6. Do you agree with adding the existing CIP Exceptional Circumstance language to the Requirement/Part listed below? Please provide a detailed explanation/rationale for inclusion or exclusion of the CEC language.

CIP-010 R1, Part 1.4.1: Prior to the change, except during CIP Exceptional Circumstances, determine required cyber security controls in CIP-005 and CIP-007 that could be impacted by the change.

Darnez Gresham - Berkshire Hathaway Energy - MidAmerican Energy Co. - 1,3 - MRO

Answer	No
Document Name	

Comment

During CIP Exceptional Circumstance (CEC), in the interest of restoring the BES, there may not be time to determine required cyber security controls that may be impacted by the change. If this is done, due to CEC, then it logically follows that CIP Exceptional Circumstances should be applied to all parts of CIP-010 R1, Part 1.4 because they are tied together. Therefore, add the phrase at the Part 1.4 level. For example, “Except during CIP Exceptional Circumstances, for a change that deviates from the existing baseline configuration: 1.4.1……, 1.4.2…… and 1.4.3……”

All of CIP-010-2 R1 should allow for CEC exemption. CIP-010-2 R1 and each of its sub-requirements all constitute "documentation" exercises that, when responsing to a CEC, may be required to be postponed or would be considered secondary to restoring power. Without similar caveats that are found in R1.3 allowing for documentation updates to be completed within 30 days, a CEC exemption is necessary for R1.1, R1.2, R1.4, and R1.5 when commissioning new devices needed in responding to a CEC.

Exelon supports the addition of “except during CIP Exceptional Circumstance” to the Requirement part. Entity change controls require a rigorous approval and testing process for changes to a BES Cyber Asset or BES Cyber System. In the event of a CEC, existing processes may not afford enough flexibility to conduct recovery in a way that rapidly mitigates the risk to the reliability of the BES.

7. Do you agree with adding the existing CIP Exceptional Circumstance language to the Requirement/Part listed below? Please provide a detailed explanation/rationale for inclusion or exclusion of the CEC language.

CIP-010 R1, Part 1.5: Where technically feasible, for each change that deviates from the existing baseline configuration:

1.5.1. Prior to implementing any change in the production environment, test the changes in a test environment or test the changes in a production environment where the test is performed in a manner that minimizes adverse effects, that models the baseline configuration to ensure that required cyber security controls in CIP-005 and CIP-007 are not adversely affected, except during CIP Exceptional Circumstances; and

1.5.2. Document the results of the testing and, if a test environment was used, the differences between the test environment and the production environment, including a description of the measures used to account for any differences in operation between the test and production environments, except during CIP Exceptional Circumstances.

If CEC is used for CIP-010 R1, Part 1.4, it logically follows that CEC should be allowed for testing the changes. The wording works, but the CEC phrase could be added only once at the CIP-010 R1 Part 1.5 level to cover both sub-parts with one phrase.

Comment

Exelon supports the addition of “except during CIP Exceptional Circumstance” to the Requirement part. Entity change controls require a rigorous approval and testing process for changes to a BES Cyber Asset or BES Cyber System. In the event of a CEC, existing processes may not afford enough flexibility to conduct recovery in a way that rapidly mitigates the risk to the reliability of the BES.

For clarity, Exelon suggests moving the “except during CIP Exceptional Circumstances” phrase closer to the front of 1.5.1 and 1.5.2 as noted below. This ensures that the phrase applies to the entire Requirement Part, and not just the last clause of the text.

1.5.1. Prior to implementing any change in the production environment, **except during CIP Exceptional Circumstances,** test the changes in a test environment or test the changes in a production environment where the test is performed in a manner that minimizes adverse effects, that models the baseline configuration to ensure that required cyber security controls in CIP-005 and CIP-007 are not adversely affected; and

1.5.2. Except during CIP Exceptional Circumstances, document the results of the testing and, if a test environment was used, the differences between the test environment and the production environment, including a description of the measures used to account for any differences in operation between the test and production environments.

As noted in the rationale, this aligns to R3, Part 3.3. During the event, security controls testing may impede recovery efforts. Security controls should be examined on the production system following the conclusion of the declared CEC.	

ERCOT also suggests moving the exception to the beginning of the language, as follows:

1.5.1 Except during a CIP Exceptional Circumstance, and prior to implementing any change in the production environment…”

And

“1.5.2 Except during a CIP Exceptional Circumstance, document the results of the testing…”

Include the electronic and physical security controls required by CIP-003 R2 Attachment 1, sections 2 and 3. This would meet the same rational as used for the inclusion of CEC for CIP-004 and CIP-006.

When considering Requirements against the elements of the CEC Definition, the view often focuses on time limited events measured in minutes, hours, or a day. We encourage a wider view. For example: An impediment of large scale workforce availability conceivably affects Requirements with time periods of multiple days, weeks, even months. This view stems from an entity's priority of operating the BES which may replace its ability to complete administrative efforts dedicated to program updates—while important—they fall out of the active operation of the BES to maintain reliability in emergency circumstances.

It is in consideration of this type of scenario we offer the following additional Requirements:

Rationale: Difficult to Adhere to Short Time-Based Requirements if During A CEC:

CIP-004-6 R5.1 (24-hour termination);

CIP-004-6 R5.3 (1-day termination to CII Repository);

CIP-004-6 R5.4 (30-day termination to shared accounts);

CIP-007-6 R2.2 (35-day patch evaluation);

CIP-007-6 R2.3 (35-day patch implementation/mitigation);

CIP-007-6 R4.4 (15-day logged event review);

CIP-010-2 R1.3 (30-day baseline configuration update after the change);

CIP-010-2 R2.1 (35-day baseline configuration monitoring);

Rationale: Similar Rationale As Other Requirements Added By SDT FOR CIP-010 R1, Part 1.4.1: CIP-010-2 R1.2 (authorize & document changes that deviate from the baseline configuration); Rationale: Similar Rationale As Other Requirements Added By SDT FOR CIP-007-4: CIP-007-6 R4.2 (security event alerting); CIP-004-6 R4.2 (quarterly access review) depending on timing of CEC.

Any requirement that requires real-time or near real-time alerting and response should include the CEC phrase. For example, CIP-004 R5, that addresses access revocations. In the case of CEC, response to a termination action or reassignment could be significantly delayed.

CIP-004-6, R5, Part 5.1 - The Responsible Entity may not be able to remove an individual's ability for unescorted physical access and Interactive Remote Access if an asset is damaged or destroyed during a CEC. CIP-006-6, R1, Parts 1.2 – 1.7, & 1.10 – During a CEC, Physical Access Control Systems may be damaged or destroyed, preventing the Responsible Entity from strict adherence to these requirements. CIP-007-6, R4 Part 4.2 - The Responsible Entity may not be able to generate alerts for applicable security events if logging is not functional in accordance with CIP-007-6 R4 Part 4.1. CIP-007-6, R4 Part 4.4 – During a CEC, logging may not be functional if the facility is damaged or destroyed. CIP-010-2 R1, Parts 1.1 – 1.3 – Change management controls may impede recovery efforts during a CEC.

Mike Kraft - Basin Electric Power Cooperative - 1,3,5,6	

Answer	Yes
Document Name	
Comment	
Basin Electric would prefer the removal of CIP Exceptional Circumstance Language on a per standard/requirement/part level and instead focus on CIP-003 enhancements and related Implementation Guidance. The overhead of including the exception in multiple standards/requirements/parts seems to outweigh the benefit of a low frequency circumstance.

Yes- if a facility is significantly damanged or destroyed all CIP requrements and sub requirements should be considered for CEC. For Example, Update of the Recovery Plan required by CIP-009-5 R3, Part 3.1 if the CEC lasts for more than 90 days.	

Update of the CIP Cyber Asset list required by CIP-002.

Testing of the recovery plan required by CIP-009-5 R2 Part 2.3 if the CEC is occurring during the planned testing date.

Comment

- CIP-004-6 R5.1 Consider – In the case of a CEC, it may not be possible to complete the removals within 24 hours of the termination action (Removal of the ability for access may be different than deletion, disabling, revocation, or removal of all access rights). The ability to remove access may be impeded because of an event triggering a CIP exceptional circumstance.

- CIP-005-6 R1.1 Consider – In the case of a CEC, all applicable Cyber Assets connected to a network via a routable protocol may not reside within a defined ESP.

ESP might not be defined in the case that the network, including Cyber Assets connected via a routable protocol, has to be rebuilt because of an event triggering a CIP exceptional circumstance.

- CIP-005-6 R1.3 Consider – In the case of a CEC, it may not be possible to have inbound and outbound access permissions, including the reason for granting access, and deny all other access by default. Access permissions might not be defined in the case that the network, including Cyber Assets connected via a routable protocol, has to be rebuilt because of an event triggering a CIP exceptional circumstance.

- CIP-005-6 R1.4 Consider – In the case of a CEC, it may not be possible to perform authentication when establishing Dial-up Connectivity with applicable Cyber Assets. Performing authentication, when establishing Dial-up Connectivity with applicable Cyber Assets, might not be possible in the case that the network, including Cyber Assets connected via a routable protocol, has to be rebuilt because of an event triggering a CIP exceptional circumstance.

- CIP-005-6 R1.5 Consider – In the case of a CEC, it may not be possible to have one or more methods for detecting known or suspected malicious communications for both inbound and outbound communications. Having a method for detecting known or suspected malicious communications for both inbound and outbound communications, might not be possible in the case that the network, including Cyber Assets connected via a routable protocol, has to be rebuilt because of an event triggering a CIP exceptional circumstance.

- CIP-006-6 R1.2 Consider – In the case of a CEC, it may not be possible to utilize at least one physical access control to allow unescorted physical access into each applicable Physical Security Perimeter to only those individuals who have authorized unescorted physical access. In the event of a failure of a PACS, it may not be possible to have 1 factor for access control.

- CIP-006-6 R1.3 Consider – In the case of a CEC, it may not be possible to utilize two or more different physical access controls (this does not require two completely independent physical access control systems) to collectively allow unescorted physical access into Physical Security Perimeters to only those individuals who have authorized unescorted physical access. In the event of a failure of a PACS, it may not be possible to have two factor access controls.

- CIP-006-6 R1.4 Consider – Monitoring unauthorized access through a physical access point into a Physical Security Perimeter may not be possible in the case that the logging and/or monitoring system is damaged or destroyed because of an event triggering a CIP exceptional circumstance.

- CIP-006-6 R1.5 Consider – Issuing an alarm or alert in response to detected unauthorized access through a physical access point into a Physical Security Perimeter to the personnel identified in the BES Cyber Security Incident response plan within 15 minutes of detection may not be possible in the case that the logging and/or monitoring system, required to detected unauthorized access, is damaged or destroyed because of an event triggering a CIP exceptional circumstance.

- CIP-006-6 R1.6 Consider – Monitoring each Physical Access Control System for unauthorized physical access to a Physical Access Control System may not be possible in the case that the logging and/or monitoring system, required to monitor unauthorized physical access to PACS, is damaged or destroyed because of an event triggering a CIP exceptional circumstance.

- CIP-006-6 R1.7 Consider – Issuing an alarm or alert in response to detected unauthorized physical access to a Physical Access Control System to the personnel identified in the BES Cyber Security Incident response plan within 15 minutes of the detection may not be possible in the case that the logging and/or monitoring system, required to detected unauthorized access to PCAS, is damaged or destroyed because of an event triggering a CIP exceptional circumstance.

- CIP-007-6 R2.3 Consider – It may not be possible to apply applicable patches identified in Part 2.2, within 35 calendar days of the evaluation completion, if the asset to be patched is damaged or destroyed because of an event triggering a CIP exceptional circumstance.

- CIP-007-6 R4.2 Consider – Generating alerts for security events that the Responsible Entity determines necessitates an alert, that includes, as a minimum, to detected malicious code from Part 4.1 and detected failure of Part 4.1 event logging, may not be possible in the case that the system to detect malicious code and/or the system required to detect event logging failure, is damaged or destroyed because of an event triggering a CIP exceptional circumstance.

- CIP-007-6 R4.4 Consider – Reviewing a summarization or sampling of logged events as determined by the Responsible Entity at intervals no greater than 15 calendar days to identify undetected Cyber Security Incidents, may not be possible in the case that the system required to log events, is damaged or destroyed because of an event triggering a CIP exceptional circumstance.

- CIP-008-5 R2.1 Consider – It may not be possible to test each Cyber Security Incident response plan(s) at least once every 15 calendar months, by responding to an actual Reportable Cyber Security Incident, with a paper drill or tabletop exercise of a Reportable Cyber Security Incident or with an operational exercise of a reportable Cyber Security Incident. The ability to test the plan may be impeded because of an event triggering a CIP exceptional circumstance. (Example: a CEC could be invoke for that requirement in the case of a Cyber Security incident that mobilize the same staff required to test the Cyber Security response plan)

- CIP-008-5 R2.3 Consider – It may not be possible to retain records related to Reportable Cyber Security Incidents in the case that the records are damaged or destroyed because of an event triggering a CIP exceptional circumstance.

- CIP-008-5 R3.1 Consider – No later than 90 calendar days after completion of a Cyber Security Incident response plan(s) test or actual Reportable Cyber Security Incident response, it may not be possible to document any lessons learned or document the absence of any lessons learned, to update the Cyber Security Incident response plan based on any documented lessons learned associated with the plan and to notify each person or group with a defined role in the Cyber Security Incident response plan of the updates to the Cyber Security Incident response plan based on any documented lessons learned. The ability to document any lessons learned, update the plan and notify each person may be impeded because of an event triggering a CIP exceptional circumstance. (Example: a CEC could be invoked for that requirement in the case of a general strike)

- CIP-008-5 R3.2 Consider – No later than 60 calendar days after a change to the roles or responsibilities, Cyber Security Incident response groups or individuals, or technology that the Responsible Entity determines would impact the ability to execute the plan, it may not be possible to update the Cyber Security Incident response plan(s) and notify each person or group with a defined role in the Cyber Security Incident response plan of the updates. The ability to update the plan and notify each person may be impeded because of an event triggering a CIP exceptional circumstance. (Example: a CEC could be invoked for that requirement in the case of a general strike)

- CIP-009-6 R2.1 Consider – It may not be possible to test each of the recovery plans referenced in Requirement R1 at least once every 15 calendar months, by recovering from an actual incident, with a paper drill or tabletop exercise or with an operational exercise. The ability to test the recovery plan may be impeded because of an event triggering a CIP exceptional circumstance. (Example: a CEC could be invoked for that requirement in the case of a general strike)

- CIP-009-6 R2.2 Consider – It may not be possible to test a representative sample of information used to recover BES Cyber System functionality at least once every 15 calendar months to ensure that the information is useable and is compatible with current configurations. The ability to test a representative sample of information used to recover BES Cyber System functionality may be impeded because of an event triggering a CIP exceptional circumstance. (Example: a CEC could be invoked for that requirement in the case of a general strike).

- CIP-009-6 R2.3 Consider – It may not be possible to test each of the recovery plans referenced in Requirement R1 at least once every 36 calendar months through an operational exercise of the recovery plans in an environment representative of the production environment. The ability to test the recovery plans may be impeded because of an event triggering a CIP exceptional circumstance. (Example: a CEC could be invoked for that requirement in the case of a general strike).

- CIP-009-6 R3.1 Consider – No later than 90 calendar days after completion of a recovery plan test or actual recovery, it may not be possible to document any lessons learned associated with a recovery plan test or actual recovery or document the absence of any lessons learned, to update the recovery plan based on any documented lessons learned associated with the plan and to notify each person or group with a defined role in the recovery plan of the updates to the recovery plan based on any documented lessons learned. The ability to document any lessons learned, update the recovery plan and notify each person may be impeded because of an event triggering a CIP exceptional circumstance. (Example: a CEC could be invoke for that requirement in the case of a general strike)

- CIP-009-6 R3.2 Consider – No later than 60 calendar days after a change to the roles or responsibilities, responders, or technology that the Responsible Entity determines would impact the ability to execute the recovery plan, it may not be possible to update the recovery plan and notify each person or group with a defined role in the recovery plan of the updates. The ability to update the recovery plan and notify each person may be impeded because of an event triggering a CIP exceptional circumstance. (Example: a CEC could be invoke for that requirement in the case of a general strike)

- CIP-011-1 R2.1 Consider – Prior to the release for reuse of applicable Cyber Assets that contain BES Cyber System Information (except for reuse within other systems identified in the “Applicable Systems” column), it may not be possible that the Responsible Entity shall take action to prevent the unauthorized retrieval of BES Cyber System Information from the Cyber Asset data storage media in the case that the applicable Cyber Asset is no longer available because of an event triggering a CIP exceptional circumstance. (Example: A Cyber Asset containing BES Cyber System Information was stolen during a physical intrusion by terrorist)

- CIP-011-1 R2.2 Consider – Prior to the disposal of applicable Cyber Assets that contain BES Cyber System Information, it may not be possible that the Responsible Entity shall take action to prevent the unauthorized retrieval of BES Cyber System Information from the Cyber Asset or destroy the data storage media in the case that the applicable Cyber Asset or the data storage media is no longer available because of an event triggering a CIP exceptional circumstance. (Example: A Cyber Assets containing BES Cyber System Information was stolen during a physical intrusion by terrorist)

- Attachment 1, Section 2 (Physical Security Controls for low impact)

Consider – Control physical access, based on need as determined by the Responsible Entity, to (1) the asset or the locations of the low impact BES Cyber Systems within the asset and (2) the Low Impact BES Cyber System Electronic Access Points (LEAPs), if any, may not be possible in the case that the physical control in place is damaged or destroyed because of an event triggering a CIP exceptional circumstance. (Example: emergency services destroyed physical lock that controls access in order to give assistance)

CIP-003-6 Attachment 1 Section 2 should have the CIP Exceptional Circumstance language for physical security relative to the clause “shall control physical access, based on need.” While an entity could use language in their CIP-003 R2 Attachment 1 Section 2 to indicate that first responders have a “need,” it would be preferable to use the same program used for CIP-006 for consistency across all locations.

IPC would like the following CIP requirements added to the CEC list of requirements:

CIP-005-5 R1, Parts R1.1 to R1.5—There may be times during a CEC when a Responsible Entity will be in a position where holding their ESP intact is not feasible, possible, or will extend an operational outage or issue creating additional reliability concerns. A Responsible Entity should be provided with a high degree of latitude to address a CEC and be provided the tools necessary to address reliability concerns without concurrent compliance concerns.

CIP-006-6 R1, Parts R1.2 to R1.7—Although it is ideal to maintain Parts R1.2 to R1.7 in every circumstance, during a CEC, it may not be feasible for a Responsible Entity to utilize two-factor access controls, monitor physical access points, or issue alarms. A Responsible Entity should have the flexibility to determine what they are able to keep in place based on the CEC and suspend those requirements that are either ineffective or non-functioning.

CIP-007-6 R1, Parts R1.1 & R1.2—Although it is ideal to maintain Parts R1.1 and R1.2 in every circumstance, during a CEC, a Responsible Entity may not have time to document and protect every port. While port security is important, a Responsible Entity should have the flexibility to document and protect the applicable ports when the CEC has been corrected. A Responsible Entity should have the flexibility to determine what they are able to keep in place based on the CEC and suspend those requirements that are either ineffective or non-functioning.

CIP-007-6 R4, Part 4.2—If logging is unavailable due to a CEC for CIP-007-6 Part 4.1, generating alerts for security events for Part 4.1 would most likely be unavailable as well. A Responsible Entity should be given the flexibility to determine what they are able to keep in place based on the event taking place and suspend those requirements that are either ineffective or non-functioning based on the situation.

CIP-007-6 R4, Part 4.4—If logging is unavailable due to a CEC for CIP-007-6 Part 4.1, reviewing logs would not be possible for the time the logging system is down during the CEC, which may exceed 15 calendar days.

CIP-007-6 R5, Parts R5.1 to R5.3—Although it is ideal to maintain Parts R5.1 to R5.3 in every circumstance, during a CEC, a Responsible Entity may not have time to identify and enforce certain system access controls. While authentication, inventories of all generic accounts, and lists of those who can access shared accounts is important, it may not be necessary to have this documentation updated during a CEC where new devices are being implemented or old devices are being wiped and rebuilt. A Responsible Entity should have the flexibility to determine what they are able to keep in place based on the CEC and suspend those requirements that are either ineffective or non-functioning.

CIP-010-2 R1, Parts 1.1 to R1.4, including R1.4.2 & R1.4.3—Change management is a critical piece of day-to-day operations to maintain good process controls and practices. However, rigid change management processes and baseline documentation could just as easily be a hindrance to recovery efforts during a CEC. A Responsible Entity should have the flexibility to determine what they are able to keep in place based on the CEC and suspend those requirements that are either ineffective or non-functioning.

CIP-010-2, Attachment 1, Section 1.1 to 1.5—Although it is ideal to maintain Sections 1.1 to 1.5 in every circumstance, during a CEC, it may not feasible for a Responsible Entity to use only those devices that are designated as a TCA. Some instances may require additional resources from within a Responsible Entity that would not be approved TCAs. A Responsible Entity should have the flexibility to determine what they are able to keep in place based on the CEC and suspend those requirements that are either ineffective or non-functioning

CIP-010-2, Attachment 1, Section 2.1 to 2.3—Although it is ideal to maintain Sections 2.1 to 2.3 in every circumstance, during a CEC, it may not be feasible for a Resonsible Entity to mitigate software vulnerabilities and malicious code for TCAs managed by a party other that the Responsible Entity. A Responsible Entity should have the flexibility to determine what they are able to keep in place based on the CEC and suspend those requirements that are either ineffective or non-functioning.

CIP-010-2, Attachment 1, Section 3.1 to 3.2—Although it is ideal to maintain Sections 3.1 to 3.2 in every circumstance, during a CEC, it may not be feasible for a Responsible Entity to use only those devices that are designated as a RM. Some instances may require additional resources from within a

Responsible Entity that would not be approved RM. A Responsible Entity should have the flexibility to determine what they are able to keep in place based on the CEC and suspend those requirements that are either ineffective or non-functioning.

CIP-011-2 R1, Part R1.2—Although it is ideal to maintain Part R1.2 in every circumstance, during a CEC, it may not be feasible for a Responsible Entity to maintain adherence to a Responsible Entity's Information Protection Program. A Responsible Entity should have the flexibility to determine what they are able to keep in place based on the CEC and suspend those requirements that are either ineffective or non-functioning.

Response

Chris Scanlon - Exelon - 1,3,5,6

Answer	Yes
Document Name	

Comment

Exelon suggests also adding CIP Exceptional Circumstance language in these requirements:

1. CIP-010-2, R1, Part 1.1 Develop Baseline
2. CIP-010-2, R1, Part 1.2 Authorize changes to the baseline
3. CIP-010-2, R1, Part 1.3 Update baseline

The same justification that was used for CIP-010-2, R1, Part 1.5 could be applied to these three requirments.

It is a general practice that the baseline must be created prior to the Cyber Asset being put into production. If during a declared CIP Exceptional Circumstance, a new Cyber Asset type for which an existing baseline configuration does not exist must be deployed, the development of the baseline may hinder recovery and addressing BES reliability.

Additionally, where a major system outage has occurred that qualifies as a declared CIP Exceptional Circumstance, it is possible that in the interest of restoring the reliability function a new firmware version or version of software needs to be installed on the Cyber Asset outside of the traditional rigor of the change and configuration managmenet processes.

Lastly, during a declared CIP Exceptional Circumstance it may not be practical to update the baseline within 30 days while resources are addressing the CIP Exceptional Circumstance event.

Comment	
AZPS respectfully recommends that the SDT consider the addition of the CIP Exceptional Circumstances language to the following requirements: CIP-006, R1.4 – 1.7; (may be unable to perform under CEC, i.e., if the facility is destroyed); CIP-010-2, R1.1 (may impede recovery to the detriment of restoration of a reliable BES).

Colby Bellville - Duke Energy - 1,3,5,6 - FRCC,SERC,RF, Group Name Duke Energy	
Answer	Yes
Document Name	
Comment	
Duke Energy recommends that the CIP Exceptional Circumstance language be implemented across the entire suite of CIP standards and requirements. CEC(s) are implemented in situations where safety or reliability of the BES is concerned. In these most important instances, we believe it is appropriate to address the immediate safety or reliability issue first, without concern for the compliance implications that could result. Having CEC(s) as an option for all CIP requirements would eliminate the potential for an entity to take time to rationalize, and deliberate on compliance implications, prior to mitigating a safety or reliability issue. Mitigating concerns for safety and the reliability of the BES should always be first, and an entity having the ability to claim a CEC when necessary for all CIP requirements would help reinforce this way of thinking. Duke Energy recognizes that the SDT considered a holistic approach but abandoned it since it would require CMEP changes such that it wouldn't be considered as a non-compliant event. However, Duke Energy recommends that this could be solved by simply including the phrase "except during CIP Exceptional Circumstances" at the conclusion of each individual CIP requirement.

In addition to the Parts identified, we recommend adding the “except during CIP Exceptional Circumstances” language to the following Parts of the CIP Standards.

- CIP-003-7 (i) R2 Attachement 1, section 2 – In a catastrophic event, physical access controls may be affected or altered temporarily. (e.g. Katrina)
- CIP-004-6 Parts 4.2, 4.3, 4.4 – Scheduled quarter, annual, or 15 month reviews may not be delayed or not possible in the event of a catastrophic event.
- CIP-04-6, Parts 5.2, 5.3, 5.4, 5.5 – In a catastrophic event, termination and access revocation activitities may be affected.
- CIP-006-6 – 1.2, 1.3, 1.4, 1.5, 1.6, 1.7, 1.10, 3.1 – In a catastrophic event, physical access controls may be affected or altered temporarily (e.g., damage to gate cause by debris, or first responders entering facility).
- CIP-010 Part 1.3 – The timing of being able to update the baseline within 30 days may not be able to be completed after a catastrophic event.
- CIP-010 Part 1.4.2 – Although the timing of the testing of the cybersecurity controls isn’t addressed in the language of the requirement, there appears to be an expectation that testing occur soon after the change. In a catastrophic event, the timing of the actual testing needs to be prioritized after the recovery process is completed.
- CIP-010 Part 2.1 -- The timing of being able to update the baseline within 30 days may not be able to be completed after a catastrophic event.
- CIP-010 Parts 3.1, 3.2 – The timing of scheduled vulnerability assessments (paper or active) may be affected in the event of a catastrophic event.
- CIP-011 Part 2.2 – In a catastrophic event, the cyber asset may not be able to be found (e.g., picked up by a tornado)

CIP-004-6, R5, Part 5.1 Rationale - This is similar to CIP-006-6 Requirement R2, Part 2.2. During certain events, the ability to remove access may not be possible if a system is damaged or destroyed.

CIP-006-6, R1, Part 1.2 Rationale - This is similar to CIP-006-6 Requirement R2, Part 2.2. In the event of a failure of a PACS, it may not be possible to have 1 factor for access control.

CIP-006-6, R1, Part 1.3 Rationale - This is similar to CIP-006-6 Requirement R2, Part 2.2. In the event of a failure of a PACS, it may not be possible to have 2 factors for access control.

CIP-006-6, R1, Part 1.4 Rationale - This is similar to CIP-006-6 Requirement R2, Part 2.2. In certain events, monitoring may not be possible if the facility is damaged or destroyed.

CIP-006-6, R1, Part 1.5 Rationale - This is similar to CIP-006-6 Requirement R2, Part 2.2. In the event monitoring is unavailable, alerting may not be possible.

CIP-006-6, R1, Part 1.6 Rationale - This is similar to CIP-006-6 Requirement R2, Part 2.2. In certain events, monitoring may not be possible if the facility is damaged or destroyed.

CIP-006-6, R1, Part 1.7 Rationale – This is similar to CIP-006-6 Requirement R2, Part 2.2. In the event monitoring is unavailable, alerting may not be possible.

CIP-007-6, R2 Part 2.2 Rationale - This is similar to CIP-007-6 R4, Part 4.1. Security Patch Management timeline may be unattainable if there is failure of the patch assessment system during the event.

CIP-007-6, R4 Part 4.2 Rationale - This aligns to CIP-007 R4, Part 4.1. In the event monitoring under Part 4.1 is unavailable, alerting may not be possible.

CIP-007-6, R4 Part 4.4 Rationale - This aligns to CIP-007 R4, Part 4.1. In certain events, logging may not be possible if asset or a facility is damaged or destroyed.

CIP Exceptional Circumstances should be applied to Attachment 1, Section 3 Electronic Access Controls. Electronic access controls applied to Low BES Cyber Systems (BCS) may need temporarily bypassing due to a CIP Exceptional Circumstance. Examples are where a firewall or data diode used for Low BCS Electronic Access Controls must be temporarily bypassed to resolve the CIP Exceptional Circumstance.

Seattle City Light would like to see CIP Exceptional Circumstances added to CIP-003 R2, Attachment 1, Section 2 (and Section 5, as proposed).

For Section 2, the revision would read: “***Except during CIP Exceptional Circumstances***, each Respnosbile Entity shall control physical access,…”

The rationale for this addition is similar to that for requirements associated with CIP-004 and CIP-006, in that for during certain events, access controls may not be possible if the facility is damaged or destroyed.

For Section 5, the rationale would be the same as for CIP-010 R4, extended from Transient Cyber Assets and Removable Media at High and Medium location to those at Low locations.

SRP would like the following CIP requirements to be added to the CEC list of requirements:

- CIP CIP-007-6 R4, Part 4.2: If logging is unavailable due to a CEC for CIP-007-6 Part 4.1, generating alerts for security events for Part 4.1 would most likely be unavailable as well.
- CIP-007-6 R4, Part 4.4: If logging is unavailable due to a CEC for CIP-007-6 Part 4.1, reviewing logs would not be possible for the time the logging system is down during the CEC, which may exceed 15 calendar days.

CIP-006 R1 Parts 1.4 (Monitor PSP), 1.5 (Alarm within 15 minutes), 1.6 (Monitor PACS), 1.7 (Alarm within 15 minutes). Achieving compliance for these requirements depends greatly on hardware availability, including power supply. Whereas CIP-007 monitoring and logging requirements cannot be achieved in the event of a power outage to an ESP because there is no traffic flowing and without power there essentially is no ESP, the CIP-006 requires monitoring of the PSP which exists and can be accessed regardless of power outage/hardware failure/ natural disaster. Alarms cannot be generated, badge logs collected, or camera footage recorded in the event a site or system goes dark. It may be best practice for an entity to dispatch a security guard or other personnel to a site to perform manual monitoring and/or logging for some small scale events that would meet CIP Exceptional Circumstances. However, during major event such as a hurricane affecting dozens of sites across a large geographical area, it may not be feasible or within an entities safety policy to dispatch security personnel. Entities should implement compensating measures, such as fail-secure doors, for events that would affect the systems that meet compliance with these requirements during normal operations. However, it is unreasonable to expect entities to monitor and alarm at sites without appropriate support from technical solutions. Using the NERC language above, “During certain events,” physical alarming and/or monitoring “may not be possible if the facility is damaged or destroyed.”

CIP-007-6 part 2.2: If a security patch gets released 34 days after your assessment of the most recent previous patch, an entity would have one day (or possible less) to evaluate the patch. If you patch assessment system has a hardware failure (i.e. CEC) during this time, as it is now written this would be a violation. Strongly suggest adding this to the CEC list of requirements. CIP-007-6 part 4.2: If CEC is available for part 4.1 "logging of events" then it would, by inference, necessitate to have CEC available for part 4.2 since generation of alerts is probably based on logging of the events. CIP-007-6 part 4.4: Additionally for the same reason part 4.4 reviewing a summarization or sampling of logs would not be possible if all logging was offline during the CEC event, and the CEC event lasted more that 15 calendar days.

A Reliability Standard must not hinder REs in responding to situations that endanger human life and/or adversely impact system restoration.

It is possible to devise a circumstance where every one of the NERC CIP Reliability Standards may be violated while responding to a CIP Exceptional Circumstance. Instead of the proposed piecemeal approach, it is more reasonable to add a single requirement giving REs flexibility to respond to CIP Exceptional Circumstances that covers all NERC CIP requirements. NERC CIP-003 is a logical location for such a requirement.

Embedding one universally applicable CIP Exceptional Circumstances requirement provides an approach that resolves the immediate dilemma of requirements for which an RE cannot possibly comply. During the normal course of standards revisions, legacy individual CIP Exceptional Circumstance clauses could be organically phased out so as not to induce a flurry of undue burden in otherwise unsubstantive procedure revisions.

Documentation requirements associated with “documenting” the results of a previous Part, such as CIP-010 Part 3.4, should not require CEC language provided the language is afforded to the Parts subject to CEC treatment. In this example, CIP-010 Parts 3.1, 3.2, 3.3. However, if CEC is not extended to all of the Parts (CIP-010 Parts 3.1, 3.2, 3.3), then it should be considered for the documentation requirement (in Part 3.4).

AZPS would like clarification on the following statement: “CEC are included in a Responsible Entity’s cyber security policy from CIP-003 which describes how the entity would declare and respond to a CEC. During a declared CEC, the entity is allowed exception(s) to adhering to the specific reliability objective of the requirement(s); however, the entity is still compliant with the requirement(s) if the entity properly declares and responds to the CEC and adheres to its applicable cyber security policies”. The last phrase appears to contradict the concept or philosophy being expressed in the previous phrase in that it appears to require the entity to remain compliant with the requirement even if such requirement is impacted by a CEC. This would be contrary to the intent of a CIP Exceptional Circumstance	

wherein it is recognized that a responsible entity's ability to be compliant may be impacted as a result of a CEC, e.g., if a facility is substantially destroyed, a physical security perimeter may no longer be intact. AZPS requests that the SDT clarify the statement to ensure that the effect of declaring a CEC is clear and that all responsible entities understand what their continuing obligations are once a CEC is declared. Addtionally, AZPS has attached a document with recommendations to the Rationale in the table titled List of Additional Requirements for Consideration on Page 2-4 of the Unofficial Comment Form.

Aaron Austin - AEP - 3,5	

Answer	
Document Name	
Comment	
AEP recognizes the considerable effort of the SDT to establish an expansion of CIP requirements subject to exception during a CEC. AEP is concerned that like Versions 5 and 6 it will later be found that additional requirements should be subject to exception during a CEC. A more general rule for exceptions to CIP requirements would allow entities additional flexibility to manage its response during a CEC and future proof the CIP Standards in this area. The flexibility should come with a requirement to justify anyexceptions to requirements taken at specific locations or regions as they are impacted by a CEC. This or similar language could be placed in the "Exceptions" section of each CIP Reliability Standard: "4.2.3.5. A Responsible Entity may temporarily suspend compliance activities associated with CIP requirements for affected assets, BES Cyber Systems and individuals during a period when it has declared a CIP Exceptional Circumstance". And, language could be added to the existing policy requirements of CIP-003-7 as follows: R1 1.1.9. and 1.2.6 **"**Declaring, justifying and responding to CIP Exceptional Circumstances".

ERCOT supports the drafting team's position in adding the CEC language to additional requirement parts. Although a formal CEC program would have been beneficial to entities in allowing coverage for all requirements, introducing compliance that derived from the approach would be burdensome to have all instances of invoking a CEC result in potential non-compliance.

CIP Exceptional Circumstances include both a Bulk Electric System emergency when the responsible entity is delayed in, or prevented from, performing or carrying out any compliance activity required by CIP-002 through CIP-014 by reason of or through any cause reasonably beyond its control and not attributable to its neglect .

During the threat and after the impact of a CIP Exceptional Circumstance, ITC's priorities are the safety of its' employees and customers, environment compliance and the restoration of service.

Comment

Basin Electric Power Cooperative agrees with the discussion surrounding the identification of typical standards/requirement/parts likely to be affected by a CIP Exceptional Circumstance. However, Basin Electric would prefer the removal of CIP Exceptional Circumstance Language on a per standard/requirement/part level and instead focus on CIP-003 enhancements and related Implementation Guidance. The overhead of including the exception in multiple standards/requirements/parts seems to outweigh the benefit of a low frequency circumstance.

List of Additional Requirements for Consideration

Standard	Requirement	Rationale
CIP-004	Requirement R3, Part 3.5 Process to ensure that individuals with authorized electronic or authorized unescorted physical access have had a personnel risk assessment completed according to Parts 3.1 to 3.4 within the last seven years.	This is similar to the CIP-004-5 Requirement R2, Part 2.2 training requirement. A personnel risk assessment cannot be performed on first responders, would not be possible in emergency circumstances, and may not be possible on relevant vendors. Thus, this requirement should be subject to CIP Exceptional Circumstances for both ~~is would cover~~ the entity's personnel as well as contractors and service vendors
CIP-006	Requirement R1, Part 1.8 Log (through automated means or by personnel who control entry) entry of each individual with authorized unescorted physical access into each Physical Security Perimeter, with information to identify the individual and date and time of entry.	This aligns to CIP-006-6 Requirement R2, Part 2.2. During certain events, logging may not be possible if the facility in which the logging and/or supporting hardware, software, or communication networks reside is damaged or destroyed. Thus, this requirement should be subject to CIP Exceptional Circumstances.
CIP-006	Requirement R1, Part 1.9 Retain physical access logs of entry of individuals with authorized unescorted physical access into each Physical Security Perimeter for at least ninety calendar days.	This aligns to CIP-007-6 Requirement R4, Part 4.3. During certain events, a facility where the logging and/or supporting software, hardware, or communications reside may be damaged or destroyed. As a result, records already recorded for retention may also be adversely impacted and new logging may not be possible~~ if the facility is damaged or destroyed~~. Thus, this requirement should be subject to CIP Exceptional Circumstances.
CIP-006	Requirement R2, Part 2.3 Retain visitor logs for at least ninety calendar days.	This aligns to CIP-007-6 Requirement R4, Part 4.3. During certain events, a facility where the logging and/or supporting software, hardware, or communications reside may be damaged or destroyed. As a result, records already recorded for retention may also be adversely

Standard	Requirement	Rationale
		impacted and new logging may not be possible. Thus, this requirement should be subject to CIP Exceptional Circumstances.~~During certain events, logging may not be possible if the facility is damaged or destroyed.~~
CIP-007	Requirement R4, Part 4.1 Log events at the BES Cyber System level (per BES Cyber System capability) or at the Cyber Asset level (per Cyber Asset capability) for identification of, and after-the-fact investigations of, Cyber Security Incidents that includes, as a minimum, each of the following types of events: 4.1.1. Detected successful login attempts; 4.1.2. Detected failed access attempts and failed login attempts; 4.1.3. Detected malicious code.	This aligns to CIP-006-6 Requirement R2, Part 2.2. During certain events, if the facility in which hardware, software, or communication networks utilized to support logging of events resides is damaged or destroyed, the ability to log events could be adversely impacted. Thus, this requirement should be subject to CIP Exceptional Circumstances.~~During certain events, logging may not be possible if the facility is damaged or destroyed.~~
CIP-010	Requirement R1, Part 1.4.1 Prior to the change, determine required cyber security controls in CIP-005 and CIP-007 that could be impacted by the change;	This aligns to Requirement R3, Part 3.3. During ~~the~~ an event, security controls identification and testing may impede recovery efforts necessary to restore the reliable operation of the BES. Thus, this requirement should be subject to CIP Exceptional Circumstances.
CIP-010	Requirement R1, Part 1.5 Where technically feasible, for each change that deviates from the existing baseline configuration: 1.5.1. Prior to implementing any change in the production environment, test the changes in a test environment or test the changes in a production environment where the test is performed in a manner that minimizes adverse effects, that models the baseline configuration to ensure that required cyber security controls in CIP-005 and	This aligns to Requirement R3, Part 3.3. During an event, security controls identification and testing may impede recovery efforts necessary to restore the reliable operation of the BES. Thus, this requirement should be subject to CIP Exceptional Circumstances.~~During the event, security controls testing may impede recovery efforts.~~

Standard	Requirement	Rationale
	CIP-007 are not adversely affected; and 1.5.2. Document the results of the testing and, if a test environment was used, the differences between the test environment and the production environment, including a description of the measures used to account for any differences in operation between the test and production environments.	

Additional comments received from Nathan Mitchell of APPA

Questions

Note: The new (revised) language is shown in red text.

1. Do you agree with adding the existing CIP Exceptional Circumstance language to the Requirement/Part listed below? Please provide a detailed explanation/rationale for inclusion or exclusion of the CEC language.

   CIP-004 R3, Part 3.5: Process to ensure that individuals with authorized electronic or authorized unescorted physical access have had a personnel risk assessment completed according to Parts 3.1 to 3.4 within the last seven years, except during CIP Exceptional Circumstances.

   ☒ Yes

   ☐ No

   Comments:

2. Do you agree with adding the existing CIP Exceptional Circumstance language to the Requirement/Part listed below? Please provide a detailed explanation/rationale for inclusion or exclusion of the CEC language.

   CIP-006 R1, Part 1.8: Log (through automated means or by personnel who control entry) entry of each individual with authorized unescorted physical access into each Physical Security Perimeter, with information to identify the individual and date and time of entry, except during CIP Exceptional Circumstances.

   ☒ Yes

   ☐ No

   Comments:

3. Do you agree with adding the existing CIP Exceptional Circumstance language to the Requirement/Part listed below? Please provide a detailed explanation/rationale for inclusion or exclusion of the CEC language.

CIP-006 R1, Part 1.9: Retain physical access logs of entry of individuals with authorized unescorted physical access into each Physical Security Perimeter for at least ninety calendar days, except during CIP Exceptional Circumstances.

☒ Yes

☐ No

Comments:

4. Do you agree with adding the existing CIP Exceptional Circumstance language to the Requirement/Part listed below? Please provide a detailed explanation/rationale for inclusion or exclusion of the CEC language.

   CIP-006 R2, Part 2.3: Retain visitor logs for at least ninety calendar days, except during CIP Exceptional Circumstances.

   ☒ Yes

   ☐ No

   Comments:

5. Do you agree with adding the existing CIP Exceptional Circumstance language to the Requirement/Part listed below? Please provide a detailed explanation/rationale for inclusion or exclusion of the CEC language.

   CIP-007 R4, Part 4.1: Log events, except during CIP Exceptional Circumstances, at the BES Cyber System level (per BES Cyber System capability) or at the Cyber Asset level (per Cyber Asset capability) for identification of, and after-the-fact investigations of, Cyber Security Incidents that includes, as a minimum, each of the following types of events:

   ☒ Yes

   ☐ No

   Comments:

6. Do you agree with adding the existing CIP Exceptional Circumstance language to the Requirement/Part listed below? Please provide a detailed explanation/rationale for inclusion or exclusion of the CEC language.

   CIP-010 R1, Part 1.4.1: Prior to the change, except during CIP Exceptional Circumstances, determine required cyber security controls in CIP-005 and CIP-007 that could be impacted by the change.

   ☒ Yes

   ☐ No

   Comments:

7. Do you agree with adding the existing CIP Exceptional Circumstance language to the Requirement/Part listed below? Please provide a detailed explanation/rationale for inclusion or exclusion of the CEC language.

CIP-010 R1, Part 1.5: Where technically feasible, for each change that deviates from the existing baseline configuration:

1.5.1. Prior to implementing any change in the production environment, test the changes in a test environment or test the changes in a production environment where the test is performed in a manner that minimizes adverse effects, that models the baseline configuration to ensure that required cyber security controls in CIP-005 and CIP-007 are not adversely affected, except during CIP Exceptional Circumstances; and

1.5.2. Document the results of the testing and, if a test environment was used, the differences between the test environment and the production environment, including a description of the measures used to account for any differences in operation between the test and production environments, except during CIP Exceptional Circumstances.

☒ Yes

☐ No

Comments:

8. Are there other Requirement(s) or Part(s) that should include the CIP Exceptional Circumstance language other than those already identified in this request? If so, please identify and provide the rationale.

☒ Yes

☐ No

Comments:

Include the electronic and physical security controls required by CIP-003 R2 Attachment 1, sections 2 and 3. This would meet the same rational as used for the inclusion of CEC for CIP-004 and CIP-006.

9. If you have additional comments on the proposed approach that you have not provided in response to the questions above, please provide them here.

Comments:

Consider simplifying the application of CEC in CIP-006 by applying the term to R1 and R2 and not to the sub-sections.

NORTH AMERICAN ELECTRIC
RELIABILITY CORPORATION

Unofficial Comment Form

Project 2016-02 Modifications to CIP Standards
Virtualization in the CIP Environment

Do not use this form for submitting comments. Use the electronic form to submit comments on the **use of Virtualization in the CIP environment**. The electronic form must be submitted by **8 p.m. Eastern, Tuesday, April 11, 2017**.

Additional information is available on the project page. If you have questions, contact Mat Bunch (via email) or at (404) 446-9785.

Background Information

On January 21, 2016, the Federal Energy Regulatory Commission (Commission) issued Order No. 822, *Revised Critical Infrastructure Protection Reliability Standards,* approving seven CIP Reliability Standards and new or modified definitions. On March 9, 2016, the NERC Standards Committee authorized a Standards Authorization Request (SAR) to be posted for a 30-day informal comment period from March 23 – April 21, 2016. Based on the comments received, the Standard Drafting Team (SDT) made minor revisions to the SAR which was posted for an additional 30-day informal comment period June 1-30, 2016.

The purpose of this project is to; (1) consider the Version 5 Transition Advisory Group (V5TAG) issues identified in the CIP V5 Issues for Standard Drafting Team Consideration (V5TAG Transfer Document), and (2) address the Commission directives contained in Order 822. These revisions will increase reliability and security to the Bulk Power System (BPS) by enhancing cyber protection of BPS facilities.

The V5TAG, which consisted of representatives from NERC, Regional Entities, and industry stakeholders, was formed to issue guidance regarding possible methods to achieve compliance with the CIP V5 standards and to support industry's implementation activities. During the course of the V5TAG's activities, the V5TAG identified certain issues with the CIP Reliability Standards that were more appropriately addressed by the existing SDT for the CIP Reliability Standards. The V5TAG developed the V5TAG Transfer Document to formally recommend that the SDT address these issues during the standards development process and to consider whether modifications can be made to the standard language.

The current informal posting document is an effort to gather input on the V5TAG issue related to virtualization in the CIP environment. The CIP standards are based primarily on concepts dating back to Version 1 and as technology has evolved, issues have begun to arise as entities attempt to take new concepts and fit them into some of the Version 1 paradigms. These issues revolve around topics such as:

- Hypervisor – the virtualization component that manages the guest operating systems (OSs) on a host and controls the flow instructions between the guest OSs and the physical hardware.

- Virtual machines – With virtualization technologies, a single physical Cyber Asset can be used as an execution platform for numerous virtualized operating systems, micro-service containerized applications, and virtual network functions of all classifications. A single physical Cyber Asset can appear to an external network as many complete Cyber Assets. Virtual switches and networks can be defined so these virtual machines can communicate with each other as if they are separate physical nodes on the network. Virtual machines and functions can also migrate around a physically clustered cyber system such that the singular physical Cyber Asset where an application resides can change at any moment.

  The virtualization of Cyber Assets provides advantages for the availability, resiliency, and reliability of applications and functions hosted in such an environment and the CIP standards must not stand in the way of these benefits as long as they are implemented in a secure manner. Virtualization affords enhanced security in some cases as the security controls themselves can be virtualized and placed within the virtual environment closer to the workloads they are protecting. However, there are also different security risks introduced by these environments. The management systems or consoles for these environments allow for the complete control of numerous components of the infrastructure. Virtual machines or networks can be added, modified, or deleted from one central management system. For example, rogue virtual components can starve legitimate workloads of the shared resources (processor, memory, etc.) they need to reliably perform their function. In summary, changes to the CIP Requirements may be needed to account for virtualization.

- Virtual Networks – Electronic Security Perimeter (ESP) constructs within the current CIP standard are limited to defining security zones at Open Systems Interconnection (OSI) Layer 3 and do not support security zones defined at layers other than OSI Layer 3. With current, widely deployed technology, networks are no longer solely defined by the arrangement of physical hardware and cables *inside* or *outside* of a *perimeter*. Networks can exist as a mixture of physical and virtual segments or purely in a virtual state within one device. Virtual firewalls and other security tools are also available to help secure these environments. Typical hardware network switches can be configured with internal logical isolation to implement multiple virtual networks within them. Accordingly, the SDT is reviewing the CIP standards to validate that definitions, requirements, and guidance regarding ESPs and Electronic Access Points (EAPs) continue to provide for secure and reliable operations.

- Virtual Storage – Historically, servers were limited to dedicated storage within the device. Typically, the operating system and the applications resided in the server on hard drives. Virtual storage technologies such as Storage Area Networks (SANs) present virtualized logical drive storage units to all attached servers. These types of environments then become a shared resource among many physical and virtual hosts.

With all of this in mind, the SDT is considering:

1) Areas in the current CIP requirements that might prevent or hinder the adoption of virtualization technologies for BES Cyber Systems and related systems;

2) Areas of new risks introduced by virtualization technologies and how to address them in the standards.

Questions

The SDT has determined that some of the concepts in CIP Version 5 must be fully realized in order to support virtualization. For example, while Version 5 introduced the “cyber system” concept and most requirements are now written at the cyber system level, the advantages of this approach have not been fully integrated into all levels of planning, design or compliance assessment approaches. Most entities still manage their CIP programs at a device level and auditors still look for device-centric evidence of compliance. This paradigm poses substantial issues with the use of virtual technologies. Infrastructure resources are pooled, apportioned to a given workload, and withdrawn or re-assigned when no longer needed. Infrastructure components (including instances of operating systems) come and go according to the current workload, making individual Cyber Asset level inventories difficult or impossible. The mobility of these resources makes permanently describing their physical locations problematic. Hardware (both computer and network) becomes a general-purpose commodity — merely a pool of resources on top of which the actual infrastructure is designed and created at a logical/virtual level. As technology increasingly blurs the line between physical and virtual systems, managing compliance in terms of individual devices or Cyber Assets becomes more challenging.

1. Version 5 introduced the BES Cyber System concept, and requirements reference applicability at the *BES Cyber System* level. However, language in the measures shows that, implicitly, many controls are expected to be implemented at the *BES Cyber Asset* or *device* level. The SDT assumes that most auditors expect entities to demonstrate compliance at the device level. Do you agree with the SDT’s assumption? If so, how should the SDT address these inconsistencies?

   ☐ Yes
   ☐ No

   Comments:

To incorporate virtualization and address the V5TAG transfer issue to clarify the meaning of the term *programmable* in the current definition of *Cyber Assets*, the SDT is proposing changes to the definition that include defining the term in the singular rather than the plural. Updating the definition to include virtual environments allows the definition of other terms based on *Cyber Asset*, such as Electronic Access Control or Monitoring Systems (EACMS) and Protected Cyber Asset (PCA) to also include virtual environments.

The proposed *Cyber Asset* definition is:

> Redlined
> *~~Programmable~~An electronic device~~s~~ (physical or virtual) whose operation is controlled by a stored program that can be changed or replaced by the end user, including the hardware, software, and data in ~~those devices~~ the device. A virtual machine is itself a distinct asset from its host(s).*
>
> Clean
> *An electronic device (physical or virtual) whose operation is controlled by a stored program that can be changed or replaced by the end user, including the hardware, software, and data in the device. A virtual machine is itself a distinct asset from its host(s).*

2. The SDT proposes that each virtual machine and hypervisor are separate Cyber Assets. Do you agree with this position? Please provide a rationale to support your position.

   ☐ Yes
   ☐ No

   Comments:

3. Do you agree that the proposed Cyber Asset definition clarifies the term *programmable*? Please provide a rationale to support your position.

   ☐ Yes
   ☐ No

   Comments:

In virtualized environments, the physical infrastructure can be shared between BES Cyber Systems and other non-CIP Cyber Assets while maintaining isolated virtualized environments for each.

4. Such configurations are not addressed explicitly in CIP-005-5. Are modifications required to address the issue? Please provide your rationale.

   ☐ Yes
   ☐ No

   Comments:

Concerning virtual networks, network devices can have multiple logical networks configured (e.g. virtual local area networks (VLANs)). Physical or virtual devices perform “logical isolation” when configured such that some network interfaces are available inside an ESP, and other interfaces are outside an ESP and the two networks cannot communicate with each other inside of the device. This would not prevent the VLANs configured inside the device from communicating through an EAP.

5. The SDT asserts that VLANs providing logical isolation are not addressed explicitly in CIP-005-5, and controls may be necessary to isolate BES Cyber Systems. Are the current requirements of CIP-005-5 sufficient to address logical isolation using VLANs? Please provide your rationale.

   ☐ Yes
   ☐ No

   Comments:

The SDT has identified certain risks inherent to virtualization regarding the use of centralized management automation. The SDT is proposing to classify *Centralized Management System* (CMS) explicitly as a type of applicable system for some CIP requirements. In examining management architecture and risk management for virtual environments, the SDT identified an increased risk inherent to the span of control of hypervisor management consoles. Further, the SDT noted that similar risks exist in CMSs used to manage physical devices, and recognized these risks may not be fully addressed in current CIP standards and the *EACMS* definition. The SDT is considering a new definition of this class of system.

