May 2026: Entities shall comply with Requirements R1 through R7 within 15 calendar months following the effective date of the standard or the commercial operation date, whichever is later. “

Does the DT confirm that interpretation of the phrase is correct? Effective date of standard plus 15 calendar months OR commercial operation date whichever is later is the correct way to read that phrase.

Most implemtation plans are effective on the first day of a quarter. If May is actually the desired month, the IP should not simply say “May 2026” it should be specivic such as May 1, May 15, or May 31, 2026.

Having a process for extension of compliance embedded within an Implementation Plan is not conducive or supportive to reliability. As written, this will be an administrative effort with NO defined timeline in sight and no process to support it. The ERO Enterprise should utilize the current processes in place. That is, if the entity, who has had years to be ready, is noncompliant they self-report the issue and follow the mitigation process. Putting this process in place requires a second set of books for compliance determination and status. The Implementation Plan (and the dependence of other Implementation Plans) does not set any expectation for IBRs to be compliant by any set date and does not support FERC’s intention of having Standards applied to IBRs no later than 2030. What happens if the entity does not

provide information or provides information that is found to be incorrect and the CEA does not approve the extension? What happens if the entity does not supply the extension request in less time than "required" (i.e., "no later than three months prior to the compliance date")? FERC recently ruled on cold weather standards regarding Corrective Action Plans being too long. The timing for these exemptions is non-existent and provides a compliance loophole that can be easily exploited by entities not addressing reliability in an effective manner. Those entities invested in reliability should be working towards implementation of these Requirements now. Unfortunately, the system is experiencing entities that are more interested in the bottom line versus reliability. Implementation Plans are not enforceable but set dates for enforcement based on the Standard Requirement language. No extension process should be considered. The electrical ecosystem has been experiencing IBR issues for a decade already and the risk this technology has exposed can not continue by allowing extensions. This again begs for a timeline diagram for the implementation of these 3 Standards (PRC-028/029/030) so that everyone knows the exact expectations for compliance dates.

Response	
Thanks for your comment. The PRC-028 implementation plan is designed considering engineering, procuring, and commissioning of DME to record stated SER, FR, and DDR data. The SDT agrees that the PRC-029 and PRC-030 implementation plans need to coordinate with the PRC-028 implementation plan, where the data recorded under PRC-028 is needed for compliance with PRC-029 and PRC-030. For BES IBRs, the implementation plan provides an example to clarify meaning of "within 15 calendar months following the effective date of the standard or the commercial operation date, whichever is later". The SDT agrees with the interpretation that timeline is the effective date plus 15 calendar month OR the commercial operation date, whichever is later. "May 2026" is replaced with "May 1, 2026". The framework to seek extension from the Compliance Enforcement Authority is based on feedback from NERC staff. The PRC-028 may require engineering, procuring, and commissioning of new DME at majority of plant. To account for issues outside of Entity's control, the SDT in good faith provided a framework to seek extension from the compliance enforcement authority.

Comment	
NIPSCO agrees with the majority of the implementation plan but still has concerns with the “15 calendar months following the effective date of the standard” requirement for inverter-based resources entering commercial operation after the effective date, and believes that more time is needed to properly budget, modify designs and procure equipment for projects already under development. NIPSCO proposes modifying the following language: For inverter-based resources entering commercial operation after the effective date: Entities shall comply with Requirements R1 through R7 within “36 calendar months following the effective date of the standard or by" the commercial operation date, whichever is later.

Although the PRC-028 Implementation Plan mirrors PRC-002-2 Implementation Plan, PRC-028 requires all BES IBRs and many non-BES IBRs to have DME installed. If the GO has a large IBR fleet, numerous DME installations would be required with a demanding project schedule. With the large amount of DME required to be installed per PRC-028, OEMs might not be able to provide GOs with a timely supply of DME equipment. Kimberly Turco on behalf of Constellation Energy Segments 5 and 6.

Richard Vendetti - NextEra Energy – 5	
Answer	No
Document Name	
Comment	
For the implementation plan, we recommend focusing on those sites with a COD post the Standard becoming effective. Having an implementation for units with a COD prior to the Standard becoming effective does not appear consistent with implementation of other Standards, being retroactive, and will create undue burden to IBR owners who will need to perform rework on existing sites, as vendors have already indicated the equipment to meet compliance will not be available until 2026. In addition, we note the duration to implement has become an issue as the timeline has shifted by one year and the deadline to fully implement remains by 2030. NextEra recommends an implementation of 2032 to be fully compliant, providing reasonable time for the first 50% and the remainder of the sites. While we appreciate the Implementation Plan's note recognizing the potential supply chain issues and the potential for registered entities to address delays outside of their control, we do not think addressing these known issues as part of Compliance and Enforcement is the most effective for both industry and the ERO. As currently written, not only will we have further supply chain issues generated from the timeline reduction and the retroactive nature of requirement 1.3. but additional administrative burden post Standards development.

PRC-002 allowed ~6 years for implementation. It appears that PRC-028 will allow ~3.5 years for non-BES IBR owners to meet compliance following the registration deadline and ~4.5 years assuming an effective date of 7/1/25 for BES owners. If non-BES or BES owners have multiple existing facilities to update for compliance this may be difficult. Consider giving a similar time window of ~6 years to meet compliance. It seems larger facilities meeting this standard would be more beneficial than the numerous non-BES facilities.

We believe the Process for Requesting an Extension from Compliance Data has embedded inefficiencies that could place undue burdens on Generator Owners. As Generator Owners patiently await on an approval for an extension from their Compliance Enforcement Authority (CEA), even providing additional follow-up information requested from that CEA in a timely matter, the compliance burden still lies with the Generator Owner until such an extension is finally granted. Industry continues to see some CEAs struggle with addressing their backlogs for	

handling potential non-compliance of existing registered entities. Some of these registered entities have not even received a response from their CEA in years. We believe some accountable on the ERO Enterprise should be included within this Implementation Plan, whether under the Requesting an Extension Process or as a general consideration. This includes the development of a standard template that would be used across the ERO Enterprise for Generator Owners to complete when making an extension request. This template would identify all the information that is required to make the extension upfront. A completed template by the Generator Owners then would not impede the request because of insufficient information. The process should also have some timeline constraints, such that a request is never left unanswered. This time could be reasonable to account for impacts on CEA resources, such as six months and at which time, the CEA is required to provide an update to the requesting Generator Owner on its review of the request. Failure to provide an update, or continuously extending this period for the CEA to process the request, would automatically imply the request for extension has been granted to the Generator Owner. NERC should also oversee the requesting process to ensure consistency is evenly applied by each CEA.

Thomas Foltz - AEP - 5	
Answer	No
Document Name	
Comment	
AEP supports the implementation schedule for R1-R7 for units in commercial operation prior to the effective date but requests the same implementation schedule be used for R8 as the DME system most likely will not have been installed by the effective date of R8. If the intent is to have a CAP to identify the targeted compliance date, this would create excessive administrative burden on the GO.	

The example provided for compliance of IBR facilities entering commercial operation *after* the effective date does not make sense as stated. AEP recommends that the effective date for IBR facilities entering commercial operation after the effective date be required to comply with the standard within three (3) calendar years of the effective date of Reliability Standard PRC-028-1 to align with the requirements for existing IBR facilities. For the reasons stated above, the compliance date for R8 for Non-BES IBR facilities should be the same as R1-R7.	
Likes 0	
Dislikes 0	
Response	
Thanks for your comment. The requirement R8 applies only if the DME is installed. The compliance date for R8 could be independent of compliance date for R1-R7. The SDT considered time needed to engineer, procure, and commission DME at the plants under development and concludes that "15 calendar months following the effective date of the standard" is an adequate time.

3. Do you agree the modifications made in PRC-028-1 are cost effective at unit level cost versus plant level cost compared to the benefit to reliability?	
Marty Hostler - Northern California Power Agency – 4	
Answer	No
Document Name	
Comment	
The SDT has not provided any cost or expected reliability indices improvement estimates. Consequently, it is impossible for entities to determine if this proposal is cost effective, or not; or to what extent, this proposal will improve reliability. Reliability standards should not be added or changed until the SDT provides said information so that Registered Entities can make educated determinations related to the cost and benefits of reliability standard modifications or new proposals. Basically, what we are being asked to do is to analyze the cost and reliability benefits this proposal would provide without any data. And, ironically GO/GOP IBR Entities are being asked to spend money to procure and install a bunch of devices to record data and/or to perform new activities that may, or may not, improve reliability. And if they do improve reliability, we don't have any idea if the reliability benefits are worth the cost. Electricity customers Nationwide will have the rates raised and there is no justification or hard evidence related to the improved reliability increase magnitude; i.e. no cost/benefit justification to provide customers as to why then rates will be increased.