The proposed *Centralized Management System* (CMS) definition is:

> *A centralized system for administration or configuration of BES Cyber Systems, including but not limited to systems management, network management, storage management, or patch management.*

6. Do you agree with the proposed definition of CMS? If not, please provide alternative language for the definition and your rationale.

   ☐ Yes
   ☐ No

   Comments:

7. Do you agree with the SDT's approach to reference the CMS specifically as a type of applicable system in the CIP standards? Please provide your rationale.

   ☐ Yes
   ☐ No

   Comments:

In examining virtualization, the SDT considered centralized management systems or consoles for these environments. These systems allow for the mass addition, deletion and modification of virtual machines and networks. Access to the control surface of a cyber system is known as the *management plane*. The management plane is where the virtual infrastructure is configured and managed by a limited group of administrators as opposed to the *data plane*. The data plane is where the end user's access to the virtual machine's business function takes place. To meet the security objective of protecting a BES Cyber System from threats in the data plane, the management plane should be isolated from the data plane. These types of controls are referred to as *out of band* management.

The SDT is considering limiting the scope of management plane protection requirements to high and medium impact Control Centers because these environments contain the highest risk.

8. Do you agree with the SDT's approach to require the isolation between the data plane and the management plane? Please provide your rationale.

   ☐ Yes
   ☐ No

   Comments:

9. Do you agree with limiting the applicability to high and medium impact Control Centers? Please provide your rationale.

   ☐ Yes
   ☐ No

Standards Announcement

2016-02 Modifications to CIP Standards
Transmission Owner Control Center Performing Transmission Operator Obligations and Virtualization

Informal Comment Periods Open through April 11, 2017

Now Available

The Project 2016-02 Standard Drafting Team (SDT) is requesting stakeholder input on two issues it is addressing from the Version 5 Transition Advisory Group (V5TAG): (1) the applicability of the CIP Reliability Standards to BES Cyber Systems for a Transmission Owner Control Center performing the functional obligations of a Transmission Operator; and, (2) the use of virtualization in the CIP environment. Two concurrent 29-day informal comment periods are open through **8 p.m. Eastern, Tuesday, April 11, 2017,** for stakeholders to provide feedback on the SDT's approach and draft language for each issue.

Commenting

Use the electronic form to submit comments. If you experience any difficulties using the electronic form, contact Wendy Muller. Unofficial Word versions of the comment forms are posted on the project page.

If you are having difficulty accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out, contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern).

- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*
- *Please be mindful of ballot and comment period closing dates. We ask to **allow at least 48 hours** for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts **prior to the last day** of a comment/ballot period.*

Next Steps

The drafting team will review all responses received and determine the next steps of the project.

For more information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance regarding TOCC, contact Senior Standards Developer, Al McMeekin (via email) or at (404) 446-9675. For additional assistance regarding Virtualization, contact Standards Developer, Mat Bunch (via email) or at (404) 446-9785.

Comment Report

Project Name:	2016-02 Modifications to CIP Standards | Virtualization
Comment Period Start Date:	3/14/2017
Comment Period End Date:	4/11/2017
Associated Ballots:	

There were 54 sets of responses, including comments from approximately 136 different people from approximately 89 companies representing 10 of the Industry Segments as shown in the table on the following pages.

Questions

1. Version 5 introduced the BES Cyber System concept, and requirements reference applicability at the *BES Cyber System* level. However, language in the measures shows that, implicitly, many controls are expected to be implemented at the *BES Cyber Asset* or *device* level. The SDT assumes that most auditors expect entities to demonstrate compliance at the device level. Do you agree with the SDT's assumption? If so, how should the SDT address these inconsistencies?

(Refer to the Unofficial Comment Form for more information on this question)

2. The SDT proposes that each virtual machine and hypervisor are separate Cyber Assets. Do you agree with this position? Please provide a rationale to support your position.

(Refer to the Unofficial Comment Form for more information on this question)

3. Do you agree that the proposed Cyber Asset definition clarifies the term *programmable*? Please provide a rationale to support your position.

(Refer to the Unofficial Comment Form for more information on this question)

4. In virtualized environments, the physical infrastructure can be shared between BES Cyber Systems and other non-CIP Cyber Assets while maintaining isolated virtualized environments for each.

Such configurations are not addressed explicitly in CIP-005-5. Are modifications required to address the issue? Please provide your rationale.

5. The SDT asserts that VLANs providing logical isolation are not addressed explicitly in CIP-005-5, and controls may be necessary to isolate BES Cyber Systems. Are the current requirements of CIP-005-5 sufficient to address logical isolation using VLANs? Please provide your rationale.

(Refer to the Unofficial Comment Form for more information on this question)

6. Do you agree with the proposed definition of CMS? If not, please provide alternative language for the definition and your rationale.

(Refer to the Unofficial Comment Form for more information on this question)

7. Do you agree with the SDT's approach to reference the CMS specifically as a type of applicable system in the CIP standards? Please provide your rationale.

(Refer to the Unofficial Comment Form for more information on this question)

8. Do you agree with the SDT's approach to require the isolation between the data plane and the management plane? Please provide your rationale.

(Refer to the Unofficial Comment Form for more information on this question)

9. Do you agree with limiting the applicability to high and medium impact Control Centers? Please provide your rationale.

(Refer to the Unofficial Comment Form for more information on this question)

Lan Nguyen - CenterPoint Energy Houston Electric, LLC - 1 - Texas RE

Answer	No
Document Name	

Comment

CenterPoint Energy does not agree with the SDT's assumption about the expectation of auditors and believes each entity should have the flexibility to defend compliance decisions based on the requirement language in the CIP Standards. Entities may find some controls easier or more effective to implement and provide evidence at a BES Cyber System level rather than at the BES Cyber Asset or device level, or vice versa depending on the requirement and the current CIP Standards provide this option.

Response

Scott Downey - Peak Reliability - 1

Answer	No
Document Name	

Comment

For some of the standards, like anti-virus/malware protection, a holistic approach can yield a design that protects assets without being draconian regarding the installation of anti-virus/malware protective software on every individual asset. Peak suggest the SDT consider real-world scenarios for situations and decide, for each standard, which ones can be addressed on an individual-asset basis only, and which ones can be addressed at the BES Cyber System level.

Response

Julie Hall - Entergy - 6, Group Name Entergy/NERC Compliance

Answer	No

Document Name	

Comment

Entergy understands that entities must be able to prove that each device that is part of a BES Cyber System need to be evaluated for compliance, but expect the distinction to be that controls do not have to be implemented at the individual device level provided evidence can prove the they benefit from controls implemented at the BES Cyber System level. For example, depending on the architecture every device may benefit from Intrusion Prevention Systems (IPS) with deep packet inspection for malware prevention, but that does not mean IPS is running on each individual device.

To incorporate virtualization and address the V5TAG transfer issue to clarify the meaning of the term *programmable* in the current definition of *Cyber Assets*, the SDT is proposing changes to the definition that include defining the term in the singular rather than the plural. Updating the definition to include virtual environments allows the definition of other terms based on *Cyber Asset*, such as Electronic Access Control or Monitoring Systems (EACMS) and Protected Cyber Asset (PCA) to also include virtual environments.

The proposed *Cyber Asset* definition is:

An electronic device (physical or virtual) whose operation is controlled by a stored program that can be changed or replaced by the end user, including the hardware, software, and data in the device. A virtual machine is itself a distinct asset from its host(s).

Response

Steven Rueckert - Western Electricity Coordinating Council - 10

Answer	Yes
Document Name	

Comment

The SDT should consider removing or further clarifying the purpose of including language (per BES Cyber System capability) or at the Cyber Asset level (per Cyber Asset capability) [see CIP-007-6, Part 4.1]. Additionally, the SDT could consider adding in the Appplicable Systems language, ‘and their associated BES Cyber Systems:’ if the intent of CIP v5 was to leverage a system-centric approach to affording the required controls for all Cyber Assets.

This may require the same change in the purpose statement found in all CIP Reliability Standards:

‘To identify and categorize BES Cyber Systems and their associated BES Cyber Assets…’

The SDT may want to reconsider the following cyber system concept paper –

http://www.nerc.com/docs/standards/sar/Concept_Paper_Categorizing_Cyber_Systems_2009July21.pdf

Response

Aaron Cavanaugh - Bonneville Power Administration - 1,3,5,6 - WECC

Answer	Yes
Document Name	

Comment

It has been BPA’s experience that guidance provided to auditors leads them to expect and look for controls to be applied to the Cyber Asset. Also, they seem skeptical of implementations where a given device performs a portion of the control function and additional components of the security strategy are implemented across multiple devices on the network. Auditors might consider only the device portion of an overall control and evaluate it outside of the network-based defense-in-depth strategy.

One way to address this inconsistency would be to normalize the use of the term “system” across the example measures rather than “device” wherever applicable. The SDT should add Guidance in the Technical Basis sections to clarify that defense in depth strategies are desirable. The Electronic Access Control and Monitoring System (EACMS) paradigm should be revised in line with standard IT Security practice and terminology as performing Authentication, Authorization, and Accounting (AAA). It is also important to explicitly allow for distributed systems to perform this AAA function for a security zone rather than the legacy concept of hardened perimeter.

There may also be a need to revisit the Reliability Standards Audit Worksheets in light of system vs device to provide better guidance to auditors attempting to apply the questions in the RSAW to an entity’s evidence.

Sean Bodkin - Dominion - Dominion Resources, Inc. - 3,5,6, Group Name Dominion

Answer	Yes
Document Name	

Comment

Dominion agrees with the statement that it appears auditors are expecting entities to show compliance at the device level for CIP v5 standards. However, the standard clearly allows compliance to be demonstrated at the system level. If the applicability of the controls is at the system level, then controls can be at the system level OR at the device level (where each device in the system has appropriate controls). If the applicability of the standards is intended to be at the BCA level, the applicability column clearly state that the expectation is for monitoring to occur at that level. To reinforce the applicability at the system level, the SDT should include specific system examples in the Measures section and similar system examples in the GTB or an Implementation Guidance document.

Response

Chris Scanlon - Exelon - 1,3,5,6

Answer	Yes
Document Name	

Comment

Exelon agrees with the assumption that the current expectation from auditors is to see compliance demonstrated at the BCA or device level. We view this as a concern that should be addressed, and we would welcome more clarity in the guidance on when device level compliance is required versus when protections can be demonstrated at the BES Cyber System level.

In the meantime, Exelon does continue to demonstrate compliance down to the BCA and device level, including all individual logical or virtual machines as well as their VM Host machine(s).

Preston Walker - PJM Interconnection, L.L.C. - 2 - SERC,RF

Answer	Yes
Document Name	

Comment

It was PJM’s experience during our version 5 audit that auditors did expect many controls were implemented at the device level. We found this was expected more for requirements that contained prescriptive language. Objective based controls lend themselves more to implementing controls at the BES Cyber System level. In order to help clarify how to handle the requirements for systems vs individual assets, additional guidance with respect to virtualization for both scenarios may be helpful.

SRP agrees there are inconsistencies between the language of the requirement and the measures regarding applicability of the requirements at the BES Cyber System level. It has been our experience that in some instances auditors looked at the device level instead of evaluating the controls applied at the system level. SRP utilizes a Defense in Depth security architecture, which applies controls and additional security measures across multiple devices on the network. SRP suggests the SDT add discussion of this strategy in the guidelines and technical basis section.

Joe Tarantino - Sacramento Municipal Utility District - 1,3,4,5,6 - WECC	
Answer	Yes
Document Name	
Comment	
Yes – SMUD Agrees. Virtualization is a proven secure method for sharing physical resources, and should be incorporated as an acceptable technology for network, firewall, compute (virtual machines), and storage. The acceptance for each of the areas should be outlined such that auditors and utility companies fully understand the acceptable configurations. At a minimum, the “device level” term should be changed to “operating system” as it is inclusive for processes, data, authentication, configuration, and traffic forwarding. This “operating system” could serve as the basis for all fully virtualized functions including virtual machines, virtual routers, virtual firewalls, etc. For systems that provide services with a shared “operating system”, such as a router with multiple isolated routing tables (VRF), guidelines should summarize the constraints.

N&ST believes that most Responsible Entities have reconciled to the notion that CIP requirements should be applied on a per- Cyber Asset basis, notwithstanding the fact many requirements are formally applicable to BES Cyber Systems that may comprise multiple Cyber Assets. N&ST also believes the SDT is correct in its belief that most, if not all, auditors expect to see evidence of device-level compliance. If the SDT is convinced this should be codified by revising the Standards, N&ST suggests adding language that clarifies requirements applicable to BES Cyber Systems must be applied to each Cyber Asset comprising a given BES Cyber System.

Ginette Lacasse - Seattle City Light - 1,3,4,5,6 - WECC, Group Name Seattle City Light Ballot Body

Answer	Yes
Document Name	

Comment

CIP v5 was conceived and described to industry as a "systems-based" approach, and this conceptual framework should be promoted as much as possible. As such, Seattle City Light believes that new or revised requirements should be structured and written at the BES Cyber System level as much as possible, and new measures and VSL should be developed to reinforce the system-based approach. In some cases there may need to be new parallel VSLs for both systems and devices, but in the long run, the device-focused approach should be phased out over time.

Comment

Where virtual machines behave like physical machines (run an OS such as Windows), it makes sense to request the same sort of evidence as for a physical machine that is also one component of a BES Cyber System. With regard to hypervisors due consideration should be given to their specialized nature to avoid treating them like just another OS, although change control and cybersecurity still apply.

Karie Barczak - DTE Energy - Detroit Edison Company - 3,4,5, Group Name DTE Energy - DTE Electric

Answer	Yes
Document Name	

Comment

Add the clear definitions for Hyper Visor (as a required asset) and Virtual Server (as a required asset) and then don't be concerned with the commodity abilities to add/remove processor, memory, disk, etc. Require that Virtual Servers remain constant in an environment regardless of what physical hypervisor asset they are running at any given time. This will ensure consistency and allow for clear asset level tracking. Scaling is a normal part of operating in a virtual environment and needs to account for virtual scaling. With respect to horizontal scaling, an entity would need to have at least one consistent virtual asset that is listed on the BES Asset List with a stated program for how and when horizontal instance is created/destroyed to account for spikes in demand. The entity would need to clearly show how they protect (via a program) for CIP007 requirements as instances are created. The burden would be on each entity to prove their model of protection (which is the model other security compliance standards such as PCI take).

ITC understands that today security is assigned at the device level and technologies have surpassed the language used in the CIP standards. Regardless, ITC recommends revising the CIP-005, CIP-007, and CIP-010 standards that reflect BES Cyber Systems to address virtualization.

We agree that controls should be applied at the device level, however, there should be specific language instead of vague and ambiguous language regarding virtualization. For instance, if a hypervisor is installed on a physical server device it should be stated that the guest OS's are all part of the same cyber asset classification. To add further clarity, if the hypervisor and physical server host BCAs then all devices should be BCAs.

The standard should offer exceptions for other methods of virtual and physical separation such as virtual firewalls, virtual switch instances, and other technologies that offer security between virtualized networks or hosts. Vendors such as CheckPoint offer VSec (a technology used to spin up virtual firewalls) both at hypervisor and host levels. Other vendors such as Cisco offer ACI technology on their Nexus 9000 switching platforms. These allow for a single layer 2 network to have enterprise security groups which isolate devices and hosts from each other.

Aaron Austin - AEP - 3,5

Answer	Yes
Document Name	

Comment

AEP has observed that Regional Entity compliance staff expect evidence at the Cyber Asset level even where the applicability to the standard is at the "Cyber System" level. Regarding the definition of Cyber Asset, AEP believes the best approach is to modify the definition of Cyber Asset to make it general enough to encompass virtual machines or virtual Cyber Assets. Additional recommendation would be to evaulate inconsistencies of Applicable Systems and Measures columns.

Comment

This is an ongoing problem that extends beyond virtualization. The SDT should consider using the Applicable Systems column to address distinctions between BES Cyber System application of requirements and BES Cyber Asset application on an explicit and per requirement basis.

Is there a recommendation include in the auditors audit guide about the ways the control should be implemented? (at the *BES Cyber Asset* or *device* level) If it's the case this guide needs to be updated.

To incorporate virtualization and address the V5TAG transfer issue to clarify the meaning of the term *programmable* in the current definition of *Cyber Assets*, the SDT is proposing changes to the definition that include defining the term in the singular rather than the plural. Updating the definition to include virtual environments allows the definition of other terms based on *Cyber Asset*, such as Electronic Access Control or Monitoring Systems (EACMS) and Protected Cyber Asset (PCA) to also include virtual environments.

An electronic device (physical or virtual) whose operation is controlled by a stored program that can be changed or replaced by the end user, including the hardware, software, and data in the device. A virtual machine is itself a distinct asset from its host(s).

Kara White - NRG - NRG Energy, Inc. - 3,4,5,6 - FRCC,MRO,WECC,Texas RE,NPCC,SERC,SPP RE,RF

Answer	Yes
Document Name	

Comment

Ideally, the host should be treated as the high watermark of any of the devices (should be able to operate in a mixed mode, as long as demonstratable that none of the other devices have the potential to impact a higher risk impact virtual machine). NRG recommends that the language should be rewritten to accommodate the different nuances that virtual technology presents. Especially concerning the differences between a physical desktop (device level), a standalone virtual desktop (device level), and virtual linked-clone pools (system level) which contain a virtual base/parent image and their linked clones (cloned children images). The requirement is written such that the auditors are bound to look at the system level, but all of the standards have to be applied at the device level. Ultimately the choice should be up to the entity to define how they want to set up their Virtual Environment as long as all of the security controls are in place.

We agree with the assumption. This may be the expectation of an auditor. However, more education and guidance may be required for auditors to fully understand the technology being used by industry and how to appropriately audit it.

The requirements do allow protections to be performed at a BCS level. There are some requirements where it is easier to apply a control at a BCS level. This would include malware protection at the BCS level, patch assessment at the BCS level, and event logging at a BCS level. Conversely, there are some requirements where it is easier to demonstrate compliance at the Cyber Asset level. For us, that includes baseline of assets.

When addressing compliance with virtual systems, it will be important to have the controls allowed at the host or template level as long as the entity is capable of showing how the control is inherited by a guest.

The BES Cyber System needs to be more defined. Utilities can declare BES Cyber Systems pretty much how they see fit. This means the SDT must enforce compliance at the device level since the ‘system’ concept is still inconsistent. Provide better examples of what a ‘system’ is and how it can be audited. CIP-007 and CIP-010 require verification of things like ports open, software versions, and logging that can only be checked at the asset level, not the System Level.

Duke Energy agrees with the assumption of the SDT that auditors have been expecting entities to demonstrate compliance at the device level. We recommend that greater efforts be made so that a measure will support/reinforce the level of control set forth in the requirement. Secondly, we feel that more coordination between a standard drafting team and auditors may be beneficial. In some instances, a standard could be audited differently than what an SDT had intended. Perhaps auditor representation, or SDT members that have audit experience may be beneficial to have on an SDT as well.

Anthony Jablonski - ReliabilityFirst - 10	
Answer	Yes
Document Name	
Comment	
The present definition of BES Cyber System is very broad, as it is a grouping of BES Cyber Assets to perform one or more reliability tasks. As a result, Responsible Entities have been observed to implement this definition in many ways, from the one-to-one mapping of BES Cyber Assets into BES Cyber Systems to the other extreme of grouping all BES Cyber Assets at one impact level into a single BES Cyber System. This wide range of implementation has made evidence sampling at the BES Cyber System level impossible, forcing audits to focus on BES Cyber Assets rather than on BES Cyber Systems. Also, the term “reliability tasks” has not been defined, and this appears to contribute to the variety of groupings of BES Cyber Assets into BES Cyber Systems. If the concept of the BES Cyber System is to become truly useful, the definition must be modified such that the BES Cyber System becomes a small grouping of BES Cyber Assets that performs a specific function. It may be beneficial to identify a list of functions performed at each type of physical asset, Control Center, substation, and generator. A starting point for such a list can be found in the NERC CIPC document, “Security Guideline for the Electricity Sector: Identifying Critical Cyber Assets,” dated June 17, 2010. While obsolete for the current Standards, this document provided an extensive list of the types of functions performed at each physical asset.

Requirements and controls should be still enforced at a BES Cyber System level, but evidence should be provided at a device level. In virtualization and Software Defined Data Centers infrastructure is typically policy driven, meaning IT Engineers specify the ways systems should work via configuration files that apply to all systems within that container. Virtualization in particular adopted this methodolgy very early on in deployment. Therefore, applying rulesets at a system level (i.e.: All Hypervisors must require vendor-signed installation packages) makes sense -- we would want all nodes of the cluster to operate the same. However, evidence should be gathered at the device level (i.e.: provide evidence that hypervisor Cluster01-Node5 only allows vendor-signed installation packages). NIPSCO OT has already taken this stance and it seems to be the best way to manage and maintain compliance.

Brandon Cain - Southern Company - Southern Company Services, Inc. - NA - Not Applicable - SERC

Answer	Yes
Document Name	

Comment

Southern Company agrees with the SDT assumption. Version 5 introduced the BES Cyber System concept; however, for most of the high and medium impact requirements, auditors expect Responsible Entities to demonstrate compliance at the device level rather than the system as a whole. To address this issue, the SDT could add system-level implementation examples to the Guidelines and Technical Basis along with new system-level evidence examples to the measures of the requirements. Southern agrees that the current standards have a “everything is a Cyber Asset and all requirements apply to all devices” framework which can present numerous issues when applied to the seemingly endless variety of programmable electronic devices in the entire Bulk Electric System. The “per device capability” phrasing helps but often requires research and documentation to prove the negative in its own right.

The current CIP V5 standards allow for the implementation and documentation for virtualization. However because some features of virtualization are not clear, additional guidance should be considered for the implementation of mixed virtual environments, hardware pooling, and temporary virtual machines.

Warren Cross - AEP - 1,3,4,5 - WECC,Texas RE,SERC,SPP RE,RF, Group Name ACES Standards Collaborators

Answer	Yes
Document Name	

Comment

ACES does believe the current standards are designed at the BES Cyber Asset or device level. The CIP standards were created to protect industrial controls systems that impact the BES within 15 minutes. Virtualized machines are not designed with those cyber systems in mind. How can an auditor audit a virtual system that exists in one minute and is gone the next? The two worlds, assumption and architecture do not mesh well, if at all. We would like to see a completely new set of standards that reflect the intangibles of virtualization, storage and networking without being tied to 5 year old definitions and concepts of NERC CIP.

OPG agrees that much of CIP is implemented and audited at the individual asset or device level. However, it is not unreasonable to have both a device level and a system level focus. Indeed, device level inadequacies are often mitigated by system level compensatory measures. SDT should continue to allow flexibility in how some risks are addressed where either level might be appropriate. In addition, it may be useful to consider introducing another level for virtualization host resources to address the systemic risks they introduce, as touched on in later responses.

AZPS agrees with the SDT’s assumption that most auditors expect entities to demonstrate compliance at the device level and that it can introduce inconsistencies in the treatment of physical or virtual assets. However, AZPS respectfully submits that there are additional areas of potential inconsistency that would need to be evaluated and addressed (where determined necessary). AZPS identifies the following areas of inconsistencies for the SDT’s consideration:

- Potential for inconsistent language between the Requirement and associated Measure;
- Potential for inconsistency in audit approaches between regions and/or regional audit staff and the audit documentation utilized during a registered entity’s audit, e.g., interpretation of RSAW “blue notes,” use of sampling tools and methods, etc.; and
- Potential for inconsistency between the language of the Requirement and associated Measure and the audit approaches, as discussed above.

All of these areas of inconsistencies must be considered by the SDT as the addition of virtualized devices has the potential to significantly complicate both compliance and audit approaches and, without clarification regarding these, inconsistencies could introduce complexity, ambiguity, and inefficiency. For example, where a requirement is applicable to a virtualized system, will each component of that system be evaluated or will the system be evaluated at the system or “common” platform level. Additionally, where such systems communicate with external networks or devices, there will need to be a common understanding of how compliance will be evaluated as controls may be “common” under certain configurations and, therefore, applied at the management plane for distribution across all data planes. For these reasons, AZPS recommends that the SDT evaluate each of these potential inconsistencies as it moves through the standards drafting process to minimize the potential for ambiguity and inconsistency by and between both registered and regional entities relative to the demonstration of compliance and the methods and documentation for compliance monitoring.

All of these areas of inconsistencies must be addressed by the SDT to ensure that both registered and regional entities have consistent understanding of the demonstration of compliance and the methods and documentation for compliance monitoring.

2. The SDT proposes that each virtual machine and hypervisor are separate Cyber Assets. Do you agree with this position? Please provide a rationale to support your position.

(Refer to the Unofficial Comment Form for more information on this question)

Joseph Mosher - EDF Renewable Energy - NA - Not Applicable - WECC

Answer	No
Document Name	

Comment

The answer to this question is no since a hypervisor is defined as software that allocates resources to VMs. Therefore, a hypervisor should not be a Cyber Asset. The hardware running the hypervisor software should be labeled as a Cyber Asset. This distinction should be clear for all future requirements. Virtualized hardware (VM), and its associated OS, should be classified as Cyber Assets.

Response

Julie Hall - Entergy - 6, Group Name Entergy/NERC Compliance

Answer	No
Document Name	

Comment

The hypervisor’s host machine and the virtual machine are the separate Cyber Assets. The hypervisor is computer software or firmware that creates or runs the virtual machine, but does not have its own OS or system to enforce CIP controls, similar to a SCADA application running on a server. With regards to protecting the hypervisors, controls should be implemented on the host machine.

Mike Smith - Manitoba Hydro - 1,3,5,6

Answer	No
Document Name	

Comment

The new definition does not address a Cyber Asset with virtualized storage which should be treated as separate Cyber Assets. The definition offers no guidance for identifying virtual Cyber Assets. A methodology is required for example, start with the function performed, then identifies each component –

Virtual Machine, storage, host and hypervisor using a high water mark. The proposed definition uses the term “[A virtual] electronic device”. A virtual Cyber Asset is not an electronic device, or a device at all. A function, for example providing control of a BES element, could be completed by a software program that runs on a vitual operating system (OS). This virtual OS is its self software, the operation of which is controlled by a hardware hypervisor. The vitual system does not function on its own, the identification of components of the system must be addressed by the standard. Managing each component can be done separately.

The definition does not address how to handle a hyper converged environment where building blocks can include storage, network compute and memory resources.

Rachel Coyne - Texas Reliability Entity, Inc. - 10

Answer	No
Document Name	

Comment

Texas RE does not agree with the SDT’s proposal to treat each virtual machine and hypervisor as separate Cyber Assets. The hypervisor (parent) is the device or software which runs the virtual machine (child). The virtual machine (VM) cannot operate without the hypervisor. This shared relationship means that neither can be separate Cyber Assets. For example, if a VM has been identified as a BES Cyber Asset (BCA); the hypervisor that runs the VM is also a BCA; which also applies to PACS, EACMS, and PCA’s

Treating the VM and hypervisor as separate Cyber Assets can cause mixed-trust virtual environments; the hypervisor runs CIP and corporate VM’s. CIP controls are only being applied to the CIP VM and not the hypervisor; even though the hypervisor “*if rendered unavailable, degraded, or misused*” can impact the CIP and corporate VM’s.

AZPS agrees that each virtual machine and hypervisor are separate Cyber Assets. To ensure clarity, AZPS asserts that virtualized assets, if represented by physical hardware, would meet the current definition of Cyber Asset. Thus, simply virtualizing these assets does not change their criticality or role in the operation of the BES and, as such, these virtualized assets should still meet the definition of Cyber Asset. Moreover, hypervisors running on hardware that manage the resources for virtualized Cyber Assets would also meet the definition of Cyber Assets. Without these physical Cyber Assets, the virtualized Cyber Assets cease to exist. Because these virtualized assets can be identified, classified, and evaluated as Cyber Assets, AZPS strongly recommends that the SDT consider opportunities to modify the existing CIP requirements to expand or clarify that their applicability extends to virtual AND physical Cyber Assets. AZPS understands that there may be some requirements that will not directly apply, e.g., CIP-007-6 R1, Part 1.2's physical port protection requirements would not be applicable to virtualized Cyber Assets. Nonetheless, because these virtualized assets meet the definition of Cyber Asset, they have similar capabilities to meet the majority of the current requirements language. Thus, review and revision to the existing requirements would allow the requirements applicable to all Cyber Assets (based on capability) to be consolidated, which would reduce the potential for confusion and ambiguity given the physical and virtualized nature of virtualized devices and increase the likelihood for the application of consistent approaches by both Regional and Registered Entities.

Based on modifications to the definition of Cyber Asset, each host and virtual machine can be separately managed and, therefore, should be distinct Cyber Assets. However, AE finds the use of the term "host" problematic when used in connection with a virtual machine. Host is very general and typically refers to servers and systems. AE would recommend using the following definition: An electronic device (physical or virtual) with its operation controlled by a stored program which the end user can change or replace and includes the hardware, software and data. A virtual machine is itself a distinct asset from its hypervisor-host.

EEI agrees that a virtual machine is distinct from a hypervisor. The guest machine or virtual machine is what the hypervisor manages/controls on a host machine. Host machines are another distinct component in the virtualization environment; however, we have found that the host (or VM host) and hypervisor may be used interchangeably or the hypervisor term may include the host machine. It would be helpful for the SDT to clearly define these terms so that all Responsible Entities, the ERO, and other stakeholders are using the same meaning for each term. A common lexicon that can be applied to all virtual or logical technologies will be required to enable all stakeholders to understand the concepts being presented by the SDT.

This clarifies, the definition of the term *programmable*. See note above about the flexibility of what is a virtual machine. The entities should be allowed to define how they setup their virtual environments. We agree with the first sentence and how it is defined. The second sentence should be modified to allow the entities to determine whether the Hypervisor and its children are a BES Cyber Asset or multiple BES Cyber Assets.

While this distinction may help to alleviate confusion, virtualization is a complex subject where incorrect or interchangeable use of these technical terms could lead to misinterpretation. ATC recommends that the SDT consider providing additional clarity around these terms through guidance and examples without officially them. ATC recommends that the SDT resist the temptation to reinvent/redefine these terms as historically this approach had the	

unintended consequences of creating ‘new terms’ that are too prescriptive, do not scale to ever-changing technology, and/or contradict or otherwise render commonly acceptable technological terms moot.

- Agree that “virtual machines” should be treated as separate cyber assets because applying the CIP requirements to “host devices” without recognizing that “virtual devices” are, in actuality, being managed as individual logical devices is fundamentally counterproductive and introduces many artificial, confusing, and unnecessary dilemmas.

- However, special consideration likely should be given to “host devices” as they represent a new systemic risk to potentially many hosted, dependant BCSs.

- Furthermore, the real risk of virtual machine “escape” attacks (ref: https://en.wikipedia.org/wiki/Virtual_machine_escape) is difficult to address but should be acknowledged. Virtualization discussions presented so far have not mentioned this low probability but very high impact risk. A successful such attack would put at risk all virtual assets in the host environment at once by taking control of the virtualization manager (or CMS). In light of this new, elevated risk, should it be acceptable, for instance, to host “non-CIP” virtual machines on a host shared with CIP virtual machines? It might be advisable, for instance, to deem “non-CIP” virtual assets as PCA equivalents unless some agreed upon mitigating measures are met to better protect the host devices and manager. An example of such a measure might be having the CMS non-virtualized and protected by non-virtual firewalls (i.e. The CMS would not be self-hosted). This is similar to separation of management and data planes addressed in question 7, however either variation might not be sufficient to mitigate these virtual machine escape attacks.

- As a minor matter of terminology, the “hypervisor” is more akin to an operating system and not the actual physical host hardware. As such, use of terms such as “host device” or “host cyber asset” would be more appropriate in the question wording than “hypervisor”.

Brandon Cain - Southern Company - Southern Company Services, Inc. - NA - Not Applicable - SERC

Answer	Yes
Document Name	

Comment

Southern Company agrees each virtual machine and hypervisor are separate Cyber Assets. The purpose of the hypervisor is to manage one or more virtual machines. Virtual machines provide the same functionality of a physical computer or a Cyber Asset. Since many of the CIP requirements are at the device level, we view each instance of an OS as its own Cyber Asset and we agree it is not simply a disk image data file or application.

The virtual machine represents a separate and unique attack surface from the underlying hypervisor and therefore needs to be protected as a distinct asset. Treating the hypervisor and guest virtual machines as a single device confuses physical and virtual domains and doesn’t make sense from a practical standpoint. For example, management of the ports/services of the hypervisor with numerous virtual operating systems running on the same physical hardware becomes very difficult.

It is impossible to secure a guest VM and the physical hypervisor using the same technology in a requirement. For example, we would have BIOS firmware to maintain on the hypervisor. We do not have that in a virtual machine. Likewise, there are security updates for Windows guest Operating Systems that is updated much more frequently than the hypervisor -- however a vulnerability in the guest operating system does not impact the host hypervisor, and therefore it is critical to treat the two as separate entities. NIPSCO OT has always considered the hypervisor and the guest VMs as separate entities even under CIP Version 3.

Comment

AEP recommends the lead-in sentence be reworded as follows, “The SDT proposes that each virtual machine and host are separate Cyber Assets.” The hypervisor is a piece of software running on the host and serves as an abstraction layer between the virtual machines and their physical host. Accounting for physical hosts and virtual machines separately is appropriate as they are often managed and supported as separate entities.

Comment

For some common virtualization platforms (VMWare, XenServer), there appears to be clear separation between the host OS and guest OS’s. This is evidenced by the ability to update the hypervisor OS and VM OS’s independently of each other. However, this does not preclude a design existing where there is much tighter integration between the Host OS and Guest OS’s which blurs any separation. Also any system in which VM’s are dynamically created and destroyed based on workload (e.g. dynamic provision) could complicate treating each VM as a distinct asset as opposed to an instance of an application.

Any device that communicates should be considered a separate cyber asset. For example, the host physical machine that has an installed hypervisor would have ethernet interfaces for the hypervisor as well as interfaces for the virtualized devices. The virtual machines could be connected to a virtual switch which is connected to the physical Ethernet interface of the host/hypervisor machine. Therefore, any device that communicates and performs a dedicated function should be considered a separate cyber asset.

BPA agrees that the proposed definition of Cyber Asset must include virtual machines (see caveat in question 3 regarding "data inside the device"). BPA believes that both "virtual machine" and "hypervisor" are well-understood terms with formal definitions (NIST SP 800-125, SP 800-125A {Draft}, SP 800-125B) and broad IT Industry acceptance, thus do not need further definition in the NERC Glossary. BPA agrees that each Hypervisor and Virtual Machine is a distinct Cyber Asset. Controls and strategies for securing virtual machines across a variety of industries have been published by agencies such as NIST and SANS.

The key issue the SDT appears to address in this revised definition is clarifying the scope or boundaries of a given virtual cyber asset in order to apply requirements and controls to each. Clarifying the definition is only necessary to address gaps in current requirements language that allow for miss-applying the requirement. BPA believes Industry understands and can securely apply the technical controls.

3. Do you agree that the proposed Cyber Asset definition clarifies the term *programmable*? Please provide a rationale to support your position.

(Refer to the Unofficial Comment Form for more information on this question)

Aaron Cavanaugh - Bonneville Power Administration - 1,3,5,6 - WECC

Answer	No
Document Name	

Comment

BPA agrees that the SDT's proposed definition of *programmable* encompasses a device subject to hardware and software changes by the end user.

However, BPA disagrees that the definition should apply to the data stored in the device.

- Data inside the device is peripheral and irrelevant to the operation of the device.
- The use of *data* in the current definition of *Cyber Asset* does not match Section 215 of the Energy Policy Act of 2005 that reads: "…programmable electronic devices and communication networks including hardware, software and data **that are essential to the reliable operation of the bulk power system**."
- Best practice IT Security across a broad spectrum of industries typically separates the mechanisms of protecting a *system* (better known as *Information Assurance,* Source: NIST SP 800-50, CNSSI-4009) from the mechanisms of protecting *data* transiting or resident on that system (the latter being *Information Security,* Source: NIST SP 800-59; SP 800-53; SP800-53A; SP 800-60; CNSSI-4009; FIPS 199; 44 U.S.C., Sec. 3542).
- The introduction of the concepts of *management plane* and *data plane* which are referenced in question 8 is a useful addition to the NERC CIP discussion because it enables appropriate controls to specifically protect systems or data.

Sean Bodkin - Dominion - Dominion Resources, Inc. - 3,5,6, Group Name Dominion

Answer	No
Document Name	

Comment

Dominion does not recommend a change to the current definition of Cyber Assets. If a change to the definition is made, Dominion recommends using the more generic term “logical” instead of “virtual”, as outlined below. The term “logical” would encompass any virtual environment including dual-bootable OS machines. Additionally, the phrase, “*including the hardware, software, and data in the device* “ is misplaced and should be moved. Finally, Dominion proposes that the term “machine” should be replaced by “device” for consistency:

Recommended language change:

“An electronic device (physical or virtual logical), including the hardware, software, and data in the device, whose operation is controlled by a stored program that can be changed or replaced by the end user, including the hardware, software, and data in the device. A virtual logical machine device is itself a distinct asset from its host(s).”

Response

Chris Scanlon - Exelon - 1,3,5,6

Answer	No
Document Name	

Comment

Exelon does not agree that the proposed update to the Cyber Asset definition sufficiently clarifies the meaning of “programmable.” The addition of the language “a stored program that can be changed or replaced by the end user” can be interpreted to extend the scope of the CIP requirements down to all field-updateable devices. This includes chipsets that are configurable but not programmable. If changing the device requires physical removal of a chip or any other disassembly or destruction of the device to change or update the device, then the device should be categorized as “not programmable”.

The CIP-002-5: BES Cyber Assets Lessons Learned published by the NERC CIPV5 Transition Program provides examples of what the study participants used to address “programmable” during the implementation of the CIPV5 standards. Specifically, page 3 states: “study participants set the scope to be evaluated as those devices that have a microprocessor and can accept firmware, software or logic. Additionally, the study participants considered devices that had a physical or wireless port or a web interface that can be used to “flash” firmware to be Cyber Assets and then evaluated them to determine whether they meet the BES Cyber Asset definition.”

Since the term “Cyber Asset” is foundational to the entire suite of CIP Standards, Exelon is concerned with the removal of the word “programmable” and changes to the Cyber Asset definition unnecessarily prompting an entire reassessment of our Cyber Assets. Exelon has an internal definition of “programmable” that is consistent with the BES Cyber Asset Lessons Learned and encourages the CIP SDT to use a similar approach. If the CIP SDT determines to make adjustments to the Cyber Asset term, any updates to clarify “programmable” should make use of example statements that are consistent with the published Lessons Learned and not replace the word “programmable” within the Cyber Asset definition.   Additionally, Exelon would support the addition of a statement to the Cyber Asset definition that clarifies that “A virtual machine is itself a distinct Cyber Asset from its host(s).” Exelon does not believe that it is necessary to add the parenthetical reference “(physical or virtual)” to the Cyber Asset definition.

Preston Walker - PJM Interconnection, L.L.C. - 2 - SERC,RF

Answer	No
Document Name	

Comment

PJM suggests removing “by the end user.” A stored program that can be replaced or updated “by the end user” does not take into account the principle of least privilege. End users should not have the ability to update software, but rather to only perform system functions relevant to their roles. For example, a server is a programmable device, but the operating system software and firmware cannot be updated by end users – only by system administrators.

Response

Lan Nguyen - CenterPoint Energy Houston Electric, LLC - 1 - Texas RE

Answer	No
Document Name	

Comment

CenterPoint Energy believes the proposed Cyber Asset definition does not clarify the term programmable and is not clear where "data in the device" is concerned. In a virtual environment, the data accessible to a virtual machine (VM) is still "in" the hypervisor, but not accessible to it. Data stored on a storage area network (SAN) may not be accessible to the administrator of the SAN, but only authorized users of the SAN. CenterPoint Energy believes the clause "including hardware, software, and data in the device" does not add value and clarity to the Cyber Asset definition and should be removed.

As an alternative, CenterPoint Energy recommends addressing data that is either a) accessible by an authorized user of an asset; or b) data that is impacted by the availability of an asset, but not accessible to an authorized user of that asset. The latter case could be data stored in a VM or container that can be made unavailable by actions of the hypervisor administrator, but is not accessible or modifiable by the administrator. Data that is not accessible to users of a device cannot be modified by programmable instructions, and therefore might be excluded from the definition.

Response

Scott Downey - Peak Reliability - 1

Answer	No
Document Name	

Comment

Creating a definition specific to the CIP standard does not benefit the SDT or the industry. Standards-based language should be used for these kinds of terms, not newly created terms with questionable interpretations. For example, why use the terms "Cyber Asset" and "programmable"? Why not use the dictionary definition of a "Computer" as "an electronic device for storing and processing data, typically in binary form, according to instructions given to it in a variable program", followed by giving specific examples of what the SDT considers to be a "Computer" in scope of the standard?

Response

Anthony Jablonski - ReliabilityFirst - 10

Answer	No
Document Name	

Comment

While the change does help clarify the term “programmable,” other issues have been introduced. In addition, the phrase “that can be changed or replaced by the end user” is both ambiguous and ill-advised from a security perspective.

The phrase is ambiguous in that it can be construed as broadly as a laptop PC that has been locked down by its administrators so that the end user cannot modify the programming, only the data.

However, even if the definition is changed to something like “a stored program that can be changed or replaced only by direct intervention in the hardware,” this will still leave many devices out of scope. It can be argued that these devices are some of the most risky devices in a Responsible Entity’s inventory, as any programs on these devices cannot be patched even when vulnerabilities are found. As an example, see “https://krebsonsecurity.com/2016/10/hacked-cameras-dvrs-powered-todays-massive-internet-outage/”.

Changing the definition of Cyber Asset such that these devices are not included in the required CIP protections, but will be out of scope for the CIP Standards (and thus completely invisible to audit teams) should not be considered acceptable.

This definition does not take the distinction between configurable and programmable as was discussed under the V5 project into account. This new definition would seek to include devices that are configurable (i.e. via dip-switches) as changes to these predefined configurations/inputs would result in a change to a stored program by an end-user. Devices that have embedded programming that cannot be changed by end users, except through pre-defined configurations/inputs should be excluded.

Prefer leaving the use of the term “programable” in the definition as is. Entities may have an internal definition in their existing CIP compliance program. Changing this foundational concept has multiple far-reaching impacts. Modifying the Cyber Asset definition to address scripts and irmware is unnecessary since they are already covered in CIP-010. Guidance could be added to CIP-002 on possible defintinos of the term “programable”.

Brandon Cain - Southern Company - Southern Company Services, Inc. - NA - Not Applicable - SERC	
Answer	No
Document Name	
Comment	
Southern Company does not agree with the proposed changes to the Cyber Asset definition. The current Cyber Asset definition is an integral part of the the CIP Standards. Modifications to the Cyber Asset definition would require a review of the current compliance documentation for thousands of devices. NERC has provided implementation guidance on defining BES Cyber Assets that Southern finds sufficient regarding the term programmable. The SDT should add guidance, and measures to enable the secure use of virtualization in the CIP environment.

I don’t think it is clear as to how that included virtualization. Is a virtualized storage device, programmable? Trying to fit virtualization concepts into Cyber Assets that are tangible is problematic. I would recommend using a NIST Virtualization Guidance and have two set of standards. That perform functions in different way, terminology and capabilities.

EEI does not support any modifications to the Cyber Asset definition because it is foundational to the existing implementation of the CIP Standards. Any change will create a significant compliance exercise that requires burdensome compliance paperwork review and updates with no benefit to the reliability of the BES. Instead of modifying definitions, the SDT should seek to add requirements, guidance, and measures to enable the secure use of virtualization in the CIP environment.

NV Energy does not believe that the proposed definition clarifies the term programmable. A possible alternate definition could be: An electronic device (physical or virtual) that is controlled by a stored program and has a locally or remotely accessible input interface such as a management port or a web interface that would allow the introduction of firmware, software, or a logic update. NV Energy does have some concerns with the changing of the Cyber Asset definition. Because this definition is the foundation to the existing CIP Standards any change will create a significant compliance exercise that requires burdensome compliance paperwork review and updates with no benefit to the reliability of the BES. Instead of modifying definitions, the SDT should seek to add requirements, guidance, and measures to enable the secure use of virtualization in the CIP environment.

AZPS respectfully asserts that the proposed definition introduces new areas and potential for ambiguity and confusion relative to the term "programmable." In particular, AZPS identified the following questions:

- Where is/can the "stored program" stored?
- Can it be stored on a separate Cyber Asset for the control of a virtualized or different asset?
- Who is the "end user" and how is "changed or replaced by the end user" defined?
- Does such change or replacement have to be performed directly by the "end user" or can it be performed by a third party through a contractual service obligation?
- Does the phrase require that an "end user" have the actual technical or other capability to make such a change or replacement before the asset would qualify as a Cyber Asset?
- If an "end user" has no one on staff that can change the stored program and no service provider, is the asset not considered a Cyber Asset?

Given the potential confusion associated with these questions, AZPS offers the following definition of Cyber Asset:

"A physical or virtual electronic device containing operating system(s), software, and/or firmware which programming and configuration can be modified.

Physical electronic devices include the hardware, software, and data in the device.

A virtual electronic device includes its virtual hardware, software, and data, and is distinct and separate from its physical host(s)."

It seems clear from the definition that what is being talked about is re-programmability—the ability for a devices function to be changed, which obviously has cybersecurity implications that a hard-coded, un-alterable device does not. Whether a device is virtual doesn’t seem to alter they fact that it may be re-programmable.

The updated definition accounts for the ability to change hardware, software, and data for an asset. This provides for firmware, data, and other software that can change or update the functionality of the device and hence is programmable. This differs from a fixed device that is purpose built to perform one action and cannot change hardware, software, or data to change the functionality.

We suggest "computing" rather than "electronic". Please give a definition of “end user” that includes administrators. However, I think it is beneficial to retain “by the end user” because this limits the inclusion of additional devices that might not apply because they are not truly programmable as in the ability to be provided with coded instruction for performance of an automatic task either serially or through Ethernet. I disagree with this alternative. I think the 4th alternate example is the best suggestion with the added language regarding the virtual machine.

This new definition is significantly clearer and leaves must less room for interpretation. This aligns closely with how NIPSCO OT has deployed virtualization, treating every virtual machine as it's own BES Cyber Asset. **However** I would caution that the SDT somehow accounts for things such as the firmware on a hard disk. Firmware on a disk controls the operations of the drive, which especially in enterprise-grade hardware is certainly modifiable. I do believe it is the intent of the SDT that hard drives, peripherals, etc of the asset are all logically grouped together, providing they're managed together. For example, most of our servers get hard drive firmware as part of the server firmware package. The server as a whole is placed at a certain firmware version, which includes hard drives. I would suggest that if a Storage Area Network was used to store the data for a device the

Storage Area Network device should be maintained separately from the collective BCAs. Hard Drives, IO cards, etc should all be considered part of the same BES Cyber Asset. While this new definition is much clearer, some additional scope restrictions would further reduce confusion.

Yes, this definition better describes the essence of cyber assets and their malleable nature versus devices whose functionality is permanently set. There is yet some concern that devices that may appear “permanently set” or “non-programmable” might actually consist of common programmable computer architectures “under the hood” and that this might be something of a loophole. If an irresponsible vendor of such a system elects not to disclose the internals of a device and refuses to release updates of any type, then the device could harbor CIP related concerns, elevated for lack of updates, and yet still not qualify as a cyber asset under the proposed definition. This concern might be partially addressed by dropping the words “*by the end user*”.

While the Cyber Asset definition is foundational to the existing implementation of the CIP Standards, in its current form it does not go far enough to adequately capture the devices that should be under the purview of the standards. ATC supports the revised definition and recommends the SDT consider replacing the word “program” with the word “executable code” for added clarity. The use of the word “program” might may have the unintended consequences of bringing in digital logic based devices.

Agree with the below rationale for question #5.

Concerning virtual networks, network devices can have multiple logical networks configured (e.g. virtual local area networks (VLANs)). Physical or virtual devices perform "logical isolation" when configured such that some network interfaces are available inside an ESP, and other interfaces are outside an

ESP and the two networks cannot communicate with each other inside of the device. This would not prevent the VLANs configured inside the device from communicating through an EAP.

CIP-005-5 does not need to explicitly address virtualization. The Standard is adequate as written, and allows for the use of virtualized systems within an ESP boundary. Mixed-used virtualization which crosses ESP boundaries is an insecure practice, because any vulnerability in hosted systems can expose networks and host that share the same hypervisor.

We are concerned about scope creep into non-BCA CIP assets, e.g. EACMS. Virtualized EACMS should not inherit the same protections required of BCS.

Response

Aaron Austin - AEP - 3,5

Answer	No
Document Name	

Comment

AEP recommends the SDT modify the guidelines and technical basis of CIP-005 or other standards to include additional language supporting the hosting of multiple impact ratings on the same Cyber Asset. The impact ratings of BCS comprised, in part or in whole, of virtual Cyber Assets can be independent of the impact rating of the physical Cyber Asset host. Cyber Assets hosting virtual Cyber Assets are assigned the impact rating of the highest impact BCS or highest impact rating EACMS, PACS, or PCA it hosts. A "non-CIP Cyber Asset" hosted on a CIP Cyber Asset would not have an impact rating imparted on it. Responsible Entities should be expected to demonstrate segmentation between virutal Cyber Assets of differing impact ratings. Further, AEP recommends the SDT develop reference architectures accounting for potential use cases.

Yes. Assuming that virtualization is permitted for BES Cyber Systems, which AZPS supports, to the extent possible, AZPS recommends revising and/or clarifying through revisions to defined terms that the existing CIP Reliability Standards (such as CIP-005) are applicable to virtualized devices. Additionally, AZPS recommends that the SDT clearly address the following:

- Whether or not non-CIP Cyber Assets are permitted to operate on physical infrastructure used by virtualized CIP Cyber Assets;
- Whether CIP Cyber Assets of different impact ratings are permitted to operate the physical infrastructure used by virtualized CIP Cyber Assets;
- How a Registered Entity should extend CIP-005-5 controls through lower level elements of a virtualization stack, such as a hypervisor or other shared virtualization services;
- Whether, if BCS(s) of different CIP-002 impact ratings reside on the same physical/shared virtualization environment, all BCS would be subject to a “high-water mark” requirement based on the highest impact BCS utilizing the shared environment.

There is the concern, as raised in response 2, of "escape attacks", which it might be appropriate to acknowledge or address in part or in full in CIP-005. As discussed in response 2, it may be prudent to require more stringent risk mitigation approaches before allowing mixing of CIP and non-CIP Cyber Assets on a shared host resource or else all otherwise non-CIP virtual assets would be held to the PCA requirements. It would perhaps be advisable to explicitly state that all virtualization host devices which host CIP virtual BCAs would in turn be classified as BCAs. This could tie in with the idea of a third level to complement the device and BCS levels as discussed in response 1 and 2. Finally, in the case of software defined network "switches" that reside completely in the virtualization platform as an instantiated component of that platform, it is currently unclear if that would be regarded as a separate virtual cyber asset, as would be the case with a virtual machine or physical switch. In many cases these virtual networking components aren't managed in a way that's analogous to their physical counterparts (no user accounts, passwords, patching, etc.) because they are managed entirely in the "management plane". Do they need be treated as a distinct virtual asset?

From the CIP compliance standpoint, one of the reasons to isolate virtualized environments, whether physical or virtual, is to allow for different impact level for each environment. It is unclear at this time, the SDT's intent in allowing mixed mode configurations. As currently written, CIP-005-5 requires all components contained in a virtual system to be protected at the impact level of the highest single component of the system. CIP-005-5 would need to be revised to allow for mixed impact levels within a single virtual host.

Current CIP-005 does not describe how to handle these boundaries or if any additional protection / configuration is required. The current CIP-005 is based on physical connections and a physical inspection. This does not work well at all with virtual systems. If a virtual host spans multiple networks, the standards must address how to treat each component of the virtual system. There must be some framework for grouping of systems on a host such that guest systems of a different security level are not mixed with high security systems.

From the CIP compliance standpoint, one of the reasons to isolate virtualized environments, whether physical or virtual, is to allow for different impact level for each environment. It is unclear at this time, the SDT's intent in allowing mixed mode configurations. As currently written, CIP-005-5 requires all components contained in a virtual system to be protected at the impact level of the highest single component of the system. CIP-005-5 would need to be revised to allow for mixed impact levels within a single virtual host. Concerning virtual networks, network devices can have multiple logical networks configured (e.g. virtual local area networks (VLANs)). Physical or virtual devices perform "logical isolation" when configured such that some network interfaces are available inside an ESP, and other interfaces are outside an ESP and the two networks cannot communicate with each other inside of the device. This would not prevent the VLANs configured inside the device from communicating through an EAP.