Thanks for your comment. The SDT acknowledges your concerns. The SDT has addressed the scope of the SAR and FERC order 901 directives while considering cost impact. The SDT developed requirements in this standard while balancing the need for monitoring data for IBR performance evaluation and model validation and cost of installing the DME. One example of this is that the FR data requirements are moved from IBR unit terminals to collector feeder breakers.

This standard makes sense for new inverter-based resources (IBRs). However, for the legacy IBRs the reliability benefits do not justify the costs. The costs to design, purchase and install the required equipment for IBRs that are 10 years old or older, does not make sense if the facility has limited or no controls compared to the modern IBR equipment being installed today. PRC-028-1 provides a limited exemption in Requirement R1 for the data to be collected, but the data could be useless if the IBR's legacy controls place hard limitations on the ability of the IBR to actually ride-through a system disturbance.

Thanks for your comment. The various disturbance reports published by NERC over last five years or so justifies monitoring on legacy plants. The intent is to analyze plants performance and use recorded data for model validation. Additionally, the FERC order 901 directs that legacy plants are included in the applicability of this standard.	

Casey Jones - Berkshire Hathaway - NV Energy - 5 – WECC	
Answer	No
Document Name	
Comment	
PRC-028-1 will result in costs that are not in-line with the reliability benefits provided. These costs are not only for the design and implementation of the monitoring but also for new communications infrastructure for legacy locations or compliance related staff to monitor, track and maintain compliance where it was not required before. For those owners that stream PMU data this standard could add significant communications costs to upgrade older facilities. The reliability benefit of installing, maintaining, and operating monitoring capabilities on existing equipment does not justify the cost.

1. We believe the recent modifications to reintroduce the individual IBR unit to the proposed NERC Reliability Standard provide very little benefit to reliability. The information available at the IBR collector bus level and main power transformers are more than sufficient to determine how a IBR facility performed following a Disturbance. We question how operational entities would incorporate fault code and fault alarm data into their post-event analyses for improving BPS reliability. Generator Operators and Generator Owners, who are more familiar with fault codes and fault alarms, use such data for troubleshooting a localized issue detected within the IBR facility and to generate more immediate corrective actions in response.

Comment	
AES CE believes this is not a cost effective approach to meet FERC Order 901. The requirement for SER data at every IBR Unit offers marginal benefit to reliability as compared to having SER data at the end of every feeder while incurring significant additional costs. AES CE recommends that the SDT leverage the expertise of Project Finance SMEs at the entities to understand the feasibility of implementing this new Standard, and the potential impacts to reliability that these additional costs could incur.

There are concerns about cost effectiveness if the entity is required to purchase hardware in order to reach the level of data recording suggested. If the entity is only required to update software, then the suggested updates appear cost-effective. We recommend incorporating an exception process for smaller entities who do not have the ability to configure existing equipment to gather the requested level of data recording.

AEPC has signed on to ACES comments: ACES agrees with the approach taken by the SDT to create a new Standard to specifically address inverter-based resources; however, we disagree with making this new standard inclusive of all BES inverter-based resources regardless of risk to the BPS.	

In the opinion of ACES, a blanket approach requiring every IBR to install SER, FR, and/or DDR capabilities is overly gratuitous. We believe that the industry's finite resources would best be spent by first ascertaining which inverter-based resources pose the biggest risk to the BPS, and where disturbance monitoring and reporting would provide the most benefit to the BPS, before selectively adding such capabilities.

We believe that a risk-based approach is the best and only truly cost-effective option for all applicable IBRs, we believe that this is especially true for existing IBRs. In summary, it is our recommendation that PRC-028-1 take a similar risk-based approach for IBRs as is done in PRC-002-5 for synchronous generating resources.

Response

Thanks for your comment.

Please note that the purpose of PRC-028 is very different from purpose of PRC-002. The PRC-002 requires disturbance monitoring equipment at appropriate locations on the BES to help analyze wide-spread system disturbances. Hence, criteria in PRC-002 to identify locations where SER, FR, and DDR data is required is appropriate. The purpose of PRC-028 is to gather data to analyze performance of each IBR as well as use recorded data to validate models of IBRs.