NRG recommends that the standards need to allow for mixed trust devices as long you can logically separate them. The CIP standards need to be modified to support this because currently they do not address this. Not all companies have the resources to have multiple hypervisors for both CIP and Non-CIP. (The Hypervisor would need to be operated as the high water-mark).

Absolutely! In order to account for the sharing of physical virtualization infrastructure for NERC CIP and no-NERC CIP assets the requirements need to be updated to account for virtual LANs, Virtual Firewalls, and the protection of the base hypervisor and physical infrastructure. It is possible to manage this in a secure and auditable fashion but the current standards do not account for how to collect and verify the correct level of separation and security controls.

Auditors have evolved over time significantly in what they consider mixed trust, making it hard for entities to be inline with a moving target. The standards should clearly define by a deterministic process or via specific examples what the limits are on sharing infrastructure between CIP and non-CIP systems. It may be better to prescribe security controls that must exist when sharing, rather than forbidding the sharing due to the existing of technologies which leverage shared technology while providing significant isolation.

Seattle suggests that the concept of ESP needs to be made even more “logical” in nature, removing all vestige of a physical nature. To achieve this end, it might help to assign the revised concept a new name that does not implicitly imply anything physical (as does the term “perimeter”). Perhaps “electronic security isolation” or ESI?

Seattle further wishes to see virtualization concepts to expanded to address cloud-based systems. We are highly frustrated, for example, that NERC itself appears since early 2015 to have employed cloud storage for sensitive E-ISAC information including CIP incident reports from registered entities (see slide 6 of ES-ISAC Update in: http://www.nerc.com/gov/bot/botsotc/board%20of%20trustees%20%20standards%20oversight%20and%20tech1/sotc_presentations_february_2015.pdf*) and yet has been unable to provide audit guidance as to whether the cloud systems with the FedRAMP protections would satisfy the security requirements of CIP-004 and CIP-011. We encrouage the SDT to address cloud matters if possible.*

Comment

Yes, in order for CIP and non-CIP environments to share a physical infrastructure via a virtualized environment, additional language in CIP-005 would be helpful to provide guidance for what methods are considered to be adequate to overcome risks and provide secure isolation or separation of the environments.

Having said that, Exelon does not currently envision undertaking the risk inherent in utilizing a “mixed” virtualized environment to host CIP and non-CIP VM’s, unless the entire “mixed” environment is afforded NERC CIP protections. In other words, we would not want to trust implementing security only at the software level to isolate virtualized CIP and non-CIP components.

It is BPA’s position that CIP-005-5 would benefit from being modified to a security objective-oriented standard rather than a requirements-based standard. The security objective in this case would be isolation of CIP-applicable Cyber Assets from Cyber Assets that are out of scope of CIP controls.

The mechanisms of that protection are primarily Boundary Protection and Control of Network Ports, Protocols, and Services (SANS 20 Critical Security Controls).

CIP v5 narrowly focuses on routable protocols and Layer 3 controls and does not address the other layers of the OSI model. For example, under CIP-005-5 Layer 2 protocols are not addressed and can convey malware as well as allow information exfiltration and cyber-attacks even if no routable IP communications are present. Controls for these protocols should not be limited to or defined by Layer 3/4 ACLs on a firewall or router as the only or even the best means of achieving in-bound and out-bound access control. Entities need the opportunity to provide technical controls at whatever conceptual layer is appropriate to meet the security objective.

BPA recommends expanding CIP-005 language to include security zones with the ESP construct. When framed in terms of Boundary Protection, a security zone is more inclusive and granular because it is not limited to routable protocols at the OSI Model's Layer 3. A security zone construct does not force any particular interpretation or control onto serial or other non-routable means of transporting data or accessing the management plane of any systems. Security zones apply to physical and logical separation equally. An example of logical isolation provided by other than ACLs would be when a hypervisor provides isolation between Guest VMs or between Virtualized Network Functions. This isolation is implemented in the control plane by means of logic embedded in code base (NIST SP 800-125A – Draft, Section 1.2: Hypervisor Baseline Functions) and not at a conceptual network layer.

Current CIP standards take a broad stroke approach by requiring the protection of all cyber assets within an ESP in a singular manner at the highest impact level of controls. This is not cost effective or flexible enough for individual entities' needs. Security zones provide a scalable means of appropriately protecting Cyber Systems of differing security risks by further isolation within the zone.

Modifications are not required to address the issue since, virtual environments should be treated the same as physical environments.

Such configurations can exist; the hypervisor (physical infrastructure) that is shared between BES Cyber Systems and other non-CIP Cyber Assets must be protected at the impact level of the BES Cyber System.

Furthermore, proper isolation (network segmentation, DMZ, virtual firewalls, vlans, etc,) must be implemented to reduce the risk of non-CIP Cyber Assets impacting BES Cyber Systems (e.g. Denial Of Service (DoS) attack).

Steven Rueckert - Western Electricity Coordinating Council - 10	
Answer	No
Document Name	
Comment	
The current Electronic Security Perimeter definition establishes the protective enclave at a network (Layer 3). This is further identified in CIP-005-5, Part 1.3 access control lists. VLANs (layer 2) have not been an acceptable approach to establishing an Electronic Security Perimeter with a layer 2 switch; the switch cannot afford the required controls of Part 1.3. The SDT should clearly identify at what OSI model layer the SDT is asserting an Electronic Security Perimeter can be established and require controls to ensure isolation.

BPA believes the same modifications necessary to make CIP-005-5 adequate to question 4 would apply to addressing the specific question of 802.1 Q VLANs providing adequate logical isolation in question 5. The security objective should be to provide isolation by means of Boundary Protection as well as Control of Network Ports, Protocols, and Services. Legacy software vulnerabilities that have long since been patched or known exploits that are mitigated through proper configuration should not require the blanket rejection of VLANs as a component of a particular entity’s specific security scheme. Newly discovered exploits and vulnerabilities are addressed through CIP-007 testing and patching, CIP-010 baseline configuration, change management, vulnerability scanning and assessment.

Exelon agrees that the current requirements of CIP-005-5 do not explicitly allow for VLANs providing logical isolation. Exelon has serious concerns that virtual isolation may not be adequately secure, and rewriting the CIP Standards is not the answer. There may not be an acceptable way to revise CIP standards to allow use of VLANs for mixed environments, as the risk for compromise is too high. Virtualization is one configuration mishap away from revoking logical isolations, no matter how well thought out, should the management layer collapse into a single unified network. Employing technology that eliminates the possibility of collapse provides a much more effective mitigation by removing the possibility of any collapse. Firewalls provide an active control environment meeting CIP-005-5 by utilizing a comprehensive security toolset, including rulesets, the deny-all rule, bidirectional controls, scanning for malware, etc. However, a Layer 3 network switch does not have these features, and cannot provide the same level of security. Exelon contends that implementing VLANs using a Layer 3 network switch will not meet current requirements or security needs. While VLANs can be configured to go thru a firewall, the switch itself is still vulnerable to reconfiguration to directly connect separated VLANs. Layers of manual processes to manage the risks are the only alternative, and would be considered weak security as well as additional cost (possibly offsetting any cost-savings from virtualizing). As such, we consider that VLANs are not an appropriate technology to provide adequate security in a CIP environment.

Comment

While traditional network technologies such as VLANs can provide an an easy way to isolate traffic within a network, software-defined networking technology provides a much stronger protection by not forwarding tagged packets in the first place. I assert that methods of isolation are not explicitly addressed within CIP-005-5 and that expanded language should be added to detail additional controls. I also assert that if language such as “physical separation” is used that controls such as software defined networking be recognized as “physical separation.” If a software defined networking Ethernet switch does not have any flow rules programmed into the switch, then there is no physical connectivity (deny by default) with devices attatched to the same switch. Software-defined networking employs a superior approach in that no additional data must be inserted into the header (e.g., VLAN TAG), rather the grouping can be accomplished with flow rules and executed at the packet forwarding devices (SDN Switches) in a highly simplified and automated manner. This ensures the tamper resistant flow of communication, limiting what an adversary could do with a man-in-the-middle attack, e.g., modifying the VLAN tag.

SRP does not feel this is addressed in any of the CIP-005-5 requirements. CIP-005-5 addresses ESPs, which are a layer 3 concept. VLANs are a layer 2 concept. Addressing this in CIP-005-5 would assist with clarifying acceptable isolation. SRP requests clarification regarding why VLANs are a concern. Is using VLANs for isolation a concern because of inadvertent traffic between VLANs (i.e., VLAN hopping)?

What about the shared storage from which the hypervisor serves VMs? Is the entire storage array CIP if there is a single CIP VM on it?

Response

Lan Nguyen - CenterPoint Energy Houston Electric, LLC - 1 - Texas RE

Answer	No
Document Name	

Comment

CenterPoint Energy believes VLANs are a separate topic from "virtualization" as it relates to virtual machines and that the requirements around VMs will be difficult to apply equally to network infrastructure. These requirements, when written, should be separate without an attempt to write one requirement applicable to all virtual technology.

CenterPoint Energy believes the logical protection afforded by a VLAN is well established, having been in broad usage in industry for decades, but has risks not addressed in existing requirements. Entities should be free to maximize hardware utilization through use of VLANs if they choose. The practical examples of VLAN-escape attacks, exploiting default VLANs or the trunk protocol used to manage VLANs, are well known and easily mitigated with switch configuration. The requirements of CIP-005 do not address these mitigations, and the Cyber Vulnerability Assessment may or may not address them. To adopt VLANs securely, CenterPoint Energy recommends creating a new CIP-005 requirement and suggests the following wording: "Implement a process to ensure that a virtual network infrastructure, fully or partially within an Electronic Security Perimeter, is configured to mitigate the risk of VLAN escape attacks."

Furthermore, the terms "connected using a routable protocol within or on an ESP" in the Protected Cyber Asset definition is confusing in relation to virtual machines. CenterPoint Energy recommends clarification to the PCA definition:

1. A hypervisor hosting a BCS virtual machine must be a BCS since it can impact the availability of a BCS within 15 minutes.

2. An asset hosted by a hypervisor in an ESP that is not part of the BCS within the same ESP must be treated as a Protected Cyber Asset.

CIP 005 does not sufficiently address modern network topologies. The use of layer-2 VLANs should be an explicitly acceptable method of segregation for BES Cyber Systems and non-CIP Cyber Assets on a shared physical network infrastructure.

Security measures to protect virtualized workloads can be implemented in an equivalent security posture as a traditional physical workload. Complete datapath isolation can be achieved on routers and firewalls using virtualized routing tables and virtualized operating systems. This virtualized datapath isolation provides a secure foundation for enabling workloads, such as virtual BES Cyber Systems and non-CIP Cyber Assets, to share physical network infrastructure.

If the SDT asserts that VLANs isolation is not sufficient security to protect the ESP from communication beyond the ESP, explicit language forbidding the practice is necessary which would open a can of worms since there will always be emerging security issues too numerous to itemize in regulations. When entities do not use a best-practice, or common-practice approach to security, it is probably not best addressed in CIP regulations, but rather as an evidence-based, educational communique indicating the risk of a certain approach. Any entity that continues to take on such a risk can be later evaluated on their CVA process as to why they are not remediating risks above a certain level.

The SDT should add requirements to address all the risk presented in the virtualization risk map file.

The SDT has identified certain risks inherent to virtualization regarding the use of centralized management automation. The SDT is proposing to classify *Centralized Management System* (CMS) explicitly as a type of applicable system for some CIP requirements. In examining management architecture and risk management for virtual environments, the SDT identified an increased risk inherent to the span of control of hypervisor management consoles. Further, the SDT noted that similar risks exist in CMSs used to manage physical devices, and recognized these risks may not be fully addressed in current CIP standards and the *EACMS* definition. The SDT is considering a new definition of this class of system.

The proposed *Centralized Management System* (CMS) definition is:

A centralized system for administration or configuration of BES Cyber Systems, including but not limited to systems management, network management, storage management, or patch management.

Response

Nathan Mitchell - American Public Power Association - 3,4

Answer	No
Document Name	

Comment

The SDT should consider defining a term such as “Virtual Security Perimeter (VSP)” or modifying the existing ESP term to allow for the isolation fo BES Cyber Assets or BES Cyber Systems using virtual technologies.

While CIP-005 is applicable to High and Medium Impact only, therefore, request the SDT to address VLANs for Low Impact in CIP-003. Currently, a VLAN may be part of the electronic security controls (per CIP-003-6 and CIP-003-7) for a low impact BES Cyber System. The determination by the SDT to allow or eliminate these VLANS in CIP-005 may have an unintended corresponding consequences on the interpretation of CIP-003 for low impact.

Suggest that the SDT provide guidance on the use of the isolation of traffic provided by VLANS as an electronic control.

Brandon Cain - Southern Company - Southern Company Services, Inc. - NA - Not Applicable - SERC

Answer	No
Document Name	

Comment

Southern Company does not agree with the SDT assertion that VLANs providing logical isolation are not addressed in CIP-005-5. The CIP-005 Standard requirements can be applied to VLANs without additional clarification as CIP-005 requires that applicable Cyber Assets must

reside in a "logical border" and any external routable connectivity through that logical border must be through an identified Electronic Access Point, and that EAP must deny all traffic except for what is explicitly allowed. These objectives can be met with physical or virtual networks and logical isolation.

Comment

VLAN implementation is all ready being used and relied on extensively in CIP environments. CIP-003-7 Model 9 also supports use of virtualization, so it seems VLANs have already been adopted as acceptable.

What is not clear is that CIP-005 does not state that CIP related and non-CIP related though isolated on VLANs can be mixed on a single physical switch. Up to this point we have used seperate switches for CIP related traffic and VLANS have been only used to further subdivide the CIP related traffic. For instance into a SCADA network and a DMZ supporting EACMS and PACS. An explicit statement allowing mixed virtually isolated CIP and non-CIP traffic on shared physical host networking devices, and under what conditions, if any, would give more compliance certainty about VLAN acceptibility in these circumstances.

Also, as a second concern, it might be pruduent to disscuss the issue that it is inherently easier to misconfigure virtual networking and VLANS in such a way that a setup is intended and thought to be secure and compliant with CIP-005 but in fact is not, even though it appears to be "working". Mandating an independent review/verification by a second person/party (fresh set of eyes) or actual security testing during comissioniong or some other verification measure might be an appropriate mitigation for this risk in a virtual environment.

ATC agrees that the regulation is not clear as to when layer 2 or layer 3 VLANs constitute access, or the requirement for an EAP on the device configured to use VLANs. Additionally, ATC supports EEI’s comments in that CIP-005-5 is insufficient because it does not enable the use of VLANs for logical isolation since the requirements cannot be met and the use of VLANs (i.e., layer 3 switch) to logically isolate CIP from non-CIP environments does not provide the same level of security as a layer 2 switch with a firewall.

If the host (or hypervisor) carries routable protocol communications destined for both inside and outside of the ESP, then it would itself be a conundrum (it should be a BCA or PCA if inside, but cannot be a BCA or PCA if outside). The current language in CIP-005-5 (and CIP-002, CIP-007, and CIP-010) do not support this current configuration and would need to be modified to allow it.

The current requirements of CIP-005-5 are clear in their assertion that virtualized systems may reside within an ESP. ESPs should be isolated from other networks. Virtualized systems should not cross ESP boundaries. We do not believe that logical controls are sufficient to define an ESP boundary. VLANs should not be permitted to define ESP boundaries.

We are concerned that the SDT is confusing VLANs and hypervisor based virtual switches.

Comment	
Logical isolation is not the equivalent of security isolation. While VLANs are useful within environments containing different levels of trust to reduce broadcast domains and to isolate different types of traffic, VLANs should not be considered a security mechanism used to separate highly critical traffic from untrusted traffic. As traffic not within CIP scope must be considered as completely untrusted by the CIP audit teams, mixing non-CIP-scope traffic and CIP traffic within the same physical network should not be considered acceptable.

Abstains from vote. LCRA TSC seeks clarification on types of modifications SDT would implement prior to voting yes or no.

The SDT has identified certain risks inherent to virtualization regarding the use of centralized management automation. The SDT is proposing to classify *Centralized Management System* (CMS) explicitly as a type of applicable system for some CIP requirements. In examining management architecture and risk management for virtual environments, the SDT identified an increased risk inherent to the span of control of hypervisor management consoles. Further, the SDT noted that similar risks exist in CMSs used to manage physical devices, and recognized these risks may not be fully addressed in current CIP standards and the *EACMS* definition. The SDT is considering a new definition of this class of system.

The proposed *Centralized Management System* (CMS) definition is:

A centralized system for administration or configuration of BES Cyber Systems, including but not limited to systems management, network management, storage management, or patch management.

AZPS respectfully submits that the development and creation of additional terms and asset classifications is unnecessary.   As discussed above, all cyber assets (physical or virtual) can be classified in existing classification of Cyber Asset if it is modified as recommended in AZPS's response to Question #2. Hence, AZPS does not agree with or support the creation of a new definition for CMS or the use of such a term in the CIP Reliability Standards.

Answer	No
Document Name	

Comment

No.

KCP&L identifies several points of concern and offers an alternative. The alternative, in concept, is not perfect; we offer it to address our concerns and the inherent risks identified by the SDT.

Concerns

1. **Impact to Applicability of Existing CIP Standards**: A new CMS definition is considerable and far-reaching; it requires a review of applicability in the complete suite of CIP Standards and, where impactful changes are identified, the effected Standard going through the revision process.

2. **Impact on Entities**: A new CMS definition requires entities to review and incorporate the new definition and subsequent revisions to Standards because of the new definition into their documentation, policies and procedures.

3. **Potential Scope Expansion**: The proposed CMS definition's scope may potentially swell to include physical systems.

Alternative

The concept is to move away from a CMS new asset type approach to incorporating management devices into existing EACMS asset types. To integrate this concept into the existing NERC EACMS Glossary definition, we offer:

Electronic Access Control, Monitoring or Management Systems (EACMS):

Cyber Assets that perform electronic:

1. Access control of the Electronic Security Perimeter(s) or BES Cyber Systems;

2. Security incident and event monitoring of the Electronic Security Perimeter(s) or BES Cyber Systems; and,

3. System management functions associated with the Electronic Security Perimeter(s) or BES Cyber Systems.

EACMS include, but are not limited to, Intermediate Systems; firewall management; patching management; virtual system management; access control; security incident and event monitoring; and server and workstation management. Management systems are limited to systems capable of modifying the configuration; applying patches, updates or code changes; remotely starting, shutting down, or restarting the asset—rebooting, its services or processes; or has the capability of altering a Cyber Asset's function within in a BES Cyber System.

In addition to the revised EACMS glossary term, a revision to CIP-007-6, Table R1, adding a new subpart under the R1 Table could address when there are instances Out-of-band networks required for Cyber Asset management. The new subpart to Table R1, Ports and Services, would apply to High

Impact and Medium Impact EACMS used for management devices to connect to things like iLOs, virtual switches, firewalls, network devices, and devices that require a port on a network that is separated physically or logically from normal production traffic.

This new definition seems broad and is hard to support without a clear idea of how it will be used in requirements and how this will impact existing CIP implementations. The scope of the new requirements needs to be very clear. For example, is this term intended to apply only to virtualized environments or will it extend to other management systems? Will this create duplicative classifications, e.g., as an EAMCS and a CMS or as a PCA and a CMS? Also, CMS is an acronym commonly used for Content Management Systems, which may cause confusion.

Brandon Cain - Southern Company - Southern Company Services, Inc. - NA - Not Applicable - SERC	
Answer	No
Document Name	
Comment	
In the absence of more information on how it would be used, Southern Company does not agree with the proposed definition of Centralized Management System (CMS). Assuming the typical virtualization environment, management consoles may be within the ESP and protected at least as PCA's, including CIP-010 change management for the console and all configured BES Cyber Systems. Alternatively, management consoles classified as an EACMS may be used to support many EACMS outside an ESP, and therefore would complicate the identification, classification, and applicable requirements of various Centralized Management Systems used in different capacities (BCS, EACMS, PCA).

Response

Mike Smith - Manitoba Hydro - 1,3,5,6

Answer	No
Document Name	

Comment

A CMS should be managed/protected. The definition does not give clear criteria on what is included as a CMS. How is the term “administration” defined and what type of administration is included. If a system provides operational monitoring but cannot change an end point is it included? If a system stores backup configuration files or data is it included? How is the term “configuration” defined? The text in the statement “including but not limited to” should be moved to a guidance section and do not belong in a definition. There is no clear definition of what functions a “systems management system” performs.

The types of devices in the examples typically require Interactive Access to Cyber Assets, and as such are already in scope of the standard based on CIP-005 R2. A network communication centric identification is better suited to these types of assets.

Also, it’s not clear how to differentiate a CMS from an EACMS. For example, an Active Directory server seems to fit the definitions of both CMS and EACMS. Should it be designated as both, and if not, which designation should take precedence?

Response

Lan Nguyen - CenterPoint Energy Houston Electric, LLC - 1 - Texas RE

Answer	No
Document Name	

Comment

CenterPoint Energy does not agree with the CMS definition and the intent to add CIP requirements to the proposed asset category. First, the proposed CMS definition contains open ended wording subject to broad interpretation by auditors beyond the intent of the SDT. The proposed definition will expand the scope of CIP applicable systems. CenterPoint Energy believes the term should address the intended system explicitly in order to limit scope creep.

Centralized management systems could be in place to provide services to multiple systems within a data center, or enterprise-wide, both in and out of scope for NERC CIP. The required regulatory response of entities to comply with requirements to protect CMS, as yet unwritten, may be much broader than the intent of the SDT. In particular, the addition of patch management systems is a concern. If the CIP Standards dictate how entities deploy patches and restrict the ways this can occur, better solutions will be abandoned in exchange for compliant ones. This has already occurred in response to the malware signature deployment testing requirement. Patch management systems have no place in the CMS definition. Similarly, storage management is a huge area, often managed enterprise-wide. SDT is well advised to focus on protection of data per CIP-011 in storage rather than expanding scope of CIP to cover storage systems as well.

Finally, hypervisors are not listed among the examples even though this term is clearly meant to cover them.

As an aside, the acronym CMS is well-known and used in data centers to refer to a Content Management System and the new acronym might cause confusion.

Patch management is an act, not a system, and should not be included in the definition. Using the term “management” (systems management, network management, etc.) is much too broad, as it pulls in aspects of management that have no impact on the reliability of the BES. More emphasis should be placed on configuration. There should also be more definition around “administration.” SRP proposes revising the definition to, “A tool used for the configuration, turn-up, or deployment of BES Cyber Systems…”

Response

Chris Scanlon - Exelon - 1,3,5,6

Answer	No
Document Name	

Comment

Exelon is concerned with the proposed definition extending what “Centralized Management Systems” would be in scope for the CIP standards. A definition should focus on virtualization so as not to create confusion since not all centralized management systems are virtualized, and not all virtualized systems are for central management. Exelon understands that the CIP SDT has to refrain from using any specific terms that could identify any one vendor product.

One approach the CIP SDT could take, if they believe that there needs to be a definition for the management system, is to use “Virtualization Management System” instead of “Centraized Management System” along with the definition in this posting. This would correctly scope the applicability to not include other “Centrlized Management Systems.”

In examining virtualization, the SDT considered centralized management systems or consoles for these environments. These systems allow for the mass addition, deletion and modification of virtual machines and networks. Access to the control surface of a cyber system is known as the *management plane*. The management plane is where the virtual infrastructure is configured and managed by a limited group of administrators as opposed to the *data plane*. The data plane is where the end user’s access to the virtual machine’s business function takes place. To meet the security objective of protecting a BES Cyber System from threats in the data plane, the management plane should be isolated from the data plane. These types of controls are referred to as *out of band* management.

Centralized Management Systems are a huge issue for NIPSCO OT. We have wrapped a number of our CMS' into EACMS which causes a ton of grief for our operability. These suites of systems require special protections but not the same level as an EACMS. I agree with this definition as it identifies areas that are of significant security concern while potentially minimizing impacts to our operability. NIPSCO OT has taken a conservative approach with our management consoles and made all of them EACMS systems. This causes significant costs and difficult operability for my teams. I would encourage further development on this term and encourage that the requirements are placed somewhere between a TCA and an EACMS.

We support the general concept and approach, but are concerned that the concept, being new and unfamiliar to industry and auditors alike, may end up bringing other, non-CIP systems into scope or otherwise impact non-virtualized BES Cyber Systems. To minimize the risk of unintended consequences, *we suggest that the scope of a CMS be narrowed to apply only to virtual systems at this time. The expansion of the CMS concept to address risks that may be present in managing physical devices is beyond the SAR of this project.*

It is BPA's opinion that the SDT's proposed definition of CMS captures most types of systems that support automation with a large span of control and privileged access. A similar span of control risk exists in that EACMS is a type of CMS for electronic access but the term *EACMS* is specific to NERC CIP and used nowhere else in IT Security or Information Assurance in any other industry. This inherently limits the amount of expertise, guidance, and documentation available for solving the root problem of controlling access to CIP-applicable systems.

BPA recommends that the SDT should retire the NERC CIP defined term *Electronic Access Control & Monitoring System* from the NERC Glossary and adopt the industry solution *Authentication, Authorization, and Accounting* System (AAA System). Non-standard jargon should be avoided when adequate terms and concepts exist already. See link: http://www.cisco.com/c/en/us/about/press/internet-protocol-journal/back-issues/table-contents-35/101-aaa-part1.html

Further, BPA recommends that the SDT should clarify in Guidelines and Technical Basis, that:

- AAA *clients* that subscribe to AAA services (e.g. via a protocol such as LDAP, RADIUS or TACACS+) but do not maintain any account information are not AAA Systems in themselves
- Remote access *clients* or terminal emulators that are used to connect to a CMS, are not a CMS in themselves

N&ST recognizes there are legitimate security concerns associated with systems used to manage and/or configure BES Cyber Systems and associated EACMS and PACS systems (especially, and for example, network firewalls whose interfaces include one or more EAP). However, N&ST is concerned that the SDT’s well-intentioned attempt to define “Centralized Management System” could result in significant pushback from industry and endless arguments about what type of system would meet the proposed definition of “CMS.” What does “centralized” mean? It is technically feasible (to borrow a phrase) for a firewall administrator to modify the configuration of multiple firewalls using his or her smartphone. Would doing so render his or her smartphone a CMS? N&ST believes that hypervisors used to create, modify, or remove virtual machines that qualify as BES Cyber Assets should themselves be evaluated as potential BES Cyber Assets or other Cyber Assets subject to CIP requirements, and that the Standards should make this clear. However, N&ST believes that security for other types of devices used for management and configuration in CIP environments is adequately addressed by existing requirements (e.g. CIP-005 requirements for Remote Interactive Access). This opinion is based, in part, on the fact many N&ST clients have chosen to locate systems used for the administration and/or configuration of BES Cyber Systems INSIDE defined ESPs, which makes them Protected Cyber Assets and therefore already subject to many CIP requirements.

The proposed definition of CMS is more general than just those types of CMS associated with command and control of virtual resource environments. This takes the discussion beyond the scope intended for addressing virtualization technology in the context of CIP. If the SDT decides to include CMS applicability, the definition should be refined to include only virtualization or addressed in a new CIP standards modification project. This type of systems are not addressed in the standard and represent risks that need to be addressed.

Scott Downey - Peak Reliability - 1	
Answer	No
Document Name	
Comment	
There are a myriad of ways to manage systems. Trying to add these definitions now, and bringing those systems into the scope of the CIP standards, would be burdensome on entities, and provide very little risk management. For example, patch management systems frequently have methodologies to ensure that the content of the patch management system has not been tampered with (checksum, digital signatures, and so on). Further, entities very well may rely on logical separation of the management of systems from the user access of systems. Trying to create standards around these types of assets would create confusion and complexity, and not inherently improve security. There would also be overlap with existing definitions in the standards, such as EACM, which could also qualify as a CMS. Instead, focus on which types of management systems should be specifically included in the scope of the standards, and write requirements specific to those assets to ensure the integrity of the CMS, instead of applying the general CIP-007 standards to them. Using the previously referenced patch management system example, a standard for an application deployment or patch management system could be that the system must demonstrate methods to ensure the integrity of deployment packages to endpoints (authorization of deployments, validation of deployment content, and that's it).

Southern Company does not agree with the SDT’s approach to reference the CMS specifically as a type of applicable system in the CIP Standards. As stated in Question 6, CIP-010 change management is being administered for the BES Cyber Systems that are administered through these CMS systems. Also additional clarity would be required for how the definition would be used and why it would be an applicable system different than a PCA or other already in-scope Cyber Asset.

We do not think you should differentiate CMS from EACMS. If anything, you should broaden the definition of an EACMS to include other central management and administration systems. Many of these systems perform both functions, which would only increase ambiguity.

No, as discussed above, AZPS respectfully submits that the development and creation of additional terms and asset classifications is unnecessary. All cyber assets (physical or virtual) can be classified in existing classification of Cyber Asset if it is modified as recommended in AZPS's response to Question #2. Hence, AZPS does not agree with or support the creation of a new definition for CMS or the use of such a term in the CIP Reliability Standards.

Chris Scanlon - Exelon - 1,3,5,6	
Answer	Yes
Document Name	
Comment	

Consistent with Exelon’s response to question 6 above, we support specific applicability; however, as long as the definition is sufficiently scoped to only be those “Centralized Management Systems” related to the tools to manage the virtualized environments.

Additionally, the informational posting states that the SDT is concerned with risks to the virtualized environment presented by the use of a centralized management system (CMS) to meet CIP requirements. It would be helpful if the CIP SDT would more fully explain what those risks are and the scope of CMS that require protections. The definition as presented could apply to any CMS used for general administration of existing BES Cyber Systems (e.g., configuration management, patching, etc.). We do not believe the SDT has provided a sufficient reason to extend CIP applicability to all CMSs, especially if those systems do not fall within CIP scope now because they do not qualify as BES Cyber Systems and are not associated with their PCAs, EACMS or PACS. The approach used should be clear in limiting the applicability of the CMS to virtualized environments.

In examining virtualization, the SDT considered centralized management systems or consoles for these environments. These systems allow for the mass addition, deletion and modification of virtual machines and networks. Access to the control surface of a cyber system is known as the *management plane*. The management plane is where the virtual infrastructure is configured and managed by a limited group of administrators as opposed to the *data plane*. The data plane is where the end user's access to the virtual machine's business function takes place. To meet the security objective of protecting a BES Cyber System from threats in the data plane, the management plane should be isolated from the data plane. These types of controls are referred to as *out of band* management. The SDT is considering limiting the scope of management plane protection requirements to high and medium impact Control Centers because these environments contain the highest risk.

Southern Company agrees with the SDT’s approach to require the isolation between the data plane and the management plane, but it is unclear at what level the SDT is asking the question. The data plane and the management plane are isolated by the nature of the configuration of the virtual system and the role authorizations which are provided for each. If the SDT is concerned with network level connectivity and that network access to administrative environments should only occur over separate physical networks or connections, then caution is required as not all systems or Cyber Assets can support physical out of band management. Even if limited to only Control Centers (as in Question 9), not every Cyber Asset in a Control Center can be administered out of band. This goes back to the issue in Question 1 where every requirement is expected to be applied to every device.

This decision should be up to the entity. In-band management may be appropriate in a small environment. Some vendors also require in-band management in their reference architecture. The definition of a CMS includes systems such as patch management servers. Typically these communicate in-band to systems using built-in operating system mechanisms. If included this would involve creating a separate management plane for all systems, and additional work to segregate data and management planes. This architecture may not be supported by EMS vendors. Other devices have only a single network port and the data and management planes cannot be segregated. In some cases management systems are created specifically for high-risk systems. These management systems are treated at the same level and are used in band to manage a small number of devices.

Out of band management is only one way to isolate the management of systems from user access. Dedicated management VLANs and perimeter and host firewall rules are effective at this, for example, and don't require out of band management to be an effective method of securing the administrative functions of a system.

The isolation of the two planes would only make sense in a mixed trust environment. These additional controls should be determined based on the increased risk to the BES due to the management of multiple BES Cyber Systems from a single source. The addition of the controls should not be based solely on the existence of the management plane. If the Entity chooses to not high watermark then the Entity must isolate. This isolation should not be required in all situations.

Virtualization brings new risks. I think this is one of them. These new risks need to be analysed and addressed.

NRG disagrees. The management plane should be addressed at the high water-mark. The management plane needs controls but, it doesn't necessarily have to be isolated from the data plane (this would mean that an entity would have to create a separate network). It should be sufficient that the management plane has controls which protect it from the data plane.

We are concerned that the language would not allow for single plane management if the virtual system resides wholly within an ESP. Also there does not appear to be a distinction between EACMS and BES Cyber System.

We are also concerned that this approach would require entities to build a separate architecture to manage the data plane and management plane.

The language is too ambiguous to understand the requirements. Out of band management comes with many connotations when it comes to deployment methods. More specificity needs to be provided in the proposed requirement. For example, should console servers be deployed to provide out of band management? Would VLAN separation of management interfaces vs. non-managed interfaces be sufficient? All this is unclear in the proposed language.

N&ST believes that proper separation of end-user and administrative capabilities is important in any information processing context. However, N&ST recommends against trying to develop new data / management plane isolation requirements in virtual environments unless the SDT can (a) reach consensus on a clear definition of what “isolation” means and (b) can identify specific examples, to be included in requirement statements, of approaches to achieving “isolation” that would satisfy the requirement(s).

Lan Nguyen - CenterPoint Energy Houston Electric, LLC - 1 - Texas RE

Answer	No
Document Name	

Comment

CenterPoint Energy does not support the addition of a new conceptual framework for provision of security controls on a *management plane* and *data plane*. These concepts are new to NERC CIP, with potential for confusion and mis-interpretation by auditors and registered entities, as well as unforeseen special cases that do not fit the binary concept as presented.

Existing security controls applied to hypervisors and VMs are sufficient without the need for a new conceptual framework, through use of the definitions for Cyber Asset, BCS, and PCA including hypervisors, as previously commented. The management and data plane concepts would be useful to publish in guidance, rather than to requirement language. CenterPoint Energy suggests language in the guidance to explain the distinction between access controls to data that is accessible to authorized users of a system versus data isolated in a VM or container with authorized users of its own inaccessible to users of the host.

While out of band management is a good practice, it should not be a requirement. There are other ways to segregate traffic. CIP does not require this for physical systems. If this is not requested for physical systems, then it should not be required for virtual systems. Additionally, the requirement should not be as specific as this may limit future technology. Stating “the data plane should be protected from the management plane” would be an alternative. Having specific ways to do this could be listed in the Guidelines and Technical Basis section.

David Ramkalawan - Ontario Power Generation Inc. - 5

Answer	Yes
Document Name	

Comment

Clarification is needed if logical isolation is sufficient or if physical isolation is intended here. Either seems prudent however physical might be cost prohibitive for smaller virtualization setups. Perhaps there should be some manner of threshold for when this becomes necessary, for instance when the number of virtual cyber assets is some multiple greater than he underlying phyiscal hosts.

One factor that separation of the management and data plane does not address is the additional systemic risk posed by the physical hosts themselves, even with a segregated management plane. For instance, in the most simple case without physical reduancy to illustrate the point, if 10 physical cyber assets are converted to virtual machines on a single physical host, the cyber assets are still "leveraged up" 10:1 to a physical failure or to a direct cyber attack that quite possibly bypasses the management plane. This is a systemic risk not addressed by the data / management plane speration proposal.

Mike Smith - Consultant - NA - Not Applicable - NA - Not Applicable

Answer	Yes
Document Name	

Comment

The risk inherent with the management plane is elevated because of the potential impact of a malicious or non-malicious change to the device. The approach to separate the management and data planes is fundamentally sound. The issue that must be addressed, however, is the implementation used to separate these two planes. For example, utilization of logical separation via VLANs creates an easy and simplistic method for the separation. However, this is not necessarily the most secure method of separation. Likewise, the use of VLANs with a two byte tag to the header is not secure; this tag can be modified by an adversary through various techniques. When looking at the current state of technology and discussing physical separation, what does this imply? For example, if two devices that should be physically separated were to be connected to a SDN switch (e.g., SEL-2740S) there is no 'physical' connectivity between the devices. The switch has no capability to route/forward traffic between these two devices until an appropriate instruction (e.g., Match/Action rule in the case of OpenFlow) is sent to the switch. With SDN technology and SDN Ethernet switches, virtual separation equals physical separation.

Language should be clear and concise enough to define a separation between the management and data planes where adversarial techniques cannot cause routing or access of communication between these two planes. Specifically, the language stating OOB (Out of Band) and other technology that allows for the equivalent of OOB.

SDN offers the capability to isolate flows within the packet forwarding device (Ethernet switch). In this case, it is not necessary to populate the header or payload of the Ethernet frames with switching isolation data. The SDN switch should have a secure encrypted command channel to the switch's controller to prevent a man-in-the-middle (MiM) type of attack that would allow it to receive instructions from an illegitimate assigned controller. This type of solution allows the use of the same physical network infrastructure and the policy and flow rules of the SDN to create the separation in a highly secure manor.

Chris Scanlon - Exelon - 1,3,5,6

Answer	Yes
Document Name	

Comment

Exelon would like to see this addressed in the Guidance and Technical Basis section. Additional guidance can help by providing examples of data plane vs. management plane and how they could be adequately isolated. We interpret this isolation to include limiting the ability of any data plane to expand permissions into the underlying management plane. This is a standard security control within virtualized system management. There are also vulnerabilities that would constantly challenge this isolation – which could position a compliant solution one day as non-compliant the next.

Intermediate systems and other assets that are not completely located within an ESP benefit from data plane/management plane isolation. However, the systems that are entirely contained within an ESP may not benefit from the isolation at the cost of additional logical and physical complexity to provide that isolation. Any additional guidance should clearly address only the case where a virtualized environment is not completely contained within an ESP, and not imply isolation requirements for systems already contained entirely within an ESP (and protected accordingly).

Aaron Cavanaugh - Bonneville Power Administration - 1,3,5,6 - WECC

Answer	Yes
Document Name	

Comment

BPA agrees with the SDT’s proposal to require isolation between Data Plane and Management Plane for centralized management systems when system capability allows and risk justifies it. BPA cautions the SDT against overly rigid prescriptions for providing isolation. Combinations of other controls may afford the same or better protection in a particular circumstance. When the use of automated tools can improve security and manageability, it is important to avoid discouraging automation with overly burdensome compliance requirements.

AZPS recommends the SDT provide the industry with clarity on this topic by not limiting the application of virtualization or requirements applicable to virtualized assets to a given BCS type. This will ensure that both the security and reliability objectives of the reliability standards are met and that points of confusion, potential for human error, etc. with respect to virtualization are reduced. AZPS is concerned that the limitation of applicability could introduce complexity, confusion, and ambiguity into the applicability of the requirements to virtualized assets especially where there is co-mingling of CIP and non-CIP assets that have been assigned different impact ratings. For example, if there is a management system that is virtualized across generating units which range from medium impact to non-CIP or low impact or that is virtualized physical locations, the requirements that are applicable to the shared portions of the Cyber Assets may become unclear for both Registered and Regional Entities.

Comment

Yes. The cost of separating management plane traffic is often difficult with equipment rolled out to low impact sites. The risk is typically very minor and the costs are typically significant. The return on investment is just not present and the risks do not justify this need.

There is significantly more risk at control centers because of the type of connectivity and number of devices they have that are capable of Multi-Tenancy and out of band management. Enforcing this control at substations would be impractical in many configurations.

Southern Company agrees with limiting the applicability to High and Medium Control Centers. These assets pose the highest risk to the BES and are in the locations with the primary need for virtualization technologies. However, see the issue on Question 8 as location or facility type alone does not mean the technical capability of all Cyber Assets within it are at a certain level.

Low impact facilities should not be in scope for virtualization. Smaller entities are having a hard enough time adjusting to the current v5 requirements. If a Low impact facility wants to move into a virtual work then that is their option. NERC had been so opposed to virtualization for so long, it will take some time for new comers to the technology to become proficient in supporting it.

Thank you for your time and consideration to comment.

This seems prudent espeically given this initiative is in the early stages. Adding controls to Low systems might better be kept until after experience with controls on high and medium systems is more developed. However, consideration should be given to situatios where Low Impact BCAs are managed with the same CMS as used for High and Medium BCAs such that controls intended for high and medium related CMS do not unduely carry over as requirements on the managed low impact cyber assets in such cases.

Unofficial Comment Form

Project 2016-02 Modifications to CIP Standards
Concepts for Virtualization and Definitions

Do not use this form for submitting comments. Standards Balloting and Commenting System (SBS) to submit comments on **Project 2016-02 Modifications to CIP Standards Virtualization in the CIP Environment.** The electronic form must be submitted by **8 p.m. Eastern, Thursday, November 2, 2017.**

Additional information is available on the project page. If you have questions, contact Katherine Street (404) 446-9702 or Mat Bunch (404) 446-9785.

Background Information

The Standard Drafting Team (SDT) for Project 2016-02 Modifications to CIP Standards continues to work to address transferred issues from the Version 5 Transition Advisory Group (V5 TAG). The V5 TAG consisted of six volunteer Responsible Entities who worked with NERC and the Regional Entities to implement the CIP Version 5 standards in an accelerated time frame. During the implementation study, study participants focused on the technical solutions and processes needed to meet the standards. As a result of this effort, issues were identified with the definition of Cyber Asset as well as the use of virtualization. These issues were documented in CIP V5 Issues for Standard Drafting Team Consideration.

The SDT has conducted outreach to industry on the concepts of virtualization through webinars that are published on the Project 2016-02 Modifications to CIP Standards related files page. To address the topics of the Cyber Asset definition and virtualization, the SDT has developed concepts for which we are seeking informal comment to gather further input from stakeholders. In reviewing these concepts and risks, it became clear that other areas may need to be adjusted to provide a clearer categorization of assets and applicable requirements to address the risk of virtualization.

As a result of this work, this comment form introduces new concepts which may result in the development of new requirement language, new definitions, and modifications to existing definitions. SDT proposes these concepts to:

1) Refine terms related to virtualization, such as Cyber Asset and Centralized Management System (CMS).
2) Improve areas in the current CIP Standard requirements that might hinder the adoption of virtualization technologies for BES Cyber Systems and other related systems;
3) Address areas of new cybersecurity risks, technological concepts, and techniques introduced with virtualization technologies; and
4) Clarify the context of virtualization technologies and mixed physical and/or virtual environments where advancing technologies have blurred boundaries or made legacy approaches obsolete.

The concepts noted within this informal comment form are not an obligation for Responsible Entities to implement virtual technology. The target audience for this informal comment form are those Responsible Entities that have implemented or are planning to implement virtual technology.

Concept 1: Modifications to allow use of secure multi-instance environments

Cyber Asset Definition

The V5 TAG implementation study noted issues with the use of the term Cyber Asset in the context of virtualization. In virtual environment, how does the construct of a virtual system align to the definition when the various components are distributed across a vast array of infrastructure components? Additionally, the V5 TAG requested that the SDT clarify the intent of “programmable” by considering such factors as whether a device is merely configurable, its executable code is not field upgradable, or if its functionality can only be changed via physical DIP switches, swapping internal chips, etc.

In April 2017, the SDT received comment from industry that indicated that the definition of Cyber Asset would benefit from clarification how it relates to physical and virtual systems. Many comments also indicated that through broader industry implementation, issues with the meaning of “programmable” had been resolved and the definition of Cyber Asset did not need to be modified to address this. Additionally, ERO Enterprise-endorsed Implementation Guidance exists on the term "programmable".

Due to the foundational nature of the Cyber Asset definition as well as the comments received in April 2017, the SDT seeks comment on the following conceptual definition of Cyber Asset in the Glossary of Terms Used in NERC Reliability Standards (NERC Glossary).

Current:

Cyber Asset:

Programmable electronic devices, including the hardware, software, and data in those devices.

Redline

Cyber Asset:

A programmable electronic physical or virtual device~~s~~, including the hardware, software, and data in th~~os~~e device~~s~~. Each virtual machine and host is a distinct device.

Clean

Cyber Asset:

A programmable electronic physical or virtual device, including the hardware, software, and data in the device. Each virtual machine and host is a distinct device.

1. Do you agree that the proposed change to the Cyber Asset definition makes it inclusive of both physical and virtual devices, including treatment of each virtual machine and hypervisor? If you do not agree, please provide rationale to support your position.

   ☐ Yes
   ☐ No
   Comments:

2. Do you agree that the term programmable in the Cyber Asset definition does not need further clarification at this time? If yes, please provide rationale to support your position.

   ☐ Yes
   ☐ No
   Comments:

3. If programmable does need further clarification, how would you prefer it to be addressed? Use comments to detail necessary definition changes or guidance that could be developed.

   Comments:

Centralized Management Systems (CMS)

As the SDT worked through issues related to virtual systems, it became clear that there was no straightforward way within the current CIP Standards to adequately address the risk of systems used to manage virtual environments. Management systems in virtual environments, through their consolidated interfaces and automation, can modify and delete entire infrastructures including virtual servers, networks, and storage. Given the broad capabilities of management systems in a virtual environment, they present specific and significant risk to the reliability of the BES Cyber Systems associated with those management systems.

The SDT considered several options to address the risks of management systems such as grouping management systems into the existing EACMS definition. This, however, would place these assets inappropriately in the EACMS category when they do not perform access control or access monitoring. Using the EACMS category in this manner creates a one-size-fits-all approach to requirements that does not consider the degree of risk or technical constraints posed by the particular system. For example, a system that only monitors and logs access does not pose the same level of risk as a management system for a large virtualized Control Center with the capability to modify or delete a complete infrastructure. Technical controls to mitigate the risk may differ depending on the capabilities of the management system. An electronic access monitoring system presents a risk of leaking BES Cyber System Information; an electronic access control system presents a risk of unauthorized access to, or modification of, a BES Cyber System’s operational parameters; and a management system presents a risk of unwanted or unintended modification or deletion of a complete infrastructure.

Proposed requirements related to this definition are detailed below.

The SDT determined a more appropriate option was to create a new definition for Centralized Management System (CMS) and apply appropriate and specific security requirements. The SDT seeks comment on the following conceptual definition of Centralized Management System in the Glossary of Terms Used in NERC Reliability Standards (NERC Glossary).

Centralized Management System (CMS):
A centralized system used for administration or configuration of BES Cyber System(s) through which the configuration of the BES Cyber System can be altered.

4. Do you agree with the proposed definition of Centralized Management Systems (CMS)? If not, please provide rationale to support your position.

   ☐ Yes
   ☐ No
   Comments:

Virtualization Terms and Requirements

The foundational pieces have now been set for the use of virtualization solutions. However, these solutions still pose risk. These risks and the nature of virtual systems may require some modifications to Standards. The concepts being proposed include additional access control and separation of the management plane from the data plane. This can help to prevent users of the applications on a virtualized system gaining access to the management system that can modify and delete the underlying infrastructure including virtual servers, networks, and storage.

The SDT uses the terms “instance” and “multi-instance” within the proposed requirements below. For the purposes of these proposed changes, the SDT intends for “instance” and “multi-instance” to be understood as:

- Instance: Discrete organizational environments with specific privileges or security levels, consisting of functions that consume resources from the shared infrastructure. Instances are logically isolated but physically interconnected.
- Multi-instance: An environment where a shared infrastructure provides containers for more than one instance.

In reviewing the risks that are unique and inherent to the use of virtualization technologies, the SDT identified the following risks:

1) Shared infrastructure,
2) Span of control, insider threats, and lateral privilege expansion,
3) Misconfiguration, excessive privileges, and capability of administrators, and
4) Escalation of privilege.

The SDT proposes the following definition and requirements in support of the use of virtual technologies.

Electronic Security Zone (ESZ)

The SDT contends that the Electronic Security Perimeter (ESP) definition does not accurately describe the proper isolation of virtual systems within shared infrastructure. Details of the analysis are captured in network isolation portion of the industry webinar presented on March 21, 2017. To address the concerns noted, the SDT seeks comment on the following conceptual definition of Electronic Security Zone (ESZ) in the Glossary of Terms Used in NERC Reliability Standards (NERC Glossary).

Electronic Security Zone:
The area defined by the logical separation of one or more Cyber Asset(s).

5. Do you agree that the proposed definition of ESZ more adequately applies to proper isolation of multi-instance environments, regardless of OSI layer? If not, please provide a rationale to support your position.

   ☐ Yes
   ☐ No
   Comments:

6. Do you agree that the proposed definition of ESZ would aid the development of future CIP Standards by providing a more relevant level of separation? If not, please provide a rationale to support your position.

   ☐ Yes
   ☐ No
   Comments:

New Requirement CIP-005 Requirement 1, Part 1.6

The SDT proposes a new requirement part 1.6 for CIP-005 Requirement R1. This requirement part is for Responsible Entities to implement one or more Electronic Security Zones (ESZ) to meet the security objective of separating the management plane and the data plane of high and medium impact BES Cyber Systems in a multi-instance environment. Part 1.6 would also require Responsible Entities to implement one or more ESZs to meet the security objective of protecting the infrastructure associated with high and medium impact BES Cyber Systems in a multi-instance environment by limiting access to the Centralized Management Systems using a management plane ESZ.

Responsible Entities maintain the flexibility for grouping by cyber system function, by risk, by type of applicable security controls, or other logical groupings. The ESZ contains a distinct subset of the Responsible Entity's Cyber Assets. These are characterized as requiring (or benefiting from) similar security controls and separation from other distinct Cyber Assets. Properly implemented ESZs can limit damage and impact to availability to other surrounding ESZs, specifically by helping protect against span-of-control risks, insider threats, and lateral privilege expansion.

Again, the requirement would only be applicable to high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS.

Part 1.6:
Logically separate all Applicable Systems into defined groups of one or more Cyber Asset(s) to achieve the objective of mitigating the risks of span-of-control, insider threats, and lateral privilege expansion. At a minimum:
1. The management plane and the data plane of the applicable BES Cyber System shall be separated;
2. The CMS of the applicable BES Cyber System shall be separated from its data plane

7. Do you agree that the proposed CIP-005 Requirement R1, Part 1.6 provides sufficient security controls for the high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS to reduce the stated risks inherent to virtualization? If not, please provide a rationale to support your position.

   ☐ Yes
   ☐ No
   Comments:

New Requirement CIP-005 Requirement 1, Part 1.7

Similarly to CIP-005 Requirement R1, Part 1.3, the SDT proposes new requirement Part 1.7. Part 1.7 requires Responsible Entities to identify, control, and explicitly allow only necessary inbound and outbound communication between ESZs of high and medium impact BES Cyber Systems residing in a multi-instance environment. Part 1.7 would be added to CIP-005 to reduce the risks inherent to virtualization related to misconfiguration, excessive privileges, capability of administrators, as well as information protection and data leakage.

The requirement would be applicable to high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS(s).

Part 1.7:
Implement technical controls that enforce separation between ESZs by allowing only necessary inbound and outbound communication between the separated Cyber Asset(s) residing in a multi-instance environment.

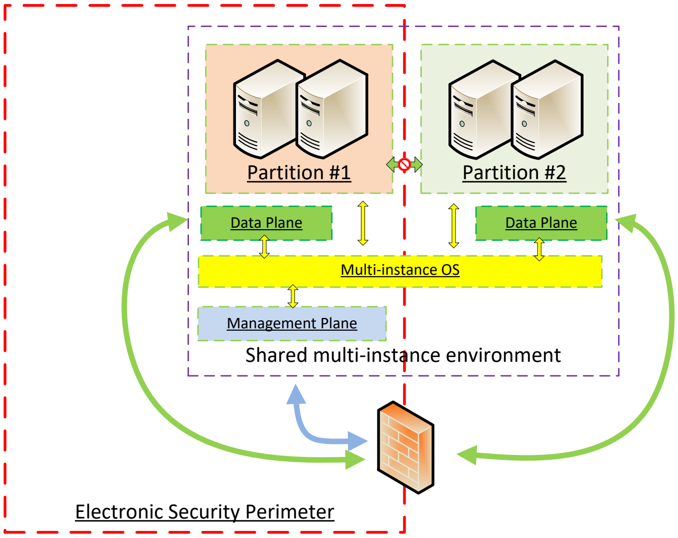
8. Do you agree that the proposed CIP-005 Requirement R1, Part 1.7 provides a necessary security control to the high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS(s) to reduce risks inherent to virtualization? If not, please provide a rationale to support your position.

   ☐ Yes
   ☐ No
   Comments:

New Requirement CIP-005 Requirement 1, Part 1.8

Through the SDT work on virtualization, situations have been identified where a Responsible Entity may choose to share the same system infrastructure between applicable Cyber Assets and other programmable devices. As the footprint of cyber assets outside the scope of the CIP Standards in an organization might be significantly larger in size from the Cyber Assets in scope of the CIP Standard, a Responsible Entity may invest in its IT infrastructure with greater capability and more robust features. As presented in the third webinar on virtualization, this is particularly true with storage virtualization implementations. Under certain circumstances, leveraging enterprise infrastructure solutions will provide a better security posture for applicable Cyber Assets. Part 1.8 has been drafted with the objective of allowing such leverage as long as controls mitigating the additional risks are implemented.

A CIP Standard requiring the complete physical separation of applicable Cyber Assets and other programmable devices might adversely affect the overall security posture and reduce operational efficiency for the Responsible Entity through unnecessary expense and complexity of processes or technical implementation. Security controls exist to manage secure logical separation in multi-instance environments and there are operational benefits to sharing a common infrastructure as well. Technological advancements are often coupled with new security mechanisms which often benefit legacy infrastructure.



The diagram above shows an example of a shared multi-instance environment. The green arrows in the diagram represent the data communication. To exchange data between Partition 1 and 2, communication has to go through an EAP represented in the diagram by a firewall. The blue arrows in the diagram represent the management communication. In order to manage Partition 2, or any Cyber Asset hosted by the multi-instance environment and outside the ESP, IP communication to the management plane from outside the ESP has to go through the EAP since the management plan of shared multi-instance environment has to reside inside the ESP. The yellow arrows in the diagram represent the resource management activities performed by the multi-instance operating system necessary to ensure separation of data plane and management plane as well as partitions between Cyber Assets inside the ESP and Cyber Assets outside the ESP.

The SDT proposes CIP-005 Requirement 1, Part 1.8 to provide protection where the infrastructure used in a multi-instance environment is shared between applicable Cyber Assets and other programmable devices. This allows Responsible Entities to leverage the investments and protection of infrastructure shared between applicable Cyber Assets and other programmable devices. The requirement would be applicable to high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS(s).

Part 1.8:
When an infrastructure is shared between BES Cyber Systems and other Cyber Assets not part of a BES Cyber System:

1. The BES Cyber System, the management plane of the shared infrastructure, and any hosted Cyber Assets not part of a BES Cyber Systems shall all be separated; and
2. Communications between the BES Cyber System and any hosted Cyber Assets not part of a BES Cyber System shall all be denied by default

9. Do you agree that the proposed CIP-005 Requirement R1, Part 1.8 provides sufficient security control to reduce the risks associated with shared multi-instance environments? If not, please provide a rationale to support your position.

☐ Yes
☐ No
Comments:

New Requirement CIP-005 Requirement 3, Part 3.1

In reviewing the risks associated with communications in a virtual environment, the SDT identified a gap with remote access used to perform CMS functions. These communications using a CMS do not align appropriately to Interactive Remote Access. Tasks may be performed from outside the ESP that are a blend of interactive and automated tools, allowing for misinterpretation and unjustified relaxation of security mechanisms required for Interactive Remote Access. Using jump servers to perform CMS functions might not be the most effective or the most secure. Also, remote access to a Cyber Asset inside an ESP could benefit from other methods besides Interactive Remote Access for performing CMS functions.

CIP-005 Requirement R3, Part 3.1 allows for a new type of remote access to be used to perform CMS functions from outside of an ESP. Part 3.1 allows the CMS function to be performed outside an ESP using an access method other than an Intermediate Systems to fix the gap that may exist between Interactive Remote Access and system-to-system communication. It does this by introducing requirements that are commensurate with the risk inherent to the management function in a multi-instance environment.

The SDT proposes new requirement CIP-005 Requirement 3, Part 3.1. Part 3.1 would be applicable to high and medium impact BES Cyber Systems.

Part 3.1:
Require authentication, integrity and non-repudiation controls for all sessions initiated outside of the ESZ, whether user initiated or system-to-systems communications, used to perform CMS functions.

10. The SDT asserts that the proposed CIP-005 Requirement 1, Part 3.1 provides additional security controls for remote access when performing CMS functions. These are necessary to reduce the risk associated with remote access to multi-instance environments. Do you agree with this assertion? If not, please provide a rationale to support your position.

    ☐ Yes
    ☐ No
    Comments:

11. Should the gap between Interactive Remote Access and system-to-system communication that was exposed by the examination of the risks inherent to virtualization be addressed for systems other than high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS? If not, please provide a rationale to support your position.

    ☐ Yes
    ☐ No
    Comments:

New Requirement CIP-004 Requirement 4, Part 4.5

The SDT has identified “too much privilege” as an inherent risk in virtualization. This risk can be reduced by adding controls in CIP-004. Limiting of the privileges granted to the minimum necessary is only present in the guidance. It is not a requirement. This security risk can be mitigated, however, by implementation of least privilege access and separation of duties in the requirement language. This means fewer people get high level privileges, and no single individual gets privileges that are too broad. For efficiency, it can be implemented via role-based access control (RBAC), which requires an initial effort to define roles properly. But also provides an opportunity for internal review of the span-of-control risk. Role-based access control and separation of duties are both available in virtual environments. Implementation of RBAC varies by vendor but is generically the same in principle.

The SDT proposes new requirement CIP-004 Requirement 4, Part 4.5. Part 4.5 would be applicable to high and medium impact BES Cyber Systems.

Part 4.5:
The Responsible Entity shall document and implement process(es), except under CIP Exceptional Circumstances, to authorize electronic and unescorted physical access to BES Cyber Systems and BES Cyber

Systems Information that implements the principles of need-to-know, least privilege, and separation of duties as determined by the Responsible Entity, as per system capability.

12. The SDT asserts that the new proposed CIP-004 Requirement R4, Part 4.5, provides additional security control to the electronic and unescorted physical access to multi-instance environment processes which reduces the “too much privilege” risk inherent to virtualization which has been identified. Do you agree with this assertion? If not, please provide a rationale to support your position.

    ☐ Yes
    ☐ No
    Comments:

Concept 2: Modifications to the EACMS definition

As noted above, the SDT reviewed the scope of the current definition, the requirements, and risk of the types of assets contained within EACMS. The current construct does not differentiate controls based on the functionality and risk of the system. The current construct does, however, create what is known as the “hall of mirrors” effect. Specifically, there may be some types of EACMS that should be required to be inside an ESP and behind a firewall. An example could be the management system of a firewall that is categorized in such a way that it must reside within an ESP. That requirement, however, cannot exist for all EACMS because a firewall is itself an EACMS. Without defining a new category, the result would be that every EACMS would need to be inside an ESP and therefore protected by another EACMS. This creates the recursive "hall of mirrors" effect.

There are a number of systems that both monitor and provide part of the solution of controlling access, but do not actually control traffic at the point of entry. These devices or systems may or may not benefit from being inside a protected boundary, or they may form part of the strategy that protects BES Cyber Assets. The technical means of implementing some multi-part systems may require components to be outside, or span the ESP.

To address this, the SDT proposes breaking up the EACMS categorization of applicable systems by function so that the appropriate requirements for each can be applied. The SDT does not, however, want to create a reclassification and documentation exercise for Responsible Entities who would not see benefit and would try to create a way for those Responsible Entities to continue to use EACMS with no changes. There are also other options in addition to these two.

Electronic Access Control System (EACS)

The SDT seeks comment on the following conceptual definition of Electronic Access Control System in the Glossary of Terms Used in NERC Reliability Standards (NERC Glossary).

Electronic Access Control System (EACS):
Cyber Assets that perform electronic access control of the BES Cyber Systems. This includes Intermediate Systems.

An Electronic Access Control System performs authentication and authorization of traffic or users. This is the “gatekeeper” function or the classic authentication and authorization functions of standard AAA. In many cases these systems do not perform any active filtering of the traffic passing through any particular interface. The primary duty of EACS is to authenticate and authorize. EACS move beyond the risk of unauthorized access to meta-information about an environment, to unauthorized access to BES Cyber Systems and modification of their operational parameters.

Electronic Access Gateway (EAG)

The SDT seeks comment on the following conceptual definition of Electronic Access Gateway in the Glossary of Terms Used in NERC Reliability Standards (NERC Glossary).

Electronic Access Gateway:
Cyber Assets that perform electronic access control of the Electronic Security Perimeter(s). The Electronic Access Gateway also hosts the EAP(s).

An Electronic Access Gateway hosts the EAP and performs the active function of filtering or forwarding traffic at the demarcation point (boundary protection). Primarily, these are firewalls and routers that perform gateway functions at the layer 3 ESP boundary demarcation point.

Electronic Access Monitoring Systems

As technologies and cyber attacks advance and become more complex, Responsible Entities are becoming increasingly interested in collecting and correlating electronic access monitoring events across their enterprises. This broad-based information collection provides Responsible Entities with more visibility into emerging threats and trends. Responsible Entities can then analyze and share this information more readily and take action to improve the overall cybersecurity and reliability of the BES through early detection of compromise.

Under the currently effective CIP Reliability Standards, if a Responsible Entity uses enterprise wide electronic access monitoring tools, the Cyber Assets used to perform the monitoring may meet the definition of EACMS and become subject to the CIP Reliability Standards applicable to EACMS. This may discourage or prevent Responsible Entities from using enterprise wide electronic access monitoring due to the device level requirements of an EACMS. Responsible Entities may be discouraged from providing and correlating security events across enterprise and control networks, even though cyber-attacks against control systems could enter through business networks. The SDT concludes there is value in correlating security events across both control and enterprise networks.

The SDT proposes that the information within the electronic access monitoring systems should be protected as a BCSI repository, rather than having the system categorized as an EACMS. The systems performing electronic access monitoring are used to monitor and collect information about BES Cyber Systems or Electronic Security Perimeter(s) and pose a risk of information leakage. These monitoring systems are not used to control access to the BES Cyber Systems or Electronic Security Perimeter(s). The monitoring function has been in scope of the EACMS definition due to the sensitivity of certain information that may be collected. The proposed change is to treat the data collected through the monitoring capability as BCSI rather than having the monitoring systems categorized as EACMS. This change will enable Responsible Entities to better leverage enterprise-wide monitoring to improve overall situational awareness, and in the process more proactively address security events.

This will result in improved security and reliability. This does not change a Responsible Entity's obligations to monitor under CIP-007 R4.

To transition electronic access monitoring from EACMS to BCSI, the SDT seeks comment on the following conceptual modification to the definition of BES Cyber System Information in the Glossary of Terms Used in NERC Reliability Standards (NERC Glossary).

Clean:
BES Cyber System Information:
Data about the BES Cyber System that is processed, organized, structured, or presented in a context that could be used to gain unauthorized access or pose a security threat to the BES Cyber System.

BES Cyber System Information does not include individual pieces of information that by themselves do not pose a threat or could not be used to gain unauthorized access to BES Cyber Systems, such as, but not limited to, device names, individual or collections of IP addresses without context of location and purpose, ESP names, individual security logs, or policy statements.

Examples of BES Cyber System Information may include, but are not limited to: security procedures, collections of security logs, or security configuration information about BES Cyber Systems, Physical Access Control Systems, Electronic Access Control Systems, Electronic Access Gateway Systems, Centralized Management Systems, and Electronic Access Control or Monitoring Systems that are not publicly available; and network topology with network addresses of the BES Cyber System.

Redline:
BES Cyber System Information:
Data ~~Information~~ about the BES Cyber System that is processed, organized, structured, or presented in a context could be used to gain unauthorized access or pose a security threat to the BES Cyber System.

BES Cyber System Information does not include individual pieces of information that by themselves do not pose a threat or could not be used to allow unauthorized access to BES Cyber Systems, such as, but not limited to, device names, individual or collections of IP addresses without context of location and purpose, ESP names, individual security logs, or policy statements.

Examples of BES Cyber System Information may include, but are not limited to:~~,~~ security procedures, collections of security logs, or security configuration information about BES Cyber Systems, Physical Access Control Systems, Electronic Access Control Systems, Electronic Access Gateway Systems, Centralized Management Systems, and Electronic Access Control or Monitoring Systems that is not publicly available ~~and could be used to allow unauthorized access or unauthorized distribution~~; ~~collections of network addresses~~; and network topology with network addresses of the BES Cyber System.

Current:

BES Cyber System Information:

Information about the BES Cyber System that could be used to gain unauthorized access or pose a security threat to the BES Cyber System. BES Cyber System Information does not include individual pieces of information that by themselves do not pose a threat or could not be used to allow unauthorized access to BES Cyber Systems, such as, but not limited to, device names, individual IP addresses without context, ESP names, or policy statements. Examples of BES Cyber System Information may include, but are not limited to, security procedures or security information about BES Cyber Systems, Physical Access Control Systems, and Electronic Access Control or Monitoring Systems that is not publicly available and could be used to allow unauthorized access or unauthorized distribution; collections of network addresses; and network topology of the BES Cyber System.

Proposed Requirements Related to EACMS Changes

Based on the concepts presented above, the table below lists the current requirement scope of EACMS and those proposed for CMS, EACS, and EAG. In the table below, the "X" indicates where the requirement currently applies to the system category in the Applicable Systems column of CIP Standards. The "+" sign indicates an additional requirements being considered to address risk for that specific system category in the Applicable Systems column of CIP Standards. To the extent that there is no difference in requirement applicability, the SDT would look to consolidate the terms into as few classifications as necessary.

Please keep in mind that the SDT does not want to create a reclassification and documentation exercise for Responsible Entities who would not see sufficient benefit and would look to create a way for those Responsible Entities to continue to use EACMS with no changes.

Requirement	EACMS	CMS (+)	EACS (+)	EAG (+)
CIP-004 R1.x		+	+	+
CIP-004 R2.x	X	X	X	X
CIP-004 R3.x	X	X	X	X
CIP-004 R4.x	X	X	X	X

Requirement	EACMS	CMS (+)	EACS (+)	EAG (+)
CIP-004 R5.x	X	X	X	X
CIP-005 R1.x		+	+	X (Part 1.5)
CIP-005 R2.x		+		
CIP-005 R3		+		
CIP-007 R1.1	X	X	X	X
CIP-007 R2.x	X	X	X	X
CIP-007 R3.x	X	X	X	X
CIP-007 R4.x	X	X	X	X
CIP-007 R5.x	X	X	X	X
CIP-009 R1.x	X		X	X
CIP-009 R2.1	X		X	X
CIP-009 R2.2	X		X	X
CIP-009 R2.3			+	+
CIP-009 R3.x	X		X	X
CIP-010 R1.x	X	X	X	X
CIP-010 R2.x	X	X	X	X
CIP-010 R3.1	X	X	X	X
CIP-010 R3.2		X	+	+
CIP-010 R3.3	X	X	X	X
CIP-010 R3.4	X	X	X	X
CIP-010 R3.5	X	X	X	X
CIP-011 R1.x	X	X	X	X
CIP-011 R2.x	X	X	X	X

13. Do you agree with the SDT’s assertion that the definition of EACMS is too broad and does not differentiate the capabilities and risk(s) of the systems that fall within that definition scope? If not, please provide rationale to support your position.

☐ Yes
☐ No
Comments:

14. Do you agree that the language of the proposed definitions of EACS provides better consistency and clarity to the CIP Standards? If not, please provide rationale to support your position and alternative language.

☐ Yes
☐ No
Comments:

15. Do you agree that the language of the proposed definitions of EAG provides better consistency and clarity to the CIP Standards? If not, please provide rationale to support your position and alternative language.

    ☐ Yes
    ☐ No
    Comments:

16. Do you agree that the current compliance requirements related to EACMS monitoring systems are precluding or discouraging solutions that could reduce risk to security and reliability? Please provide your rationale in support or against this assertion.

    ☐ Yes
    ☐ No
    Comments:

17. Should the security requirements for the access control portion of the EACMS to be different from the monitoring portion of the EACMS? If you do, please provide your rationale.

    ☐ Yes
    ☐ No
    Comments:

18. Should CIP-011 Requirement R2 scope be expanded to include designated storage locations for access monitoring systems? If not, please provide rationale to support your position.

    ☐ Yes
    ☐ No
    Comments:

19. Do you agree with assignment of CIP Standard requirements to each of the EACS, EAG, and CMS categories as presented in the table above? If not, please provide rationale to support your position.

    ☐ Yes
    ☐ No
    Comments:

Concept 3: Compliance Guidance

The SDT has explored the idea that no changes are necessary to the CIP Standards to address virtualization. ERO Enterprise-endorsed Compliance Guidance could be used to address many industry concerns with the proper implementation of virtualization.

20. As the standards today do not prohibit the use of virtualization technologies, do you support an approach where no changes are made to the CIP Standards in response to the virtualization issue identified by the V5 TAG? Please provide a rationale to support your position.

    ☐ Yes
    ☐ No
    Comments:

Summary

The SDT has provided very diverse concepts for your consideration. Each of these concepts can be moved forward in the drafting process independently. Please provide your responses to each of the questions below.

21. Is your organization in support of Concept 1: Modifications to allow use of secure multi-instance? Please provide rationale to support your position.

    ☐ Yes
    ☐ No
    Comments:

22. Is your organization in support of Concept 2: Modifications to the EACMS definition? Please provide rationale to support your position.

    ☐ Yes
    ☐ No
    Comments:

23. Is your organization in support of Concept 3: Compliance Guidance? Please provide rationale to support your position.

    ☐ Yes
    ☐ No
    Comments:

24. If you have additional comments that you have not provided in response to the questions above, please provide them here.

    Comments:

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Standards Announcement

2016-02 Modifications to CIP Standards

Informal Comment Period Open through November 2, 2017

Now Available

An informal comment period is open through **8 p.m. Eastern, Thursday, November 2, 2017**, for stakeholders to provide feedback on the **Standard Drafting Team's (SDT's) approach to addressing the use of virtualization in the CIP environment**.

Commenting

Use the Standards Balloting and Commenting System (SBS) to submit comments. If you experience any difficulties navigating the SBS, contact Wendy Muller. An unofficial Word versions of the comment form is posted on the project page.

If you are having difficulty accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out, contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern).

- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*
- *Please be mindful of ballot and comment period closing dates. We ask to **allow at least 48 hours** for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts **prior to the last day** of a comment/ballot period.*

Next Steps

The drafting team will review all responses received and determine the next steps of the project.

For more information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact, Katherine Street at (404) 446-9702 or Mat Bunch at (404) 446-9785.

Comment Report

Project Name:	2016-02 Modifications to CIP Standards | Concepts for Virtualization and Definitions
Comment Period Start Date:	10/6/2017
Comment Period End Date:	11/2/2017
Associated Ballots:	

There were 48 sets of responses, including comments from approximately 141 different people from approximately 94 companies representing 10 of the Industry Segments as shown in the table on the following pages.

Questions

1. Do you agree that the proposed change to the Cyber Asset definition makes it inclusive of both physical and virtual devices, including treatment of each virtual machine and hypervisor? If you do not agree, please provide rationale to support your position.

2. Do you agree that the term programmable in the Cyber Asset definition does not need further clarification at this time? If yes, please provide rationale to support your position.

3. If programmable does need further clarification, how would you prefer it to be addressed? Use comments to detail necessary definition changes or guidance that could be developed.

4. Do you agree with the proposed definition of Centralized Management Systems (CMS)? If not, please provide rationale to support your position.

5. Do you agree that the proposed definition of ESZ more adequately applies to proper isolation of multi-instance environments, regardless of OSI layer? If not, please provide a rationale to support your position.

6. Do you agree that the proposed definition of ESZ would aid the development of future CIP Standards by providing a more relevant level of separation? If not, please provide a rationale to support your position.

7. Do you agree that the proposed CIP-005 Requirement R1, Part 1.6 provides sufficient security controls for the high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS to reduce the stated risks inherent to virtualization? If not, please provide a rationale to support your position.

8. Do you agree that the proposed CIP-005 Requirement R1, Part 1.7 provides a necessary security control to the high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS(s) to reduce risks inherent to virtualization? If not, please provide a rationale to support your position.

9. Do you agree that the proposed CIP-005 Requirement R1, Part 1.8 provides sufficient security control to reduce the risks associated with shared multi-instance environments? If not, please provide a rationale to support your position.

10. The SDT asserts that the proposed CIP-005 Requirement 1, Part 3.1 provides additional security controls for remote access when performing CMS functions. These are necessary to reduce the risk associated with remote access to multi-instance environments. Do you agree with this assertion? If not, please provide a rationale to support your position.

11. Should the gap between Interactive Remote Access and system-to-system communication that was exposed by the examination of the risks inherent to virtualization be addressed for systems other than high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS? If not, please provide a rationale to support your position.

12. The SDT asserts that the new proposed CIP-004 Requirement R4, Part 4.5, provides additional security control to the electronic and unescorted physical access to multi-instance environment processes which reduces the “too much privilege” risk inherent to virtualization which has been identified. Do you agree with this assertion? If not, please provide a rationale to support your position.

13. Do you agree with the SDT’s assertion that the definition of EACMS is too broad and does not differentiate the capabilities and risk(s) of the systems that fall within that definition scope? If not, please provide rationale to support your position.

14. Do you agree that the language of the proposed definitions of EACS provides better consistency and clarity to the CIP Standards? If not, please provide rationale to support your position and alternative language.

15. Do you agree that the language of the proposed definitions of EAG provides better consistency and clarity to the CIP Standards? If not, please provide rationale to support your position and alternative language.

16. Do you agree that the current compliance requirements related to EACMS monitoring systems are precluding or discouraging solutions that could reduce risk to security and reliability? Please provide your rationale in support or against this assertion.

17. Should the security requirements for the access control portion of the EACMS to be different from the monitoring portion of the EACMS? If you do, please provide your rationale.

18. Should CIP-011 Requirement R2 scope be expanded to include designated storage locations for access monitoring systems? If not, please provide rationale to support your position.

19. Do you agree with assignment of CIP Standard requirements to each of the EACS, EAG, and CMS categories as presented in the table above? If not, please provide rationale to support your position.

20. As the standards today do not prohibit the use of virtualization technologies, do you support an approach where no changes are made to the CIP Standards in response to the virtualization issue identified by the V5 TAG? Please provide a rationale to support your position.

21. Is your organization in support of Concept 1: Modifications to allow use of secure multi-instance? Please provide rationale to support your position.

22. Is your organization in support of Concept 2: Modifications to the EACMS definition? Please provide rationale to support your position.

23. Is your organization in support of Concept 3: Compliance Guidance? Please provide rationale to support your position.

24. If you have additional comments that you have not provided in response to the questions above, please provide them here.

1. Do you agree that the proposed change to the Cyber Asset definition makes it inclusive of both physical and virtual devices, including treatment of each virtual machine and hypervisor? If you do not agree, please provide rationale to support your position.

Joel Charlebois - AESI - Acumen Engineered Solutions International Inc. - 5

Answer	No
Document Name	

Comment

The proposed wording in the second sentence of the revised definition may still lead to some instances of inconsistent interpretation or application of the definition. It would be preferable to specifically use both of the terms “physical” and “virtual” in the second sentence, consistent with their use in the first sentence of the definition.

Suggested language for the second sentence: “Each virtual machine and physical host is a distinct device.”

Response

Richard Kinas - Orlando Utilities Commission - 3,5

Answer	No
Document Name	

Comment

- OUC has identified Concerns over the proposed definition to address virtual Cyber Assets including physical/hardware as many standards/requirements do not apply to a virtual device. For example, there are no physical i/o ports so the application of port locks (CIP-007-6 R1.2) does not exist in a virtual environment.
- The SDT should address the future proofing of the definition that will apply to all types of virtualized environments including storage, servers, switches, firewalls, routers, etc.
- The definition must take into consideration a virtual machine running on a virtual machine.
- The original terms “hardware, software and data” implied a physical device, with hardware and data residing within it. Within a virtual environment, the Virtual hosts (at the physical threshold) will be comprised of “hardware, software and data” while the virtual guests will be comprised of “software and data” however they may or may not be comprised of hardware. Virtual hosts not existing at the physical threshold may or may have physical aspects.
- We suggest that a different type of Cyber System be identified within the standards to address all infrastructure required to run the BES Cyber Asset/BES Cyber System in a virtual environment. We considered that the hypervisor becomes more impactful and may need even higher level of security controls. The BES Cyber System would continue to be those BCS that perform control & operation of the BES.
- If a follow-on sentence must be included in a definition, then the definition is not sufficient.
- If the second sentence must be retained then the clarification should make it clear that a virtual machine is by definition a Cyber Asset and not just a distinct device. However Hypervisors by their unique functioning, must include additional baseline information to ensure that the “entire system” remains stable, such as configuration information related to partitioning hardware, etc. used to prevent resource starvation.
- The requirement around baseline information is different between virtual hosts (infrastructure) and virtual guest/physical guests (BES Cyber Assets/Systems). With virtual hosts configuration information is critical and must be monitored to ensure that risks specific to virtual environments such as resource starvation are not modified without knowledge.

The interchanged use of the word Virtual Machine vs. Virtual Device can be misleading. The definition should be consistent for clarity.	

Cyber Asset:

A programmable electronic physical device or virtual machine, including the hardware, software, and data in the device or asset. Each physical host and each virtual machine are considered distinct Cyber Assets.

Lan Nguyen - CenterPoint Energy Houston Electric, LLC - 1 - Texas RE

Answer	No
Document Name	

Comment

CenterPoint Energy Houston Electric, LLC (“CenterPoint Energy”) does not agree with the proposed change to the Cyber Asset definition. The current definition covers virtual machines. Additionally, using the term “virtual device” without a corresponding definition may unintentionally broaden the scope of applicability. For example, it is not clear whether a container would be considered a “virtual device” alongside a virtual machine or a virtual local area network.

N&ST supports the intent of the proposed change but believes the revised definition needs more clarity, particularly with regard to the word, “host.” Suggested wording: ”A programmable electronic physical or virtual device, including the hardware, software, and data in the device. Each virtual device, commonly referred to as a virtual machine, and the underlying hardware and operating system that serve as the host for one or more such virtual machines are to be considered distinct Cyber Assets."

Comment

APPA does not agree that the proposed change is inclusive and believes that there is a better way to include both physical and virtual devices. Therefore, public power proposes the following:

“Programmable electronic devices, including the hardware, software, and data in those devices.
Virtualized systems or devices are distinct devices.”

This proposed change would help in “future-proofing” the definition.

David Francis - Midcontinent ISO, Inc. - 2,3 - MRO,Texas RE,NPCC,SERC,SPP RE,RF, Group Name SRC + SWG

Answer	No
Document Name	

Comment

The SWG offers the following comments.

- The original definition does not exclude the use of virtualization, therefore it should be read to be inclusive of virtual systems. This is supported by the ***Security Guideline for the Electricity Sector: Identifying Critical Cyber Assets*** published in 2010. It states that Cyber Assets to be considered under CIP-002-1 include, at a minimum, “hardware platforms running virtual machines or virtual storage”.
- The addition of “physical or virtual” does not add clarity to the definition.
- The question uses the term “hypervisor”, but the definition uses “host”. Please ensure consistency of the terms. Hypervisor is the more commonly understood term.
- If the SDT is determined to revise the definition in this manner, we recommend “Each virtual machine and each host is a distinct and separate device” to provide more clarity about the treatment of each guest and host.
- ERO-endorsed implementation guidance would be a more appropriate means to address the treatment of the hardware, software, and data and provide examples of implementation.
- Virtual system cannot be categorized as “electronic” due to the fact that they have no measureable electronic output. Virtual systems simply mimic an electronic device.

Brandon Cain - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - FRCC,MRO,WECC,Texas RE,SERC,SPP RE, Group Name Southern Company

Answer	No
Document Name	

Comment

In a VDI environment, there may be no persistent virtual device; in some cases, only an image may exist that is then spun up at the point in time it is needed. Given the definition above, all programmable electronic devices consisting of a virtualized host would be classified as a Cyber Asset, regardless of the persistence of a virtual machine on the host that may or may not be used in the context of Applicable System. The asset hosting the virtualized host would be, itself, a completely separate Cyber Asset. Consider changing this part of the proposed definition “Each virtual machine and host is a distinct device.” to read “Each virtual device is distinct from it’s host(ing) device.”

Comment

ERCOT signs on to the SRC comments and provides the following additional descriptive detail on the SRC’s comments, as well as responses for Questions #18 and #20.

ERCOT does not see the value of modifying the definition of Cyber Asset as noted in the comment form. The addition of the words “physical or virtual” does not add clarity to the definition. Virtual systems cannot be categorized as “electronic” due to the fact that they have no measureable electronic output. Virtual systems simply mimic an electronic device. ERCOT also notes that the current approved definition does not exclude the use of virtualization, therefore it should be read to be inclusive of virtual systems. This is supported by the ***Security Guideline for the Electricity Sector: Identifying Critical Cyber Assets*** published in 2010. It states that Cyber Assets to be considered under CIP-002-1 include, at a minimum, "hardware platforms running virtual machines or virtual storage".

In lieu of modifications to the definition of Cyber Asset, ERCOT recommends ERO-endorsed implementation guidance as a more appropriate means to address the treatment of the hardware, software, and data comprising a virtual Cyber Assets. ERCOT recommends drafting of examples of implementation through such guidance. Examples will aid industry in understanding the ways that virtual technologies can be implemented in a complaint manner.

Although we do not support modifications to the definition, if the SDT is determined to revise the definition in this manner ERCOT requests that the SDT ensure consistency of the terms. The question uses the term "hypervisor", but the definition uses "host". Hypervisor is the more commonly understood term, rather than host. We recommend the language be modified as, "Each virtual machine and each host is a distinct and separate device" to provide more clarity about the treatment of each guest and host.

Response

Wendy Center - U.S. Bureau of Reclamation - 1,5

Answer	No
Document Name	

Comment

Reclamation recommends the proposed definition of Cyber Asset be changed:

from: A programmable electronic physical or virtual device, including the hardware, software, and data in the device

to: A microprocessor-based device, including the hardware and software in the device, that is programmable by the end user or contains firmware/BIOS that is updatable by the end user in the field.

Inclusions:

1. Devices that can be "flash" updated by end user personnel, such as programmable logic controllers, distributed control system controllers, and other similar devices.
2. Virtual Machines
3. Workstations
4. Servers

Reclamation also recommends adding the following terms to the NERC Glossary of Terms:

Virtual Machine (VM) – An operating system (OS) or application environment that is installed on software, which imitates dedicated hardware. Each Virtual Machine is a distinct Cyber Asset on the Host Machine.

Host Machine – A physical Cyber Asset used to run one or more Virtual Machines.

Response

Douglas Webb - Great Plains Energy - Kansas City Power and Light Co. - 1,3,5,6 - SPP RE

Answer	No
Document Name	

Comment

The proposed Cyber Asset definition:

Adds Implementation and Compliance Complexity. The following terms, incorporated into the definition, are ambiguous and will necessitate creating additional glossary terms:

- virtual device,
- virtual machine, and
- virtual host.

Creates uncertainty that increases the opportunity for unintended negative consequences. For example, it is unclear if the proposed network virtualization definition establishes a scenario where VLAN on a switch becomes its own virtual device.

If the SDT concludes action is necessary, please consider the following:

A programmable electronic physical or virtual devices, including the hardware, software, and data in those devices. Each virtual machine and host is a distinct device.

Response

Ronald Donahey - TECO - Tampa Electric Co. - 1,3,5,6

Answer	No
Document Name	

Comment

- TEC has identified concerns over the proposed definition to address virtual Cyber Assets including physical/hardware as many standards/requirements do not apply to a virtual device. For example, there are no physical i/o ports so the application of port locks (CIP-007-6 R1.2) does not exist in a virtual environment. The definition must take into consideration a virtual machine running on a virtual machine.
- The original terms "hardware, software and data" implied a physical device, with hardware and data residing within it. Within a virtual environment, the Virtual hosts (at the physical threshold) will be comprised of "hardware, software and data" while the virtual guests will be comprised of "software and data" however they may or may not be comprised of hardware. Virtual hosts not existing at the physical threshold may or may have physical aspects.
- If a follow-on sentence must be included in a definition, then the definition is not sufficient.
- If the second sentence must be retained then the clarification should make it clear that a virtual machine is by definition a Cyber Asset and not just a distinct device. However Hypervisors by their unique functioning, must include additional baseline information to ensure that the "entire system" remains stable, such as configuration information related to partitioning hardware, etc. used to prevent resource starvation.
- The SDT should address the future proofing of the definition that will apply to all types of virtualized environments including storage, servers, switches, firewalls, routers, etc.
- We suggest that a different type of Cyber System be identified within the standards to address all infrastructure required to run the BES Cyber Asset/BES Cyber System in a virtual environment. We considered that the hypervisor becomes more impactful and may need even higher level of security controls. The BES Cyber System would continue to be those BCS that perform control & operation of the BES.
- The requirement around baseline information is different between virtual hosts (infrastructure) and virtual guest/physical guests (BES Cyber Assets/Systems). With virtual hosts configuration information is critical and must be monitored to ensure that risks specific to virtual environments such as resource starvation are not modified without knowledge.

Yes, the proposed change to the Cyber Asset definition makes it inclusive of both physical and virtual “devices,” but the proposed change introduces new problems for compliance.

One use of virtualization that has been observed in the field is in the area of virtual desktops for Control Center operator consoles. In the observed case, a “base image” is instantiated each time a user logs in, thus giving each user a fresh system for each shift. The base image is kept up to date as required by CIP-007-6, etc. Because the Cyber Asset is considered to be the physical device on which the virtualization software runs, the changes effected by each new instance of the base image are simply data changes that are logged by log in/log out monitoring. If each new instance is required to be treated as a new Cyber Asset, per the proposed definition, then each individual instance must be documented with baselines (CIP-010-2 R1), an active vulnerability assessment (CIP-010-2 R3 Part 3.3), etc. This will prove unworkable.

The present definition permits wide flexibility in the use of virtualization technologies for BES Cyber Systems, EACMS, and PACS, as long as each VM is protected at the same level as the hardware device it is capable of running on.

Response

Russell Noble - Cowlitz County PUD - 3,5

Answer	Yes
Document Name	

Comment

Cowlitz PUD agrees the proposed Cyber Asset definition will be inclusive. However, it may be over inclusive of devices that are not vulnerable to “network or internet” remote access. We believe the generic definition of “cyber” currently identifies computer based electronic devices that execute program instructions (code) from a memory medium, of which is living in an environment that allows modification via code execution. Electronic devices requiring physical manipulation, such as contact connections or replacement of hardware, to modify or replacement for upgrade should be excluded as they are not subject to circular code on code modification. The term “programmable electronic device” is subject to future definitional changes, and results in uncertain compliance interpretations. In agreement with APPA’s comment, we believe the definition of Cyber Asset should be restricted to a distinct virtual ***entity*** or physical device.

Brian Millard - Tennessee Valley Authority - 1,3,5,6 - SERC, Group Name Tennessee Valley Authority

Answer	Yes
Document Name	

Comment

TVA requests the SDT consider removing the sentence “Each virtual machine and host is a distinct device.” The term “virtual machine” carries significant connotations and potential for confusion. For example, a virtualized network switch may not be called a virtual machine, it may be a virtual router instance, virtual firewall instance, or a virtual device context. Each are somewhat analogous to the term virtual machine. However, calling out virtual machine specifically may hinder understanding.

Response	

Larry Heckert - Alliant Energy Corporation Services, Inc. - 4	
Answer	Yes
Document Name	
Comment	
Alliant Energy agrees, assuming that "host" is equal to "hypervisor." We also have a general request that terms are used consistently throughout the requirements, definitions, and rationale/guidance. The definition of "Cyber Asset" should clarify what is meant by "host" - the question refers to "virtual machine and hypervisor" but the definition refers to "virtual machine and host." The second sentence of the definition should be clarified as to whether the virtual machine and hypervisor are different entities. Unless these updates are aimed specifically for hypervisors, we suggest avoiding using that specific terminology and instead suggest to use a more generic reference like "mulit-instance OS."

Texas RE would like to clarify that the virtual machine and host are one Cyber Asset as the virtual machine cannot operate without the host machine. This shared relationship means that neither can be separate Cyber Assets. For example, if a virtual machine has been identified as a BES Cyber Asset (BCA); the host machine that runs the virtual machine is also a BCA; which also applies to PACS, EACMS, and PCAs. Texas RE is concerned that treating the virtual machine and its host as separate Cyber Assets can cause mixed-trust virtual environments; the host runs CIP and corporate virtual machines. CIP controls are only being applied to the CIP virtual machine and not its host; even though the host "*if rendered unavailable, degraded, or misused*" can impact the CIP and corporate virtual machines.

2. Do you agree that the term programmable in the Cyber Asset definition does not need further clarification at this time? If yes, please provide rationale to support your position.

Paul Haase - Seattle City Light - 1,3,4,5,6 - WECC, Group Name Seattle City Light

Answer	No
Document Name	

Comment

City Light believes programmable should be clarified to clearly differentiate between configurable hardware (which was not envisioned to be in scope in the original CIP v5 or in the never-published NERC guidance, and should be in scope now) and devices that execute easily modified instructions. The risks presented by configurable hardware are much less than those from truly programmable devices, and they should not be lumped together.

Comments: As noted in question 1, ERCOT does not support modifying the definition of Cyber Asset unless a modification to address “programmable” provides clarity to address risk and aids in cyber asset identification across all entities. There is a risk of inconsistency of definition across the industry if the term is not defined. If there is not an ERO-wide benefit, it should remain up to the entity to define the term for their own purposes.

Implementation guidance should not be used to define a term. It is an illustration of a way to comply. This is fundamentally different from the authoritative purpose of a definition. Implementation guidance should not be used to define the scope of the assets as a foundation of a standard.

The definition of the word programmable means a device is capable of being programed via electronic code or configuration changes. A dip switch should not consider an electronic programmable device since a physical action is required to change the setting. However, there may be critical devices/equipment that are considered Non-programmable but can have an adverse effect on the a BES Cyber System (i.e. Net Gear –Non-managed Switches, or similar).

There is still a gray area where it is questionable on whether a device is programmable or not. Most would agree a device that is configured by DIP switches is not programmable. But functionally, a device that takes settings via software, but has no field-changeable executable code is no different, and it is unclear if such a device would be considered “programmable”. Another area of question would be live OS virtual machines. These devices are read-only and the executable code cannot be altered.

There are a few varying interpretations of the term programmable being used by the industry. Even the referenced ERO Enterprise-endorsed Implementation Guidance which is a Lessons Learned document, indicates that different Entities were interpreting the term differently. Also, the ERO Enterprise-endorsed Implementation Guidance, as the reference suggests, is meant as guidance, and not meant to be the only way to be compliant. In addition, Entities who fail to document their own definition of programmable in their BES Cyber System Categorization process or methodology, and even Entities who do document their own definition of programmable, are subject to auditor interpretation of the term, which can be different than the Entity's interpretation.

Lauren Price - ATCO Electric - 1 - MRO,RF

Answer	Yes
Document Name	

Comment

ATC agrees that the term programmable in the Cyber Asset definition does not need further clarification at this time based on the following rationale. ATC closely monitored the SDT's prior attempts to define and provide guidance on this term. In addition, during earlier revisions to the standards, the SDT's formal responses to previous comments about this term have provided ATC adequate visibility into, and understanding of, the SDT's intent for the term. ATC had leveraged available information and guidance to formulate a methodology that assures programmable devices are considered for evaluation, and we have been able to provide clarity within our implementation through the use of our internally defined the term(s) Electronically Programmable and Mechanically Configurable. This approach provides our Subject Matter Experts with a uniform understanding of the term programmable that is consistent with the SDT's intent for the term thereby obviating the need for the SDT to further clarify it within the regulation.

Russell Noble - Cowlitz County PUD - 3,5

Answer	
Document Name	

Comment

Cowlitz PUD agrees in part with BPA that the term programmable should be retired. We differ in that the definitional objective is not clear. We believe there are four concepts requiring clear identification: A computational device or entity that:

1. Autonomously reads code assembled into a set of instructions (a program) to process data;
2. Uses a memory medium to contain the code and data using read and write actions;
3. Communicates with like or similar devices to exchange code and/or data;
4. And, installs and modifies its programs by executing a program.

Concerning "virtual devices," we believe this to be confusing. Rather, we propose BPA's use of "entity" or "virtual machine" Thus, a Cyber Asset is a “discrete device” that is contained within a physical cabinet with visible ports, or a discrete ***virtual entity or machine*** with hidden virtual ports logically contained in a "discrete device." Further, we are not confident that guidance is sufficient to convey the above in a manner that protects stakeholders from contrary audit standard requirement interpretation.

We recommend a definition that the device meets all of the criteria below:

- A device that has a microprocessor and field-updateable firmware or software.
  - “Field-Updatable” would include devices that have a management port, web interface, or any external interface that would allow the introduction of a firmware, software or logic update.
  - If the device’s case is sealed in such a way that would require it to be damaged to gain access to the chipset or internal ports then the device is to be considered to be not Field-Updatable.

Aaron Cavanaugh - Bonneville Power Administration - 1,3,5,6 - WECC

Answer	
Document Name	

Comment

BPA believes that industry understands the term programmable as described in SDT Considerations for V5 Posting: “an electronic device which can execute a sequence of instructions loaded to it through software or firmware, and configuration of an electronic device is included in programmable.” The capability of being modified exists for every independent executable entity such as virtual machines or hypervisor hosts. Associated controls to prevent unauthorized or unintended modification apply to all independent executable entities because vulnerabilities may exist in either entity and are not reduced without protecting both individually.

4. Do you agree with the proposed definition of Centralized Management Systems (CMS)? If not, please provide rationale to support your position.

Paul Haase - Seattle City Light - 1,3,4,5,6 - WECC, Group Name Seattle City Light

Answer	No
Document Name	

Comment

City Light supports the concept of identifying and defining CMS, but is concerned about the details and possible unintended consequences of the proposed definition. City Light supports APPA's comments to this question. Alternatively, if the proposed definition is prefered by the SDT, City Light recommends that it be modified to apply to virtualized systems, as follows:

CMS: A system used for administration or configuration of VIRTUALIZED BES Cyber System(s) through which the configuration of the VIRTUAL BES Cyber System(s) can be altered. (new words in CAPS; deleted 2nd word "centralized" as unnecessary)

Likes 0	
Dislikes 0	

Response

Ronald Donahey - TECO - Tampa Electric Co. - 1,3,5,6

Answer	No
Document Name	

Comment

The current proposed definition is too ambiguous and will pull in unintended systems and potential classification of a device as both an EACM and a CMS.

The definition as proposed should be revised to only include the administration of the BES Cyber System. The current definition may expand the scope to other tools with unintended consequences. TEC suggests that the definition of CMS needs to follow the format of other Glossary Terms by referring to the configuration of BES Cyber Assets instead of BES Cyber Systems

We envision that there will either be new requirements around CMS or adding them to other requirements/parts. Our efforts here must be to protect the right devices/systems and improve the reliable/secure operation of the BES. As indicated in question 1 above, we suggest that the shared components and shared infrastructure may need different defined terms than BES Cyber System.

Douglas Webb - Great Plains Energy - Kansas City Power and Light Co. - 1,3,5,6 - SPP RE

Answer	No
Document Name	

Comment

KCP&L does not support the proposed Centralized Management Systems (CMS) definition for the following reasons:

Definition is Unnecessary. Introducing a new designation for this class of devices is unnecessary.

Overly Burdensome Implementation. The company's analysis estimates it will take thousands of hours to review, update documentation with references to CMS assets, and to develop the related processes and procedures.

Alternative. If the SDT concludes the proposed definition is required to address the identified issues, an alternative approach is to modify the existing definition of EACMS to include management systems like those considered in the proposed CMS definition. The approach provides a simpler compliance view by not creating a new class of devices.

Likes 0	
Dislikes 0	

Response

Aaron Austin - AEP - 3,5

Answer	No
Document Name	

Comment

AEP suggests that, at most, the existing definition for EACMS be modified to incorporate "CMS" functions. The CMS definition allows the benefits of (1) the CMS to be within the ESP (Transmission's current implementation) and (2) applying the CMS definition to other appropriate devices (e.g. Domain Controllers or McAfee EPO).

Response

Lauren Price - ATCO Electric - 1 - MRO,RF

Answer	No
Document Name	

Comment

ATC requests further consideration of the use and applicability of this term as it relates to other existing categories of Cyber Assets under purview of the Standards today, as well as those extrapolated categories of EACMS proposed later in this concept/comment form. For the below reasons, ATC does not agree with the proposed definition:

1. It is unclear if the proposed CMS definition is intentionally silent to systems used for administration or configuration of Electronic Access Control and Monitoring Systems (EACMS) or Physical Access Control Systems (PACS)? Does this infer that EACMS and PACS cannot be virtualized? Where EACMS and PACS are virtualized, is an associated CMS to be identified and protected?
2. In addition, the creation of a newly defined term increases the number of Cyber Asset classification categories, thereby creating the potential for a given Cyber Asset to have yet another categorization. Careful consideration must be given to the controls applicable to each category so as to assure they are not at odds with each other. Where a Cyber Asset's functionality results in categorization under multiple categories, an unintended consequence cannot be the impossibility of compliance due to conflicting applicable controls.

Response

Elizabeth Axson - Electric Reliability Council of Texas, Inc. - 2

Answer	No
Document Name	

Comment

ERCOT notes that the definition is not limited to virtualization. This also introduces questions to some fundamental understanding of physical systems that have been in place since CIP Version 1. ERCOT does not see the value defining Centralized Management System (CMS) as noted in the comment form. It should be left to the determination of the entity on the classification of the systems. The ***Security Guideline for the Electricity Sector: Identifying Critical Cyber Assets*** published in 2010 addressed the concept of management systems. When identifying CCAs, entities were encouraged to consider Cyber Assets in a secondary or supporting role. Based on this guidance, an entity may choose to high watermark the management systems to be equivalent to what they manage due to risk. This means that a management system for a BCA could be classified as a BCA. This approach could also have been applied to EACMS devices.

However, if the SDT is determined to treat management systems as a distinct class of devices, the management systems should be added to the definition of EACMS. Splitting these out will lead to inconsistency in the application of security controls across asset types and increase risk to security programs. Adding management systems to the EACMS definition will present minimal disruption for entities based on the proposal to remove monitoring from the definition.

With regards to the CMS definition proposed, the SDT should clarify the use of "centralized" in the term. The context of "centralized" should be defined. Would this apply to distributed management tools in a virtual environment?

Response

Brandon Cain - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - FRCC,MRO,WECC,Texas RE,SERC,SPP RE, Group Name Southern Company

Answer	No
Document Name	

Comment

Southern Company has concerns that the proposed definition too broadly scopes in system-to-system management consoles used for things like patch management, malicious code prevention signature updates, and other systems that may currently not meet any applicable system definitions that would bring them into scope of the CIP requirements. For example, SCOM/SCCM and Symantec Endpoint protection used to push security patches and AV signatures to enterprise systems, and currently classified as BCSI repositories, would be scoped in and subject to additional compliance requirements as a CMS. Additional clarification is needed to understand the full scope of systems that this proposed definition would apply to. Also, the above notes state "adequately address the risk of systems used to manage virtual environments" and initially speaks specifically to "management systems in a virtual environment", yet, the proposed definition would be applicable to all environments, physical or virtual. The currently proposed definition could have further reaching impacts to management systems that are not used in virtual environments, and is overly broad and does not properly scope to virtualized environments.

Response

sean erickson - Western Area Power Administration - 1,6

Answer	No
Document Name	

Comment

Comments: So many systems if used incorrectly or maliciously can gravely affect multiple cyber assets in a BES Cyber System. These include centralized antivirus systems where a defective signature file (e.g. McAfee) could shutdown systems, centralized patching systems, baselining systems (e.g. Tripwire), vulnerability detection systems (e.g. Nessus), software defined networking systems and others. To single out virtualization control consoles seems short-sighted as it does not relate directly to the virtualized devices once they are provisions. There are also the issues around whether a client computer with a fat-client application for VM provisioning is particularly more of a risk, than a system that has a web-interface to the hypervisor that can also effect provision. In summary, centralized control systems are their own security domain, and should either be addressed separately, or under the auspices of protections afforded to all physical and virtual cyber assets.

CMS communication is usually classified as system to system communication and not interactive remote access. The intent is to clarify how entities should implement virtual infrastructure. This definition should be limited to CMS systems that support virtual systems as that is the risk being addressed. This broad of an addition would require a re-write of interactive remote access vs. system to system communication requirements.

N&ST believes the proposed definition falls well short of SDT’s intent and, if adopted, would result in endless arguments over its applicability. What does “centralized” mean? Would it apply to the administration and configuration of ALL BES Cyber Systems? Would it apply to ANY device through which an IT or OT administrator could make ANY type of configuration change? Would it apply to systems used to push software patches and/or anti-virus signature files to BES Cyber Systems (N&ST believes some Regional Entity auditors would probably assert that it does)? If it is the SDT’s intent to address systems used to create, configure, modify, and delete virtual machines, then this definition should say so explicitly. In fact, N&ST believes the SDT should consider using the well-understood term, “hypervisor” in any proposed definition.

Lan Nguyen - CenterPoint Energy Houston Electric, LLC - 1 - Texas RE	
Answer	No
Document Name	
Comment	
CenterPoint Energy disagrees with the proposed definition of Centralized Management Systems (CMS) due to the potential for mis-interpretation of the word “centralized.” Entities may avoid classifying management systems as CMS because they are not centralized or, in the case of a PC running a management tool, because they are not “systems”. Vendors provide centralized management systems that automate management of many systems, but the proposed definition could apply to any system that manages another, even if there is only a one-to-one relationship and even if the management is performed by an administrator running commands or simple scripts from a terminal. CenterPoint Energy believes both scenarios do not meet the intended definition of “Centralized Management System,” but the proposed definition may create uncertainty as to the applicability. Further, many management consoles are embedded systems incapable of the security controls required by the standards. Finally, it seems the intent of the SDT is to classify hypervisors as a CMS, but the hypervisor is local, not centralized, and can only impact guests running on that machine. The CMS concept is better left to the entity to categorize, based on impact of unavailability, degradation, or misuse of the management systems on BES reliability.

The definition as presented is overly broad and would pull in many other types of systems in place for other functions. Systems such as centralized backup, patching platforms, or anti-malware policy servers are certainly capable of modifying the configuration of an Applicable System, but are not currently in scope. They would be unnecessarily brought into scope by this definition. It should be made clear in the definition that CMS would only apply to virtual/multi-instance configurations.

Comment

Any management system that can alter the configuration of BCS should be included rather than only the centralized management system, whereas the CMS definition excludes the decentralized management system. Moreover, it can cause dual classification issue as some CMS devices could be the EACMS. We disagree to creating unnecessary new terms that are used to cover the management system and differentiate the electronic access control from the electronic access monitoring devices. These new terms can cause more confusing and more work for the entities to reclassify EACMS and identify the CMS while EACMS have complied with CIP standards. Furthermore, this would require SDT to update all applicable Systems in the CIP standards and create additional requirements for the newly reclassified and identified Cyber Assets such as CMS, EACS and EAG. To meet the same goal and reduce the complexity, we suggest modifying the EACMS definition to include all Cyber Assets that can alter the configuration of BCS into EACMS definition as follows:

“Cyber Assets that perform electronic access control or electronic access monitoring of the Electronic Security Perimeter(s) or BES Cyber Systems. This includes Intermediate Systems and the cyber systems that can alter the configuration of BES Cyber System.”

Definitions should not rely on words from the term being defined. In this case, the use of “centralized” in the definition is unnecessary. Also, the definition contains redundant wording. Suggested wording: “One or more Cyber Assets used for administration or configuration of one or more BES Cyber Systems.” The capability for administration or configuration includes the ability to alter a configuration.

Also, this appears to be a new class of system that should be protected by the CIP Standards. Which Standards, Requirements, and Parts will need to have “CMS” added to their Applicable Systems designations?

The definition as proposed should be revised to only include the administration of the BES Cyber System. The current definition may expand the scope to other tools with unintended consequences. Does the definition of CMS need to follow the format of other Glossary Terms by referring to the configuration of BES Cyber Assets instead of BES Cyber Systems? Or is it sufficient as it stands? Does it apply to the administration only of the BCS?

We envision that there will either be new requirements around CMS or adding them to other requirements/parts. Our efforts here must be to protect the right devices/systems and improve the reliable/secure operation of the BES.

Based on group discussions, we have concerns over what is meant by administration or configuration. There were different interpretations based on individual understanding. This should be resolved with a defined term that can be plugged in to the requirements and be implemented by industry. As indicated in question 1 above, we suggest that the shared components and shared infrastructure may need different defined terms than BES Cyber System

It is becoming probablamatic when we have devices that meet multiple definitions, and potentiall when these definitions are used for determinint applicability. I can envision a device being part of a PACs and being a CMS at the same time. Is the CMS intended to be limited to just BCA's and not control devices that are implemented to meet a requirement?