Monitoring of all BES and non-BES IBRs is also one of the directives in the FERC order 901.

The purpose of PRC-028 is to gather data to analyze performance of each IBR as well as use recorded data to validate models of IBRs. Monitoring of all BES and non-BES IBRs is also one of the directives in the FERC order 901.

Kyle Thomas - Elevate Energy Consulting - NA - Not Applicable - NA - Not Applicable	
Answer	
Document Name	
Comment	

Elevate appreciates the opportunity to comment on the draft NERC standards, particularly those pertaining to future IBR NERC Reliability Standards, and FERC Order No. 901 directives.

Elevate continues to strongly encourage NERC to reconsider adoption of IEEE 2800-2022. The unwillingness to adopt IEEE 2800-2022 by NERC is leading to entirely duplicative efforts that are not serving any additional value as compared to the work conducted in the IEEE 2800-2022 developments. It does not appear that a holistic approach and strategy is being taken to meet the FERC Order No. 901 directives, which is leading to very low ballot scores, significant rework, and misalignment with industry recommended practices.

Elevate strongly recommends a single NERC standard that adopts IEEE 2800-2022 in a uniform and consistent manner. NERC can also issue a reliability guideline or implementation guidance that supports industry implementation of the standard. Rather than recreate parts of IEEE 2800-2022 inconsistently over multiple different standards, Elevate recommends a singular standard for BPS-connected IBR capability and performance requirements related to IEEE 2800-2022. Additional NERC standards can be developed where needed in situations where they are not covered directly with IEEE 2800-2022 (e.g., NERC PRC-030).

While improvements have been made in this latest draft of the NERC PRC-028 standard, this standard is duplicative with IEEE 2800-2022 Clause 11 yet the latest draft of the standard is still missing some of the monitoring aspects covered in the IEEE 2800 standard, including power quality monitoring data and IBR unit FR/DDR data (and additional fault code types). The 2021 Odessa Disturbance report and the NERC IBR Reliability Guideline document both give a recommendation to include FR/DDR data on some IBR units on the collector busses at IBR plants, but currently the draft PRC-028 standard has no FR/DDR requirement for IBR units. This PRC-028-1 standard and other NERC IBR-focused standards should be conforming to/matching the IEEE 2800 standard.

Dislikes 0	

Response

Thanks for your comment. The scope of this SAR is to specify disturbance monitoring requirements. This SDT has reviewed and build upon the monitoring requirements from the IEEE Std 2800-2022. In few instances, the SDT has intentional deviated from requirements in IEEE Std 2800 because requirements in IEEE 2800 may be impractical (e.g., time synchronization requirements, sampling rate and associated time duration of recording, etc.).

Steven Rueckert - Western Electricity Coordinating Council - 10

Answer	
Document Name	

Comment

PRC-028 R1 is using “IBR unit” versus IBR and provides a “definition” in the footnote 3 (only footnoted once but used several time in Requirement). Why complicate the issue with a definition in a footnote that would not be needed if using IBR only? That lacks consistency with PRC-029 and PRC-030 (which are inconsistent between each other as well). The use of commercial operation is ambiguous. Different entities may have a different definition of "commercial operation." Suggest clarification of what commercial operation is. Suggest something to the effect of IBRs must have these installed prior to first synch. Entities will have to maintain and provide ALL commercial operating dates for all IBRs.

The VSLs as written will require an extent of condition (entity will have to supply ALL applicable “Elements” and /or electrical quantities to determine severity level if a single issue is found with a sample.)

Likes 0	
Dislikes 0	

Response

Thanks for your comment. The PRC-028 requires SER data from IBR units as well as plant level SER, FR, and DDR data at plant level (IBR). The PRC-029 and PRC-030 are plant level standards, hence, uses IBR only. As noted in a footnote, IBR unit is part of IBR. It is important to include a footnote explaining a meaning of IBR unit.

A footnote is added to clarify meaning of commercial operation. The VSLs in PRC-028 are similar to VSLs in PRC-002.

Given the reliance on electronic communications for compliance such as the Secure Evidence Locker, the SRC notes that it seems inappropriate to allow for hard-copy documentation, e.g. M1: The Generator Owner has evidence (electronic or hard copy) of data, as applicable, as specified in Requirement R1 This also seems contradictory to the more specific data format requirements contained elsewhere in the standard, such as in Parts 7.3 and 7.4, and the SRC requests that the SDT consider revising M1. 7.3. SER data shall be provided in ASCII Comma Separated Value (CSV) format following Attachment 1. 7.4 FR data shall be provided either in CSV format with appropriate headers or in electronic files that are formatted…	
Likes 0	
Dislikes 0	
Response	
The measure in M1 and other similar measures in the standard are consistent with the PRC-002 standard. In cases where there is no recorded data to show as evidence, an entity is allowed to show evidence of data recording capability using one-line diagrams showing design, recording equipment configuration and manual etc., which could be hard copy.

Response	
Thanks for your comment. Please note that the purpose of PRC-028 is very different from purpose of PRC-002. The PRC-002 requires disturbance monitoring equipment at appropriate locations on the BES to help analyze wide-spread system disturbances. Hence, criteria in PRC-002 to identify locations where SER, FR, and DDR data is required is appropriate. The purpose of PRC-028 is to gather data to analyze performance of each IBR as well as use recorded data to validate models of IBRs.

R1.2.1, R1.2.2, R1.3.1, and **R1.3.2** are far too broad as currently drafted and must be amended to target specific categories of fault codes that the SDT deems relevant to the analysis of BES disturbances. Depending on the OEM, there may be thousands of fault codes, a vast majority of which would be entirely irrelevant to the purpose of analyzing BES disturbances. **R6.2** should be amended to include "if capable." Invenergy thanks the drafting team for the opportunity to provide feedback.

Thanks for your comment.	

Additional content is added in the technical rationale to clarify that fault codes ad alarms associated with IBR unit tripping or entering ride-through operations are required to be recorded.

The time synchronization is required for all recorded data. The technical rationale explains a need for this. However, recognizing challenges in synchronizing device clock for IBR units, a higher tolerance is permitted for IBR unit clock accuracy.

Southern Company does not agree with the language in PRC-028, R8 requiring a Corrective Action Plan to be submitted to the Regional Entity. If at any time a Regional Entity desires to review a TO's or GO's Corrective Action Plans, they have the authority to request them. Requiring the Corrective Action Plans to be submitted to the Regional Entity with no requirement for action by the Regional Entity is purely administrative and does nothing to improve the reliability of the Bulk Electric System. Further, the timely development and implementation of a Corrective Action Plan needed to repair equipment can be thoroughly examined during an audit engagement. This same reasoning applies to PRC-002, R12 and is also recommended to be removed.	
Likes 0	
Dislikes 0	

Response	
The requirement R8 in PRC-028 is like requirement R12 in PRC-002. The PRC-002 standard in effect (and since revision in 2014 under the project 2007-11) already require entities to develop a Corrective Action Plan and submit it to the Regional Entity. The PRC-028 follows the precedent set in PRC-002 standard.

Comment	
1. Based on the purpose statement, this standard appears to be creating double jeopardy. If a non-compliance occurs with PRC-028, the entity is presumably non-compliant with Modeling standards in addition to PRC-029. However, it seems that the intent of the standard is similar to PRC-002: to capture adequate data to facilitate analysis of BES System Disturbances. 2. We recommend that the DT recreate the purpose statement of PRC-028 to align with the PRC-002 purpose statement. We believe the intent of the standard is to gather the necessary event data to analyze system disturbances. PRC-002 focuses on the TO (and some large generation facilities that meet the threshold in R5) gathering the appropriate data and doing it in a manner that is consistent so it can be	

analyzed in a more efficient manner when a large system disturbance occurs. PRC-028 suggests that IBR's, regardless of size, have significant event recording capabilities. For the smaller IBR facilities that will inevitably be applicable to this standard, this data may not be useful at all. If this standard requires upgrades to hardware or additional hardware to meet the recording capabilities, this may not be commercially viable for these smaller entities that may not have any relevant data for analysis. Therefore, if care is not taken when further development of this standard occurs, the majority of these Requirements would end up being administrative in nature and not be beneficial for improved reliability of the BES. 3. In our entity's review of this project, we are voting in the affirmative. We understand and appreciate that this project addresses important considerations for reliability and security responsiveness. However, we also recognize that this project in its current form presents compliance and performance risks that remain unresolved. While affirmatively supporting this project to address the immediate regulatory assignments tied to FERC Order 901, NERC and the ERO must continue a constructive dialog with industry beyond this vote to truly optimize the impacts of this project on reliability, sustainability, and affordability. We encourage NERC to permit extending the SDT team and project to offer prospective enhancements or revisions to satisfy these compliance and performance risks.