Current definition is too ambiguous and will pull in unintended systems (possibly something that would be both an EACM and a CMS)

Is CMS intended to extend to BCSs that have no virtual components? If so, this might be outside the scope of the virtualization mandate.

To further the earlier question about if AD is intended to be included in a CMS definition, would the user, group, and permissions management functionality fall under CMS definition or would that continue to be EACMS functionality (or the new EACS category)?

Suggest that a CMS be defined as permanent to distinguish from Transient Cyber Assets used for administration/configuration. The risk associated with a CMS would be greater because it could be used inappropriately at any time and potentially remotely. Even if the CMS used the proposed CIP-005 R3 method of communication that might be intermittent, presumably that communication channel would be “on demand” and so would be present the same risk as a permanently connected system.

We agree that with the model proposed by the SDT, that the term Centralized Management System needs to be defined but are feel that the existing definition provides the clarity needed.	

By just applying the CMS definition and not including any previous conception of a CMS I have the following concerns.

1) Could a Transient Cyber Asset used to configure BCS (protection relays) be considered a CMS? It is probably not a “Centralized system” but I don’t know what that is.

2) Could the cyber systems, owned by the entity or a SCADA vendor, uses to remotely administer or configure multiple SCADA systems (possible at multiple entities) be considered a CMS? Using a intermediate system may eliminate the “centralized system” applicability but would still allow the remote computer to be a CMS in a low impact configuration that does not require an intermediate system.

3) The current definition would identify an Active Directory Server as a CMS. Is this what is intended?

It is BPA’s opinion that the proposed definition of CMS captures most types of systems that support automation with a large span of control and privileged access.

BPA recommends that the SDT moves away from the old model of devices and prescriptive requirements to a model of systems and security objectives. Under the current approach, Applicable Systems definitions are necessary to target requirements. However, under a security objectives-based approach, definitions of Applicable Systems would be less critical.

We agree with the definition, but it potentially includes systems outside the scope of virtualization – e.g., a network configuration management system can be used to push out configurations to various networking components, configuration management software (e.g., Puppet, Salt, Chef, etc.) can do the same for virtually any class of cyber asset. Similar systems exist for IEDs (e.g. Subnet Solutions PowerSYSTEM Center, EATON IMS, etc.) A domain controller can push out group policy, altering the configuration of a BCS.

Is the intent for these systems to be covered by this definition?

- If yes, that is the intent, then the definition is fine.

- If no, it is meant to only encompass virtualization management systems, then the definition is too broad and covers more than just virtualizion management systems as written.

Regardless, we believe that all configuration management systems that could affect BCS should be covered because they all have the potential to have impactful effects on the BCS whose configurations they manage.

5. Do you agree that the proposed definition of ESZ more adequately applies to proper isolation of multi-instance environments, regardless of OSI layer? If not, please provide a rationale to support your position.

Karie Barczak - DTE Energy - Detroit Edison Company - 3,4,5, Group Name DTE Energy - DTE Electric

Answer	No
Document Name	

Comment

Creating a new definition for the same concept of an ESP is counter-productive and does not add additional clarity. Additionally, even if we reused ESP, the definition above is not clear. Keep using ESP, but change the definition to be explicitly clear that either physical or virtual (logical is implied with the use of virtual) networks are allowed for the creation of the required security perimeter to isolate network boundaries. As example, "The logical border network border with one or more defined EAPs implemented using physical network topology or virtual (software defined) network tools to which BES Cyber Systems are connected using a routable protocol." This at least defines the allowed methods and the expected boundary without adding a new term with a vague definition.

Richard Kinas - Orlando Utilities Commission - 3,5

Answer	No
Document Name	

Comment

What will be required to have logical separation? Need a logical definition. Do ESP's become mandatory ESZ's?

Baselines for virtual devices—hypervisor, need more data than just the ports & service, OS, SW, patches (resource definitions, other security controls, to do comparison). Configuration must prevent resource starvation—hardening guide for VMware—SSH port/TFE….

What is sufficient here: "proper isolation of multi-instance environments"? Can't create a requirments that relies on entities and auditors to interpret what is proper isolation. Need to define it and or replace the language.

TVA supports flexibility within the standard to accommodate a multi-tenant architecture and the benefits provided by adaptation of industry standard architectures such as on premises cloud computing and hyper-converged infrastructures. TVA is concerned the ESZ concept as presented is overly complex and creates potential to hamper entities in constructing appropriate security controls or programmatic boundaries for their compliance programs. Loading definitions and program boundaries with new, undefined terms such as “multi-instance, shared infrastructure, management plane, data plane, and containers,” will only compound confusion and fragmentation of interpretation.

Comments: How appropriate various forms of logical and physical isolation are will always be dependent on the software and hardware implementations. A definition of the boundary between a VM and its hypervisor, or a VM and another VM may be useful to delineate a boundary where security/isolation controls can be evaluated/applied, but by no means addresses the concept of "proper isolation". The concept of proper isolation is a diffuse one and can broach on a multitude of shared infrastructure concerns, including SANs, power distribution systems, separation of computing instructions from data in hardware, etc. Risk can also be evaluated in the context of the systems design, or can encompass the possibility of privilege	

elevation bugs which further muddies the water. In summary, the isolation of virtual cyber assets isn't necessarily a greater concern than the isolation of physical cyber assets, with the possible exception of how a hypervisor might be treated. It is even conceivable that a VM platform could securely isolate even systems with different security contexts depending on the implementation.

Response

Elizabeth Axson - Electric Reliability Council of Texas, Inc. - 2

Answer	No
Document Name	

Comment

Comments: ERCOT recommends that the ESP and ESZ definitions should be aligned within a single definition. There is no need for two definitions that address basically the same idea. Creating two definitions will add to confusion and may require Entities that have implemented to CIP Version 5/6 to re-assess and re-design their configurations at substantial cost without much added benefit. The ESZ definition is broad and appears focused on a single or few use cases (based upon vendor technologies), but could have negative impact on other use cases (other vendors) beyond the intended purpose. ERCOT asserts that a single definition could be used to address network boundaries holistically and asked that the SDT consider a modification such as, "The border that provides logical separation to isolate BES Cyber Systems from other Cyber Assets."

Response

Wendy Center - U.S. Bureau of Reclamation - 1,5

Answer	No
Document Name	

Comment

Reclamation does not support the proposed definition of ESZ. The term ESZ can impact virtualized and non-virtualized systems.

Reclamation recommends the term Electronic Security Zone be changed to Virtual Electronic Security Zone (VESZ), applying only to virtualized environments, and the proposed definition be changed:

from: The area defined by the logical separation of one or more Cyber Asset(s).

to: A boundary housing one or more Virtual Machines logically separated from other BES Cyber Systems or other non-BES Cyber Systems using partitioned and isolated service set identifiers (SSIDs), virtual local area networks (VLANs), or other technologies.

The term “logical” should be more specific, up to and including relevant OSI layers. It should also be specified if the ESZ will require separation of specific assets from each other. In physical servers, the communication between devices in an ESP is not controlled and we believe the analogy should carry to virtual infrastructure. Two VMs of the same BES Cyber System could share an ESP and an ESZ, for instance.

- The proposed definition of an ESZ is insufficient to provide guidance to industry.
- TEC has included some of the questions/discussion around the logical separation and layers for the SDT to better understand where the confusion may lie.
    - More than just OSI layer 3 connectivity; need to provide controls at the other layers, but which layers? Who makes the call?.
    - VMware: Can put virtual firewalls inside the cluster; can separate the traffic with controls in place. Which OSI layers—segment layer 2 or layer 3. Concept for ESZ is for non-layer 3.
    - If it is on the same SAN, if you have the potential to use the other hardware, then you have to protect it. Or could encrypt the device. Definition of Cyber Assets—electronic physical or virtual….would apply to the financial box in the image on p. 8.
    - What will be required to have logical separation? Need a logical definition and Virtual Cyber Asset…should not be physical plane into virtual plane.
    - Baselines for virtual devices—hypervisor, need more data than just the ports & service, OS, SW, patches (resource definitions, other security controls, to do comparison). Configuration must prevent resource starvation—hardening guide for VMware—SSH port/TFE….
    - Implement vendor hardening guide—(but that brings in new requirements related to

    Mixed trust—create vm dedicated to CIP; VM for high BES Cyber Systems… what about the EACMs—in a separate environment but not an ESP? What about PACS—now on corporate; separate VM environment for PACS. Will get to be cost prohibitive to use virtual environments if they all have to be separate. Every device on the virtual environment has to be treated according to the high water mark;

    - May apply to one instance but may not apply to others. What is sufficient here: “proper isolation of multi-instance environments,”

Fundamentally disagree with the creation of a new ESZ concept. It seems to be an attempt to arrange virtual resources in a way similar to what is currently done with Cyber Assets as network nodes in an ESP. However they are not analogous, do not work that way and should not be managed that way. The ESZ concept is not a good fit and explains why most of remaining question is this section are difficult to interpret. Please see summary answer 21 for suggestion of a simpler approach. Also, use of “multi-instance”, if, as it seems to be, is meant to be analogous with the idea of “multi-tenant”, than this would seem to exclude most virtualized systems. Is this intended?

NERC has clearly stated that Ethernet VLANs are not considered acceptable logical separation. If NERC will not accept VLANs as acceptable (which have been around for 15 years) there is no chance or at least there should be no chance that the ESZ would be found sufficient.

We understand the intent is to ensure that VMs in shared environments have controls to keep their data separate, however as written it is ambiguous and appears to be adding security that doesn't exist for physical machines, e.g. separating individual virtual hosts in one BES Cyber System vs. allowing physical BES Cyber Assets in one BES Cyber System to communicate within an ESP.

See our response to proposed ESZ definition, Question 5. Also, we do not see the proposed ESZ definition would apply any differently to future CIP Standards. **Request.** If the SDT concludes the proposed definition is required to address the identified issues, clarity is needed to understand the relationship between the Electronic Security Zones and the existing structure of the Electronic Security Perimeter. For example, are the terms ESZ and ESP complementary, or does implementing an ESZ eliminate the need for an ESP?

Aaron Austin - AEP - 3,5	
Answer	No
Document Name	
Comment	
While the proposed definition does for today give a more specific method of isolation, AEP believes a more effective solution would be to, at most, modify the definition of ESP to allow for greater latitude in establishing logical segmentation of networks whether physical or virtual. AEP believes implementation of processes to meet CIP-005 R1, Parts 1.6-8 would produce sufficient evidence and meet the intent of the proposed requirements without introducing the new definition of an ESZ.

Comments: The adequacy of separation is dependent upon the hardware and software of a specific implementation, and also to the evaluation of issues with such separation overtime. A definition as a placeholder for future VM isolation requirements seems to presuppose that the need of logical segregation for virtual cyber assets exceeds that of physical cyber assets.

AZPS is concerned that the definition and concept as proposed could lead to ambiguity and confusion if it does not address all of the concepts and potential configurations indicated in this document and its associated diagrams. In particular, AZPS recommends that the definition needs to address the separation controls as mentioned in the rationale provided in Questions 5, 7, 8, etc. Additionally, AZPS recommends that the terms instance and multi-instance be revised to refer to tenancy as this is a more accurate representation of virtualized devices and environments. The term instance could be confused relative to whether it is referencing a segment of the virtualized environment or the assets within that environment. To alleviate that confusion, AZPS believes that use of the terms tenant and multi-tenant will more clearly delineate the cyber assets versus the environment. • Tenant: Discrete organizational environment with specific privileges or security levels, consisting of functions that consume resources from the shared infrastructure. Tenants are logically isolated, but physically interconnected. • Multi-Tenant: An environment where a shared infrastructure provides containers for more than one tenant.

The ESZ concept is potentially confusing and will not aid in clarity for future Standards. Standards relevant to logical separation can state requirements for logical separation where appropriate. Further, business needs vary in different environments, and an entity may have valid reasons for not logically separating systems that do not introduce unacceptable security risks. Requiring an ESZ to be defined limits the flexibility an entity has to design and manage systems in their own environments.

It is difficult to tell from the definition alone. It would need to be shown in context to determine if it is useful. It is sufficiently high level to cover many different types of logical separation, but it may be so abstract that entities will have trouble interpreting what to do. Based on some of the following requirements though, it looks like it will aid in development of future CIP Standards.

7. Do you agree that the proposed CIP-005 Requirement R1, Part 1.6 provides sufficient security controls for the high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS to reduce the stated risks inherent to virtualization? If not, please provide a rationale to support your position.

Scott Downey - Peak Reliability - 1

Answer	No
Document Name	

Comment

In many instances the management plane uses centralized authentication such as radius or Idap. This makes the management plane dependent on the supporting authentication servers. The supporting authentication servers often have a managmeent backplane. For simplicity the managment plane of the authentication servers may be connected to the date plane as the benefit of separating the planes is limited due to the dependency.

This is close, but needs more definition and a requirement to ensure that the CMS still reside within the ESP (again remove the use of an ESZ as this adds more confusion). Suggestion re-write:

Logically separate, using Hypervisor controls and an associated CMS, all Applicable Systems into defined groups of one or more Cyber Asset(s) to achieve the objective of mitigating the risks of span-of-control, insider threats, and lateral privilege expansion. At a minimum:

1. The management plane (CMS) and the data plane of the managed BES Cyber system shall be separated on different managed networks while ensuring both must reside in the same ESP.
2. The CMS of the managed BES Cyber Systems shall be separated from the data planes in which the BES Cyber Systems operate.

Part 1.6.1 potentially mitigates the risk of lateral privilege expansion and possibly insider threats We are concerned that none deal with mitigation of span-of-control In addition, not all vendor solutions may be able to address Part 1.6. If it is added, there should be TFE capability. In addition, the proposed Part 1.6 introduces the requirement for lists to demonstrate compliance. We also suggest that the word "achieves " is not the appropriate term for the requirement part. We recommend changing it as follows: Logically separate all Applicable Systems (is this a new defined term?) into defined groups of one or more Cyber Asset(s) to **address potential risks** related to span-of-control, insider threats, and lateral privilege expansion.

We suggest changing the wording from “defined groups of one or more Cyber Assets to “defined ESZs”. Also we suggest changing the wording from “The management plane and the data plane of the applicable BES Cyber System shall be separated” to “The management plane and the data plane of the applicable BES Cyber System shall be separated by ESZ”. As we proposed EACMS definition modification, “CMS” would be changed to “EACMS”. Please clarify whether the management plane and data plane need to be separated by ESZ, provided that both planes reside inside ESP. Given that the modified Cyber Asset definition includes physical and virtual devices, this requirement will apply to physical cyber system as well, where it means the current in-band network architeture is required to be changed. For instance, an EACMS inside ESP would requires a ESZ to separate it from the BES Cyber Systems.

The Requirement language as written will be challenging for entities to demonstrate compliance because it is objective and intent based. Registered entities may have difficulty producing evidence of intent. Also, entities may encounter situations where there is a valid reason for not separating the management and data plane of an asset or system, and the proposed Requirement R1, Part 1.6 would not allow that. Further, many assets do not have a capability of logical separation of management and data plane. For those that do have the capability of such separation, it is not clear what evidence can be provided to prove the separation is achieved and that no management activity has or can occur from the data plane. This requirement seems to be aimed at multi-instance environments but does not state this in the language, and it would be difficult to achieve and demonstrate for many non-virtual environments. If the proposed Requirement R1, Part 1.6 is intended for multi-instance environments, the wording should be revised to make such intent clear.

N&ST considers the stated objectives to be worthy but they should not be included in a requirement statement. How would an entity actually demonstrate they have effectively mitigated the identified risks? N&ST assumes “applicable systems” are “BES Cyber Systems comprising one or more virtual machines” and “associated CMS” but the SDT should say explicitly what are “applicable systems.” N&ST wonders why the SDT, having defined “ESZ,” doesn’t use it here. Why not say, “The data and management planes of applicable systems shall reside in separate ESZs”? N&ST also	

recommends that, at a minimum, any potential requirement such as this include a brief description of what is meant by “management planes” and “data planes.”

Too prescriptive because some products do not allow separation of management and data planes

It is difficult to answer this question because it is not completely clear what the proposed R1.6 requires.

The first part of this requirement is almost identical to the definition of ESZ. If this requirement is to implement ESZ(s) than it should use the ESZ term. If not, it should be clarified on how this is not an ESZ.

Have the same concern as with the use of “logical” in the ESZ definition. The use of “logically separate” in this requirement could redefine the “logically grouped” in the BCS definition. How is “logically separate … into defined groups” used here different than “logically grouped” used in the BCS definition?

Comments: While defining groups of cyber assets (physical or virtual) that need to communicate to perform a function, and isolating/limiting such communication within the group makes sense, bringing management and data planes into the standards when so many products do not even have a cohesive mapping to the concepts seems unwise, not to mention the omission of the control plane.

ERCOT asserts that the requirement increases complexity while creating confusion for Entities that have already implemented CIP Version 5/6. The standard requires an Entity to configure and implement based upon specific configurations concepts creating risk for other technologies. Result or outcome-based standards should be used and not be as prescriptive as the requirement proposed. This allows Entities to use definitions to illustrate their architecture and implementation.

ERCOT offers that the requirement could simply state “Logically separate Applicable Systems”. The proposed requirement offers a security objective, but also goes into specifics that are prescriptive in nature. The SDT should ensure that a proposed requirement is clear and implementable as defined by industry.

With regards to the proposed requirement, ERCOT offers the following feedback. (1) The SDT should clarify the meaning of separation. Is this intended to be routable protocol separation or memory separation within the hypervisor itself? Seems to be a judgment call, which is not appropriate for a mandatory and enforceable requirement. (2) The SDT should consider defining span of control and insider threats. (3) ERCOT requests clarification of the context of “lateral”. Lateral relative to what? (4) The SDT should clarify what “its” refers to in item 2 of the requirement. (5) Management and data functions should be defined and common access prohibited. ERCOT also notes that in the diagram below, the management and data plane in the same ESP.

Comment	
Too prescriptive because some products do not allow separation of management and data planes It is difficult to answer this question because it is not completely clear what the proposed R1.6 requires. The first part of this requirement is almost identical to the definition of ESZ. If this requirement is to implement ESZ(s) than it should use the ESZ term. If not, it should be clarified on how this is not an ESZ.	

Have the same concern as with the use of “logical” in the ESZ definition. The use of “logically separate” in this requirement could redefine the “logically grouped” in the BCS definition. How is “logically separate … into defined groups” used here different than “logically grouped” used in the BCS definition?

SDG&E considers this proposed requirement to be far too undeveloped to be considered for advancement. SDG&E would like more detailed explanations of the separation of management plane, storage element and data plane. Seek further clarification of where the CMS can reside and be compliant with this requirement. How does a multi-impact criteria CMS meet this requirement?

The proposed CIP-005 R1, Part 1.6. creates: **Compliance Uncertainty.** The terms “applicable systems,” “span-of-control,” “insider threats,” and “lateral privilege expansion” used in proposed Part 1.6 can easily be construed and interpreted broadly, creating significant compliance uncertainty. Recognizing that some of the terms occasionally popup within the context of cybersecurity, we have not been able to identify additional prescriptive language or determine how to define the terms to mitigate that uncertainty. Without additional clarity, the terms create compliance uncertainty. **Burdensome Costs.** The cost to implement and maintain Part 1.6 compliance is burdensome. The compliance uncertainty associated with the subpart further muddies determination of the eventual security benefit, if any. **System Performance Impacts.** It is expected that implementing Part 1.6 will require new or modification to current systems, processes, and procedures. The added complexity will unfavorably affect system performance. **Unintended Consequence.** It is generally accepted that added complexity weakens security by increasing potential cyber vulnerability paths.

These terms appear to specifically reference VMWare NSX. The webinar showed that it would be acceptable to address management interfaces on one LAN and the public VM on another. That makes sense to us and is a best-practice in general. That said, the definitions should reflect that concept better and be specific about how “deep” that separation needs to be, e.g. does it require two ESPs? Can they be VLAN-separated? (See later comments on VLANs.)

We suggest that the proposed requirement Part 1.6 could this be a policy with entity documentation of risk mitigation.

1. Part 1.6.1 potentially mitigates the risk of lateral privilege expansion and possibly insider threats
2. We are concerned that neither minimum inclusions deal with mitigation of span-of-control

In addition, not all vendor solutions may be able to address Part 1.6. If it is added, there should be TFE capability. In addition, the proposed Part 1.6 introduces the requirement for lists to demonstrate compliance. We also suggest that the word “achieves“ is not the appropriate term for the requirement part. We recommend changing it as follows:

Logically separate all Applicable Systems (is this a new defined term?) into defined groups of one or more Cyber Asset(s) to address potential risks related to span-of-control, insider threats, and lateral privilege expansion.

Paul Haase - Seattle City Light - 1,3,4,5,6 - WECC, Group Name Seattle City Light

Answer	No
Document Name	

Comment

City Light supports the concept of the new requirement but cannot support the wording. Management plane and data plane must be clarified or defined, if used within a legal requirement, and the term "Cyber Asset" must be modified to ensure only 'applicable' or 'virtualized' Cyber Assets are in scope, not all possible Cyber Assets (because the CIP Standards only apply to BES Cyber Assets and applicable Cyber Assets as identified by CIP-002, and not all possible Cyber Assets). Considerable conflict remains between the logical-based concepts on ESZ and the physical-based concepts of devices and Cyber Assets.

City Light further supports APPA's additional comments.

Agree this is a good idea. However, in practice what it means is most control, at least in terms of interaction by a user through a CMS cyber asset, is via network connection. The simple approach is to require all such CMS cyber assets (virtual or real) to be in a distinct ESP from the hosted cyber assets. Possibly a requirement could be made that any non-IP interaction (a proprietary management plane or direct hooks into the host OS) b/w the CMS cyber asset and the host have some security provisions, but this is usually proprietary and vendor specific and difficult to define in a universal way.

Response

Joel Charlebois - AESI - Acumen Engineered Solutions International Inc. - 5

Answer	Yes
Document Name	

Comment

Yes but there needs to be some provision for separating the management planes for BCA and non-BCA. Separation of the management plane is necessary to ensure Cyber Assets are appropriately categorized and that unnecessary cyber assets are not brought into scope when not needed to be.

For instance some entities will use one CMS for all virtualized Cyber Assets. Some of these may be BCA, some may not. Entities will often separate the data planes of these virtual Cyber Assets, but may forget to separate the management plane, thus inadvertently making all of the non-BCAs PCAs even though the data planes are separated. There should be some guidance on this topic to make sure entities are separating virtualized Cyber Assets appropriately.

By not requiring an ESZ, public power believes that this Requirement construct simplifies the requirement and provides the appropriate control objectives. The use of the word “achieve” in the draft standard sets a requirement that could be impossible to maintain as new risks emerge. Therefore, APPA proposes replacing “achieve the objective of mitigating the risks” with “address the known risks associated with,” in the standard. Additionally, public power proposes that this Requirement have the “per device capability” clause. Public power is concerned that the use of “logically separate” in this proposed requirement could redefine “logically grouped” in the BCS definition. Consequently, members would need to understand how “logically separate … into defined groups” is specifically different than “logically group.” APPA recommends that this aspect of the standard language be clarified.

We recommend that the SDT consider the scoping on this requirement part. Would this be identified in the applicability table since it only applies to multi-instance? At the top of the standard/requirement? Or as shown within the requirement? We recommend the SDT provide additional clarity on the ability to have technical controls for other layers (aside from the communication layer) and with shared memory space. We would also like the SDT to consider the ramifications on the use of a cloud based SIEM vendor who is most likely using a virtualized environment. In the cloud environment, an entity would be transferring risk as well as trust

As above, the type of communication should be enumerated. Network and Systems engineers are aware of constructs like OSI layers and so avoiding terms like “layer 2” and “layer 3” are counterproductive in our opinion. We support the idea. We had significant internal discussion about whether you are describing a typical VMWare environment, which we consider multi-instance, or if you meant one layer removed such as Containers. The fact that we had significant internal disagreement indicates that this is unclear.

ERCOT asserts that the intent of this requirement is unclear. The proposed ESZ appears to be focused on specific vendor technologies. Virtualization of networks verses host or integrated systems all have very different implementation based upon vendors. Adding a CMS outside of the ESP further complicates security controls.	

ERCOT requests examples of systems that can basically “firewall” non-routable protocols. Additionally, ERCOT requests clarification of an EAP equivalent for the ESZ boundary where inbound and outbound permissions can be applied. If the intention is to only refer to a routable protocol, this requirement part is redundant to the existing firewall requirement in CIP-005 Requirement R1, Part 1.3.

Southern Company respectfully requests additional clarity around the use of the term “communications” as it is used in the proposed requirement to achieve micro-segmentation. Does “communications” include resource usage between instances, and does it include LANs, VLANs, virtual switches, port groups, and backplane communications? Consider that for some entities, meeting strict compliance with this requirement as proposed may demand additional procurement of network virtualization solutions from vendors, such as VMWare NSX.

The use of an ESZ is still confusing. Rather than introduce a new concept, simply state that multiple networks (either virtual or physical) may be used in the same Shared Multi-Instance Environment (the diagram for Part 1.8 perfectly illustrates this). What then is required is that traffic between any ESP or outside of an ESP defined in the same Shared environment must implement the required security controls to enforce secured traffic between the boundaries. This then ensures that all the same controls already required for ESPs must be enforced regardless of whether it is a physical network or virtual network with physical hardware or virtualized environments.

It is difficult to answer this question because it is not completely clear what the proposed R1.7 requires. Shouldn't this be "only necessary inbound and outbound communication outside the ESZ"? It seems that using "Cyber Asset(s)" could require inbound and outbound controls between two VM's in the same ESZ. The applicability for this is for BCS in a multi-instance environment. It is seems that both a single VM and an ESZ could meet the definition of "instance".

Comment

This is still not clear and does not even match the diagram given. The problem with the current definition is that it does not account for the fact that I may have multiple virtual servers on the same VLAN defined within the Hypervisor that are still in the same ESP, but not part of the BES Cyber System (e.g. a PCA that is taking advantage of the Virtual Environment). Instead, this should be used:

1. The BES Cyber System, the management plane of the shared infrastructure, and any hosted Cyber Assets not part of a BES Cyber Systems shall all be separated using an ESP defined virtually within the Virtual environment or using physical equipment linked to the virtual environment; and
2. Communications between the BES Cyber System and any hosted Cyber Assets not part of the same ESP shall all be denied by default.

Comment

There are discrepancies between the language in the Part 1.8 and in the question. Question identifies “shared multi-instance environments “ where the requirement does not. We recommend that the SDT provide guidance on what is infrastructure (possibly using language such as BES related infrastructure) and suggest that the SDT define “Multi-instance”.

If a Jump-host (a required security control for IRA for High BESCS) which is outside of the ESP, then requirement would not be applicable. (remember that EACMs will be split—EAC and EAM). If the Jump-host was on the VM infrastructure is this a multi-instance environment?

Question—how much security do you have to implement (how many firewalls? Reside in same physical location? Trade ease of administration for security…trying to balance it; how far do you have to go to prove that it is “secured”; each environment is different.

Logical separation and “deny by default” communications are insufficient to ensure complete separation of two environments. Suggested rewording:

When an infrastructure is shared between BES Cyber Systems and other Cyber Assets not part of a BES Cyber System:

1. The BES Cyber System, the management plane of the shared infrastructure, and any hosted Cyber Assets not part of a BES Cyber Systems shall all be separated. Such separation shall achieve the objective of preventing data leakage across the separation. Such separation shall also achieve the objective of preventing code, malicious or otherwise, from migrating across the separation; and
2. Communications, if any, between the BES Cyber System and any hosted Cyber Assets not part of a BES Cyber System shall be through a defined Electronic Access Point.

Given that the modified Cyber Asset definition includes physical and virtual devices, this requirement will apply to physical cyber system as well. For the existing EACMS, PACS and PCA that are sharing the same network infrastructure, please clarify if now they need to be separated from the BES Cyber Systems. Please define what constitutes a separation and whether the separation means the authentication, inbound and outbound access control or both. Please clarify how a BES Cyber System achieves denied by default and whether it means no listening ports are allowed.

Comment

As with the comments provided for #8 above, the term Electronic Security Zone should be explicitly used, i.e. “The BES Cyber System, the management plane of the shared infrastructure, and any hosted Cyber Assets not part of a BES Cyber System shall reside in separate ESZs”.

Additionally, this requirement does not account for Protected Cyber Assets which may need to reside within the Electronic Security Perimeter and Electronic Security Zone with the BES Cyber Assets they are associated with but do not meet the criteria for classification, or BES Cyber Assets that are treated as such because of high-water marking.

This requirement would be unecessary if the ESZ definition were amended as listed in #8 above.

N&ST believe the proposed wording does not address the scenario depicted in the diagram that accompanies the narrative preceding proposed Part 1.8. Suggested rewording: “When a virtual computing infrastructure is shared between BES Cyber Systems within an ESP and other Cyber Assets outside of that ESP, the hosting virtual infrastructure shall be configured so that: (1) the infrastructure’s management plane is entirely within the ESP, (2) the infrastructure’s management plane is in a separate ESZ from both the BES Cyber Systems and other Cyber Assets that share the infrastructure, (3) communications between BES Cyber Systems and other hosted Cyber Assets that are outside of the ESP are denied by default, and (4) any and all allowed communications between BES Cyber Systems and other hosted Cyber Assets that are outside of the ESP must take place through a defined EAP."

Comment	
TVA supports flexibility within the standard to accommodate a multi-tenant architecture and the benefits provided by adaptation of industry standard architectures, such as on premises cloud computing and hyper-converged infrastructures. The ESZ concept, as presented, is overly complex, and lacks clarity to help entities how to institute separation between tenants, and shared underlying physical compute resources, whether processor (compute), storage, or transport (network). In the language provided, it is unclear as to the target of the separation (e.g., specific groups of Cyber Assets). Policies and procedures to restrict storage of VM images and snapshots do not exist. Formal change management processes that govern image creation, security, distribution, storage, use, retirement, and destruction must be created or incorporated into the existing NERC CIP controlled change management process. Additional security monitoring and control of stored images and snapshots should be implemented. This requirement does not cover striping of BES data, where system information may cross multiple volumes and assets.

Answer	No
Document Name	
Comment	
Southern Company requests additional clarification on why the management plane must reside fully within the ESP? Additionally, a description of the ESZ applicable to the example diagram would help clarify the concepts behind the proposed requirement. Southern has concerns that, if the management plane must reside fully within the ESP, the gains proposed for an Entity “to leverage the investments and protection of infrastructure shared between applicable Cyber Assets and other programmable devices” might not be realized due to the compliance burden of doing so. As stated in question 8, Part 2 of the proposed requirement needs additional clarification with regard to the use of the term “communications”. Is Part 2 of the requirement analogous to firewall rule base language, is it also applicable to shared SAN, fiber, etc. resources, and how is that expected to be implemented with regard to all forms of “communication”?

Yes, but it is unclear where the CMS should/must reside. The management plane is inside the ESP, but is the implication that the CMS is also inside the ESP or some equivalent ESZ meant for CMS?

Putting the CMS outside a protected area such as an ESP/ESZ increases the risk to the BCS and an EAP between the CMS and the management plane reduces some of the risk, but not all.

Request clarification of “infrastructure.” Does infrastructure refer to only the virtual environment?

Is this the “infrastructure” in the Virtualization Terms and Requirements section of the comment form which only listed virtual components? Could “infrastructure” mean the UPS systems, equipment racks, HVAC systems, floors, lighting…. The “management plane of the shared infrastructure” seems to limit and define “infrastructure” to be components of the virtual environment.

Should 1 be “logically separated” and not just “separated”?

Consider striking “by default.”

This Part is the foundation for virtualization requirements.

The guidance provided above in the question, states: “In order to manage Partition 2, or any Cyber Asset hosted by the multi-instance environment and outside the ESP, IP communication to the management plane from outside the ESP has to go through the EAP since the management plan of shared	

multi-instance environment has to reside inside the ESP." APPA believes that the Requirement does not address the management plane inside the ESP. Consequently, APPA believes both aspects should be included in this Requirement.

The proposed language in Question 8 would eliminate the need for the "denied by default" in R1.8.2.

The word "infrastructure" is not defined in the proposed Standard. Consequently, the "infrastructure" on page 4 appears to only include virtual components. APPA questions if this would also include the UPS systems, equipment racks, HVAC systems, floors, lighting, etc.? The "management plane of the shared infrastructure" seems to limit and define "infrastructure" to be components only of the virtual environment.

As CIP-005 Requirement 1, Part applies to remote access, we considered that authentication takes place to the application or the management interface not to the communication. Authentication may be considered to be digital certificates for layer 2 tunnel. The requirement as written states for all sessions. Meaning each session established must perform the requirement, which may prevent an entity from using a layer 2 tunnel to perform this activity depending on particular vendor implementation.

The SDT should add Implementation Guidance that digital certificates meet the “authentication, integrity and non-repudiation controls”. The requirement does not prescribe where they have to terminate. Could be to the jump host—then connect to CMS to perform CMS functions.   If the communication is scheduled via scripts – first attempt to define either user initiated or system-to-systems communications? As it is currently written, any communication between device and CMS might have to meet the requirement. CMS should include administration….not with configuration, otherwise unintended systems are brought in (ivanti, Solar Winds)

Should include the virtual concept in that definition/term. The following is a potential definition for consideration by the SDT:

“Hypervisor or products with other similar functionality”

This would be difficult to implement in practice for many types of assets and their integrations and management systems. Non-repudiation generally requires some type of cryptographic signature and a majority of system-to-system communications inherently do not support that mechanism. Requiring it for Interactive Remote Access for a CMS makes sense, but we imagine that will be enumerated in existing standards as in-scope for CMS the way it would be in-scope for PACS, as an example.

ERCOT asserts that this requirement is redundant to the existing firewall requirement in CIP-005 Requirement R1, Part 1.3. As written, ERCOT offers the following comments. (1) The requirement lacks complete and appropriate details necessary for evaluation and implementation. (2) The requirement may create conflict with existing CIP Version 5/6 implementations. (3) While the security controls may be appropriate, the technologies may not support all or some of the requirement. Clarification for network verses host technologies is required. (4) The requirement does not specify it is for multi-instance. (5) The SDT should be specific about the meaning of “authentication, integrity and non-repudiation controls”. Are these existing controls in the CIP standards for non-virtual systems? (6) With non-repudiation, the SDT appears to be adding an additional requirement for key management that is not clearly stated. (7) As noted in question 8, ERCOT requests examples of systems that can basically “firewall” non-routable protocols. ERCOT recommends the creation of ERO-endorsed guidance before standards to aid in evaluating options. The guidance can document the implementation under various vendor and technology types.

Comment

The SPP Standards Review Group has a concern on how the terms “ESP” and “ESZ” are used in this section of the documentation while discussing the risks associated with communication. At this point, we feel that there is no consistency in reference to the use of the terms. For example, the supporting details for the section mentions “ESP” while language in Part 3.1 mentions “ESZ”.

Question:

What are the drafting team’s expectation in reference to meeting the compliance need of the terms “integrity” and “non-repudiation” controls?

Will the drafting team have the expectation of all system to system communication outside of the ESZ to communicate with system inside of the ESZ to be encrypted?

Is this redundant with CIP-005, Requirement 1, Part 1.3? Request specifics on “authentication, integrity and non-repudiation controls.” Please clarify if non-repudiation controls is a technical control. If YES, are we moving too far away from outcome based controls? This requirement may need to include the “per device capability” phrase.

TVA requests additional context for understanding the proposed requirement. If an entity has multiple ESZs and/or ESPs, it is unclear how an entity would satisfy the proposed language. Network traffic traversing does not identify itself on a technical level as being interactive or machine-to-machine. Unless an entity has implemented software defined networking, which can associate traffic flows to and process identity end-to-end, it is difficult to envision a technical solution that satisfies the draft language.

While N&ST agrees there should be strong technical and procedural protections around hypervisors, N&ST does not believe this goal is well-served by the proposed requirement and is not convinced there are “gaps” in the current requirements for Interactive Remote Access. In addition, N&ST notes:

(1) The narrative section preceding the proposed requirement discusses CMS access from outside an ESP, whereas the proposed requirement language says, “ESZ.”

(2) Authentication is already required for access by human operators.

(3) System-to-system communications from outside an ESP are already subject to controls implemented by EAPs.

(4) It is unclear what type of “integrity” control(s) the SDT envisions in this context.

(5) It is unclear what goal(s) would be served by “non-repudiation,” nor is it clear how it might be achieved in this context. Perhaps all CMS transactions should be logged, with an accompanying requirement that the entity be capable of determining what individual or system initiated any given recorded transaction.

CenterPoint Energy does not agree with the proposed requirement because of the difficulty in implementation and demonstration of compliance. It is not clear how an entity can distinguish between sessions used for CMS functions and those that are not. Further, it may be challenging to distinguish between user initiated and system-to-system sessions, when such communications are allowed between the hosts, ports, and applications involved. Further, it does not account for system capability. The requirement can be even more challenging to comply with if the logical separation in the ESZ is not through a firewall.

There has not been enough definition around ESZ’s and if they exist inside or outside of a ESP. The required controls are vague and poorly defined. We do not recognize a gap in the intermediate system. The CMS should always reside inside the ESP on separated hardware. This alleviates the remote access to perform CMS function gap.

The language of the proposed requirement is unclear as to what communications this applies to. Does it apply to the client connection to the CMS, or to the CMS connection to the BES Cyber Asset? The language of this requirement is also not consistent with the rationale given, as the rationale describes issues with communications from outside the ESP, but the requirement addresses the ESZ.

Comment

As CIP-005 Requirement 1, Part 3. Applies to remote access, we considered that Authentication takes place to the application or the management interface not to the communication. Authentication may be considered to be digital certificates for layer 2 tunnel. The requirement as written states for all sessions. Meaning each session established must perform the requirement, which may prevent an entity from using a layer 2 tunnel to perform this activity depending on particular vendor implementaions.

The SDT should add Implementation Guidance that digital certificates meet the “authentication, integrity and non-repudiation controls”. The requirement does not prescribe where they have to terminate. Could be to the jump host—then connect to CMS to perform CMS functions. If the communication is scheduled via scripts – first attempt to define either user initiated or system-to-systems communications? As it is currently written, any communication between device and CMS might have to meet the requirement. CMS should include administration….not with configuration, otherwise unintended systems are brought in (ivanti, Solar Winds)

Yes but this may not be enough – e.g., the system-to-system communications between an out of ESZ CMS and the management plane may in fact meet all of the items in part 3.1, but if the CMS is already compromised (which is more likely if it is not in the ESZ) then these controls do nothing to prevent the attacker controlling the CMS from causing damage.

Public power believes that this Requirement conflicts with the implied requirement identified in comments to question 8 that the management plane of the BCS must be inside the ESZ. APPA recommends replacing the proposed language with: “Require authentication, integrity and non-repudiation controls for all CMS functions, per device capability.”

If the suggested modification is not used, in the alternative APPA proposes that this Requirement have the “per device capability” clause.

Encryption of network traffic form CMS to device could make compliance with this Requirement impossible to achieve.

TVA requests that any controls associated with the use of a CMS apply to individuals' access to the CMS itself, rather than the network traffic that may originate from a CMS to an applicable BES Cyber Asset. Network traffic traversing does not identify itself on a technical level as being interactive or machine-to-machine. Unless an entity has implemented software defined networking which can associate traffic flows to and process identity end-to-end, it is difficult to envision a technical solution that satisfies the draft language. As a case study, consider a CMS tool used to manage network devices (e.g., routers, firewalls, switches) via SSH. The tool may have a daily backup configured whereby it initiates an SSH session to a target device for the purposes of collecting a complete device backup. The SSH traffic, from a firewall and access control perspective, cannot be identified as “machine to machine”, even though no human is interactively driving the SSH session. However, the same CMS tool may facilitate real time, Interactive Remote Access to a target device where each command was issued by a human facilitated by an SSH connection. From a network perspective, the SSH session’s origin as human or machine-to-machine is indistinguishable.

TVA suggests a more effective manner to address these concerns would be to utilize controls similar to those used for gaining access to an Intermediate System for remotely gaining access to a CMS.

Finally, TVA suggests the concerns about “the gap between Interactive Remote Access and system-to-system communication” are not proprietary to virtualized environments. The use of CMS tools can be manifest with or without virtualized technologies.

The gap between Interactive Remote Access, and system-to-system communication does not need to be addressed for systems other than high and medium impact BES Cyber Systems. Outside of the multi-instance environment, the risk associated with system to system for individual discrete assets is limited to within the company’s environment. Anything outside of the company’s environment should be covered under CIP-012.

Comments: It would seem wise to resolve issues with high and medium impact BES Cyber Systems before addressing low if there is inherent risk to virtualization greatly exceeding that posed by any systems using shared resources whether physical or virtual. The idea occurs that the inherent potential reduction in risk provided by virtualization be properly weighed as well as so much redundancy can be built into these systems.

The question incorporates the proposed CMS term. See our response to the proposed CMS definition, Question 4.

Also, Standards are to address risk but cannot address every iteration of risk. To develop requirements to address every security risk is not sustainable and an unreasonable expectation. Security threats emerge more quickly than can be addressed by a process of law.

It needs to be addressed for any virtualized PCA, PACS or EACMS as they pose similar risks. It should also be addressed for any similar communications in non-virtualized systems – e.g., a lights out management system for servers or a network management system. These pose similar risks to the BCS they support. This may not be enough to protect the BCS appropriately.

12. The SDT asserts that the new proposed CIP-004 Requirement R4, Part 4.5, provides additional security control to the electronic and unescorted physical access to multi-instance environment processes which reduces the “too much privilege” risk inherent to virtualization which has been identified. Do you agree with this assertion? If not, please provide a rationale to support your position.

Paul Haase - Seattle City Light - 1,3,4,5,6 - WECC, Group Name Seattle City Light

Answer	No

Ronald Donahey - TECO - Tampa Electric Co. - 1,3,5,6

Answer	No
Document Name	

Comment

We recommend the addition of “Per system capability” similar to “per device capability”.

Does the SDT consider that AD provides enough of these controls? Can it do “need-to-know, least privilege, and separation of duties”?

Could this requirement part be include with the current CIP-004 R4 Part 4.3 review? Will the applicability extend to BCS and associated EACMs? Associated PACS?

We recommend that this become Requirement 4 Part 4.2 as the Authorization takes place in 4.1; implementation should become 4.2; then the quarterly review is 4.3, etc. We recommend that the SDT shift the CIP-004 R4 Parts to have the steps occur in order of operation. We recommend that the SDT provide guidance to small entities that they may identify each role but may need to (resource constrained) add the same person to each role

Douglas Webb - Great Plains Energy - Kansas City Power and Light Co. - 1,3,5,6 - SPP RE

Answer	No
Document Name	

Comment

Current Standards Already Address Risk. Proposed Part 4.5 is not significantly different from existing CIP-004 Part 4.1 which already requires a process to authorize based on need.

Compliance Uncertainty. The terms “need-to-know,” “least privilege,” and “separation of duties,” are currently used in the Standards and, also, open to a broad level of interpretation; as such, they create compliance uncertainty. It is expected that will not change.

We do not believe additional prescriptive language or defining the terms is sufficient to mitigate the uncertainty.

This Requirement seems to expand the scope of Requirements 4.1 – 4.4. The question asks about “multi-instance.” We recommend the applicability section should be similar to CIP-005 R1.8 It is unclear why virtual systems need additional physical access to the virtual systems. Request clarification of “separation of duties.” The entity, as part of their “based on need” approval process for 4.1 could include need-to-know, least privilege, and separation of duties “. This added requirement seems like additional administrative tasks and extends to all BES Cyber systems and not just virtual systems.

The proposed addition of CIP-004 Requirement R4, Part 4.5 is too broad, and applies to everything including virtualization. If the SDT is trying to reduce the “too much privilege” risk inherent to virtualization, the requirement should be specific about virtualization privileges. As proposed, entities would have to apply these security controls to all BES Cyber Systems.

Comment

Reclamation does not support the addition of Part 4.5. Reclamation recommends that revising the definition of BES Cyber System and the Impact Rating Criteria will provide sufficient security controls and reduce the “too much privilege” risk inherent to virtualization. Refer to the principles, recommended definitions, rationale, and recommended Impact Rating Criteria described in the response to Question 24.

Elizabeth Axson - Electric Reliability Council of Texas, Inc. - 2

Answer	No
Document Name	

Comment

ERCOT asserts that the concept noted in this requirement should not be added at all. It is redundant and unneccessary. The proposal is too specific and will create adverse impact to many existing implementations without improving the security desired. Entities with high and medium impact BES Cyber Systems already have to provide justification for access at least every 15 months. Entities are required to provide evidence supporting that access is (1) necessary, and (2) for performing assigned work functions. These two criteria should be seen as the obligation to address the principles of need-to-know, least privilege, and separation of duties. Any further clarification should be made in implementation guidance.

Brandon Cain - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - FRCC,MRO,WECC,Texas RE,SERC,SPP RE, Group Name Southern Company

Answer	No
Document Name	

Comment

Southern disagrees with the need for this additional requirement under CIP-004-6 R4. First, existing CIP requirements under CIP-004-6 R4 already require the authorization of access based on need, and it is not necessary to repeat that tenant of cyber security in another requirement. When implementing ‘principles’ of least privilege and separation of duties, that can be exhibited in various ways to meet the needs of an Entity’s operations while maintaining adequate security. The currently proposed requirement leaves too broad a level of ambiguity to auditor interpretation regardless of an Entity’s efforts to comply. Additionally, as stated, “The SDT has identified “too much privilege” as an inherent risk in virtualization”, however the proposed requirement in not scoped to virtual environments and would be applicable across the board. All of CIP-004-6 R4 is currently scoped to High

Impact BES Cyber Systems and Medium Impact BES Cyber Systems with ERC – and Southern requests explanation on why the ERC scoping for Mediums would be excluded in this context.

Answer	No
Document Name	

Comment

The Applicable Systems of this requirement should be updated to say “high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS(s)”. Additionally, BES Cyber System Information should be changed to “designated storage locations for BES Cyber System Information” to align with CIP-004 Part 4.1, Part 4.4 and Part 5.3. Furthermore, the currently approved requirement CIP-004 Part 4.1 incorporates the concept of “need”. We feel that adding this new requirement is a duplication of the already existing requirement of need and provides a chance of double jeopardy for the entities and should be removed.

Comment

The SPP Standards Review Group has a concern that the proposed language presents redundancy issues. Additionally, we feel that the topic is already covered in the CIP-004 Standard section 4.1 and should not be added to the Virtualization process.

Question:

With this proposed language, who will be impacted by the applicability?

Comment	
While AZPS agrees with the intent to protect BES Cyber Assets and BCSI, it suggests that the proposed R4.5 is not as clear and unambiguous as it could be and, therefore, could result in confusion regarding applicability. To ensure that the scope of the requirement is clear, AZPS recommends that the language of R4.5 specifically reference virtual, multi-tenant environments. Additionally, while AZPS understands and acknowledges the value of the concepts of need-to-know, least privilege and separation of duties from a security perspective, AZPS cautions the drafting team regarding the cost/benefit ratio of including separation of duties in R4.5. In particular, AZPS is concerned that the inclusion of separation of duties would represent a significant cost impact to the Responsible Entity for very little attendant benefit to reliability.

Some organizations may lack staff to separate duties to multiple people. Additionally, the requirement does not establish a measureable span of control. The current CIP-004 requirements sufficiently address the need to implement an effective access control policy to limit privileges using these principles.

CenterPoint Energy believes the proposed requirement is more of a best practice and should not be a requirement. Existing CIP-004 requirements already require authorization of access based on need. Similar to the language in proposed CIP-005 Requirement 1, Part 1.6, this requirement asserts an objective to the requirement, where evidence of objectives (or principles) is difficult to provide compared with evidence of activities. The proposed CIP-004 Requirement 4, Part 4.5 will be challenging to implement for smaller entities with limited staff, where the level of separation “in principle” cannot be achieved to satisfy the requirement.

Part 4.5 does not address virtualization or segmentation of duties for virtualization management. However, in a shared environment, processes would need to be created or authorizations changed and documentation would need to spell out duties and access. There should be more guidance and direction on what is appropriate separation of duties.

Response

Robert Ganley - Long Island Power Authority - 1

Answer	No
Document Name	

Comment

All EACMS's and CMS's, and ESZ's, etc. should be afforded equal protections to the highest watermark level within the associated environment. The compromise of one or more BCS's/BCS's (and/or associated systems) i.e. compromise of information, or ESP, or CMS can have an adverse effect on the BES regardless of the number or type of asset compromised.   The risks may seem different however; the BES would be impacted in some way.

Lan Nguyen - CenterPoint Energy Houston Electric, LLC - 1 - Texas RE

Answer	No
Document Name	

Comment

CenterPoint Energy believes the existing EACMS definition should be clarified for EACMS used for access monitoring. CenterPoint Energy proposes the following clarification:

"Cyber Assets that perform electronic access control **or are used for** electronic access monitoring of the Electronic Security Perimeter(s) or BES Cyber Systems. This includes Intermediate Systems."

Some misinterpretation of EACMS is based on capability, rather than use, of tools where no access monitoring is intended. A system that is actually used and intended to capture all access activity should also be protected as other systems in scope for EACMS due to the risk posed by compromise of those systems. A tool used for monitoring configuration with no system management capability, antivirus, or security functions other than access control with some limited capability to pick up information related to access control should not be considered access control systems.

EACMS includes too many different functions to have prescriptive requirements applied broadly. Additionally, the requirements currently discourage entities from using vendor-based security monitoring services that could provide significant security benefit. At a minimum, monitoring systems (logging and event monitoring) that have no technical capacity or permission to configure BCSs should have risk assessed differently. There may also be value in separating security objectives between access control (authorization and permissions) and gateway functions (filter/forward traffic).

14. Do you agree that the language of the proposed definitions of EACS provides better consistency and clarity to the CIP Standards? If not, please provide rationale to support your position and alternative language.

Ronald Donahey - TECO - Tampa Electric Co. - 1,3,5,6

Answer	No
Document Name	

Comment

The proposed definition provides more clarity but has its own set of issues: Hall of mirrors—"this includes Intermediate Systems" should be removed. The definition needs to be clear enough to indicate that an intermediate system needs to be covered.

That being said, the current definition of an Intermediate System states that it can't be inside the ESP. The new EACS does not apply 5.1 correctly. We suggest adding a "one pass rule" so that entities don't have to go through the requirements multiple times.

In addition, we believe that requirements should not put additional controls on top of a security control. If there is a need to do that, the additional controls need to be based on risk.

We also encourage the SDT to consider using an approach similar to that used for CIP-014 (NIST allows that as well…develop security controls): Requirement 1: Here are the minimum requirements. Requirement 2: address security risks that are not addressed that are not covered above.

Response

Douglas Webb - Great Plains Energy - Kansas City Power and Light Co. - 1,3,5,6 - SPP RE

Answer	No
Document Name	

Comment

We can see some value from the proposed EACS definition but struggle in identifying how it supports security and reliability issues that are already addressed in the current Standards. The concern is adding EACS as another NERC Glossary Term will create unnecessary compliance and implementation complexity. When taken in total with all the proposed new and revised Glossary Terms and Requirements presented in this commenting form, the cumulative and gross effect is increased complexity with, likely, marginal improvement in security or reliability.

Reclamation does not support a new definition of EACS. Reclamation recommends the SDT use existing industry-recognized terms to address the components of EACMS that control and authenticate electronic access, such as firewall, proxy server, router, etc.

If the SDT decides to use the proposed definition of EACS, Reclamation recommends the proposed EACS definition be changed

from: Cyber Assets that perform electronic access control of the BES Cyber Systems. This includes Intermediate Systems.

to: Cyber Assets that control electronic access to BES Cyber Systems.

Reclamation also recommends the SDT change the definition of BES Cyber System as described in the recommended definitions section of the response to Question 24.

Comment

While we agree with the concept of separating out monitoring and control we do see some possible confusion with the EACS and EAG definitions. We believe that there may be instances where a system or asset performs both functions. How would you classify and protect this device? Additionally, it appears from the chart above, “Proposed Requirements Related to EACMS Changes”, that all updated requirements for EACS and EAGs are applicable to the same requirements. For simplicity purposes, we suggest that EACS and EAG be combined into one definition: “Cyber Assets that perform electronic access control of the Electronic Security Perimeter(s) or BES Cyber Systems. This includes Intermediate Systems”.

The proposed definition of EACS appears vague, and would benefit from additional language in the text of the definition. We recommend inserting some of the language used in the paragraph below the proposed definition, to be inserted in the text.

See example below:

- *Electronic Access Control System (EACS):*

Cyber Assets that perform electronic access control, and authentication and authorization of traffic or users of the BES Cyber Systems. This includes Intermediate Systems.