Likes 0	
Dislikes 0	

Response
Thanks for your comment. The PRC-028 requires certain type of data to be recorded. If the data is not recorded then data cannot be used as evidence for PRC-029 standard. However, that does not mean that an entity is out of compliance with the PRC-029 standard. Please note that the purpose of PRC-028 is very different from purpose of PRC-002. The PRC-002 requires disturbance monitoring equipment at appropriate locations on the BES to help analyze wide-spread system disturbances. Hence, criteria in PRC-002 to identify locations where SER, FR, and DDR data is required is appropriate. The purpose of PRC-028 is to gather data to analyze performance of each IBR as well as use recorded data to validate models of IBRs. The SDT appreciates your support for this standard.

Answer	
Document Name	
Comment	
Ameren agrees with and supports EEI's comments. Ameren offers the following for consideration: **R1**: Ameren recommends that the drafting team clarify what is meant by "fault codes" and "fault alarms" as applied to the standard for R1. **R2**: The standards drafting team requires real and reactive power expressed on a three-phase basis. However, during a fault, these values would be zero. Ameren recommends that Volts and Amps are the only necessary data collected during a fault event. **R3**, Ameren proposes 30 to 60 cycles per event with 2 cycles of pre-event data at 32 samples per cycle, which can be accomplished with most modern relays. The values for output recording rate and synchronized device clock accuracy should match PRC-002. Additionally, the number of days in R7.1 and R7.2 should also match PRC-002.	
Likes 0	
Dislikes 0	
Response	
Thanks for your comment. Additional content is added in the technical rationale to clarify what is meant by fault code and fault alarms. The real and reactive power would be zero only in cases of close-in faults. The standard requires measured quantities to “determine” real and reactive power, which inherently means that voltage and current recordings are needed. The purpose of PRC-028 is very different from purpose of PRC-002. The sampling rate, recording duration, etc., is justified based on IBR technology and to align with purpose of the standard.

Comment	
MRO NSRF is concerned about Regional Entities' ability to objectively and correctly evaluate requests for Seeking Extensions to Compliance Dates. MRO NSRF recommends that the SDT create clear and auditable criteria that if met, allow for the extension of compliance dates. GOs and TOs would submit notification to the Regional Entity that they will require an extension to the compliance dates, based on the met criteria. The Regional Entities' role would be to ensure that the proper criteria are indicated by the GO or TO to allow for an extension of compliance dates, rather than make subjective decisions on approval of requests. This would also eliminate concerns about differences between regions in allowing for extensions. MRO NSRF does not agree with the language in R8 of PRC-028 and R12 of PRC-002, requiring a Corrective Action Plan to be submitted to the Regional Entity. If at any time a Regional Entity desires to review a TO's or GO's Corrective Action Plans, they have the authority to request them. Simply requiring the Corrective Action Plans to be submitted to the Regional Entity with no requirement for the Regional Entity to do something with them is purely and administrative and does nothing to improve the reliability of the Bulk Electric System. While MRO NSRF supports much of this proposed standard, MRO NSRF does not agree with requiring the retrofitting of monitoring equipment on existing individual inverter based generating resources as included by I4, MRO NSRF does however believe that forward looking design standard addressing new installations would be reasonable.

Thanks for your comment. NERC anticipates that an ERO Enterprise process will be developed, similar to the TPL-007 CAP Extension Request Review Process that is included as Appendix C in the 2024 Periodic Data Submittal Schedule. This ERO Enterprise process could address items such as information needed as part of the extension request, roles and responsibilities, and timelines. The requirement R8 in PRC-028 is like requirement R12 in PRC-002. The PRC-002 standard in effect (and since revision in 2014 under the project 2007-11) already require entities to develop a Corrective Action Plan and submit it to the Regional Entity. The PRC-028 follows the precedent set in PRC-002 standard.	

The inclusion of IBRs already in commercial operation is required by FERC order 901 directives.

1. Purpose: we suggest harmonizing the usage of the term Inverter Based Resources and its acronym across the projects 2021-04, 202-02 and 2023-03. We suggest adding the acronym IBR in brackets after the capitalized term Inverter Based Resources, and to refer to IBR throughout the document. 2. We suggest that the drafting team modify section 4.2.2 to reflect the changes that were made to PRC-029-1 in Project 2020-02 and PRC-030-1 in project 2023-02. We suggest the following wording: “The Elements associated with (1) Bulk Electric System (BES) IBRs and (2) Non-BES IBRs that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.”	
Likes 0	
Dislikes 0	

Response	
Thanks for your comment. It is not clear why the "elements associated with" is included in PRC-029. Perhaps it will be removed as standard is being revised at this time. There is no need to include "elements associated with" in PRC-028.

Comment	

The language in **Section 4, Applicability** does not match the language used in the latest proposed versions of PRC-029-1 and PRC-030-1.

The drafting team should remove the words "that owns equipment as identified in section 4.2" in Section 4.1.1. and ensure that the Section 4, Applicability language match the language in PRC-029-1 and PRC-030-1. The final, preferred language for Section 4, Applicability is shown below. This change is non-substantive and could be made in the final ballot.

The existing language in PRC-028-1 is as follows:

4.1. Functional Entities:

4.1.1. Generator Owner ***that owns equipment as identified in section 4.2***

4.2. Facilities:

4.2.1 BES Inverter-Based Resources

4.2.2 Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV

SMUD’s preferred language in PRC-028-1 Section 4, Applicability is as follows:

4.1 Functional Entities:

4.1.1. Generator Owner

4.2. Facilities:

4.2.1 BES Inverter-Based Resources

4.2.2 Non-BES Inverter-Based Resources that either have or contribute to an aggregate nameplate capacity of greater than or equal to 20 MVA, connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage greater than or equal to 60 kV.

Duke Energy agrees with and supports the following EEI comment:

EEI offers the following non-substantive change to PRC-028-1 for consideration:

•   Footnote 2 should be deleted. “IBR unit” is no longer used in the proposed definition of IBR and therefore has no meaning within the context of this Reliability Standard, negating the need for Footnote 2.

Likes 0	
Dislikes 0	

Response
Thanks for your comment. The PRC-028 has a requirement to record SER data for IBR units. The footnote 2 explains meaning of IBR unit as definition of IBR unit does not exist anywhere else.

"There are concerns about reliably modeling IBRs on the grid. With the vast amount of intermittent capacity being added each year, we are affecting the system in ways that are currently unpredictable which reduces reliability. A contributing factor to this is the vast amount of data that is expected to be stored and analyzed. Can the Standards Drafting Team explain the reasoning behind the need to store a large amount of data that will likely go unused? Data Centers create a huge draw on the electric grid so the need to retain this amount of data seems counterintuitive to improving the reliability of the grid. Would it be possible to systematically study the effects before allowing more resources to be added instead of requiring a post-mortem review?"

Thanks for your comment. The several NERC disturbance reports over last five years have shown that IBR's performance during system disturbances is far from ideal. For event analysis, model validation, etc., the specified data in PRC-028 is necessary.

Thanks for your comment. Your comments are consistent with previously submitted comments. The FERC order 901 directives require that standard applies to non-BES IBRs and IBRs already in commercial operation before the effective date of this standard. The SDT is aware of cost burden of installing DME to record data as required by this standard. The SDT has tried to balance directives of FERC order 901, need of recorded data for performance evaluation and model validation, cost burden etc. while developing this standard. The implementation plan also allows for sufficient time within a timeframe permitted by the FERC order 901 directives. The purpose of PRC-028 is very different from purpose of PRC-002.	

Reminder

Standards Announcement

Project 2021-04 Modifications to PRC-002 – Phase II |PRC-028-1

Additional Ballots and Non-binding Poll Open through August 12, 2024

Now Available

Additional ballots for **PRC-028-1 – Disturbance Monitoring and Reporting Requirements for Inverter-based Resources** and implementation plan, as well as the non-binding poll of the associated Violation Risk Factors and Violation Severity Levels, are open through **8 p.m. Eastern, Monday, August 12, 2024**.

This will be the last opportunity for NERC to ballot this project through traditional mechanisms. The Board may take requisite action during the August 2024 Board of Trustees meeting to ensure directives are met.