While AZPS agrees with the proposal to differentiate control and monitoring, AZPS is concerned that monitoring includes more than data collection and storage. For example, alerting occurs utilizing inputs from monitoring and may occur concurrently in the same system. Accordingly, the alerting and monitoring systems may not be completely independent. For this reason, AZPS recommends that the SDT give some additional consideration to the proposal to ensure that all aspects of monitoring and dependent processes are fully evaluated and addressed.

TVA agrees that the language provides more clarity, but the term “pose a security threat” needs additional explanation. Does this term mean any security threat, or does the requirement allow the registered entity to determine a risk tolerance for the data? With all of the information that is excluded, what data remains to be considered BES Cyber System Information? The only remaining data for consideration would be user names, passwords, and security vulnerability information.

CenterPoint Energy does not agree with the proposed definitions EACS or EAG. The existing definition of EACMS is sufficient with the added language suggested in #13. The intent, to distinguish authentication activity with packet inspection and filtering activity, is not stated in the proposed definitions. The separation into EACS and EAG might be better achieved by defining “access control” as either user/credential authentication or filtering performed at an EAP.

The proposed definition provides more clarity but has its own set of issues: Hall of mirrors—“this includes Intermediate Systems” should be removed. The definition needs to be clear enough to indicate that an intermediate system needs to be covered. That being said, the current definition of an Intermediate System states that it can’t be inside the ESP. The new EACS does not apply 5.1 correctly. We suggest adding a “one pass rule” so that entities don’t have to go through the requirements in multiple pases as they are currently doing. In addition, we believe that requirements should not put additional controls on top of a security control. If there is a need to do that, the additional controls need to be based on risk. We also encourage the SDT to consider using an approach similar to that used for CIP-014 (NIST allows that as well…develop security controls): Requirement 1: Here are the minimum requirements. Requirement 2: address security risks that are not addressed that are not covered above.

Comments: We think that the SDT is attempting to differentiate hardware from virtual environment. The EAG hosts the EAP makes it seem that it is virtual. Some entities share a concern that the EACS and EAG are the same; is the EACS addressing lateral movement? Part 1.5 is applicable to EAPs for high & medium at control centers. With the new definition, will that no longer be applicable for EAPS?

Is the BES Cyber Asset an EACS? Is it physical or virtual? Is the implication there that it is both? (for example: Domain controllers/TACACS) This creates an implementation challenge for entities given the dual nature of some devices.

An Electronic Access Gateway hosts the EAP and performs the active function of filtering or forwarding traffic at the demarcation point (boundary protection). Primarily, these are firewalls and routers that perform gateway functions at the layer 3 ESP boundary demarcation point. Separation of duties issues here?

The EAG hosts the EAP…makes it sound as if it is virtual. Internal discussions raised the question of whether the Electronic Access Gateway term is required.

Cisco FW is more virtual; Checkpoint the language makes sense; Checkpoint offers IPS to run in parallel; or in line IPS appliance

CenterPoint Energy does not agree with the proposed definitions EACS or EAG. The existing definition of EACMS is sufficient with CenterPoint Energy's added language in the response to Question No. 13. The proposed EAG definition creates a risk that requirements restricted in scope with the granular description of an EAP as a specific interface will be reinterpreted to apply an entire gateway or group of gateways. The EAG concept also encourages entities to employ dedicated CIP gateways to avoid confusion, which runs counter to the move to multi-instance environments.

BPA believes the EAG definition is too similar to the EACS definition to be useful. The EAG definition should explicitly reference the filter/forward function rather than state “perform electronic access control.” Proposed: EAG - Cyber Assets that perform filtering or forwarding of traffic at the Electronic Security Perimeter(s) OR between ESZs. The EAG also hosts the EAP(s) if any.

The use of the term “hosts” in the proposed language is vague. We suggest the following alternative language:

- *Electronic Access Gateway:*

Cyber Assets that perform electronic access control of the Electronic Security Perimeter(s). The Electronic Access Gateway exists on the EAP(s).

We believe the phrase “exists on” rather than using the word “hosts” is more appropriate in this context.

Wendy Center - U.S. Bureau of Reclamation - 1,5

Answer	No
Document Name	

Comment

Reclamation does not support the proposed definition of EAG. EAPs may exist without an EAG. Reclamation recommends the SDT use existing industry-recognized terms to address the components of EACMS that control and authenticate electronic access, such as firewall, proxy server, router, etc.

If the SDT decides to use the proposed definition of EAG, Reclamation recommends the proposed EAG definition be changed

from: Cyber Assets that perform electronic access control of the Electronic Security Perimeter(s). The Electronic Access Gateway also hosts the EAP(s)

to: Cyber Assets (including Electronic Access Points) that control electronic access to and from virtual and non-virtual Electronic Security Perimeter(s).

Reclamation also recommends the SDT change the definition of BES Cyber System as described in the recommended definitions section of the response to Question 24.

Comment

We can see some value from the proposed EAG definition but struggle in identifying how it supports security and reliability issues that are already addressed in the current Standards. The concern is adding EAG as another NERC Glossary Term will create unnecessary compliance and implementation complexity. When taken in total with all the proposed new and revised Glossary Terms and Requirements presented in this commenting form, the cumulative and gross effect is increased complexity with, likely, marginal improvement in security or reliability.

Alternative. If the SDT concludes the proposed definition is required to address the identified issues, an alternative approach is to remove electronic access control from the definition and include language that addresses the function of the EAG:

Electronic Access Gateway: Cyber Assets that perform electronic access control of the Electronic Security Perimeter(s) the active function of filtering or forwarding traffic at the demarcation point (boundary protection). The Electronic Access Gateway also hosts the EAP(s).

ERCOT agrees that the current compliance requirements related to EACMS monitoring systems are precluding or discouraging solutions that could reduce risk to security and reliability. The current requirements are written to an asset level that requires the entities to be the ones managing the devices. With vendors going to more hosted service based solutions, the asset focus of the CIP requirements for EACMS pose serious problems when picking security solutions that provide more event correlation and expertise.

Entities are choosing to deploy a second monitoring solution (e.g., SIEM) for monitoring BCS only, in order to avoid expanding compliance obligations to enterprise systems. Due to the smaller scope of this second monitoring solution, the chosen application may be inferior to existing enterprise solutions to reduce costs. Additionally, the entity now loses the ability to correlate enterprise and BCS events, reducing the effectiveness of both monitoring solutions.

Comment

N&ST believes that within the context of the existing CIP Standards, it is reasonable for the same set of security requirements to be applied to both access control and monitoring functions. Moreover, N&ST believes that trying to establish two different sets of requirements, one for each major function addressed by the existing definition of EACMS, could lead to confusion over how to identify and apply CIP-mandated controls to systems that perform both functions.

N&ST is strongly opposed to the idea of allowing systems that perform security event monitoring to be categorized as BSCI repositories rather than EACMS and disagrees with the assertion it would “result in improved security and reliability.” At the present time, systems acting as “designated storage locations” for BSCI and performing no other reliability function are not subject to any CIP requirements other than CIP-004 R4 and R5.

The risks presented by the two types of systems are different. Compromise of the control portion gives the attacker immediate access to the systems being protected. Compromise of the monitoring portion may provide the attacker the ability to mask their actions and it may also provide them with information they can use to breach the control portion, but it does not grant them immediate access to the protected systems. The requirements should be different, but should take into account the risks posed by each system and address them appropriately.

TVA supports the SDT’s efforts to implement graduated levels of controls aligned with the functions executed by EACMS subsystems. Access control and access monitoring are separate security control functions, and consequently have different security requirements that should be considered separately. Access control systems inherently pose a greater risk if compromised than a monitoring system.

We agree that there are differing risks based on the functionality of EACMS. The risk associated with monitoring access is greatly reduced compared to the risk of controlling access. If a system that controls access to a BES Cyber System or Asset is compromised, the real-time ability to operate or control the BES could be reduced or severed altogether. Conversely, if a system the monitor's access to a BES Cyber System or Asset is compromised, the real-time ability to operate or control the BES is not compromised. Therefore, we agree that the requirements for the access control portion of the EACMS should be different from the monitoring portion.

Comment

The CIP-011 discussion on the SIEM (re-use and disposal) may be a separate concern; a recent FRCC workshop comment made by RE auditors put forth the concept that all BCAs contain BCSI; by addressing CIP-011 R2 have to protect the SIEM even if it was not identified as an EACMS. The scope might need to be reduced.

ERCOT does not agree with expanding CIP-011 R2 to include a all repositories of BCSI. The context of removing “monitoring” from the EACMS was to address information that may be with a third party. As such, the Responsible Entity cannot provide asset-level compliance evidence for a third part.

BES Cyber System Information, whether stored in a “designated storage location for access monitoring systems” or stored in a “designated storage location for BES Cyber System Information”, is at its core BES Cyber System Information. Adding levels of BES Cyber System Information risk based on storage location will cause confusion within the industry and provides no reliability benefit.

Some auditors are already putting forth the concept that all BCAs contain BCSI; by addressing CIP-011 R2 have to protect the SIEM even if it was not identified as an EACMS. The scope might need to be reduced. Need to provide more clarificaiton and the security benefit on the definition of BCSI as it relates to various information. It is not all a the same risk level. Need to use words like "information uesful to plan a cyber attack? Simply useful, or does the information provide just about eveything you need.

Brandon Cain - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - FRCC,MRO,WECC,Texas RE,SERC,SPP RE, Group Name Southern Company

Answer	Yes
Document Name	

Comment

Yes – because there is current ambiguity in the “Applicable Systems” assigned to CIP-011-2 R2. The requirement currently states “Prior to the release for reuse (or R2.2 disposal) of applicable Cyber Assets”, which only includes High Impact BES Cyber Systems and Medium Impact BES Cyber Systems, and their associated EACMS, PACS, and PCAs; however, BCSI could reside in other places besides on those applicable systems. The requirement should be made clearer to direct the sanitization requirements to BCSI, regardless of where it resides, prior to the release for reuse or disposal.

Yes – access monitoring systems can potentially contain BCSI and should be protected as such. That being said, monitoring systems also pose an additional risk that BCSI on its own does not: i.e. compromise of a monitoring system can be used to mask attempts to compromise the access control systems and the BCS itself. This additional risk needs to be addressed.

CIP-004 R1.1 Awareness messages should not be limited by system type or function. All employees have a role to play in the BES security and should receive awareness.

CIP-004 R2 Cyber Security training should not be limited by system type of function.

CIP-004 R3.1 This requirement should not apply to EAGs as some work is done by a collection of analysts and reported on as a group such as a watch floor.

CIP-004 R3.4 Service providers should be able to provide evidence of their employee risk assessment process as an alternative to risk assessment conducted by the registered entity.

CIP-004 R4.2 CMS, EACS, EAGs should be able to show a process for granting and removing access, but a quarterly review should not be required.

CIP-004 R4.4 EACS & EAGs should not be labeled as BES Cyber System Information and a 15-month review should not be required.

CIP-004 R5.5 This should only apply to systems with ERC.

CIP-007, CIP-009, CIP-010, and CIP-011 should be modified to reflect the risk/impact of these systems to the BES.

While we agree that many requirements will need to be updated based on the changes proposed in this comment form, there is some confusion on how the Applicable Systems will look based on the chart above. For instance, are the systems in the chart associated with high or medium impact BES Cyber Systems? Also, it is unclear how the CIP-005 Part 1 requirements will be applied to EACS. Furthermore, based on risk and current Applicable Systems, it is unclear what the justification is for adding EACS and EAGS to CIP-004 Part 1, CIP-009 Part 2.3 and CIP-010 Part 3.2 considering that EACMS are not currently part of the requirements.

ERCOT does not agree with the assignments of the requirements as shown in the table. First, ERCOT does not see the need to define EACS, EAG, and CMS. With regards to the table, there are several concerns noted. (1) Awareness is not a good means of providing necessary content to SMEs managing these assets. The existing training requirements are more beneficial and appropriate. (2) The 36 month operational recovery exercise is limited to BES Cyber Systems. This should remain as the scope. (3) Recovery plans should be required for all assets other than PCA. This is the current requirement level. (4) See comments on question 18 regarding CIP-011 requirements.

The question is asking for support of the assignment of CIP Standards to proposed EACS, EAG, and CMS definitions in which we have concerns. We are unable to analyze the assignments with uncertainty around the definitions. We would note that the table illustrates how the proposed Glossary Terms—EACS, EAG, and CMS—potentially create more questions than clarity regarding compliance requirements and may present an undesirable effect of obscuring compliance obligations.

20. As the standards today do not prohibit the use of virtualization technologies, do you support an approach where no changes are made to the CIP Standards in response to the virtualization issue identified by the V5 TAG? Please provide a rationale to support your position.

Paul Haase - Seattle City Light - 1,3,4,5,6 - WECC, Group Name Seattle City Light

Answer	No
Document Name	

Comment

City Light believes new approaches are necessary to accomodate virtualization with the CIP Standards, and generally supports the comments of APPA and BPA. City Light, however, would prefer the a more general cyber security approach be used for virtualization. NIST or PCI provide useful frameworks, rather than the VM Ware-centric approach proposed here.The VM Ware approach is not unreasonable, but aligns with a particular vendor.

Comment

The current CIP standards do not explicitly prohibit all types of virtualization but require “high water marking” of the impact level even where this is not the most secure and reliable control. For example the separation of data plane and management plane between hypervisor and guest is a more effective control than applying high water mark CIP Requirements and keeping hypervisors inside the same security zone.

Also, CIP Requirements do not separate the electronic access controls from the electronic access monitoring to allow for different requirements when only monitoring is done. This has a high risk of misallocating scarce resources (money, time, manpower) that could be more effectively applied elsewhere for increased reliability.

Compliance Guidance is written to show one or more compliant solutions in order to clarify and help in applying the Requirements. It does not supersede Requirements language. The Guidance cannot show all possible solutions and is therefore inadequate because it is specific and limited, rather than a framework one can apply to generate new and unique solutions.   Solutions currently known to the SDT are only a snapshot in time that may become obsolete at any moment due to technical innovation or changes in the threat environment, while security objectives are more enduring than requirements for a specific solution. Entities may be aware of or devise a solution unknown to the SDT that provides equal or greater security but if the Requirements language doesn’t allow for the solution, it is not compliant. For these reasons, I think that the issues must be dealt with by revisions to the standards that emphasize security objectives and allow the Entity to demonstrate and explain how the solution meets the objective.

Response

Lauren Price - ATCO Electric - 1 - MRO,RF

Answer	No
Document Name	

Comment

ATC believes that there is merit to this concept; however, we answered “No” because guidance alone cannot solve the specific subject of virtualization due to the current construct of the CIP Requirements and its reliance on prescriptive controls that lean toward less advanced technological solutions. ATC could support ERO Enterprise-endorsed Compliance Guidance as an alternative if it were complimented by a paradigm shift to reshape the CIP Standards such that they are focused on technology agnostic security objectives and written with flexibility so Registered Entities are able to define and implement an adaptive risk-based cybersecurity program that timely detects, responds to, and mitigates emerging threats. ATC welcomes thought leadership on the subject of ERO Enterprise-endorsed Compliance Guidance as an alternative to mandatory regulations to position the industry

for a more nimble, sustainable, and mature security posture. While there has been improvement in the requirement language as the CIP Standards have evolved, they continue to suffer because prescriptive mandatory regulations cannot keep pace with emerging technologies and the rapidly changing cybersecurity threat landscape. Until this paradigm shift occurs, the industry will continue to face the unintended consequences of the current construct, be distracted by the conundrum, divided between security and compliance, limited in our ability to leverage advances in technology, and will continue to be hindered by the antiquated ideals of a regulation that is chasing cybersecurity.

Comment
Even though the requirements today do not prohibit the use of virtualization, the implementation of virtualization in today's CIP regulatory construct discourages an entity from realizing the full potential of virtualization. Making the right changes to the requirements will allow entities the ability to fully utilize emerging technologies while supporting the reliable operations of the BES.

Response	
Jack Cashin - American Public Power Association - 4	

Answer	No
Document Name	

Comment

The current CIP standards do not explicitly prohibit all types of virtualization but require “high water marking” of the impact level even where this is not the most secure and reliable control. For example, the separation of data plane and management plane between hypervisor and guest is a more effective control than applying rigorous CIP Requirements and keeping hypervisors inside the same security zone.

Also, CIP Requirements do not separate the electronic access controls from the electronic access monitoring to allow for different requirements when only monitoring is done. This has a high risk of misallocating scarce resources (money, time, manpower) that could be more effectively applied elsewhere for increased reliability.

Compliance guidance is written to show one or more compliant solutions to clarify and help in applying the Requirements. Such guidance does not supersede standard requirements language. Moreover, such guidance cannot show all possible solutions and is specific and limited, rather than a framework where one can generate new and unique solutions. Solutions currently known to the SDT are only a snapshot in time that may become obsolete at any moment due to technical innovation or changes in the threat environment, while security objectives are more enduring than requirements for a specific solution. Entities may be aware of, or devise a solution unknown to the SDT that provides equal or greater security, that the Requirements language finds the solution non-compliant. Therefore, the proposed standard must emphasize security objectives that allow entities to demonstrate and explain how solutions meets the objective.

Comment

BPA believes that changes to the standards language are required to enable virtualization in a secure and reliable manner and that implementation should allow for secure shared infrastructure.

The NERC CIP SDT has a responsibility to evolve the standards language with our industry and not restrict its progress in adopting new, more efficient, fiscally responsible, secure, and reliable technology solutions. The current CIP reliability standards, as written, are not easily applied to new technologies, such as virtualization. They are written specific to dated industrial control systems of our industry and do not address virtualization technologies. If NERC uses only guidance rather than security objectives standards language, we can expect significant impacts, such as compliance violations, costly rework of in-flight and future planned upgrade projects, and slowing the adoption of new technologies that can better secure and improve the reliability of the Bulk Electric System.

- Guidance outside of the standards does not address the V5TAG mandate from the SAR to address virtualization in the standards language
- Without direct guidance in standards, entities can find themselves at risk of compliance violations due to individual different interpretations.
- It is clear from the debate regarding virtualization implementations that there is no universal agreement about shared infrastructure being allowed.

- Virtual Technology that is already in the near-term pipeline and deployed in other industries would benefit the energy industry.
- Without transitioning to a security objective-based standard, flexibility to adapt to new technology is lost.
- Presidential directives for government agencies already require aggressive moves to cloud computing for reasons of common secure platforms, scalability and cost benefit.

Comment

The current CIP standards do not explicitly prohibit all types of virtualization but require “high water marking” of the impact level even where this is not the most secure and reliable control. For example the separation of data plane and management plane between hypervisor and guest is a more effective control than applying high water mark CIP Requirements and keeping hypervisors inside the same security zone.

Also, CIP Requirements do not separate the electronic access controls from the electronic access monitoring to allow for different requirements when only monitoring is done. This has a high risk of misallocating scarce resources (money, time, manpower) that could be more effectively applied elsewhere for increased reliability.

Compliance Guidance is written to show one or more compliant solutions in order to clarify and help in applying the Requirements. It does not supersede Requirements language. The Guidance cannot show all possible solutions and is therefore inadequate because it is specific and limited, rather than a framework one can apply to generate new and unique solutions. Solutions currently known to the SDT are only a snapshot in time that may become obsolete at any moment due to technical innovation or changes in the threat environment, while security objectives are more enduring than requirements for a specific solution. Entities may be aware of or devise a solution unknown to the SDT that provides equal or greater security but if the Requirements language doesn’t allow for the solution, it is not compliant. For these reasons, I think that the issues must be dealt with by revisions to the standards that emphasize security objectives and allow the Entity to demonstrate and explain how the solution meets the objective.

Comment

Currently, the standards require a bit of “common sense” interpretation to be applied to virtualized systems appropriately. Different entities may have different interpretations, some of which may not result in an appropriate level of security for the relevant BCS. Providing guidance may help in this regard, but adjusting the standards to address virtualization will ensure that a minimum enforceable level of security is applied by all entities without relying on interpretation.

KCP&L supports using current CIP Standards to address risk posed by virtualization.

Complexity Defeats Security

Some of the offered concepts may have merit but when considered independently or in total, the consequence of implementing and managing the proposed idea will assuredly add significant complexity to already complex systems.

By most any measure, complexity defeats security through obfuscation of vulnerabilities and can provide a false sense of security.

Promotes Flexibility. Virtualization technology will continue to evolve at a rate faster than the Standards can address. Compliance guidance provides a path for implementation and the Standards' role to be objective. Additionally, compliance guidance allows the flexibility to relieve compliance burdens on entities choosing not to implement virtual technologies.

Virtualization is not prohibited by the present version of the CIP Standards. Each hardware platform is considered a device and each VM running on the hardware is considered software and data on the device. This means that the hardware device and each VM running on that device must be protected at the level of the highest-impact VM running on the device. This is seldom an issue in a Control Center, where all Cyber Assets are protected at the level of the “high-water-mark.”

Economic considerations seem to be the biggest driving force in pushing forward “mixed-trust” virtual systems. These considerations will primarily benefit relatively the relatively few companies that can justify the large-scale systems needed for a significant economic return. Other companies will be required to wade through a number of new requirements that may have little benefit to them.

In addition, properly securing mixed-trust virtual systems requires a staff with substantial skills and training. The staff of mid-size and small companies may be ill-equipment to succeed in that endeavor.

In virtualization terminology, “instance” is used to describe a single *instance* of a resource. If the SDT means “multi-tenant” in their use of “multi-instance”, it is suggested to use the former term. It is easier to explain that an organization can internally have many “tenants” that for whom shared resources are compartmentalized then to explain having multiple instances of environments which in turn have multiple instances of computing resources. It’s difficult to communicate about compliance and virtualization even amongst people who understand the distinction between the two types of instances.

The CMS is a good approach. It would be preferable to only be applicable to Virtualized Systems, at least at first, in effort to address the systemic risk introduced by virtualization.

The ESZ concept does not reflect how virtualization systems work and adds an extra level of unnecessary and confusing complexity to the CIP standards. What is needed is requirements that, if met, let virtual cyber assets be treated as “normal” cyber assets. And similarly, virtual networks the same as “normal” physical networks. Then the existing body of CIP Standards can be leveraged to mitigate additional virtualization risks without adding undo complexity and exceptions.

Suggest requirements to the effect of:

> Virtualization host environments must have mechanisms to ensure virtual machines or virtual components of machines (compute, network interface, storage) utilize mechanisms to ensure they are unable to interact with each other except as necessitated by design to fulfill their function. Ie: no direct compute node to compute node interaction, storage node to storage node interaction. Compute nodes can only access the storage resources they are specifically assigned. Virtual network interfaces are constrained to one virtual network (VLAN). Etc. The specific interaction being allowed and the details how this is enforced must be documented (IE VLAN#, etc).
>
> Possibly a requirement to test that the configuration needed for above requirement correctly isolates/segregates virtual resources (again, only for virtualization).
>
> CMS used for managing virtualization hosts (ie. the management plane) must reside in a ESP that is distinct from the ESP of the virtual cyber assets it hosts (which still allows, incidentally, self hosting of management virtual machines)

Comment	
AEP agrees there is value in EACMS definition to allow the access-monitoring portion of the EACMS to be reclassified as a BSCI repository and the introduction of the CMD definitions, but does not support the additional definitions. We also believe that a revised definition of EACMS is all that is necessary to address the concerns.

While the idea of splitting the definition of EACMS to allow broader implementation of security controls is appealing, that does not appear to be what the SDT is proposing. The SDT does remove most requirements for EAMS, but ramps up the requirements on EACS and EAG. For entities who have already implemented a SIEM in their CIP environment, there is little benefit, as we have already borne the burden of implementing CIP on our SIEM. While declassification might remove some of the burden, it is far outweighed by the increased obligation proposed by the SDT.

We support the new definition of EACS, EAG, and CMS, so long as EACMS is retired. This concept allows for improved use of enterprise monitoring solutions which should lead to better risk mitigation. However, only applying the BCSI requirements to monitoring solutions may not sufficiently address the risk that a compromised monitoring solution could be used to mask additional attacks. This additional risk needs to be addressed appropriately.

23. Is your organization in support of Concept 3: Compliance Guidance? Please provide rationale to support your position.

Joel Charlebois - AESI - Acumen Engineered Solutions International Inc. - 5

Answer	No
Document Name	

Comment

Relying on guidance allows for too much interpretation on behalf of the entities and may lead to an inconsistent level of security between entities. In addition, implementation guidance is just as the name suggest, guidance, and is meant to describe one or more methods of being compliant, but is not meant to be the only method to be compliant. An entity is free to choose an alternative implementation that is not described by implementation guidance, and wether or not that alternative implementation is compliant is still subject to interpretation.

Adjusting the standards instead of just providing guidance should ensure correct and consistent interpretation of requirements across the industry, while providing entities with sufficient assurance that their methods of implementation are compliant.

Lauren Price - ATCO Electric - 1 - MRO,RF

Answer	Yes
Document Name	

Comment

ATC supports the concept of Compliance Guidance. That said, where the requirements are written in a prescriptive manner such that the guidance is at odds with the requirements, Registered Entities cannot leverage that guidance without risking non-compliance. This condition renders even the soundest guidance unusable. ATC could support ERO Enterprise-endorsed Compliance Guidance as an alternative if it were complimented by a paradigm shift to reshape the CIP Standards such that they are focused on technology agnostic security objectives and written with flexibility so Registered Entities are able to define and implement an adaptive risk-based cybersecurity program that timely detects, responds to, and mitigates emerging threats. ATC welcomes thought leadership on the subject of ERO Enterprise-endorsed Compliance Guidance as an alternative to mandatory regulations to position the industry for a more nimble, sustainable, and mature security posture. While there has been improvement in the requirement language as the CIP Standards have evolved, they continue to suffer because prescriptive mandatory regulations cannot keep pace with emerging technologies and the rapidly changing cybersecurity threat landscape. Until this paradigm shift occurs, the industry will continue to face the unintended consequences of the current construct, be distracted by the conundrum, divided between security and compliance, limited in our ability to leverage advances in technology, and will continue to be hindered by the antiquated ideals of a regulation that is chasing cybersecurity.

Compliance guidance that informs “a way” for compliance has value. Guidance establishing compliance thresholds, bright-line requirements, incents entities to meet only the minimum compliance threshold and inhibits viewing compliance through a risk lens.

The optimal guidance provides entities ideas and the flexibility to address identified risks.

We are confused about VLANs. The current guidance has been to avoid VLANs, ostensibly over concerns that their “software-based nature” is somewhat insecure. We don’t disagree that they are “less secure” than physical LANs, however we believe they have a place within the environment to separate CIP and NON-CIP assets as they traverse into the firewall. This allows us a multi-instance network environment as opposed to dedicated network hardware for CIP. This confusion arises because software-derived separations for the server-side of multi-instance environments seems to be your specific intent. In summary, NSX to separate VMs is acceptable but VLANs to separate networks is not. That seems inconsistent to us. In fact, VLANs have well-known ways in which to secure them while products like NSX are much less well-known and proven. We would view VLANs as a good way to achieve the data plane and management plane separation, in conjunction with a firewall. We need to have efficiency of network equipment as well as server equipment.

Answer	
Document Name	

Comment

Reflected in our responses is a genuine concern that BES security is not well served by increasing complexity of implementation, operating practices, and compliance obligations. We are not advocating for a lesser security posture but a clear view of the law.

The concern arises from the nature and impact of the proposed revisions and new Standards and Glossary Terms, individually and in total.

If entities cannot understand the obligations, their ability to successfully operate the BES in a responsible, secure, and reliable manner are adversely impacted.

Entities have built their compliance programs and security posture incorporating the existing definitions. To revise programs will cost time and use resources with little associated benefit--redirecting resources from the very security activities on which they need to focus.

We would appreciate if the SDT would assist industry in understanding what security objective is trying to be fulfilled and to better leverage current Standards to minimize complexity, ensure clarity, and promote implementation flexibility.

There were no questions on the revision to the BCSI definition.

Is there a difference between the “data about” in the new BCSI definition and the “data in” that is part of the Cyber Asset Definition? Network traffic is neither about or in but in transit. Is network traffic considered BCSI? If not, the change in BCSI definition and the elimination of the EACMS term could cause the monitoring of this traffic to be out of CIP scope.

For our industry to maintain security and reliability, we need to break out of the mold of creating new or revised reliability standards that chase cybersecurity. Thought leadership is necessary to position the industry for a more nimble, sustainable, and mature security posture. The industry needs to recognize and accept a paradigm shift to reshape the CIP Standards such that they are written with flexibility and are focused on technology agnostic security objectives to incent Registered Entities to define and implement an adaptive, layered, risk-based cybersecurity program that timely detects, responds to, and mitigates emerging threats. While there has been improvement in the requirement language as the CIP Standards have evolved, they continue to suffer because prescriptive mandatory regulations cannot keep pace with emerging technologies and the rapidly changing cybersecurity threat landscape. Until this paradigm shift occurs, the industry will continue to face the unintended consequences of the current construct, be distracted by the conundrum where security and compliance are at odds, limited in our ability to leverage advances in technology, and will continue to be hindered by the antiquated ideals of a regulation that is chasing cybersecurity.

Response

Wendy Center - U.S. Bureau of Reclamation - 1,5

Answer	
Document Name	

Comment

Reclamation recommends the SDT consider the following:

Principles

The impact rating of a BES Cyber System is determined by its possible impact on the Bulk Electric System, not where it resides (Control Center or any other location) or how it is identified (virtual, non-virtual, hardware, software, etc.), and regardless of a Responsible Entity's functional registration. Following this principle, phrases such as "performing the functional obligations of" are unnecessary.

Instances created within a virtual environment must meet the requirements of the impact rating of that instance.

Hardware used in virtual environments must meet the physical security requirements for the impact rating of the highest rated instance or partition within the hardware.

Recommended Definitions

Reclamation recommends to revise the definition of BES Cyber System as follows:

BES Cyber System – One or more BES Cyber Assets logically grouped to perform one or more reliability tasks. A BES Cyber System may include, but is not limited to:

PCA*

PACS*

EACMS*

Intermediate Systems*

Electronic Access Control Systems: Cyber Assets that control electronic access to BES Cyber Systems.

Virtual Centralized Management System: A centralized system used to administer or configure virtual BES Cyber System(s) or virtual BES Cyber Asset(s).

Virtual Electronic Security Zone: A boundary housing one or more Virtual Machines logically separated from other BES Cyber Systems or other non-BES Cyber Systems using partitioned and isolated service set identifiers (SSIDs), virtual local area networks (VLANs), or other technologies.

Electronic Access Gateway: Cyber Assets (including Electronic Access Points) that control electronic access to and from virtual and non-virtual Electronic Security Perimeter(s).

*Currently defined in the NERC Glossary of Terms.

If the SDT adopts Reclamation's recommended terms and definitions, each term must be added to the NERC Glossary of Terms.

In addition to the recommended terms identified in responses to previous questions, Reclamation also recommends adding the following definition to the NERC Glossary of Terms:

BES Data – Configurations necessary for the operation and security (physical and logical) of the BES.

Rationale

Reclamation recommends virtualization be addressed from the top down, by changing the definition of BES Cyber System.

If each of the new recommended terms is properly described within the recommended revised BES Cyber System definition, the CIP-002 Attachment 1 Impact Rating Criteria will accurately determine the applicable requirements.

Implementation

Reclamation recommends the SDT provide a 24-month implementation plan timeline for entities to comply with the virtualization concepts.

Recommended Impact Rating Criteria

Reclamation recommends simplifying the Impact Rating Criteria using the methodology described below.

BES Cyber Systems are to be rated as high, medium, or low impact as follows:

1. A high impact BES Cyber System has one or more of the following characteristics:
    - Is used to operate transmission lines of 500kV or above
    - Supports a sum greater than 2500kV of transmission lines above 230kV
    - Supports generation with an aggregate capacity greater than 3000MW
    - Is identified as supporting an IROL or is necessary to avoid an Adverse Reliability Impact
2. A medium impact BES Cyber System has one or more of the following characteristics:
    - Supports generation with the aggregate capacity between 1500 – 3000MW
    - Supports a sum between 1500 – 2500kV of transmission lines above 230kV
    - Supports a RAS that could negatively affect an IROL or that can perform automatic Load shedding of 300MW or more
3. A low impact BES Cyber System has one or more of the following characteristics:
    - Supports a sum less than 1500kV of transmission lines above 230kV
    - Supports transmission only between 110 – 230kV
    - Supports generation with an aggregate capacity between 75 – 1500MW
    - Supports any single generator greater than 20MW not already identified as a Medium Impact BES Cyber System
    - Supports any Facilities that are designated a blackstart resource
    - Supports any other RAS not already identified as a medium impact BES Cyber System

The “instance” and “multi-instance” concept presented throughout the new requirements is not clear. If there is one physical box with multiple virtual Cyber Assets that are a part of the same BES Cyber System, is that considered “multi-instance” and all the new requirements apply or could this be considered one “instance” and be able to protect the entire physical box under the currently approved standards without the additional burdens? For example, an entity has one physical box that houses two virtual High Impact Cyber Assets, a virtual applications server and a virtual database server. Both virtual Cyber Assets are part of one High Impact BES Cyber System. Would the entity be able to protect that physical box as they would today or would they need to also apply the new requirements CIP-005 Part 1.5, Part 1.6, etc.? We believe that the risk associated with the example above is significantly lower compared to a “mixed-mode” environment (CIP/non-CIP or High Impact/EACMS). Additionally, for clarification, if an entity has on physical box that has a High Impact Cyber Asset “instance” and a Medium Impact BES Cyber Asset “instance”, could they continue to protect the physical box at the High Impact level without these additional new requirements?

We fully support the concepts presented, but believe having clearer, approved NERC Glossary of Terms definitions of “instance” and “multi-instance” is necessary. Based on risk, the current CIP requirements provide sufficient protections when virtual CIP systems at the same Impact level reside on one physical box and that physical infrastructure is protected at the same level. Clearly stating that gives the entity the flexibility of no additional burden from

the new requirements, but also allows “mixed-mode” environments. Please consider the following when constructing the definition of *multi-instance:* Virtual systems where the separate instances are a combination of CIP and non-CIP systems or the mixture of BES Cyber System Impact levels.

The SPP Standard Review Group agrees with the proposed change in the definition of “Cyber Asset”. However, as we reviewed the document, we noticed that the background information talked about addressing Virtualization, ironically, the proposed language doesn’t discuss or include the term. We would recommend that the drafting team revised the propose language to include the term “Virtualization” and the concepts around it. We feel that this would provide more clarity on what the drafting team’s intents are in reference to the virtualization process.

Additionally, we would suggest adding the management systems to the EACMS Definition instead of breaking them up separately. From our perspective, this provides more stability and reliability when talking about the security of the virtualization process.

John Merrell - Tacoma Public Utilities (Tacoma, WA) - 1,3,4,5,6

Answer	
Document Name	

Comment

The definition of Electronic Security Zone is challenging due to the fact that virtualization utilizes shared resources within the hypervisor. There can be shared memory space and shared physical network connections. So virtual machines that are within a shared hypervisor could potentially be sharing resources from non-BES assets. There are very few vendors that can truly create logical separation in a virtualized environment. To mitigate the security risk, any hardware used to host a BES cyber asset virtual machine, should be considered a part of the ESP. Hosting ESP and non-ESP assets on the same hardware introduces the opportunity for code injection into the hypervisor from less stringent environments. With that said, there are vendors that are able to isolate the resources utilized between VM’s of various classifications. One vendor capable of segmentation is Lynx Software Technologies. VMware and Microsoft HyperV are not among the vendors capable of this level of segmentation.

Tacoma Power recommends utilizing industry standards (e.g., NIST) for guidance on mandating policy. Due to the constantly changing nature of virtualization, the slow update process of CIP standards would limit entities from following industry best practices for virtualization security.

Tacoma Power recommends caution in mandating specific security requirements in a virtualized environment. An overarching policy would be far more effective in securing a virtualized environment.

Comment

The existing NERC standards were not developed to consider the technology that currently exists or may be available in the future. In part, this contributes to more constant changes than the NERC standards process can potentially handle. Additionally, in the proposed BCSI definition, it is unclear what the term “pose a security threat” means.

Comment	
In consideration of each proposed requirement and definition, entities are asking not only does the idea make sense from a security perspective, but also, what evidence will need to be provided to show compliance with the requirement. The requirements proposed, in many cases, ask for an abstract set of objectives, intent, or principles, all of which may be challenging to demonstrate to an auditor. This should be avoided. Also, any requirement intended for a virtual environment should either be obviously applicable and adaptable to single use physical systems or explicitly exclude those systems from the scope of applicability. None of the proposed requirements consider the possibility of existing systems not being technically capable of meeting the requirement as written. Additionally, the proposed definition of BES Cyber System Information (BCSI) adds the terms “individual security logs,” which is unclear. Does this include single log entries? Further clarification needs to be provided on what is meant by “individual security logs.” The proposed definition of BCSI examples also adds “with network addresses” to network topologies. This implies that network diagrams without network addresses would not be considered BCSI. Is this the SDT’s intent?

Comments received from Brandon McCormick – FMPA

1. Do you agree that the proposed change to the Cyber Asset definition makes it inclusive of both physical and virtual devices, including treatment of each virtual machine and hypervisor? If you do not agree, please provide rationale to support your position.

   ☐ Yes
   ☒ No

   Comments: FMPA follows APPA’s comments:

APPA does not agree that the proposed change is inclusive and believes that there is a better way to include both physical and virtual devices. Therefore, public power proposes the following:

> "Programmable electronic devices, including the hardware, software, and data in those devices.
> Virtualized systems or devices are distinct devices."

This proposed change would help in "future-proofing" the definition.

2. Do you agree that the term programmable in the Cyber Asset definition does not need further clarification at this time? If yes, please provide rationale to support your position.

☒ Yes
☐ No
Comments:

3. If programmable does need further clarification, how would you prefer it to be addressed? Use comments to detail necessary definition changes or guidance that could be developed.

Comments:

Centralized Management Systems (CMS)

As the SDT worked through issues related to virtual systems, it became clear that there was no straightforward way within the current CIP Standards to adequately address the risk of systems used to manage virtual environments. Management systems in virtual environments, through their consolidated interfaces and automation, can modify and delete entire infrastructures including virtual servers, networks, and storage. Given the broad capabilities of management systems in a virtual environment, they present specific and significant risk to the reliability of the BES Cyber Systems associated with those management systems.

The SDT considered several options to address the risks of management systems such as grouping management systems into the existing EACMS definition. This, however, would place these assets inappropriately in the EACMS category when they do not perform access control or access monitoring. Using the EACMS category in this manner creates a one-size-fits-all approach to requirements that does not consider the degree of risk or technical constraints posed by the particular system. For example, a system that only monitors and logs access does not pose the same level of risk as a management system for a large virtualized Control Center with the capability to modify or delete a complete infrastructure. Technical controls to mitigate the risk may differ depending on the capabilities of the management system. An electronic access monitoring system presents a risk of leaking BES Cyber System Information; an electronic access control system presents a risk of unauthorized access to, or modification of, a BES Cyber System's operational parameters; and a management system presents a risk of unwanted or unintended modification or deletion of a complete infrastructure. Proposed requirements related to this definition are detailed below.

The SDT determined a more appropriate option was to create a new definition for Centralized Management System (CMS) and apply appropriate and specific security requirements. The SDT seeks comment on the following conceptual definition of Centralized Management System in the Glossary of Terms Used in NERC Reliability Standards (NERC Glossary).

> **Centralized Management System (CMS):**
> A centralized system used for administration or configuration of BES Cyber System(s) through which the configuration of the BES Cyber System can be altered.

4. Do you agree with the proposed definition of Centralized Management Systems (CMS)? If not, please provide rationale to support your position.

☐ Yes
☒ No
Comments:

FMPA agrees with the concept of separating the management plane from the data plane. The definition as proposed should be revised to only include the administration of the BES Cyber System. The current definition may expand the scope to other tools with unintended consequences. Based on group discussions, we have concerns over what is meant by administration or configuration. There were different interpretations based on individual understanding. This should be resolved with a defined term that can be plugged in to the requirements and be implemented by industry.

Virtualization Terms and Requirements

The foundational pieces have now been set for the use of virtualization solutions. However, these solutions still pose risk. These risks and the nature of virtual systems may require some modifications to Standards. The concepts being proposed include additional access control and separation of the management plane from the data plane. This can help to prevent users of the applications on a virtualized system gaining access to the management system that can modify and delete the underlying infrastructure including virtual servers, networks, and storage.

The SDT uses the terms "instance" and "multi-instance" within the proposed requirements below. For the purposes of these proposed changes, the SDT intends for "instance" and "multi-instance" to be understood as:

- Instance: Discrete organizational environments with specific privileges or security levels, consisting of functions that consume resources from the shared infrastructure. Instances are logically isolated but physically interconnected.
- Multi-instance: An environment where a shared infrastructure provides containers for more than one instance.

In reviewing the risks that are unique and inherent to the use of virtualization technologies, the SDT identified the following risks:

1) Shared infrastructure,
2) Span of control, insider threats, and lateral privilege expansion,
3) Misconfiguration, excessive privileges, and capability of administrators, and
4) Escalation of privilege.

The SDT proposes the following definition and requirements in support of the use of virtual technologies.

Electronic Security Zone (ESZ)

The SDT contends that the Electronic Security Perimeter (ESP) definition does not accurately describe the proper isolation of virtual systems within shared infrastructure. Details of the analysis are captured in network isolation portion of the industry webinar presented on March 21, 2017. To address the concerns noted, the SDT seeks comment on the following conceptual definition of Electronic Security Zone (ESZ) in the Glossary of Terms Used in NERC Reliability Standards (NERC Glossary).

Electronic Security Zone:
The area defined by the logical separation of one or more Cyber Asset(s).

5. Do you agree that the proposed definition of ESZ more adequately applies to proper isolation of multi-instance environments, regardless of OSI layer? If not, please provide a rationale to support your position.

☐ Yes
☒ No
Comments:

FMPA is concerned that there is not enough clarity in the definition of ESZ to separate it from the ESP. ESZs seem to apply in different areas – sometimes they can encompass things like PACS/EACMs that might already fit under different requirements. This confusion of the term will lead to different interpretations and applications of the standard. What does sufficient mean in the “proper isolation of multi-instance environments”?

6. Do you agree that the proposed definition of ESZ would aid the development of future CIP Standards by providing a more relevant level of separation? If not, please provide a rationale to support your position.

☐ Yes
☒ No
Comments:

FMPA does not believe that the proposed definition for ESZ would provide the relevant level of separation needed. “Logical separation” is based on current technology and may not be applicable to future controls. VLANs have been a subject of contention in the past with NERC – are these now considered acceptable segregations/boundaries?

New Requirement CIP-005 Requirement 1, Part 1.6

The SDT proposes a new requirement part 1.6 for CIP-005 Requirement R1. This requirement part is for Responsible Entities to implement one or more Electronic Security Zones (ESZ) to meet the security objective of separating the management plane and the data plane of high and medium impact BES Cyber Systems in a multi-instance environment. Part 1.6 would also require Responsible Entities to implement one or more ESZs to meet the security objective of protecting the infrastructure associated with high and medium impact BES Cyber Systems in a multi-instance environment by limiting access to the Centralized Management Systems using a management plane ESZ.

Responsible Entities maintain the flexibility for grouping by cyber system function, by risk, by type of applicable security controls, or other logical groupings. The ESZ contains a distinct subset of the Responsible Entity's Cyber Assets. These are characterized as requiring (or benefiting from) similar security controls and separation from other distinct Cyber Assets. Properly implemented ESZs can limit damage and impact to availability to other surrounding ESZs, specifically by helping protect against span-of-control risks, insider threats, and lateral privilege expansion.

Again, the requirement would only be applicable to high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS.

Part 1.6:
Logically separate all Applicable Systems into defined groups of one or more Cyber Asset(s) to achieve the objective of mitigating the risks of span-of-control, insider threats, and lateral privilege expansion. At a minimum:
1. The management plane and the data plane of the applicable BES Cyber System shall be separated;
2. The CMS of the applicable BES Cyber System shall be separated from its data plane

7. Do you agree that the proposed CIP-005 Requirement R1, Part 1.6 provides sufficient security controls for the high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS to reduce the stated risks inherent to virtualization? If not, please provide a rationale to support your position.

☐ Yes
☒ No
Comments:

FMPA is concerned that neither minimum inclusions outlined in Part 1.6 deal with mitigation of span-of-control. In addition, not all vendor solutions may be able to address Part 1.6. The use of the word "achieve" in the draft standard sets a requirement that could be impossible to maintain as new risks emerge. This Requirement should also have the "per device capability" clause.

We recommend changing it as follows:
Logically separate all Applicable Systems, per device capability, into defined groups of one or more Cyber Asset(s) to address potential risks related to span-of-control, insider threats, and lateral privilege expansion.

New Requirement CIP-005 Requirement 1, Part 1.7

Similarly to CIP-005 Requirement R1, Part 1.3, the SDT proposes new requirement Part 1.7. Part 1.7 requires Responsible Entities to identify, control, and explicitly allow only necessary inbound and outbound communication between ESZs of high and medium impact BES Cyber Systems residing in a multi-instance environment. Part 1.7 would be added to CIP-005 to reduce the risks inherent to virtualization related to misconfiguration, excessive privileges, capability of administrators, as well as information protection and data leakage.

The requirement would be applicable to high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS(s).

Part 1.7:
Implement technical controls that enforce separation between ESZs by allowing only necessary inbound and outbound communication between the separated Cyber Asset(s) residing in a multi-instance environment.

8. Do you agree that the proposed CIP-005 Requirement R1, Part 1.7 provides a necessary security control to the high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS(s) to reduce risks inherent to virtualization? If not, please provide a rationale to support your position.

☐ Yes
☒ No
Comments:

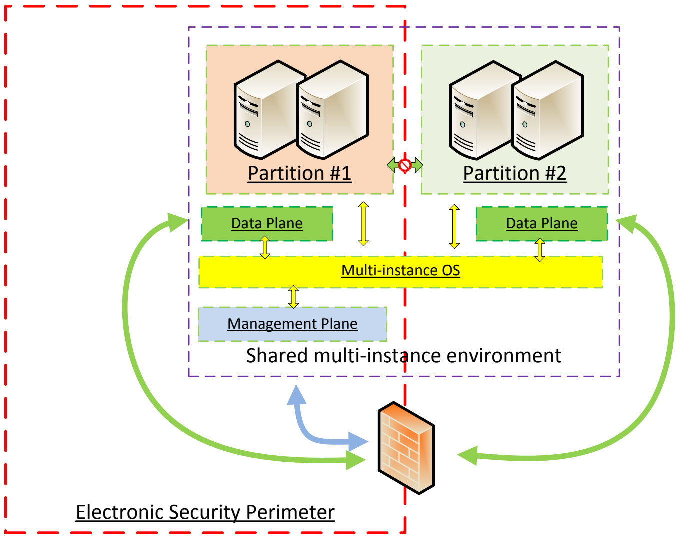
FMPA recommends that the SDT consider the scoping on this requirement part. Would this be identified in the applicability table since it only applies to multi-instance? At the top of the standard/requirement? Or as shown within the requirement? We recommend the SDT provide additional clarity on the ability to have technical controls for other layers (aside from the communication layer) and with shared memory space. We would also like the

SDT to consider the ramifications on the use of a cloud based SIEM vendor who is most likely using a virtualized environment. In the cloud environment, an entity would be transferring risk as well as trust

New Requirement CIP-005 Requirement 1, Part 1.8

Through the SDT work on virtualization, situations have been identified where a Responsible Entity may choose to share the same system infrastructure between applicable Cyber Assets and other programmable devices. As the footprint of cyber assets outside the scope of the CIP Standards in an organization might be significantly larger in size from the Cyber Assets in scope of the CIP Standard, a Responsible Entity may invest in its IT infrastructure with greater capability and more robust features. As presented in the third webinar on virtualization, this is particularly true with storage virtualization implementations. Under certain circumstances, leveraging enterprise infrastructure solutions will provide a better security posture for applicable Cyber Assets. Part 1.8 has been drafted with the objective of allowing such leverage as long as controls mitigating the additional risks are implemented.

A CIP Standard requiring the complete physical separation of applicable Cyber Assets and other programmable devices might adversely affect the overall security posture and reduce operational efficiency for the Responsible Entity through unnecessary expense and complexity of processes or technical implementation. Security controls exist to manage secure logical separation in multi-instance environments and there are operational benefits to sharing a common infrastructure as well. Technological advancements are often coupled with new security mechanisms which often benefit legacy infrastructure.



The diagram above shows an example of a shared multi-instance environment. The green arrows in the diagram represent the data communication. To exchange data between Partition 1 and 2, communication has to go through an EAP represented in the diagram by a firewall. The blue arrows in the diagram represent the management communication. In order to manage Partition 2, or any Cyber Asset hosted by the multi-instance environment and outside the ESP, IP communication to the management plane from outside the ESP has to go through the EAP since the management plan of shared multi-instance environment has to reside inside the ESP. The yellow arrows in the diagram represent the resource management activities performed by the multi-instance operating system necessary to ensure separation of data plane and management plane as well as partitions between Cyber Assets inside the ESP and Cyber Assets outside the ESP.

The SDT proposes CIP-005 Requirement 1, Part 1.8 to provide protection where the infrastructure used in a multi-instance environment is shared between applicable Cyber Assets and other programmable devices. This allows Responsible Entities to leverage the investments and protection of infrastructure shared between applicable Cyber Assets and other programmable devices. The requirement would be applicable to high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS(s).

Part 1.8:

When an infrastructure is shared between BES Cyber Systems and other Cyber Assets not part of a BES Cyber System:

1. The BES Cyber System, the management plane of the shared infrastructure, and any hosted Cyber Assets not part of a BES Cyber Systems shall all be separated; and
2. Communications between the BES Cyber System and any hosted Cyber Assets not part of a BES Cyber System shall all be denied by default

---

9. Do you agree that the proposed CIP-005 Requirement R1, Part 1.8 provides sufficient security control to reduce the risks associated with shared multi-instance environments? If not, please provide a rationale to support your position.

☐ Yes

☒ No

Comments:

There are discrepancies between the language in the Part 1.8 and in the question. Question identifies “shared multi-instance environments “ where the requirement does not. We recommend that the SDT provide guidance on what is infrastructure (possibly using language such as BES related infrastructure) and suggest that the SDT define “Multi-instance”.

If a Jump-host (a required security control for IRA for High BESCS) which is outside of the ESP, then requirement would not be applicable. If the Jump-host was on the VM infrastructure is this a multi-instance environment?

The word “infrastructure” is not defined in the proposed Standard. Consequently, the “infrastructure” on page 4 appears to only include virtual components. APPA questions if this would also include the UPS systems, equipment racks, HVAC systems, floors, lighting, etc.? The “management plane of the shared infrastructure” seems to limit and define “infrastructure” to be components only of the virtual environment.

New Requirement CIP-005 Requirement 3, Part 3.1

In reviewing the risks associated with communications in a virtual environment, the SDT identified a gap with remote access used to perform CMS functions. These communications using a CMS do not align appropriately to Interactive Remote Access. Tasks may be performed from outside the ESP that are a blend of interactive and automated tools, allowing for misinterpretation and unjustified relaxation of security mechanisms required for Interactive Remote Access. Using jump servers to perform CMS functions might not be the most effective or the most secure. Also, remote access to a Cyber Asset inside an ESP could benefit from other methods besides Interactive Remote Access for performing CMS functions.

CIP-005 Requirement R3, Part 3.1 allows for a new type of remote access to be used to perform CMS functions from outside of an ESP. Part 3.1 allows the CMS function to be performed outside an ESP using an access method other than an Intermediate Systems to fix the gap that may exist between

Interactive Remote Access and system-to-system communication. It does this by introducing requirements that are commensurate with the risk inherent to the management function in a multi-instance environment.

The SDT proposes new requirement CIP-005 Requirement 3, Part 3.1. Part 3.1 would be applicable to high and medium impact BES Cyber Systems.

Part 3.1:
Require authentication, integrity and non-repudiation controls for all sessions initiated outside of the ESZ, whether user initiated or system-to-systems communications, used to perform CMS functions.

10. The SDT asserts that the proposed CIP-005 Requirement 1, Part 3.1 provides additional security controls for remote access when performing CMS functions. These are necessary to reduce the risk associated with remote access to multi-instance environments. Do you agree with this assertion? If not, please provide a rationale to support your position.

☐ Yes
☒ No
Comments:

FMPA believes that this Requirement conflicts with the implied requirement identified in comments to question 8 that the management plane of the BCS must be inside the ESZ. APPA recommends replacing the proposed language with: "Require authentication, integrity and non-repudiation controls for all CMS functions, per device capability."

If the suggested modification is not used, in the alternative FMPA proposes that this Requirement have the "per device capability" clause.

Encryption of network traffic from CMS to device could make compliance with this Requirement impossible to achieve.

11. Should the gap between Interactive Remote Access and system-to-system communication that was exposed by the examination of the risks inherent to virtualization be addressed for systems other than high and medium impact BES Cyber Systems residing in a multi-instance environment and their associated CMS? If not, please provide a rationale to support your position.

☐ Yes
☒ No
Comments:

The NERC standards should be written to address the known risks and not limited to risks associated with managing multi-instance environments.

New Requirement CIP-004 Requirement 4, Part 4.5

The SDT has identified "too much privilege" as an inherent risk in virtualization. This risk can be reduced by adding controls in CIP-004. Limiting of the privileges granted to the minimum necessary is only present in the guidance. It is not a requirement. This security risk can be mitigated, however, by implementation of least privilege access and separation of duties in the requirement language. This means fewer people get high level privileges, and no single individual gets privileges that are too broad. For efficiency, it can be implemented via role-based access control (RBAC), which requires an initial effort to define roles properly. But also provides an opportunity for internal review of the span-of-control risk. Role-based access control and separation of duties are both available in virtual environments. Implementation of RBAC varies by vendor but is generically the same in principle.

The SDT proposes new requirement CIP-004 Requirement 4, Part 4.5. Part 4.5 would be applicable to high and medium impact BES Cyber Systems.

Part 4.5:
The Responsible Entity shall document and implement process(es), except under CIP Exceptional Circumstances, to authorize electronic and unescorted physical access to BES Cyber Systems and BES Cyber Systems Information that implements the principles of need-to-know, least privilege, and separation of duties as determined by the Responsible Entity, as per system capability.

12. The SDT asserts that the new proposed CIP-004 Requirement R4, Part 4.5, provides additional security control to the electronic and unescorted physical access to multi-instance environment processes which reduces the "too much privilege" risk inherent to virtualization which has been identified. Do you agree with this assertion? If not, please provide a rationale to support your position.

☐ Yes
☒ No
Comments:

FMPA recommends that this become Requirement 4 Part 4.2 as the Authorization takes place in 4.1; implementation should become 4.2; then the quarterly review is 4.3, etc. FMPA recommends guidance to small entities that they may identify each role but may need to (resource constrained) add the same person to each role

Concept 2: Modifications to the EACMS definition

As noted above, the SDT reviewed the scope of the current definition, the requirements, and risk of the types of assets contained within EACMS. The current construct does not differentiate controls based on the functionality and risk of the system. The current construct does, however, create what is known as the "hall of mirrors" effect. Specifically, there may be some types of EACMS that should be required to be inside an ESP and behind a firewall. An example could be the management system of a firewall that is categorized in such a way that it must reside within an ESP. That requirement, however, cannot exist for all EACMS because a firewall is itself an EACMS. Without defining a new category, the result would be that every EACMS would need to be inside an ESP and therefore protected by another EACMS. This creates the recursive "hall of mirrors" effect.

There are a number of systems that both monitor and provide part of the solution of controlling access, but do not actually control traffic at the point of entry. These devices or systems may or may not benefit from being inside a protected boundary, or they may form part of the strategy that protects BES Cyber Assets. The technical means of implementing some multi-part systems may require components to be outside, or span the ESP.

To address this, the SDT proposes breaking up the EACMS categorization of applicable systems by function so that the appropriate requirements for each can be applied. The SDT does not, however, want to create a reclassification and documentation exercise for Responsible Entities who would not see benefit and would try to create a way for those Responsible Entities to continue to use EACMS with no changes. There are also other options in addition to these two.

Electronic Access Control System (EACS)

The SDT seeks comment on the following conceptual definition of Electronic Access Control System in the Glossary of Terms Used in NERC Reliability Standards (NERC Glossary).

Electronic Access Control System (EACS):

Cyber Assets that perform electronic access control of the BES Cyber Systems. This includes Intermediate Systems.

An Electronic Access Control System performs authentication and authorization of traffic or users. This is the “gatekeeper” function or the classic authentication and authorization functions of standard AAA. In many cases these systems do not perform any active filtering of the traffic passing through any particular interface. The primary duty of EACS is to authenticate and authorize. EACS move beyond the risk of unauthorized access to meta-information about an environment, to unauthorized access to BES Cyber Systems and modification of their operational parameters.

Electronic Access Gateway (EAG)

The SDT seeks comment on the following conceptual definition of Electronic Access Gateway in the Glossary of Terms Used in NERC Reliability Standards (NERC Glossary).

Electronic Access Gateway:
Cyber Assets that perform electronic access control of the Electronic Security Perimeter(s). The Electronic Access Gateway also hosts the EAP(s).

An Electronic Access Gateway hosts the EAP and performs the active function of filtering or forwarding traffic at the demarcation point (boundary protection). Primarily, these are firewalls and routers that perform gateway functions at the layer 3 ESP boundary demarcation point.

Electronic Access Monitoring Systems

As technologies and cyber attacks advance and become more complex, Responsible Entities are becoming increasingly interested in collecting and correlating electronic access monitoring events across their enterprises. This broad-based information collection provides Responsible Entities with more visibility into emerging threats and trends. Responsible Entities can then analyze and share this information more readily and take action to improve the overall cybersecurity and reliability of the BES through early detection of compromise.

Under the currently effective CIP Reliability Standards, if a Responsible Entity uses enterprise wide electronic access monitoring tools, the Cyber Assets used to perform the monitoring may meet the definition of EACMS and become subject to the CIP Reliability Standards applicable to EACMS. This may discourage or prevent Responsible Entities from using enterprise wide electronic access monitoring due to the device level requirements of an EACMS. Responsible Entities may be discouraged from providing and correlating security events across enterprise and control networks, even though cyber-attacks against control systems could enter through business networks. The SDT concludes there is value in correlating security events across both control and enterprise networks.

The SDT proposes that the information within the electronic access monitoring systems should be protected as a BCSI repository, rather than having the system categorized as an EACMS. The systems performing electronic access monitoring are used to monitor and collect information about BES Cyber Systems or Electronic Security Perimeter(s) and pose a risk of information leakage. These monitoring systems are not used to control access to the BES Cyber Systems or Electronic Security Perimeter(s). The monitoring function has been in scope of the EACMS definition due to the sensitivity of certain information that may be collected. The proposed change is to treat the data collected through the monitoring capability as BCSI rather than having the monitoring systems categorized as EACMS. This change will enable Responsible Entities to better leverage enterprise-wide monitoring to improve overall situational awareness, and in the process more proactively address security events.

This will result in improved security and reliability. This does not change a Responsible Entity’s obligations to monitor under CIP-007 R4.

To transition electronic access monitoring from EACMS to BCSI, the SDT seeks comment on the following conceptual modification to the definition of BES Cyber System Information in the Glossary of Terms Used in NERC Reliability Standards (NERC Glossary).

Clean:

BES Cyber System Information:

Data about the BES Cyber System that is processed, organized, structured, or presented in a context that could be used to gain unauthorized access or pose a security threat to the BES Cyber System.

BES Cyber System Information does not include individual pieces of information that by themselves do not pose a threat or could not be used to gain unauthorized access to BES Cyber Systems, such as, but not limited to, device names, individual or collections of IP addresses without context of location and purpose, ESP names, individual security logs, or policy statements.

Examples of BES Cyber System Information may include, but are not limited to: security procedures, collections of security logs, or security configuration information about BES Cyber Systems, Physical Access Control Systems, Electronic Access Control Systems, Electronic Access Gateway Systems, Centralized Management Systems, and Electronic Access Control or Monitoring Systems that are not publicly available; and network topology with network addresses of the BES Cyber System.

Redline:

BES Cyber System Information:

Data ~~Information~~ about the BES Cyber System that is processed, organized, structured, or presented in a context could be used to gain unauthorized access or pose a security threat to the BES Cyber System.

BES Cyber System Information does not include individual pieces of information that by themselves do not pose a threat or could not be used to allow unauthorized access to BES Cyber Systems, such as, but not limited to, device names, individual or collections of IP addresses without context of location and purpose, ESP names, individual security logs, or policy statements.

Examples of BES Cyber System Information may include, but are not limited to:~~,~~ security procedures, collections of security logs, or security configuration information about BES Cyber Systems, Physical Access Control Systems, Electronic Access Control Systems, Electronic Access Gateway Systems, Centralized Management Systems, and Electronic Access Control or Monitoring Systems that is not publicly available ~~and could be used to allow unauthorized access or unauthorized distribution~~; ~~collections of network addresses~~; and network topology with network addresses of the BES Cyber System.

Current:

BES Cyber System Information:

Information about the BES Cyber System that could be used to gain unauthorized access or pose a security threat to the BES Cyber System. BES Cyber System Information does not include individual pieces of information that by themselves do not pose a threat or could not be used to allow unauthorized access to BES Cyber Systems, such as, but not limited to, device names, individual IP addresses without context, ESP names, or policy statements. Examples of BES Cyber System Information may include, but are not limited to, security procedures or security information about BES Cyber Systems, Physical Access Control Systems, and Electronic Access Control or Monitoring Systems that is not publicly available and could be used to allow unauthorized access or unauthorized distribution; collections of network addresses; and network topology of the BES Cyber System.

Proposed Requirements Related to EACMS Changes

Based on the concepts presented above, the table below lists the current requirement scope of EACMS and those proposed for CMS, EACS, and EAG. In the table below, the “X” indicates where the requirement currently applies to the system category in the Applicable Systems column of CIP Standards. The “+” sign indicates an additional requirements being considered to address risk for that specific system category in the Applicable Systems column of CIP Standards. To the extent that there is no difference in requirement applicability, the SDT would look to consolidate the terms into as few classifications as necessary.

Please keep in mind that the SDT does not want to create a reclassification and documentation exercise for Responsible Entities who would not see sufficient benefit and would look to create a way for those Responsible Entities to continue to use EACMS with no changes.

Requirement	EACMS	CMS (+)	EACS (+)	EAG (+)
CIP-004 R1.x		+	+	+
CIP-004 R2.x	X	X	X	X
CIP-004 R3.x	X	X	X	X
CIP-004 R4.x	X	X	X	X
CIP-004 R5.x	X	X	X	X
CIP-005 R1.x		+	+	X (Part 1.5)
CIP-005 R2.x		+		
CIP-005 R3		+		
CIP-007 R1.1	X	X	X	X
CIP-007 R2.x	X	X	X	X
CIP-007 R3.x	X	X	X	X
CIP-007 R4.x	X	X	X	X
CIP-007 R5.x	X	X	X	X
CIP-009 R1.x	X		X	X
CIP-009 R2.1	X		X	X
CIP-009 R2.2	X		X	X
CIP-009 R2.3			+	+
CIP-009 R3.x	X		X	X
CIP-010 R1.x	X	X	X	X

Requirement	EACMS	CMS (+)	EACS (+)	EAG (+)
CIP-010 R2.x	X	X	X	X
CIP-010 R3.1	X	X	X	X
CIP-010 R3.2		X	+	+
CIP-010 R3.3	X	X	X	X
CIP-010 R3.4	X	X	X	X
CIP-010 R3.5	X	X	X	X
CIP-011 R1.x	X	X	X	X
CIP-011 R2.x	X	X	X	X

13. Do you agree with the SDT's assertion that the definition of EACMS is too broad and does not differentiate the capabilities and risk(s) of the systems that fall within that definition scope? If not, please provide rationale to support your position.

☒ Yes
☐ No
Comments:

14. Do you agree that the language of the proposed definitions of EACS provides better consistency and clarity to the CIP Standards? If not, please provide rationale to support your position and alternative language.

☐ Yes
☒ No
Comments: FMPA agrees that the language provides more clarity. However, we are concerned that the change includes intermediate systems, which cannot be inside of the ESP.

15. Do you agree that the language of the proposed definitions of EAG provides better consistency and clarity to the CIP Standards? If not, please provide rationale to support your position and alternative language.

☐ Yes
☒ No
Comments: We agree that the proposed definitions of EAG provides better consistency and clarity; however, the SDT used EAG Systems in the example for the changes to the BCSI definition. Should this be EAG or EAGS?

The SDT used EAG Systems in the example for the changes to the BCSI definition. FMPA is unsure if this should be EAG or EAGS.

16. Do you agree that the current compliance requirements related to EACMS monitoring systems are precluding or discouraging solutions that could reduce risk to security and reliability? Please provide your rationale in support or against this assertion.

☒ Yes
☐ No
Comments:

Yes. The existing standards would make it difficult or potentially impossible to be compliant and use services like Dell Secureworks.

17. Should the security requirements for the access control portion of the EACMS to be different from the monitoring portion of the EACMS? If you do, please provide your rationale.

☒ Yes
☐ No
Comments:

The security controls for monitoring need to be flexible. This is because the BES cannot be negatively impacted solely by a compromise of a monitoring system.

18. Should CIP-011 Requirement R2 scope be expanded to include designated storage locations for access monitoring systems? If not, please provide rationale to support your position.

☐ Yes
☒ No
Comments:

BCSI outside the entities environment should be dealt with in the CIP standards apart from the existing Requirement R2.

19. Do you agree with assignment of CIP Standard requirements to each of the EACS, EAG, and CMS categories as presented in the table above? If not, please provide rationale to support your position.

☒ Yes
☐ No
Comments:

Concept 3: Compliance Guidance

The SDT has explored the idea that no changes are necessary to the CIP Standards to address virtualization. ERO Enterprise-endorsed Compliance Guidance could be used to address many industry concerns with the proper implementation of virtualization.

20. As the standards today do not prohibit the use of virtualization technologies, do you support an approach where no changes are made to the CIP Standards in response to the virtualization issue identified by the V5 TAG? Please provide a rationale to support your position.

☐ Yes
☒ No
Comments:

The current CIP standards do not explicitly prohibit all types of virtualization but require "high water marking" of the impact level even where this is not the most secure and reliable control. For example, the separation of data plane and management plane between hypervisor and guest is a more effective control than applying rigorous CIP Requirements and keeping hypervisors inside the same security zone.

Also, CIP Requirements do not separate the electronic access controls from the electronic access monitoring to allow for different requirements when only monitoring is done. This has a high risk of misallocating scarce resources (money, time, manpower) that could be more effectively applied elsewhere for increased reliability.

Compliance guidance is written to show one or more compliant solutions to clarify and help in applying the Requirements. Such guidance does not supersede standard requirements language. Moreover, such guidance cannot show all possible solutions and is specific and limited, rather than a framework where one can generate new and unique solutions. Solutions currently known to the SDT are only a snapshot in time that may become obsolete at any moment due to technical innovation or changes in the threat environment, while security objectives are more enduring than requirements for a specific solution. Entities may be aware of, or devise a solution unknown to the SDT that provides equal or greater security, that the Requirements language finds the solution non-compliant. Therefore, the proposed standard must emphasize security objectives that allow entities to demonstrate and explain how solutions meets the objective.

Summary

The SDT has provided very diverse concepts for your consideration. Each of these concepts can be moved forward in the drafting process independently. Please provide your responses to each of the questions below.

21. Is your organization in support of Concept 1: Modifications to allow use of secure multi-instance? Please provide rationale to support your position.

☐ Yes
☒ No
Comments:

We would support Concept 1: Modifications to allow use of secure multi-instance provided that comments herein are taken into consideration.

22. Is your organization in support of Concept 2: Modifications to the EACMS definition? Please provide rationale to support your position.

☐ Yes
☒ No
Comments:

We would support Concept 2: Modifications to the EACMS definition provided that comments herein are taken into consideration.

23. Is your organization in support of Concept 3: Compliance Guidance? Please provide rationale to support your position.

☐ Yes
☒ No
Comments:

FMPA believes that the Compliance Guidance would not be appropriate because it only shows limited compliance. Moreover, it does not resolve the issues of high-water marking of impact levels and nor does it allow for the separation of monitoring from EACMS.

24. If you have additional comments that you have not provided in response to the questions above, please provide them here.

Comments:

The existing NERC standards were not developed to consider the technology that currently exists or may be available in the future. In part, this contributes to more constant changes than the NERC standards process can potentially handle.

Additionally, in the proposed BCSI definition, it is unclear what the term “pose a security threat” means.

RELIABILITY CORPORATION

Unofficial Nomination Form

Project Number 2016-02 Modifications to CIP Standards

Do not use this form for submitting nominations. Use the electronic form to submit nominations by **8 p.m. Eastern, Wednesday, May 23, 2018.** This unofficial version is provided to assist nominees in compiling the information necessary to submit the electronic form.

Additional information can be found on the Project 2016-02 Modifications to the CIP Standards page. If you have questions, contact Standards Developer, Jordan Mallory (via email), or at 404-446-2589.

By submitting a nomination form, you are indicating your willingness and agreement to actively participate in face-to-face meetings and conference calls.

Previous drafting or review team experience is beneficial, but not required. A brief description of the desired qualifications, expected commitment, and other pertinent information is included below.

Project 2016-02 Modifications to CIP Standards

This solicitation for nominations is to augment the existing Project 2016-02 Modifications to CIP Standards drafting team that is continuing to address the Standards Authorization Request. NERC is seeking individuals from the United States and Canada who possess experience in one or more of the following areas, but are not limited to:

- Virtualization;
- Cyber Asset and BES Cyber Asset Definitions; and
- Network and Externally Accessible Devices.

Standards Affected

CIP-002-5.1, CIP-003-6, CIP-004-6, CIP-005-5, CIP-006-6, CIP-007-6, CIP-008-5, CIP-009-6, CIP-010-2, CIP-011-2, and CIP-012-1.

The time commitment for this project is expected to be up to two face-to-face meetings per quarter (on average two full working days each meeting) with conference calls scheduled as needed to meet the agreed-upon timeline the review or drafting team sets forth. Team members may also have side projects, either individually or by subgroup, to present to the larger team for discussion and review. Lastly, an important component of the review and drafting team effort is outreach. Members of the team will be expected to conduct industry outreach during the development process to support a successful project outcome.

Name:	
Organization:	
Address:	
Telephone:	
E-mail:	

Please briefly describe your experience and qualifications to serve on the requested Standard Drafting Team (Bio):

If you are currently a member of any NERC drafting team(s), please list each one here:

☐ Not currently on any active SAR or standard drafting team.

☐ Currently a member of the following SAR or standard drafting team(s):

If you previously worked on any NERC drafting team(s), please identify each one here:

☐ No prior NERC SAR or standard drafting team.

☐ Prior experience on the following team(s):

Select each NERC Region in which you have experience relevant to the Project for which you are volunteering:

☐ Texas RE
☐ FRCC
☐ MRO
☐ NPCC
☐ RF
☐ SERC
☐ SPP RE
☐ WECC
☐ NA – Not Applicable

Select each Industry Segment that you represent:

☐ 1 — Transmission Owners
☐ 2 — RTOs, ISOs
☐ 3 — Load-serving Entities
☐ 4 — Transmission-dependent Utilities
☐ 5 — Electric Generators
☐ 6 — Electricity Brokers, Aggregators, and Marketers
☐ 7 — Large Electricity End Users
☐ 8 — Small Electricity End Users
☐ 9 — Federal, State, and Provincial Regulatory or other Government Entities
☐ 10 — Regional Reliability Organizations and Regional Entities
☐ NA – Not Applicable

Select each Function[1] in which you have current or prior expertise:

☐ Balancing Authority
☐ Compliance Enforcement Authority
☐ Distribution Provider
☐ Generator Operator
☐ Generator Owner
☐ Interchange Authority
☐ Load-serving Entity
☐ Market Operator
☐ Planning Coordinator
☐ Transmission Operator
☐ Transmission Owner
☐ Transmission Planner
☐ Transmission Service Provider
☐ Purchasing-selling Entity
☐ Reliability Coordinator
☐ Reliability Assurer
☐ Resource Planner

---

[1] These functions are defined in the NERC Functional Model, which is available on the NERC web site.

Provide the names and contact information of two references who could attest to your technical qualifications and your ability to work well in a group:

Standards Announcement

Project 2016-02 Modifications to CIP Standards

Nomination Period Open through May 23, 2018

Now Available

Nominations are being sought for additional standard drafting team members through **8 p.m. Eastern, Wednesday, May 23, 2018**.

Use the electronic form to submit a nomination. If you experience difficulties using the electronic form, contact Wendy Muller. An unofficial Word version of the nomination form is posted on the Standard Drafting Team Vacancies and the project page.

By submitting a nomination form, you are indicating your willingness and agreement to actively participate in face-to-face meetings and conference calls.

The time commitment for this project is expected to be up to two face-to-face meetings per quarter (on average two full working days each meeting) with conference calls scheduled as needed to meet the agreed-upon timeline the review or drafting team sets forth. Team members may also have side projects, either individually or by subgroup, to present to the larger team for discussion and review. Lastly, an important component of the review and drafting team effort is outreach. Members of the team will be expected to conduct industry outreach during the development process to support a successful project outcome.

Previous drafting or review team experience is beneficial, but not required.

Project 2016-02 Modifications to CIP Standards

This solicitation for nominations is to augment the existing Project 2016-02 Modifications to CIP Standards drafting team that is continuing to address the Standards Authorization Request. NERC is seeking individuals from the United States and Canada who possess experience in one or more of the following areas, but are not limited to:

- Virtualization;
- Cyber Asset and BES Cyber Asset Definitions; and
- Network and Externally Accessible Devices.

Standards Affected

CIP-002-5.1, CIP-003-6, CIP-004-6, CIP-005-5, CIP-006-6, CIP-007-6, CIP-008-5, CIP-009-6, CIP-010-2, CIP-011-2, and CIP-012-1.

Next Steps

The Standards Committee is expected to appoint members to the team in June 2018. Nominees will be notified shortly after they have been appointed**.**

For information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Mat Bunch at (404) 446-9785 or Jordan Mallory at (404) 446-2589.

Atlanta, GA 30326
404-446-2560 | www.nerc.com

The Background, VRF/VSLs, and Guidelines and Technical Basis Sections have been removed for this informal posting. The Project 2016-02 is seeking comments around the concept of the Requirement/Measure language at this time. All other sections will be modified prior to the initial posting.

A. Introduction

1. **Title:** Cyber Security — Personnel & Training
2. **Number:** CIP-004-7
3. **Purpose:** To minimize the risk against compromise that could lead to misoperation or instability in the Bulk Electric System (BES) from individuals accessing BES Cyber Systems by requiring an appropriate level of personnel risk assessment, training, and security awareness in support of protecting BES Cyber Systems.
4. **Applicability:**

    4.1. **Functional Entities:** For the purpose of the requirements contained herein, the following list of functional entities will be collectively referred to as "Responsible Entities." For requirements in this standard where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are specified explicitly.

    4.1.1. **Balancing Authority**

    4.1.2. **Distribution Provider** that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:

    4.1.2.1. Each underfrequency Load shedding (UFLS) or undervoltage Load shedding (UVLS) system that:

    4.1.2.1.1. is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

    4.1.2.1.2. performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

    4.1.2.2. Remedial Action Scheme (RAS) where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

    4.1.2.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.1.3. Generator Operator

4.1.4. Generator Owner

4.1.5. Reliability Coordinator

4.1.6. Transmission Operator

4.1.7. Transmission Owner

4.2. Facilities: For the requirements in this standard, the following Facilities, systems, and equipment owned by each Responsible Entity in 4.1 above are those to which these requirements are applicable. For requirementswhere a specific type of Facilities, system, or equipment or subset of Facilities, systems, and equipment are applicable, these are explicitly specified.

4.2.1. Distribution Provider: One or more of the following Facilities, systems and equipment owned by the Distribution Provider for the protection or restoration of the BES:

4.2.1.1. Each UFLS or UVLS System that:

4.2.1.1.1. is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.2.1.1.2. performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.2.1.2. Each RAS where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.2.2. Responsible Entities listed in 4.1 other than Distribution Providers: All BES Facilities.

4.2.3. Exemptions: The following are exempt from Standard CIP-004-7:

4.2.3.1. Cyber Assets at Facilities regulated by the Canadian Nuclear Safety Commission.

4.2.3.2. Cyber Assets associated with communication networks and data communication links between BES Cyber Systems' Logical Isolation Zones.

4.2.3.3. Cyber Assets associated with communication networks and data communication links used to extend a Logical Isolation Zone to more than one geographic location.

4.2.3.4. The systems, structures, and components that are regulated by the Nuclear Regulatory Commission under a cyber security plan pursuant to 10 C.F.R. Section 73.54.

4.2.3.5. For Distribution Providers, the systems and equipment that are not included in section 4.2.1 above.

4.2.3.6. Responsible Entities that identify that they have no BES Cyber Systems categorized as high impact or medium impact according to the CIP-002-5.1 identification and categorization processes.

5. **Effective Dates:** See Implementation Plan for CIP-004-7.

B. Requirements and Measures

R1. Each Responsible Entity shall implement one or more documented processes that collectively include each of the applicable requirement parts in *CIP-004-7 Table R1 – Security Awareness Program*.

M1. Evidence must include each of the applicable documented processes that collectively include each of the applicable requirement parts in *CIP-004-7 Table R1 – Security Awareness Program* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-004-7 Table R1 – Security Awareness Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.1	High Impact BES Cyber Systems Medium Impact BES Cyber Systems	Security awareness that, at least once each calendar quarter, reinforces cyber security practices (which may include associated physical security practices) for the Responsible Entity's personnel who have authorized electronic or authorized unescorted physical access to BES Cyber Systems.	An example of evidence may include, but is not limited to, documentation that the quarterly reinforcement has been provided. Examples of evidence of reinforcement may include, but are not limited to, dated copies of information used to reinforce security awareness, as well as evidence of distribution, such as: • direct communications (for example, e-mails, memos, computer-based training); or • indirect communications (for example, posters, intranet, or brochures); or • management support and reinforcement (for example, presentations or meetings).

R2. Each Responsible Entity shall implement one or more cyber security training program(s) appropriate to individual roles, functions, or responsibilities that collectively includes each of the applicable requirement parts in *CIP-004-7 Table R2 – Cyber Security Training Program*.

M2. Evidence must include the training program that includes each of the applicable requirement parts in *CIP-004-7 Table R2 – Cyber Security Training Program* and additional evidence to demonstrate implementation of the program(s).

CIP-004-7 Table R2 – Cyber Security Training Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
2.1	High Impact BES Cyber Systems and their associated: 1. EACS; and 2. PACS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; and 2. PACS	Training content on: 2.1.1. Cyber security policies; 2.1.2. Physical access controls; 2.1.3. Electronic access controls; 2.1.4. The visitor control program; 2.1.5. Handling of BES Cyber System Information and its storage; 2.1.6. Identification of a Cyber Security Incident and initial notifications in accordance with the entity's incident response plan; 2.1.7. Recovery plans for BES Cyber Systems; 2.1.8. Response to Cyber Security Incidents; and 2.1.9. Cyber security risks associated with a BES Cyber System's electronic interconnectivity and interoperability with other Cyber Assets, including Transient Cyber Assets, and with Removable Media.	Examples of evidence may include, but are not limited to, training material such as power point presentations, instructor notes, student notes, handouts, or other training materials.

CIP-004-7 Table R2 – Cyber Security Training Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
2.2	High Impact BES Cyber Systems and their associated: 1. EACS; and 2. PACS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; and 2. PACS	Require completion of the training specified in Part 2.1 prior to granting authorized electronic access and authorized unescorted physical access, except during CIP Exceptional Circumstances.	Examples of evidence may include, but are not limited to, training records and documentation of when CIP Exceptional Circumstances were invoked.
2.3	High Impact BES Cyber Systems and their associated: 1. EACS; and 2. PACS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; and 2. PACS	Require completion of the training specified in Part 2.1 at least once every 15 calendar months.	Examples of evidence may include, but are not limited to, dated individual training records.

R3. Each Responsible Entity shall implement one or more documented personnel risk assessment program(s) to attain and retain authorized electronic or authorized unescorted physical access to BES Cyber Systems that collectively include each of the applicable requirement parts in *CIP-004-7 Table R3 – Personnel Risk Assessment Program*.

M3. Evidence must include the documented personnel risk assessment programs that collectively include each of the applicable requirement parts in *CIP-004-7 Table R3 – Personnel Risk Assessment Program* and additional evidence to demonstrate implementation of the program(s).

CIP-004-7 Table R3 – Personnel Risk Assessment Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
3.1	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; 2. PACS; and 3. PCS	Process to confirm identity.	An example of evidence may include, but is not limited to, documentation of the Responsible Entity's process to confirm identity.

CIP-004-7 Table R3 – Personnel Risk Assessment Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
3.2	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; 2. PACS; and 3. PCS	Process to perform a seven year criminal history records check as part of each personnel risk assessment that includes: 3.2.1. current residence, regardless of duration; and 3.2.2. other locations where, during the seven years immediately prior to the date of the criminal history records check, the subject has resided for six consecutive months or more. If it is not possible to perform a full seven year criminal history records check, conduct as much of the seven year criminal history records check as possible and document the reason the full seven year criminal history records check could not be performed.	An example of evidence may include, but is not limited to, documentation of the Responsible Entity's process to perform a seven year criminal history records check.

CIP-004-7 Table R3 – Personnel Risk Assessment Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
3.3	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; 2. PACS; and 3. PCS	Criteria or process to evaluate criminal history records checks for authorizing access.	An example of evidence may include, but is not limited to, documentation of the Responsible Entity's process to evaluate criminal history records checks.
3.4	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; 2. PACS; and 3. PCS	Criteria or process for verifying that personnel risk assessments performed for contractors or service vendors are conducted according to Parts 3.1 through 3.3.	An example of evidence may include, but is not limited to, documentation of the Responsible Entity's criteria or process for verifying contractors or service vendors personnel risk assessments.

CIP-004-7 Table R3 – Personnel Risk Assessment Program

Part	Applicable Systems	Requirements	Measures
3.5	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; 2. PACS; and 3. PCS	Process to ensure that individuals with authorized electronic or authorized unescorted physical access have had a personnel risk assessment completed, except during CIP Exceptional Circumstances, according to Parts 3.1 to 3.4 within the last seven years.	An example of evidence may include, but is not limited to, documentation of the Responsible Entity’s process for ensuring that individuals with authorized electronic or authorized unescorted physical access have had a personnel risk assessment completed within the last seven years.

R4. Each Responsible Entity shall implement one or more documented access management program(s) that collectively include each of the applicable requirement parts in *CIP-004-7 Table R4 – Access Management Program.*

M4. Evidence must include the documented processes that collectively include each of the applicable requirement parts in *CIP-004-7 Table R4 – Access Management Program* and additional evidence to demonstrate that the access management program was implemented as described in the Measures column of the table.

CIP-004-7 Table R4 – Access Management Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
4.1	High Impact BES Cyber Systems and their associated: 1. EACS; 2. EAMS; 3. PACS; 4. PAMS; and 5. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; 2. EAMS; 3. PACS; 4. PAMS; and 5. PCS	Process to authorize based on need, as determined by the Responsible Entity, except for CIP Exceptional Circumstances: 4.1.1. Electronic access; 4.1.2. Unescorted physical access into a Physical Security Perimeter; and 4.1.3. Access to designated storage locations (including EAMS and PAMS whether physical or electronic, for BES Cyber System Information.	An example of evidence may include, but is not limited to, dated documentation of the process to authorize electronic access, unescorted physical access in a Physical Security Perimeter, and access to designated storage locations, whether physical or electronic, for BES Cyber System Information.

CIP-004-7 Table R4 – Access Management Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
4.2	High Impact BES Cyber Systems and their associated: 1. EACS; 2. EAMS; 3. PACS; 4. PAMS; and 5. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; 2. EAMS; 3. PACS; 4. PAMS; and 5. PCS	Verify at least once each calendar quarter that individuals with active electronic access or unescorted physical access have authorization records.	Examples of evidence may include, but are not limited to: • Dated documentation of the verification between the system generated list of individuals who have been authorized for access (i.e., workflow database) and a system generated list of personnel who have access (i.e., user account listing), or • Dated documentation of the verification between a list of individuals who have been authorized for access (i.e., authorization forms) and a list of individuals provisioned for access (i.e., provisioning forms or shared account listing).

CIP-004-7 Table R4 – Access Management Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
4.3	High Impact BES Cyber Systems and their associated: 1. EACS; 2. EAMS; 3. PACS; and 4. PAMS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; 2. EAMS; 3. PACS; and 4. PAMS	For electronic access, verify at least once every 15 calendar months that all user accounts, user account groups, or user role categories, and their specific, associated privileges are correct and are those that the Responsible Entity determines are necessary.	An example of evidence may include, but is not limited to, documentation of the review that includes all of the following: 1. A dated listing of all accounts/account groups or roles within the system; 2. A summary description of privileges associated with each group or role; 3. Accounts assigned to the group or role; and 4. Dated evidence showing verification of the privileges for the group are authorized and appropriate to the work function performed by people assigned to each account.

CIP-004-7 Table R4 – Access Management Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
4.4	High Impact BES Cyber Systems and their associated: 1. EACS; 2. EAMS; and 3. PACS; and 4. PAMS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; 2. EAMS; and 3. PACS; and 4. PAMS	Verify at least once every 15 calendar months that access to the designated storage locations for BES Cyber System Information, whether physical or electronic, including EAMS and PAMS are correct and are those that the Responsible Entity determines are necessary for performing assigned work functions.	An example of evidence may include, but is not limited to, the documentation of the review that includes all of the following: 1. A dated listing of authorizations for BES Cyber System information; 2. Any privileges associated with the authorizations; and 3. Dated evidence showing a verification of the authorizations and any privileges were confirmed correct and the minimum necessary for performing assigned work functions.

R5. Each Responsible Entity shall implement one or more documented access revocation program(s) that collectively include each of the applicable requirement parts in *CIP-004-7 Table R5 – Access Revocation*.

M5. Evidence must include each of the applicable documented programs that collectively include each of the applicable requirement parts in *CIP-004-7 Table R5 – Access Revocation* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-004-7 Table R5 – Access Revocation			
Part	**Applicable Systems**	**Requirements**	**Measures**
5.1	High Impact BES Cyber Systems and their associated: 1. EACS; 2. EAMS; 3. PACS; 4. PAMS; and 5. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; 2. EAMS; 3. PACS; 4. PAMS; and 5. PCS	A process to initiate removal of an individual's ability for unescorted physical access and Interactive Remote Access upon a termination action, and complete the removals within 24 hours of the termination action (Removal of the ability for access may be different than deletion, disabling, revocation, or removal of all access rights).	An example of evidence may include, but is not limited to, documentation of all of the following: 1. Dated workflow or sign-off form verifying access removal associated with the termination action; and 2. Logs or other demonstration showing such persons no longer have access.

CIP-004-7 Table R5 – Access Revocation			
Part	**Applicable Systems**	**Requirements**	**Measures**
5.2	High Impact BES Cyber Systems and their associated: 1. EACS; 2. EAMS; 3. PACS; 4. PAMS; and 5. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACMS; 2. EAMS; 3. PACS; 4. PAMS; and 5. PCS	For reassignments or transfers, revoke the individual's authorized electronic access to individual accounts and authorized unescorted physical access that the Responsible Entity determines are not necessary by the end of the next calendar day following the date that the Responsible Entity determines that the individual no longer requires retention of that access.	An example of evidence may include, but is not limited to, documentation of all of the following: 1. Dated workflow or sign-off form showing a review of logical and physical access; and 2. Logs or other demonstration showing such persons no longer have access that the Responsible Entity determines is not necessary.

CIP-004-7 Table R5 – Access Revocation			
Part	**Applicable Systems**	**Requirements**	**Measures**
5.3	High Impact BES Cyber Systems and their associated: 1. EACS; 2. EAMS; 3. PACS; and 4. PAMS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; 2. EAMS; and 3. PACS; and 4. PAMS	For termination actions, revoke the individual's access to the designated storage locations for BES Cyber System Information, whether physical or electronic (unless already revoked according to Requirement R5.1), including EAMS and PAMS by the end of the next calendar day following the effective date of the termination action.	An example of evidence may include, but is not limited to, workflow or sign-off form verifying access removal to designated physical areas or cyber systems containing BES Cyber System Information associated with the terminations and dated within the next calendar day of the termination action.
5.4	High Impact BES Cyber Systems and their associated EACS.	For termination actions, revoke the individual's non-shared user accounts (unless already revoked according to Parts 5.1 or 5.3) within 30 calendar days of the effective date of the termination action.	An example of evidence may include, but is not limited to, workflow or sign-off form showing access removal for any individual BES Cyber Systems and software applications as determined necessary to completing the revocation of access and dated within thirty calendar days of the termination actions.

CIP-004-7 Table R5 – Access Revocation			
Part	**Applicable Systems**	**Requirements**	**Measures**
5.5	High Impact BES Cyber Systems and their associated EACS.	For termination actions, change passwords for shared account(s) known to the user within 30 calendar days of the termination action. For reassignments or transfers, change passwords for shared account(s) known to the user within 30 calendar days following the date that the Responsible Entity determines that the individual no longer requires retention of that access. If the Responsible Entity determines and documents that extenuating operating circumstances require a longer time period, change the password(s) within 10 calendar days following the end of the operating circumstances.	Examples of evidence may include, but are not limited to: • Workflow or sign-off form showing password reset within 30 calendar days of the termination; • Workflow or sign-off form showing password reset within 30 calendar days of the reassignments or transfers; or • Documentation of the extenuating operating circumstance and workflow or sign-off form showing password reset within 10 calendar days following the end of the operating circumstance.

C. Compliance

1. **Compliance Monitoring Process:**

   1.1. **Compliance Enforcement Authority:** As defined in the NERC Rules of Procedure, “Compliance Enforcement Authority” (CEA) means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

   1.2. **Evidence Retention:** The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the CEA may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

   The Responsible Entity shall keep data or evidence to show compliance as identified below unless directed by its CEA to retain specific evidence for a longer period of time as part of an investigation:

   - Each Responsible Entity shall retain evidence of each requirement in this standard for three calendar years.
   - If a Responsible Entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.
   - The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

   1.3. **Compliance Monitoring and Assessment Processes:**

   - Compliance Audits
   - Self-Certifications
   - Spot Checking
   - Compliance Violation Investigations
   - Self-Reporting
   - Complaints

   1.4. **Additional Compliance Information:**
   None.

D. Regional Variances

None.

E. Interpretations

None.

F. Associated Documents

Version History

Version	Date	Action	Change Tracking
1	1/16/06	R3.2 — Change "Control Center" to "control center."	3/24/06
2	9/30/09	Modifications to clarify the requirements and to bring the compliance elements into conformance with the latest guidelines for developing compliance elements of standards. Removal of reasonable business judgment. Replaced the RRO with the RE as a responsible entity. Rewording of Effective Date. Changed compliance monitor to Compliance Enforcement Authority.	
3	12/16/09	Updated Version Number from -2 to -3 In Requirement 1.6, deleted the sentence pertaining to removing component or system from service in order to perform testing, in response to FERC order issued September 30, 2009.	
3	12/16/09	Approved by the NERC Board of Trustees.	
3	3/31/10	Approved by FERC.	
4	1/24/11	Approved by the NERC Board of Trustees.	

Version	Date	Action	Change Tracking
5	11/26/12	Adopted by the NERC Board of Trustees.	Modified to coordinate with other CIP standards and to revise format to use RBS Template.
5	11/22/13	FERC Order issued approving CIP-004-5.	
5.1	9/30/13	Modified two VSLs in R4	Errata
6	11/13/14	Adopted by the NERC Board of Trustees.	Addressed two FERC directives from Order No. 791 related to identify, assess, and correct language and communication networks.
6	2/12/15	Adopted by the NERC Board of Trustees.	Replaces the version adopted by the Board on 11/13/2014. Revised version addresses remaining directives from Order No. 791 related to transient devices and low impact BES Cyber Systems.
6	1/21/16	FERC order issued approving CIP-004-6. Docket No. RM15-14-000	

The Background, VRF/VSLs, and Guidelines and Technical Basis Sections have been removed for this informal posting. The Project 2016-02 is seeking comments around the concept of the Requirement/Measure language at this time. All other sections will be modified prior to the initial posting.

A. Introduction

1. **Title:** Cyber Security — Personnel & Training
2. **Number:** CIP-004-7~~6~~
3. **Purpose:** To minimize the risk against compromise that could lead to misoperation or instability in the Bulk Electric System (BES) from individuals accessing BES Cyber Systems by requiring an appropriate level of personnel risk assessment, training, and security awareness in support of protecting BES Cyber Systems.
4. **Applicability:**
    - **4.1.** **Functional Entities:** For the purpose of the requirements contained herein, the following list of functional entities will be collectively referred to as "Responsible Entities." For requirements in this standard where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are specified explicitly.
        - **4.1.1.** **Balancing Authority**
        - **4.1.2.** **Distribution Provider** that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:
            - **4.1.2.1.** Each underfrequency Load shedding (UFLS) or undervoltage Load shedding (UVLS) system that:
                - **4.1.2.1.1.** is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and
                - **4.1.2.1.2.** performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.
            - **4.1.2.2.** ~~Each Special Protection System (SPS) or~~ Remedial Action Scheme (RAS) where the ~~SPS or~~ RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.
            - **4.1.2.3.** Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.1.3. Generator Operator

4.1.4. Generator Owner~~Interchange Coordinator or Interchange Authority~~

4.1.5. Reliability Coordinator

4.1.6. Transmission Operator

4.1.7. Transmission Owner

4.2. Facilities: For the ~~purpose of the~~ requirements in this standard~~contained herein~~, the following Facilities, systems, and equipment owned by each Responsible Entity in 4.1 above are those to which these requirements are applicable. For requirements~~ in this standard~~ where a specific type of Facilities, system, or equipment or subset of Facilities, systems, and equipment are applicable, these are explicitly specified~~ explicitly~~.

4.2.1. Distribution Provider: One or more of the following Facilities, systems and equipment owned by the Distribution Provider for the protection or restoration of the BES:

4.2.1.1. Each UFLS or UVLS System that:

4.2.1.1.1. is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.2.1.1.2. performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.2.1.2. Each ~~SPS or~~ RAS where the ~~SPS or~~ RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.2.2. Responsible Entities listed in 4.1 other than Distribution Providers: All BES Facilities.

4.2.3. Exemptions: The following are exempt from Standard CIP-004-7~~6~~:

4.2.3.1. Cyber Assets at Facilities regulated by the Canadian Nuclear Safety Commission.

4.2.3.2. Cyber Assets associated with communication networks and data communication links between- BES Cyber Systems’ Logical Isolation Zones~~discrete Electronic Security Perimeters~~.

4.2.3.3. Cyber Assets associated with communication networks and data communication links used to extend a Logical Isolation Zone to more than one geographic location.

~~4.2.3.2.~~4.2.3.4. The systems, structures, and components that are regulated by the Nuclear Regulatory Commission under a cyber security plan pursuant to 10 C.F.R. Section 73.54.

~~4.2.3.3.~~4.2.3.5. For Distribution Providers, the systems and equipment that are not included in section 4.2.1 above.

~~4.2.3.4.~~4.2.3.6. Responsible Entities that identify that they have no BES Cyber Systems categorized as high impact or medium impact according to the CIP-002-5.1 identification and categorization processes.

5. **Effective Dates:** See Implementation Plan for CIP-004-7~~6~~.

B. Requirements and Measures

R1. Each Responsible Entity shall implement one or more documented processes that collectively include each of the applicable requirement parts in *CIP-004-7~~6~~ Table R1 – Security Awareness Program*.

M1. Evidence must include each of the applicable documented processes that collectively include each of the applicable requirement parts in *CIP-004-7~~6~~ Table R1 – Security Awareness Program* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-004-7~~6~~ Table R1 – Security Awareness Program

Part	Applicable Systems	Requirements	Measures
1.1	High Impact BES Cyber Systems Medium Impact BES Cyber Systems	Security awareness that, at least once each calendar quarter, reinforces cyber security practices (which may include associated physical security practices) for the Responsible Entity's personnel who have authorized electronic or authorized unescorted physical access to BES Cyber Systems.	An example of evidence may include, but is not limited to, documentation that the quarterly reinforcement has been provided. Examples of evidence of reinforcement may include, but are not limited to, dated copies of information used to reinforce security awareness, as well as evidence of distribution, such as: • direct communications (for example, e-mails, memos, computer-based training); or • indirect communications (for example, posters, intranet, or brochures); or • management support and reinforcement (for example, presentations or meetings).

R2. Each Responsible Entity shall implement one or more cyber security training program(s) appropriate to individual roles, functions, or responsibilities that collectively includes each of the applicable requirement parts in *CIP-004-7~~6~~ Table R2 – Cyber Security Training Program*.

M2. Evidence must include the training program that includes each of the applicable requirement parts in *CIP-004-7~~6~~ Table R2 – Cyber Security Training Program* and additional evidence to demonstrate implementation of the program(s).

CIP-004-7~~6~~ Table R2 – Cyber Security Training Program

Part	Applicable Systems	Requirements	Measures
2.1	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; and 2. PACS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; and 2. PACS	Training content on: 2.1.1. Cyber security policies; 2.1.2. Physical access controls; 2.1.3. Electronic access controls; 2.1.4. The visitor control program; 2.1.5. Handling of BES Cyber System Information and its storage; 2.1.6. Identification of a Cyber Security Incident and initial notifications in accordance with the entity's incident response plan; 2.1.7. Recovery plans for BES Cyber Systems; 2.1.8. Response to Cyber Security Incidents; and 2.1.9. Cyber security risks associated with a BES Cyber System's electronic interconnectivity and interoperability with other Cyber Assets, including Transient Cyber Assets, and with Removable Media.	Examples of evidence may include, but are not limited to, training material such as power point presentations, instructor notes, student notes, handouts, or other training materials.

CIP-004-7~~6~~ Table R2 – Cyber Security Training Program

Part	Applicable Systems	Requirements	Measures
2.2	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; and 2. PACS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; and 2. PACS	Require completion of the training specified in Part 2.1 prior to granting authorized electronic access and authorized unescorted physical access ~~to applicable Cyber Assets~~, except during CIP Exceptional Circumstances.	Examples of evidence may include, but are not limited to, training records and documentation of when CIP Exceptional Circumstances were invoked.
2.3	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; and 2. PACS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; and 2. PACS	Require completion of the training specified in Part 2.1 at least once every 15 calendar months.	Examples of evidence may include, but are not limited to, dated individual training records.

R3. Each Responsible Entity shall implement one or more documented personnel risk assessment program(s) to attain and retain authorized electronic or authorized unescorted physical access to BES Cyber Systems that collectively include each of the applicable requirement parts in *CIP-004-7~~6~~ Table R3 – Personnel Risk Assessment Program*.

M3. Evidence must include the documented personnel risk assessment programs that collectively include each of the applicable requirement parts in *CIP-004-7~~6~~ Table R3 – Personnel Risk Assessment Program* and additional evidence to demonstrate implementation of the program(s).

CIP-004-7~~6~~ Table R3 – Personnel Risk Assessment Program

Part	Applicable Systems	Requirements	Measures
3.1	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; ~~and~~ 2. PACS; and ~~2.~~3. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S;~~ and~~ 2. PACS; and ~~2.~~3. PCS	Process to confirm identity.	An example of evidence may include, but is not limited to, documentation of the Responsible Entity's process to confirm identity.

CIP-004-7~~6~~ Table R3 – Personnel Risk Assessment Program

Part	Applicable Systems	Requirements	Measures
3.2	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; ~~and~~ 2. PACS; and ~~2.~~3. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; ~~and~~ 2. PACS; and ~~2.~~3. PCS	Process to perform a seven year criminal history records check as part of each personnel risk assessment that includes: 3.2.1. current residence, regardless of duration; and 3.2.2. other locations where, during the seven years immediately prior to the date of the criminal history records check, the subject has resided for six consecutive months or more. If it is not possible to perform a full seven year criminal history records check, conduct as much of the seven year criminal history records check as possible and document the reason the full seven year criminal history records check could not be performed.	An example of evidence may include, but is not limited to, documentation of the Responsible Entity's process to perform a seven year criminal history records check.

CIP-004-7~~6~~ Table R3 – Personnel Risk Assessment Program

Part	Applicable Systems	Requirements	Measures
3.3	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; ~~and~~ 2. PACS; and ~~2.~~3. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; ~~and~~ 2. PACS; and ~~2.~~3. PCS	Criteria or process to evaluate criminal history records checks for authorizing access.	An example of evidence may include, but is not limited to, documentation of the Responsible Entity's process to evaluate criminal history records checks.
3.4	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; ~~and~~ 2. PACS; and ~~2.~~3. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; ~~and~~ 2. PACS; and ~~2.~~3. PCS	Criteria or process for verifying that personnel risk assessments performed for contractors or service vendors are conducted according to Parts 3.1 through 3.3.	An example of evidence may include, but is not limited to, documentation of the Responsible Entity's criteria or process for verifying contractors or service vendors personnel risk assessments.

CIP-004-7~~6~~ Table R3 – Personnel Risk Assessment Program

Part	Applicable Systems	Requirements	Measures
3.5	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; ~~and~~ 2. PACS; and ~~2.~~3. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; ~~and~~ 2. PACS; and ~~2.~~3. PCS	Process to ensure that individuals with authorized electronic or authorized unescorted physical access have had a personnel risk assessment completed, except during CIP Exceptional Circumstances, according to Parts 3.1 to 3.4 within the last seven years.	An example of evidence may include, but is not limited to, documentation of the Responsible Entity's process for ensuring that individuals with authorized electronic or authorized unescorted physical access have had a personnel risk assessment completed within the last seven years.

R4. Each Responsible Entity shall implement one or more documented access management program(s) that collectively include each of the applicable requirement parts in *CIP-004-7~~6~~ Table R4 – Access Management Program.*

M4. Evidence must include the documented processes that collectively include each of the applicable requirement parts in *CIP-004-7~~6~~ Table R4 – Access Management Program* and additional evidence to demonstrate that the access management program was implemented as described in the Measures column of the table.

CIP-004-7~~6~~ Table R4 – Access Management Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
4.1	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; ~~and~~ ~~1.~~2. EAMS; 3. PACS; 4. PAMS; and ~~2.~~5. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; ~~and~~ ~~1.~~2. EAMS; 3. PACS; 4. PAMS; and ~~2.~~5. PCS	Process to authorize based on need, as determined by the Responsible Entity, except for CIP Exceptional Circumstances: 4.1.1. Electronic access; 4.1.2. Unescorted physical access into a Physical Security Perimeter; and 4.1.3. Access to designated storage locations (including EAMS and PAMS)~~,~~ whether physical or electronic, for BES Cyber System Information.	An example of evidence may include, but is not limited to, dated documentation of the process to authorize electronic access, unescorted physical access in a Physical Security Perimeter, and access to designated storage locations, whether physical or electronic, for BES Cyber System Information.

CIP-004-7~~6~~ Table R4 – Access Management Program

Part	Applicable Systems	Requirements	Measures
4.2	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; ~~and~~ ~~1.~~2. EAMS; 3. PACS; 4. PAMS; and ~~2.~~5. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; ~~and~~ ~~1.~~2. EAMS; 3. PACS; 4. PAMS; and ~~2.~~5. PCS	Verify at least once each calendar quarter that individuals with active electronic access or unescorted physical access have authorization records.	Examples of evidence may include, but are not limited to: • Dated documentation of the verification between the system generated list of individuals who have been authorized for access (i.e., workflow database) and a system generated list of personnel who have access (i.e., user account listing), or • Dated documentation of the verification between a list of individuals who have been authorized for access (i.e., authorization forms) and a list of individuals provisioned for access (i.e., provisioning forms or shared account listing).

CIP-004-7~~6~~ Table R4 – Access Management Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
4.3	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; ~~1.~~2. EAMS; ~~and~~ 3. PACS; and ~~2.~~4. PAMS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; ~~1.~~2. EAMS; ~~and~~ 3. PACS; and ~~2.~~4. PAMS	For electronic access, verify at least once every 15 calendar months that all user accounts, user account groups, or user role categories, and their specific, associated privileges are correct and are those that the Responsible Entity determines are necessary.	An example of evidence may include, but is not limited to, documentation of the review that includes all of the following: 1. A dated listing of all accounts/account groups or roles within the system; 2. A summary description of privileges associated with each group or role; 3. Accounts assigned to the group or role; and 4. Dated evidence showing verification of the privileges for the group are authorized and appropriate to the work function performed by people assigned to each account.

CIP-004-7~~6~~ Table R4 – Access Management Program

Part	Applicable Systems	Requirements	Measures
4.4	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; ~~1.~~2. EAMS; and 3. PACS; and ~~2.~~4. PAMS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; ~~1.~~2. EAMS; and 3. PACS; and ~~2.~~4. PAMS	Verify at least once every 15 calendar months that access to the designated storage locations for BES Cyber System Information, whether physical or electronic, including EAMS and PAMS are correct and are those that the Responsible Entity determines are necessary for performing assigned work functions.	An example of evidence may include, but is not limited to, the documentation of the review that includes all of the following: 1. A dated listing of authorizations for BES Cyber System information; 2. Any privileges associated with the authorizations; and 3. Dated evidence showing a verification of the authorizations and any privileges were confirmed correct and the minimum necessary for performing assigned work functions.

R5. Each Responsible Entity shall implement one or more documented access revocation program(s) that collectively include each of the applicable requirement parts in *CIP-004-7~~6~~ Table R5 – Access Revocation*.

M5. Evidence must include each of the applicable documented programs that collectively include each of the applicable requirement parts in *CIP-004-7~~6~~ Table R5 – Access Revocation* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-004-7~~6~~ Table R5 – Access Revocation			
Part	**Applicable Systems**	**Requirements**	**Measures**
5.1	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; ~~and~~ ~~1.~~2. EAMS; 3. PACS; 4. PAMS; and ~~2.~~5. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; ~~and~~ ~~1.~~2. EAMS; 3. PACS; 4. PAMS; and ~~2.~~5. PCS	A process to initiate removal of an individual's ability for unescorted physical access and Interactive Remote Access upon a termination action, and complete the removals within 24 hours of the termination action (Removal of the ability for access may be different than deletion, disabling, revocation, or removal of all access rights).	An example of evidence may include, but is not limited to, documentation of all of the following: 1. Dated workflow or sign-off form verifying access removal associated with the termination action; and 2. Logs or other demonstration showing such persons no longer have access.

CIP-004-7~~6~~ Table R5 – Access Revocation

Part	Applicable Systems	Requirements	Measures
5.2	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; ~~and~~ ~~1.~~2. EAMS; 3. PACS; 4. PAMS; and ~~2.~~5. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACMS; ~~and~~ ~~1.~~2. EAMS; 3. PACS; 4. PAMS; and ~~2.~~5. PCS	For reassignments or transfers, revoke the individual's authorized electronic access to individual accounts and authorized unescorted physical access that the Responsible Entity determines are not necessary by the end of the next calendar day following the date that the Responsible Entity determines that the individual no longer requires retention of that access.	An example of evidence may include, but is not limited to, documentation of all of the following: 1. Dated workflow or sign-off form showing a review of logical and physical access; and 2. Logs or other demonstration showing such persons no longer have access that the Responsible Entity determines is not necessary.

CIP-004-7~~6~~ Table R5 – Access Revocation

Part	Applicable Systems	Requirements	Measures
5.3	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; ~~1.~~2. EAMS; ~~and~~ 3. PACS; and ~~2.~~4. PAMS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; ~~1.~~2. EAMS; and 3. PACS; and ~~2.~~4. PAMS	For termination actions, revoke the individual's access to the designated storage locations for BES Cyber System Information, whether physical or electronic (unless already revoked according to Requirement R5.1), including EAMS and PAMS by the end of the next calendar day following the effective date of the termination action.	An example of evidence may include, but is not limited to, workflow or sign-off form verifying access removal to designated physical areas or cyber systems containing BES Cyber System Information associated with the terminations and dated within the next calendar day of the termination action.
5.4	High Impact BES Cyber Systems and their associated~~:~~ EAC~~M~~S.	For termination actions, revoke the individual's non-shared user accounts (unless already revoked according to Parts 5.1 or 5.3) within 30 calendar days of the effective date of the termination action.	An example of evidence may include, but is not limited to, workflow or sign-off form showing access removal for any individual BES Cyber ~~Assets~~ Systems and software applications as determined necessary to completing the revocation of access and dated within thirty calendar days of the termination actions.

CIP-004-7~~6~~ Table R5 – Access Revocation			
Part	**Applicable Systems**	**Requirements**	**Measures**
5.5	High Impact BES Cyber Systems and their associated ~~:~~ EAC~~M~~S.	For termination actions, change passwords for shared account(s) known to the user within 30 calendar days of the termination action. For reassignments or transfers, change passwords for shared account(s) known to the user within 30 calendar days following the date that the Responsible Entity determines that the individual no longer requires retention of that access. If the Responsible Entity determines and documents that extenuating operating circumstances require a longer time period, change the password(s) within 10 calendar days following the end of the operating circumstances.	Examples of evidence may include, but are not limited to: • Workflow or sign-off form showing password reset within 30 calendar days of the termination; • Workflow or sign-off form showing password reset within 30 calendar days of the reassignments or transfers; or • Documentation of the extenuating operating circumstance and workflow or sign-off form showing password reset within 10 calendar days following the end of the operating circumstance.

C. Compliance

1. **Compliance Monitoring Process:**

   1.1. **Compliance Enforcement Authority:** As defined in the NERC Rules of Procedure, "Compliance Enforcement Authority" (CEA) means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

   1.2. **Evidence Retention:** The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the CEA may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

   The Responsible Entity shall keep data or evidence to show compliance as identified below unless directed by its CEA to retain specific evidence for a longer period of time as part of an investigation:

   - Each Responsible Entity shall retain evidence of each requirement in this standard for three calendar years.
   - If a Responsible Entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.
   - The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

   1.3. **Compliance Monitoring and Assessment Processes:**

   - Compliance Audits
   - Self-Certifications
   - Spot Checking
   - Compliance Violation Investigations
   - Self-Reporting
   - Complaints

   1.4. **Additional Compliance Information:**
   None.

Version History

Version	Date	Action	Change Tracking
1	1/16/06	R3.2 — Change “Control Center” to “control center.”	3/24/06
2	9/30/09	Modifications to clarify the requirements and to bring the compliance elements into conformance with the latest guidelines for developing compliance elements of standards. Removal of reasonable business judgment. Replaced the RRO with the RE as a responsible entity. Rewording of Effective Date. Changed compliance monitor to Compliance Enforcement Authority.	
3	12/16/09	Updated Version Number from -2 to -3 In Requirement 1.6, deleted the sentence pertaining to removing component or system from service in order to perform testing, in response to FERC order issued September 30, 2009.	
3	12/16/09	Approved by the NERC Board of Trustees.	
3	3/31/10	Approved by FERC.	
4	1/24/11	Approved by the NERC Board of Trustees.	

Version	Date	Action	Change Tracking
5	11/26/12	Adopted by the NERC Board of Trustees.	Modified to coordinate with other CIP standards and to revise format to use RBS Template.
5	11/22/13	FERC Order issued approving CIP-004-5.	
5.1	9/30/13	Modified two VSLs in R4	Errata
6	11/13/14	Adopted by the NERC Board of Trustees.	Addressed two FERC directives from Order No. 791 related to identify, assess, and correct language and communication networks.
6	2/12/15	Adopted by the NERC Board of Trustees.	Replaces the version adopted by the Board on 11/13/2014. Revised version addresses remaining directives from Order No. 791 related to transient devices and low impact BES Cyber Systems.
6	1/21/16	FERC order issued approving CIP-004-6. Docket No. RM15-14-000	

The Background, VRF/VSLs, and Guidelines and Technical Basis Sections have been removed for this informal posting. The Project 2016-02 is seeking comments around the concept of the Requirement/Measure language at this time. All other sections will be modified prior to the initial posting.

A. Introduction

1. **Title:** Cyber Security —BES Cyber System Logical Isolation

2. **Number:** CIP-005-7

3. **Purpose:** To protect BES Cyber Systems against compromise by allowing only known and controlled communication to and from the system and logically isolating all other communication.

4. **Applicability:**

   4.1. Functional Entities: For the requirements in this standard, the following list of functional entities will be collectively referred to as "Responsible Entities." For requirements in this standard where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are explicitly specified.

      4.1.1. Balancing Authority

      4.1.2. Distribution Provider that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:

         4.1.2.1. Each underfrequency Load shedding (UFLS) or undervoltage Load shedding (UVLS) system that:

            4.1.2.1.1. is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

            4.1.2.1.2. performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

         4.1.2.2. Each Remedial Action Scheme (RAS) where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.1.3. Generator Operator

4.1.4. Generator Owner

4.1.5. Reliability Coordinator

4.1.6. Transmission Operator

4.1.7. Transmission Owner

4.2. Facilities: For the requirements in this standard, the following Facilities, systems, and equipment owned by each Responsible Entity in Section 4.1 above are those to which these requirements are applicable. For requirements in this standard where a specific type of Facilities, system, or equipment or subset of Facilities, systems, and equipment are applicable, these are explicitly specified.

4.2.1. Distribution Provider: One or more of the following Facilities, systems and equipment owned by the Distribution Provider for the protection or restoration of the BES:

4.2.1.1 Each UFLS or UVLS System that:

4.2.1.1.1 is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.2.1.1.2 performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.2.1.2 Each RAS where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.3 Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.4 Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.2.2. Responsible Entities listed in 4.1 other than Distribution Providers:

All BES Facilities.

4.2.3. Exemptions: The following are exempt from Standard CIP-005-7:

4.2.3.1. Cyber Assets at Facilities regulated by the Canadian Nuclear Safety Commission.

4.2.3.2. Cyber Assets associated with communication networks and data communication links between BES Cyber Systems' Logical Isolation Zones.

4.2.3.3. Cyber Assets associated with communication networks and data communication links used to extend a Logical Isolation Zone to more than one geographic location.

4.2.3.4. The systems, structures, and components that are regulated by the Nuclear Regulatory Commission under a cyber security plan pursuant to 10 C.F.R. Section 73.54.

4.2.3.5. For Distribution Providers, the systems and equipment that are not included in section 4.2.1 above.

4.2.3.6. Responsible Entities that identify that they have no BES Cyber Systems categorized as high impact or medium impact according to the CIP-002-5 identification and categorization processes.

5. Effective Date:

See Implementation Plan for CIP-005-7.

B. Requirements and Measures

R1. Each Responsible Entity shall implement one or more documented processes to mitigate the risk posed by unauthorized communications to and from applicable systems that collectively include each of the applicable requirement parts in *CIP-005-7 Table R1 – Logical Isolation Zones.* These processes exclude consideration of time-sensitive protection or control functions between intelligent electronic devices (e.g., communications using protocol IEC TR-61850-90-5 R-GOOSE).

M1. Evidence must include each of the applicable documented processes that collectively include each of the applicable requirement parts in *CIP-005-7 Table R1 – Logical Isolation Zones* and additional Evidence to demonstrate implementation as described in the Measures column of the table.

CIP-005-6 Table R1 – Logical Isolation Zones			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.1	High Impact BES Cyber Systems Medium Impact BES Cyber Systems	Have one or more methods to logically isolate applicable systems, either individually or as a group, by only allowing: 1.1.1. Communication that has documented inbound and outbound access permissions, including the reason for granting access; and 1.2.1. Serial port connectivity such as RS-232 and RS-485. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	Evidence may include, but is not limited to, configuration of systems that enforce logical isolation such as network infrastructure configuration (ACL, VLAN, VXLAN, MPLS), compute configuration (e.g., Hypervisor, containers), storage system configuration (e.g., SAN, NAS, DAS).

CIP-005-6 Table R1 – Logical Isolation Zones			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.2	High Impact BES Cyber Systems and their associated PCS Medium Impact BES Cyber Systems and their associated PCS	Protect the data traversing communication networks used to provide connectivity between components of a Logically Isolated Zone that spans multiple geographic locations to preserve confidentiality and integrity.	Evidence may include, but is not limited to, architecture documents detailing the methods used to mitigate the risk of unauthorized disclosure. Examples include physical protection and the points where encryption initiates and terminates.
1.3	High Impact BES Cyber Systems with Dial-up Connectivity and their associated PCS Medium Impact BES Cyber Systems with Dial-up Connectivity and their associated PCS	Perform authentication when establishing Dial-up Connectivity with applicable Cyber Assets per system capability.	An example of evidence may include, but is not limited to, a documented process that describes how the Responsible Entity is providing authenticated access through each dial-up connection.
1.4	High Impact BES Cyber Systems and their associated PCS Medium Impact BES Cyber Systems at Control Centers and their associated PCS	Have one or more methods for detecting known or suspected malicious inbound and outbound communications to and from applicable systems either individually or as grouped in Part 1.1, excluding serial port connectivity such as RS-232 and RS-485.	Evidence may include, but is not limited to, documentation that malicious communications detection methods (e.g. intrusion detection system, application layer firewall, privileged introspection, etc.) are implemented.

R2. Each Responsible Entity shall implement one or more documented processes to mitigate the risk posed by exploitation of Interactive Remote Access that collectively include the applicable requirement parts, per system capability, in *CIP-005-6 Table R2 –Remote Access Management*.

M2. Evidence must include the documented processes that collectively address each of the applicable requirement parts in *CIP-005-6 Table R2 – Remote Access Management* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-005-7 Table R2 Remote Access Management			
Part	**Applicable Systems**	**Requirements**	**Measures**
2.1	High Impact BES Cyber Systems and their associated PCS Medium Impact BES Cyber Systems and their associated PCS	Have one or more methods to ensure that Interactive Remote Access to applicable systems is through an Intermediate System that is isolated from the BES Cyber System and restricts Interactive Remote Access to only authorized users.	Evidence may include, but is not limited to, network diagrams or architecture documents.
2.2	High Impact BES Cyber Systems and their associated PCS Medium Impact BES Cyber Systems and their associated PCS	Have one or more methods to mitigate the risks posed by unauthorized modification and unauthorized disclosure of data during all Interactive Remote Access sessions that terminate at an Intermediate System.	Evidence may include, but is not limited to, architecture documents detailing the methods used to mitigate the risk of unauthorized disclosure. Examples include illustrating where encryption initiates and terminates.

CIP-005-7 Table R2 Remote Access Management			
Part	**Applicable Systems**	**Requirements**	**Measures**
2.3	High Impact BES Cyber Systems and their associate PCS Medium Impact BES Cyber Systems and their associated PCS	Have one or more methods to require multi-factor authentication for all Interactive Remote Access sessions.	Evidence may include, but is not limited to, documents detailing the authentication factors used.

CIP-005-7 Table R2 Remote Access Management			
Part	**Applicable Systems**	**Requirements**	**Measures**
2.4	High Impact BES Cyber Systems and their associated PCS Medium Impact BES Cyber Systems and their associated PCS	Have one or more methods for determining active vendor remote access sessions (including Interactive Remote Access and system-to-system remote access).	Evidence may include, but is not limited to documented methods such as: • Methods for accessing logged information or monitoring to determine active vendor remote access sessions; • Methods for monitoring activity (e.g. connection tables or rule hit counters in a firewall, or user activity monitoring) or open ports (e.g. netstat or related commands to display currently active ports) to determine active system to system remote access sessions; or • Methods that control vendor initiation of remote access such as requiring vendors to call and request a second factor to initiate remote access.

CIP-005-7 Table R2 Remote Access Management			
Part	**Applicable Systems**	**Requirements**	**Measures**
2.5	High Impact BES Cyber Systems and their associated PCS Medium Impact BES Cyber Systems and their associated PCS	Have one or more method(s) to disable active vendor remote access (including Interactive Remote Access and system-to-system remote access).	Evidence may include, but is not limited to, documented methods, such as: • Methods to disable vendor remote access for system-to-system remote access; or • Methods to disable vendor Interactive Remote Access at the applicable Intermediate System.

R3. Each Responsible Entity shall implement one or more documented processes to mitigate the risk posed by unrestricted access for communication between the management plane [1] and the data plane[2] that collectively include the applicable requirement parts, in *CIP-005-6 Table R3* – Isolation of Management Plane and Data Plane.

M3. Evidence must include the documented processes that collectively address each of the applicable requirement parts in *CIP-005-6 Table R3* – Isolation of Management Plane and Data Plane and additional evidence to demonstrate implementation as described in the Measures column of the table.

---

[1] Management plane of a system is that element that configures, monitors, and provides management, monitoring and configuration services to, all layers of the network stack and other parts of the system.

[2] Data plane (sometimes known as the user plane, forwarding plane, carrier plane or bearer plane) is the part of a network that carries user traffic.

CIP-005-6 Table R3 – Isolation of Management Plane and Data Plane			
Part	**Applicable Systems**	**Requirements**	**Measures**
3.1	High Impact BES Cyber Systems and their associated: 1. EACS 2. PCS Medium Impact BES Cyber Systems and their associated PCS: 1. EACS 2. PCS	Have one or more methods per system capability to: 1. Restrict access to the management plane; and 2. Logically isolate the management plane from the data plane.	An example of evidence may include but is not limited to documentation that includes the following: Configuration of systems that enforce authentication and logical isolation such as network infrastructure configuration (ACL, VLAN, VXLAN, MPLS), compute configuration (e.g. Hypervisor, containers), storage system configuration (e.g. SAN, NAS, DAS).

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- Each applicable entity shall retain evidence of each requirement in this standard for three calendar years.
- If an applicable entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.
- The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

3	12/16/09	Updated version number from -2 to -3 Approved by the NERC Board of Trustees.	
3	3/31/10	Approved by FERC.	
4	12/30/10	Modified to add specific criteria for Critical Asset identification.	Update
4	1/24/11	Approved by the NERC Board of Trustees.	Update
5	11/26/12	Adopted by the NERC Board of Trustees.	Modified to coordinate with other CIP standards and to revise format to use RBS Template.
5	11/22/13	FERC Order issued approving CIP-005-5.	
6	07/20/17	Modified to address certain directives in FERC Order No. 829.	Revised
6	08/10/17	Adopted by the NERC Board of Trustees.	

The Background, VRF/VSLs, and Guidelines and Technical Basis Sections have been removed for this informal posting. The Project 2016-02 is seeking comments around the concept of the Requirement/Measure language at this time. All other sections will be modified prior to the initial posting.

A. Introduction

1. **Title:** Cyber Security —~~-~~BES Cyber System Logical Isolation~~Electronic Security Perimeter(s)~~

2. **Number:** CIP-005-7~~6~~

3. **Purpose:** To protect BES Cyber Systems against compromise by allowing only known and controlled communication to and from the system and logically isolating all other communication.~~manage electronic access to BES Cyber Systems by specifying a controlled Electronic Security Perimeter in support of protecting BES Cyber Systems against compromise that could lead to misoperation or instability in the BES.~~

4. **Applicability:**

   4.1. Functional Entities: For the ~~purpose of the~~ requirements in this standard~~contained herein~~, the following list of functional entities will be collectively referred to as "Responsible Entities." For requirements in this standard where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are explicitly specified.~~ explicitly.~~

   4.1.1. Balancing Authority

   4.1.2. Distribution Provider that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:

   4.1.2.1. Each underfrequency Load shedding (UFLS) or undervoltage Load shedding (UVLS) system that:

   4.1.2.1.1. is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

   4.1.2.1.2. performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.1.2.2. Each Remedial Action Scheme (RAS) where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.1.3. Generator Operator

4.1.4. Generator Owner

~~**4.1.5. Interchange Coordinator or Interchange Authority**~~

~~**4.1.6.**~~**4.1.5. Reliability Coordinator**

~~**4.1.7.**~~**4.1.6. Transmission Operator**

~~**4.1.8.**~~**4.1.7. Transmission Owner**

4.2. Facilities: For the ~~purpose of the~~ requirements in this standard~~contained herein~~, the following Facilities, systems, and equipment owned by each Responsible Entity in Section 4.1 above are those to which these requirements are applicable. For requirements in this standard where a specific type of Facilities, system, or equipment or subset of Facilities, systems, and equipment are applicable, these are explicitly specified.~~ explicitly.~~

4.2.1. Distribution Provider: One or more of the following Facilities, systems and equipment owned by the Distribution Provider for the protection or restoration of the BES:

4.2.1.1 Each UFLS or UVLS System that:

4.2.1.1.1 is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.2.1.1.2 performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.2.1.2 Each RAS where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.3 Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.4 Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.2.2. Responsible Entities listed in 4.1 other than Distribution Providers:

All BES Facilities.

4.2.3. Exemptions: The following are exempt from Standard CIP-005-7~~6~~:

4.2.3.1. Cyber Assets at Facilities regulated by the Canadian Nuclear Safety Commission.

4.2.3.2. Cyber Assets associated with communication networks and data communication links between BES Cyber Systems' Logical Isolation Zones~~discrete Electronic Security Perimeters~~.

~~**4.2.3.2.**~~**4.2.3.3.** Cyber Assets associated with communication networks and data communication links used to extend a Logical Isolation Zone to more than one geographic location.

~~**4.2.3.3.**~~**4.2.3.4.** The systems, structures, and components that are regulated by the Nuclear Regulatory Commission under a cyber security plan pursuant to 10 C.F.R. Section 73.54.

~~**4.2.3.4.**~~**4.2.3.5.** For Distribution Providers, the systems and equipment that are not included in section 4.2.1 above.

~~**4.2.3.5.**~~**4.2.3.6.** Responsible Entities that identify that they have no BES Cyber Systems categorized as high impact or medium impact according to the CIP-002-5 identification and categorization processes.

5. Effective Date:

See Implementation Plan for ~~Project 2016-03~~CIP-005-7.

B. Requirements and Measures

R1. Each Responsible Entity shall implement one or more documented processes to mitigate the risk posed by unauthorized communications to and from applicable systems ~~-~~that collectively include each of the applicable requirement parts in *CIP-005-7~~6~~ Table R1 – Logical Isolation Zones.* These processes exclude consideration of time-sensitive protection or control functions between intelligent electronic devices (e.g., communications using protocol IEC TR-61850-90-5 R-GOOSE) ~~*Electronic Security Perimeter*~~.

M1. Evidence must include each of the applicable documented processes that collectively include each of the applicable requirement parts in *CIP-005-7~~6~~ Table R1 – Logical Isolation Zones* ~~*-Electronic Security Perimeter*~~ and additional Evidence to demonstrate implementation as described in the Measures column of the table.

CIP-005-6 Table R1 – ~~Electronic Security Perimeter~~Logical Isolation Zones

Part	Applicable Systems	Requirements	Measures
1.1~~3~~	~~Electronic Access Points for~~ High Impact BES Cyber Systems ~~Electronic Access Points for~~ Medium Impact BES Cyber Systems	Have one or more methods to logically isolate applicable systems, either individually or as a group, by only allowing: 1.1.1. ~~Require~~Communication that has documented inbound and outbound access permissions, including the reason for granting access; and~~, and deny all other access by default.~~ 1.2.1. Serial port connectivity such as RS-232 and RS-485. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	Evidence may include, but is not limited to, configuration of systems that enforce logical isolation such as network infrastructure configuration (ACL, VLAN, VXLAN, MPLS), compute configuration (e.g., Hypervisor, containers), storage system configuration (e.g., SAN, NAS, DAS). ~~An example of evidence may include, but is not limited to, a list of rules (firewall, access control lists, etc.) that demonstrate that only permitted access is allowed and that each access rule has a documented reason.~~

CIP-005-6 Table R1 – ~~Electronic Security Perimeter~~Logical Isolation Zones			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.2	High Impact BES Cyber Systems and their associated PCS Medium Impact BES Cyber Systems and their associated PCS	Protect the data traversing communication networks used to provide connectivity between components of a Logically Isolated Zone that spans multiple geographic locations to preserve confidentiality and integrity.	Evidence may include, but is not limited to, architecture documents detailing the methods used to mitigate the risk of unauthorized disclosure. Examples include physical protection and the points where encryption initiates and terminates.
1.3~~4~~	High Impact BES Cyber Systems with Dial-up Connectivity and their associated PCS ~~A~~ Medium Impact BES Cyber Systems with Dial-up Connectivity and their associated PCS~~A~~	~~Where technically feasible, P~~perform authentication when establishing Dial-up Connectivity with applicable Cyber Assets~~.~~ per system capability.	An example of evidence may include, but is not limited to, a documented process that describes how the Responsible Entity is providing authenticated access through each dial-up connection.
1.4~~5~~	~~Electronic Access Points for~~ High Impact BES Cyber Systems and their associated PCS ~~Electronic Access Points for~~ Medium Impact BES Cyber Systems at Control Centers and their associated PCS	Have one or more methods for detecting known or suspected malicious inbound and outbound communications to and from applicable systems either individually or as grouped in Part 1.1, excluding serial port connectivity such as RS-232 and RS-485.	~~An example of e~~Evidence may include, but is not limited to, documentation that malicious communications detection methods (e.g. intrusion detection system, application layer firewall, privileged introspection, etc.) are implemented.

R2. Each Responsible Entity shall implement one or more documented processes to mitigate the risk posed by exploitation of Interactive Remote Access that collectively include the applicable requirement parts, ~~where technically feasible,~~per system capability, in *CIP-005-6 Table R2 –Remote Access Management*.

M2. Evidence must include the documented processes that collectively address each of the applicable requirement parts in *CIP-005-6 Table R2 – Remote Access Management* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-005-7~~6~~ Table R2 ~~– Remote Access Management~~ Remote Access Management			
Part	**Applicable Systems**	**Requirements**	**Measures**
2.1	High Impact BES Cyber Systems and their associated ~~:~~ PCS~~A~~ Medium Impact BES Cyber Systems ~~with External Routable Connectivity~~ and their associated ~~:~~ PCS~~A~~	Have one or more methods to ~~For all Interactive~~ ensure that Interactive Remote Access~~,~~ to applicable systems is through an Intermediate System that is isolated from the BES Cyber System and restricts Interactive Remote Access to only authorized users. ~~utilize an Intermediate System such that the Cyber Asset initiating Interactive Remote Access does not directly access an applicable Cyber Asset.~~	E~~xamples of e~~vidence may include, but ~~are~~ is not limited to, network diagrams or architecture documents.
2.2	High Impact BES Cyber Systems and their associated ~~:~~ PCS~~A~~ Medium Impact BES Cyber Systems ~~with External Routable Connectivity~~ and their associated~~:~~	Have one or more methods to mitigate the risks posed by unauthorized modification and unauthorized disclosure of data during ~~For~~ all Interactive Remote Access sessions~~,~~ that terminate at an Intermediate System ~~utilize~~	~~An example of e~~Evidence may include, but is not limited to, architecture documents detailing the methods used to mitigate the risk of unauthor~~e~~ized disclosure. Examples include illustrating where encryption initiates and terminates.

CIP-005-7~~6~~ Table R2 ~~– Remote Access Management~~ Remote Access Management			
Part	**Applicable Systems**	**Requirements**	**Measures**
	~~•~~ PCS~~A~~	~~encryption that terminates at an Intermediate System~~.	
2.3	High Impact BES Cyber Systems and their associate ~~d:~~ PCS ~~A~~ Medium Impact BES Cyber Systems ~~with External Routable Connectivity~~ and their associated PCS~~A~~	Have one or more methods to ~~R~~require multi-factor authentication for all Interactive Remote Access sessions.	~~An example of e~~Evidence may include, but is not limited to, ~~architecture~~ documents detailing the authentication factors used. ~~Examples of authenticators may include, but are not limited to,~~ ~~Something the individual knows such as passwords or PINs. This does not include User ID;~~ ~~Something the individual has such as tokens, digital certificates, or smart cards; or~~ ~~Something the individual is such as fingerprints, iris scans, or other biometric characteristics.~~

Formatted: Space Before: 0 pt, Add space between paragraphs of the same style, Line spacing: single, No bullets or numbering

R3. Each Responsible Entity shall implement one or more documented processes to mitigate the risk posed by unrestricted access for communication between the management plane[1] and the data plane[2] that collectively include the applicable requirement parts, in *CIP-005-6 Table R3* – Isolation of Management Plane and Data Plane.

---

[1] Management plane of a system is that element that configures, monitors, and provides management, monitoring and configuration services to, all layers of the network stack and other parts of the system.

[2] Data plane (sometimes known as the user plane, forwarding plane, carrier plane or bearer plane) is the part of a network that carries user traffic.

M3. Evidence must include the documented processes that collectively address each of the applicable requirement parts in *CIP-005-6 Table R3* – Isolation of Management Plane and Data Plane and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-005-6 Table R3 – Isolation of Management Plane and Data Plane			
Part	**Applicable Systems**	**Requirements**	**Measures**
3.1	High Impact BES Cyber Systems and their associated: 1. EACS 2. PCS Medium Impact BES Cyber Systems and their associated PCS: 1. EACS 2. PCS	Have one or more methods per system capability to: 1. Restrict access to the management plane; and 2. Logically isolate the management plane from the data plane.	An example of evidence may include but is not limited to documentation that includes the following: Configuration of systems that enforce authentication and logical isolation such as network infrastructure configuration (ACL, VLAN, VXLAN, MPLS), compute configuration (e.g. Hypervisor, containers), storage system configuration (e.g. SAN, NAS, DAS).

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: “Compliance Enforcement Authority” means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- Each applicable entity shall retain evidence of each requirement in this standard for three calendar years.
- If an applicable entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.
- The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, “Compliance Monitoring and Enforcement Program” refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

D. Regional Variances

None.

E. Associated Documents

None.

Version History

Version	Date	Action	Change Tracking
1	1/16/06	R3.2 — Change “Control Center” to “control center.”	3/24/06
2	9/30/09	Modifications to clarify the requirements and to bring the compliance elements into conformance with the latest guidelines for developing compliance elements of standards. Removal of reasonable business judgment. Replaced the RRO with the RE as a responsible entity. Rewording of Effective Date. Changed compliance monitor to Compliance Enforcement Authority.	
3	12/16/09	Updated version number from -2 to -3 Approved by the NERC Board of Trustees.	
3	3/31/10	Approved by FERC.	
4	12/30/10	Modified to add specific criteria for Critical Asset identification.	Update
4	1/24/11	Approved by the NERC Board of Trustees.	Update
5	11/26/12	Adopted by the NERC Board of Trustees.	Modified to coordinate with other CIP standards and to revise format to use RBS Template.
5	11/22/13	FERC Order issued approving CIP-005-5.	
6	07/20/17	Modified to address certain directives in FERC Order No. 829.	Revised
6	08/10/17	Adopted by the NERC Board of Trustees.	

The Background, VRF/VSLs, and Guidelines and Technical Basis Sections have been removed for this informal posting. The Project 2016-02 is seeking comments around the concept of the Requirement/Measure language at this time. All other sections will be modified prior to the initial posting.

A. Introduction

1. **Title:** Cyber Security — Physical Security of BES Cyber Systems

2. **Number:** CIP-006-7

3. **Purpose:** To manage physical access to Bulk Electric System (BES) Cyber Systems by specifying a physical security plan in support of protecting BES Cyber Systems against compromise that could lead to misoperation or instability in the BES.

4. **Applicability:**

4.1. Functional Entities: For the requirements in this standard, the following list of functional entities will be collectively referred to as "Responsible Entities." For requirements where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are explicitly specified.

4.1.1 Balancing Authority

4.1.2 Distribution Provider that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:

4.1.2.1 Each underfrequency Load shedding (UFLS) or undervoltage Load shedding (UVLS) system that:

4.1.2.1.1 is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.1.2.1.2 performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.1.2.2 Each Remedial Action Scheme (RAS) where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.3 Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.4 Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.1.3 Generator Operator

4.1.4 Generator Owner

4.1.5 Reliability Coordinator

4.1.6 Transmission Operator

4.1.7 Transmission Owner

4.2. **Facilities:** For the requirements in this standard, the following Facilities, systems, and equipment owned by each Responsible Entity in 4.1 above are those to which these requirements are applicable. For requirements where a specific type of Facilities, system, or equipment or subset of Facilities, systems, and equipment are applicable, these are explicitly specified.

4.2.1 **Distribution Provider**: One or more of the following Facilities, systems and equipment owned by the Distribution Provider for the protection or restoration of the BES:

4.2.1.1 Each UFLS or UVLS System that:

4.2.1.1.1 is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.2.1.1.2 performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.2.1.2 Each RAS where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.3 Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.4 Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.2.2 **Responsible Entities listed in 4.1 other than Distribution Providers**:

All BES Facilities.

4.2.3 **Exemptions:** The following are exempt from Standard CIP-006-7:

4.2.3.1 Cyber Assets at Facilities regulated by the Canadian Nuclear Safety Commission.

4.2.3.2 Cyber Assets associated with communication networks and data communication links between BES Cyber Systems' Logical Isolation Zones. .

4.2.3.3 Cyber Assets associated with communication networks and data communication links used to extend a Logical Isolation Zone to more than one geographic location.

4.2.3.4 The systems, structures, and components that are regulated by the Nuclear Regulatory Commission under a cyber security plan pursuant to 10 C.F.R. Section 73.54.

4.2.3.5 For Distribution Providers, the systems and equipment that are not included in section 4.2.1 above.

4.2.3.6 Responsible Entities that identify that they have no BES Cyber Systems categorized as high impact or medium impact according to the CIP-002-5.1 identification and categorization processes.

5. Effective Dates:

See Implementation Plan for CIP-006-7.

B. Requirements and Measures

R1. Each Responsible Entity shall implement one or more documented physical security plan(s) that collectively include all of the applicable requirement parts in *CIP-006-7 Table R1 – Physical Security Plan*.

M1. Evidence must include each of the documented physical security plans that collectively include all of the applicable requirement parts in *CIP-006-7 Table R1 – Physical Security Plan* and additional evidence to demonstrate implementation of the plan or plans as described in the Measures column of the table.

CIP-006-7 Table R1 – Physical Security Plan			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.1	Medium Impact BES Cyber Systems without External Routable Connectivity Physical Access Control Systems (PACS) associated with: • High Impact BES Cyber Systems, or • Medium Impact BES Cyber Systems with External Routable Connectivity	Define operational or procedural controls to restrict physical access.	An example of evidence may include, but is not limited to, documentation that operational or procedural controls exist.

CIP-006-7 Table R1 – Physical Security Plan			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.2	Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; and 2. PCS	Use at least one physical access control to allow unescorted physical access into each applicable Physical Security Perimeter to only those individuals who have authorized unescorted physical access.	An example of evidence may include, but is not limited to, language in the physical security plan that describes each Physical Security Perimeter and how unescorted physical access is controlled by one or more different methods and proof that unescorted physical access is restricted to only authorized individuals, such as a list of authorized individuals accompanied by access logs.

CIP-006-7 Table R1 – Physical Security Plan			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.3	High Impact BES Cyber Systems and their associated: 1. EACS; and 2. PCS	Where technically feasible, use two or more different physical access controls (this does not require two completely independent physical access control systems) to collectively allow unescorted physical access into Physical Security Perimeters to only those individuals who have authorized unescorted physical access.	An example of evidence may include, but is not limited to, language in the physical security plan that describes the Physical Security Perimeters and how unescorted physical access is controlled by two or more different methods and proof that unescorted physical access is restricted to only authorized individuals, such as a list of authorized individuals accompanied by access logs.

CIP-006-7 Table R1– Physical Security Plan			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.4	High Impact BES Cyber Systems and their associated: 1. EACS; and 2. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; and 2. PCS	Monitor for unauthorized access through a physical access point into a Physical Security Perimeter.	An example of evidence may include, but is not limited to, documentation of controls that monitor for unauthorized access through a physical access point into a Physical Security Perimeter.

CIP-006-7 Table R1– Physical Security Plan			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.5	High Impact BES Cyber Systems and their associated: 1. EACS; and 2. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; and 2. PCS	Issue an alarm or alert in response to detected unauthorized access through a physical access point into a Physical Security Perimeter to the personnel identified in the BES Cyber Security Incident response plan within 15 minutes of detection.	An example of evidence may include, but is not limited to, language in the physical security plan that describes the issuance of an alarm or alert in response to unauthorized access through a physical access control into a Physical Security Perimeter and additional evidence that the alarm or alert was issued and communicated as identified in the BES Cyber Security Incident Response Plan, such as manual or electronic alarm or alert logs, cell phone or pager logs, or other evidence that documents that the alarm or alert was generated and communicated.
1.6	Physical Access Control Systems (PACS) associated with: • High Impact BES Cyber Systems, or • Medium Impact BES Cyber Systems with External Routable Connectivity	Monitor each Physical Access Control System for unauthorized physical access to a Physical Access Control System.	An example of evidence may include, but is not limited to, documentation of controls that monitor for unauthorized physical access to a PACS.

CIP-006-7 Table R1– Physical Security Plan			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.7	Physical Access Control Systems (PACS) associated with: - High Impact BES Cyber Systems, or - Medium Impact BES Cyber Systems with External Routable Connectivity	Issue an alarm or alert in response to detected unauthorized physical access to a Physical Access Control System to the personnel identified in the BES Cyber Security Incident response plan within 15 minutes of the detection.	An example of evidence may include, but is not limited to, language in the physical security plan that describes the issuance of an alarm or alert in response to unauthorized physical access to Physical Access Control Systems and additional evidence that the alarm or alerts was issued and communicated as identified in the BES Cyber Security Incident Response Plan, such as alarm or alert logs, cell phone or pager logs, or other evidence that the alarm or alert was generated and communicated.

CIP-006-7 Table R1 – Physical Security Plan			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.8	High Impact BES Cyber Systems and their associated: 1. EACS; and 2. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; and 2. PCS	Log (through automated means or by personnel who control entry) entry of each individual with authorized unescorted physical access into each Physical Security Perimeter, with information to identify the individual and date and time of entry, except during CIP Exceptional Circumstances.	An example of evidence may include, but is not limited to, language in the physical security plan that describes logging and recording of physical entry into each Physical Security Perimeter and additional evidence to demonstrate that this logging has been implemented, such as logs of physical access into Physical Security Perimeters that show the individual and the date and time of entry into Physical Security Perimeter.

CIP-006-7 Table R1 – Physical Security Plan			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.9	High Impact BES Cyber Systems and their associated: 1. EACS; and 2. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; and 2. PCS	Retain physical access logs of entry of individuals with authorized unescorted physical access into each Physical Security Perimeter for at least ninety calendar days, except during CIP Exceptional Circumstances.	An example of evidence may include, but is not limited to, dated documentation such as logs of physical access into Physical Security Perimeters that show the date and time of entry into Physical Security Perimeter.

CIP-006-7 Table R1 – Physical Security Plan			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.10	High Impact BES Cyber Systems and their associated PCS Medium Impact BES Cyber Systems at Control Centers and their associated PCS	Restrict physical access to cabling and other nonprogrammable communication components used for applicable systems in the same Logical Isolation Zone in those instances when such cabling and components are located outside of a Physical Security Perimeter. Where physical access restrictions to such cabling and components are not implemented, the Responsible Entity shall document and implement one or more of the following: • encryption of data that transits such cabling and components; or • monitoring the status of the communication link composed of such cabling and components and issuing an alarm or alert in response to detected communication failures to the personnel identified in the BES Cyber Security Incident response plan within 15 minutes of detection; or • an equally effective logical protection.	An example of evidence may include, but is not limited to, records of the Responsible Entity's implementation of the physical access restrictions (e.g., cabling and components secured through conduit or secured cable trays) encryption, monitoring, or equally effective logical protections.

R2. Each Responsible Entity shall implement, except during CIP Exceptional Circumstances, one or more documented visitor control program(s) that include each of the applicable requirement parts in *CIP-006-7 Table R2 – Visitor Control Program.*

M2. Evidence must include one or more documented visitor control programs that collectively include each of the applicable requirement parts in *CIP-006-7 Table R2 – Visitor Control Program* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-006-7 Table R2 – Visitor Control Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
2.1	High Impact BES Cyber Systems and their associated: 1. EACS; and 2. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; and 2. PCS	Require continuous escorted access of visitors (individuals who are provided access but are not authorized for unescorted physical access) within each Physical Security Perimeter.	An example of evidence may include, but is not limited to, language in a visitor control program that requires continuous escorted access of visitors within Physical Security Perimeters and additional evidence to demonstrate that the escorted access process was implemented, such as visitor logs.

CIP-006-7 Table R2 – Visitor Control Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
2.2	High Impact BES Cyber Systems and their associated: 1. EACS; and 2. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; and 2. PCS	Require manual or automated logging of visitor entry into and exit from the Physical Security Perimeter that includes date and time of the initial entry and last exit, the visitor's name, and the name of an individual point of contact responsible for the visitor.	An example of evidence may include, but is not limited to, language in a visitor control program that requires continuous escorted access of visitors within Physical Security Perimeters and additional evidence to demonstrate that the escorted access process was implemented, such as dated visitor logs that include the required information.
2.3	High Impact BES Cyber Systems and their associated: 1. EACS; and 2. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; and 2. PCS	Retain visitor logs for at least ninety calendar days.	An example of evidence may include, but is not limited to, documentation showing logs have been retained for at least ninety calendar days.

R3. Each Responsible Entity shall implement one or more documented Physical Access Control System maintenance and testing program(s) that collectively include each of the applicable requirement parts in *CIP-006-7 Table R3 – Maintenance and Testing Program*.

M3. Evidence must include each of the documented Physical Access Control System maintenance and testing programs that collectively include each of the applicable requirement parts in *CIP-006-7 Table R3 – Maintenance and Testing Program* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-006-7 Table R3 – Physical Access Control System Maintenance and Testing Program			
Part	**Applicable Systems**	**Requirement**	**Measures**
3.1	Physical Access Control Systems (PACS) associated with: • High Impact BES Cyber Systems, or • Medium Impact BES Cyber Systems with External Routable Connectivity Locally mounted hardware or devices at the Physical Security Perimeter associated with: • High Impact BES Cyber Systems, or • Medium Impact BES Cyber Systems with External Routable Connectivity	Maintenance and testing of each Physical Access Control System and locally mounted hardware or devices at the Physical Security Perimeter at least once every 24 calendar months to ensure they function properly.	An example of evidence may include, but is not limited to, a maintenance and testing program that provides for testing each Physical Access Control System and locally mounted hardware or devices associated with each applicable Physical Security Perimeter at least once every 24 calendar months, Also, additional evidence such as dated maintenance records or other documentation to demonstrate that testing and maintenance has been performed on each applicable device or system at least once every 24 calendar months.

C. Compliance

1. Compliance Monitoring Process:

1.1. Compliance Enforcement Authority:

As defined in the NERC Rules of Procedure, “Compliance Enforcement Authority” (CEA) means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

1.2. Evidence Retention:

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the CEA may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Responsible Entity shall keep data or evidence to show compliance as identified below unless directed by its CEA to retain specific evidence for a longer period of time as part of an investigation:

- Each Responsible Entity shall retain evidence of each requirement in this standard for three calendar years.
- If a Responsible Entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.
- The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Investigations

Self-Reporting

Complaints

1.4. Additional Compliance Information:

The Background, VRF/VSLs, and Guidelines and Technical Basis Sections have been removed for this informal posting. The Project 2016-02 is seeking comments around the concept of the Requirement/Measure language at this time. All other sections will be modified prior to the initial posting.

A. Introduction

1. **Title:** Cyber Security — Physical Security of BES Cyber Systems

2. **Number:** CIP-006-7~~6~~

3. **Purpose:** To manage physical access to Bulk Electric System (BES) Cyber Systems by specifying a physical security plan in support of protecting BES Cyber Systems against compromise that could lead to misoperation or instability in the BES.

4. **Applicability:**

4.1. Functional Entities: For the ~~purpose of the~~ requirements in this standard~~contained herein~~, the following list of functional entities will be collectively referred to as "Responsible Entities." For requirements~~ in this standard~~ where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are explicitly specified~~ explicitly~~.

4.1.1 Balancing Authority

4.1.2 Distribution Provider that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:

4.1.2.1 Each underfrequency Load shedding (UFLS) or undervoltage Load shedding (UVLS) system that:

4.1.2.1.1 is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.1.2.1.2 performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.1.2.2 Each ~~Special Protection System (SPS) or~~ Remedial Action Scheme (RAS) where the ~~SPS or~~ RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.3 Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.4 Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.1.3 Generator Operator

4.1.4 Generator Owner

~~**4.1.5 Interchange Coordinator or Interchange Authority**~~

~~4.1.6~~4.1.5 **Reliability Coordinator**

~~4.1.7~~4.1.6 **Transmission Operator**

~~4.1.8~~4.1.7 **Transmission Owner**

4.2. **Facilities:** For the ~~purpose of the~~ requirements in this standard~~contained herein~~, the following Facilities, systems, and equipment owned by each Responsible Entity in 4.1 above are those to which these requirements are applicable. For requirements ~~in this standard~~ where a specific type of Facilities, system, or equipment or subset of Facilities, systems, and equipment are applicable, these are explicitly specified~~ explicitly~~.

4.2.1 **Distribution Provider**: One or more of the following Facilities, systems and equipment owned by the Distribution Provider for the protection or restoration of the BES:

4.2.1.1 Each UFLS or UVLS System that:

4.2.1.1.1 is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.2.1.1.2 performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.2.1.2 Each ~~SPS or~~ RAS where the ~~SPS or~~ RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.3 Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.4 Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.2.2 **Responsible Entities listed in 4.1 other than Distribution Providers**:

All BES Facilities.

4.2.3 **Exemptions:** The following are exempt from Standard ~~CIP-006-6~~CIP-006-7:

4.2.3.1 Cyber Assets at Facilities regulated by the Canadian Nuclear Safety Commission.

4.2.3.2 Cyber Assets associated with communication networks and data communication links between~~-~~ BES Cyber Systems' Logical Isolation Zones. ~~discrete Electronic Security Perimeters~~.

4.2.3.3 Cyber Assets associated with communication networks and data communication links used to extend a Logical Isolation Zone to more than one geographic location.

~~**4.2.3.2**~~**4.2.3.4** The systems, structures, and components that are regulated by the Nuclear Regulatory Commission under a cyber security plan pursuant to 10 C.F.R. Section 73.54.

~~**4.2.3.3**~~**4.2.3.5** For Distribution Providers, the systems and equipment that are not included in section 4.2.1 above.

~~**4.2.3.4**~~**4.2.3.6** Responsible Entities that identify that they have no BES Cyber Systems categorized as high impact or medium impact according to the CIP-002-5.1 identification and categorization processes.

5. Effective Dates:

See Implementation Plan for CIP-006-7~~6~~.

B. Requirements and Measures

R1. Each Responsible Entity shall implement one or more documented physical security plan(s) that collectively include all of the applicable requirement parts in *CIP-006-7~~6~~ Table R1 – Physical Security Plan*.

M1. Evidence must include each of the documented physical security plans that collectively include all of the applicable requirement parts in *CIP-006-7~~6~~ Table R1 – Physical Security Plan* and additional evidence to demonstrate implementation of the plan or plans as described in the Measures column of the table.

CIP-006-7~~6~~ Table R1 – Physical Security Plan			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.1	Medium Impact BES Cyber Systems without External Routable Connectivity Physical Access Control Systems (PACS) associated with: • High Impact BES Cyber Systems, or • Medium Impact BES Cyber Systems with External Routable Connectivity	Define operational or procedural controls to restrict physical access.	An example of evidence may include, but is not limited to, documentation that operational or procedural controls exist.

CIP-006-7~~6~~ Table R1 – Physical Security Plan

Part	Applicable Systems	Requirements	Measures
1.2	Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; and 2. PCS~~A~~	Use~~tilize~~ at least one physical access control to allow unescorted physical access into each applicable Physical Security Perimeter to only those individuals who have authorized unescorted physical access.	An example of evidence may include, but is not limited to, language in the physical security plan that describes each Physical Security Perimeter and how unescorted physical access is controlled by one or more different methods and proof that unescorted physical access is restricted to only authorized individuals, such as a list of authorized individuals accompanied by access logs.

CIP-006-7~~6~~ Table R1 – Physical Security Plan

Part	Applicable Systems	Requirements	Measures
1.3	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; and 2. PCS~~A~~	Where technically feasible, use~~tilize~~ two or more different physical access controls (this does not require two completely independent physical access control systems) to collectively allow unescorted physical access into Physical Security Perimeters to only those individuals who have authorized unescorted physical access.	An example of evidence may include, but is not limited to, language in the physical security plan that describes the Physical Security Perimeters and how unescorted physical access is controlled by two or more different methods and proof that unescorted physical access is restricted to only authorized individuals, such as a list of authorized individuals accompanied by access logs.

CIP-006-7~~6~~ Table R1– Physical Security Plan			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.4	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; and 2. PCS~~A~~ Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; and 2. PCS~~A~~	Monitor for unauthorized access through a physical access point into a Physical Security Perimeter.	An example of evidence may include, but is not limited to, documentation of controls that monitor for unauthorized access through a physical access point into a Physical Security Perimeter.

CIP-006-7~~6~~ Table R1– Physical Security Plan

Part	Applicable Systems	Requirements	Measures
1.5	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; and 2. PCS~~A~~ Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; and 2. PCS~~A~~	Issue an alarm or alert in response to detected unauthorized access through a physical access point into a Physical Security Perimeter to the personnel identified in the BES Cyber Security Incident response plan within 15 minutes of detection.	An example of evidence may include, but is not limited to, language in the physical security plan that describes the issuance of an alarm or alert in response to unauthorized access through a physical access control into a Physical Security Perimeter and additional evidence that the alarm or alert was issued and communicated as identified in the BES Cyber Security Incident Response Plan, such as manual or electronic alarm or alert logs, cell phone or pager logs, or other evidence that documents that the alarm or alert was generated and communicated.
1.6	Physical Access Control Systems (PACS) associated with: • High Impact BES Cyber Systems, or • Medium Impact BES Cyber Systems with External Routable Connectivity	Monitor each Physical Access Control System for unauthorized physical access to a Physical Access Control System.	An example of evidence may include, but is not limited to, documentation of controls that monitor for unauthorized physical access to a PACS.

CIP-006-7~~6~~ Table R1– Physical Security Plan

Part	Applicable Systems	Requirements	Measures
1.7	Physical Access Control Systems (PACS) associated with: • High Impact BES Cyber Systems, or • Medium Impact BES Cyber Systems with External Routable Connectivity	Issue an alarm or alert in response to detected unauthorized physical access to a Physical Access Control System to the personnel identified in the BES Cyber Security Incident response plan within 15 minutes of the detection.	An example of evidence may include, but is not limited to, language in the physical security plan that describes the issuance of an alarm or alert in response to unauthorized physical access to Physical Access Control Systems and additional evidence that the alarm or alerts was issued and communicated as identified in the BES Cyber Security Incident Response Plan, such as alarm or alert logs, cell phone or pager logs, or other evidence that the alarm or alert was generated and communicated.

CIP-006-7~~6~~ Table R1 – Physical Security Plan

Part	Applicable Systems	Requirements	Measures
1.8	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; and 2. PCS~~A~~ Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; and 2. PCS~~A~~	Log (through automated means or by personnel who control entry) entry of each individual with authorized unescorted physical access into each Physical Security Perimeter, with information to identify the individual and date and time of entry, except during CIP Exceptional Circumstances.	An example of evidence may include, but is not limited to, language in the physical security plan that describes logging and recording of physical entry into each Physical Security Perimeter and additional evidence to demonstrate that this logging has been implemented, such as logs of physical access into Physical Security Perimeters that show the individual and the date and time of entry into Physical Security Perimeter.

CIP-006-7~~6~~ Table R1 – Physical Security Plan

Part	Applicable Systems	Requirements	Measures
1.9	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; and 2. PCS~~A~~ Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; and 2. PCS~~A~~	Retain physical access logs of entry of individuals with authorized unescorted physical access into each Physical Security Perimeter for at least ninety calendar days, except during CIP Exceptional Circumstances.	An example of evidence may include, but is not limited to, dated documentation such as logs of physical access into Physical Security Perimeters that show the date and time of entry into Physical Security Perimeter.

~~CIP-006-6~~CIP-006-7 Table R1 – Physical Security Plan

Part	Applicable Systems	Requirements	Measures
1.10	High Impact BES Cyber Systems and their associated PCS~~A~~ Medium Impact BES Cyber Systems at Control Centers and their associated ~~:~~ PCS~~A~~	Restrict physical access to cabling and other nonprogrammable communication components used for ~~connection between~~ applicable ~~Cyber Assets~~systems ~~within~~ in the same ~~Electronic Security~~Logical Isolation Zone ~~Perimeter~~ in those instances when such cabling and components are located outside of a Physical Security Perimeter. Where physical access restrictions to such cabling and components are not implemented, the Responsible Entity shall document and implement one or more of the following: • encryption of data that transits such cabling and components; or • monitoring the status of the communication link composed of such cabling and components and issuing an alarm or alert in response to detected communication failures to the personnel identified in the BES Cyber Security Incident response plan within 15 minutes of detection; or • an equally effective logical protection.	An example of evidence may include, but is not limited to, records of the Responsible Entity's implementation of the physical access restrictions (e.g., cabling and components secured through conduit or secured cable trays) encryption, monitoring, or equally effective logical protections.

R2. Each Responsible Entity shall implement, except during CIP Exceptional Circumstances, -one or more documented visitor control program(s) that include each of the applicable requirement parts in *CIP-006-7~~6~~ Table R2 – Visitor Control Program.*

M2. Evidence must include one or more documented visitor control programs that collectively include each of the applicable requirement parts in *CIP-006-7~~6~~ Table R2 – Visitor Control Program* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-006-7~~6~~ Table R2 – Visitor Control Program

Part	Applicable Systems	Requirements	Measures
2.1	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; and 2. PCS~~A~~ Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; and 2. PCS~~A~~	Require continuous escorted access of visitors (individuals who are provided access but are not authorized for unescorted physical access) within each Physical Security Perimeter~~,~~ ~~except during CIP Exceptional Circumstances~~.	An example of evidence may include, but is not limited to, language in a visitor control program that requires continuous escorted access of visitors within Physical