The Standards Committee approved waivers to the Standard Processes Manual at their December 2023 meeting. These waivers were sought by NERC Standards staff for reduced formal comment and ballot periods. This will assist the drafting teams in expediting the standards development process due to firm timeline expectations set by FERC Order 901. *FERC Order 901 was issued under* Docket No. RM22-12-000 *on October 19, 2023.*

To assist industry in this upcoming ballot period, NERC has released a Milestone 2 Summary that provides high-level overview of the current state of the associated projects and their interrelationships. The drafting team's considerations of the responses received from the previous comment period are reflected in this draft of the standard.

Reminder Regarding Corporate RBB Memberships

Under the NERC Rules of Procedure, each entity and its affiliates is collectively permitted one voting membership per Registered Ballot Body Segment. Each entity that undergoes a change in corporate structure (such as a merger or acquisition) that results in the entity or affiliated entities having more than the one permitted representative in a particular Segment must withdraw the duplicate membership(s) prior to joining new ballot pools or voting on anything as part of an existing ballot pool. Contact ballotadmin@nerc.net to assist with the removal of any duplicate registrations.

Balloting

Members of the ballot pools associated with this project can log in and submit their votes by accessing the Standards Balloting and Commenting System (SBS) here.

Note: Votes cast in previous ballots will not carry over to additional ballots. It is the responsibility of the registered voter in the ballot pools to place votes again. To ensure a quorum is reached, if you do not want to vote affirmative or negative, cast an abstention.

- *Contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern) for problems regarding accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out.*
- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*
- *Please be mindful of ballot and comment period closing dates. We ask to **allow at least 48 hours** for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts **prior to the last day** of a comment/ballot period.*

Next Steps

The ballot results will be announced and posted on the project page. The drafting team will review all responses received during the comment period and determine the next steps of the project.

For information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Senior Standards Developer**,** Ben Wu (via email) or at 470-542-6882. Subscribe to this project's observer mailing list by selecting "NERC Email Distribution Lists" from the "Service" drop-down menu and specify “Project 2021-04 Modifications to PRC-002 observer list” in the Description Box.

UPDATED

Standards Announcement

Project 2021-04 Modifications to PRC-002 – Phase II

Formal Comment Period Open through August 12, 2024

Now Available

A formal comment period for **PRC-028-1 – Disturbance Monitoring and Reporting Requirements for Inverter-based Resources** is open through **8 p.m. Eastern, Monday, August 12, 2024**. The drafting team decided to remove "**4.1.1. Transmission Owner that owns equipment as identified in section 4.2**" from the **Applicability** and all of the Transmission Owner referenced in the Requirements of Standard PRC-028-1.

This will be the last opportunity for NERC to ballot these projects through traditional mechanisms. The Board may take requisite action during the August 2024 Board of Trustees meeting to ensure directives are met.

The Standards Committee approved waivers to the Standard Processes Manual at their December 2023 meeting. These waivers were sought by NERC Standards staff for reduced formal comment and ballot periods. This will assist the drafting teams in expediting the standards development process due to firm timeline expectations set by FERC Order 901. *FERC Order 901 was issued under* Docket No. RM22-12-000 *on October 19, 2023.*

To assist industry in this upcoming comment and ballot period, NERC has released a Milestone 2 Summary that provides high-level overview of the current state of the associated projects and their interrelationships. The drafting team's considerations of the responses received from the previous comment period are reflected in this draft of the standard.

Note: PRC-002-5 passed the recent additional ballot (conducted June 5-15, 2024). The drafting team will be moving this standard to a final ballot when the PRC-028-1 ballots open (August 2-12, 2024) as only non-substantive revision(s) were made.

Reminder Regarding Corporate RBB Memberships

Under the NERC Rules of Procedure, each entity and its affiliates is collectively permitted one voting membership per Registered Ballot Body Segment. Each entity that undergoes a change in corporate structure (such as a merger or acquisition) that results in the entity or affiliated entities having more than the one permitted representative in a particular Segment must withdraw the duplicate membership(s) prior to joining new ballot pools or voting on anything as part of an existing ballot pool. Contact **ballotadmin@nerc.net** to assist with the removal of any duplicate registrations.

Commenting

Use the Standards Balloting and Commenting System (SBS) to submit comments. An unofficial Word version of the comment form is posted on the project page.

- *Contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern) for problems regarding accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out.*
- *Passwords expire every **6 months** and must be reset.*
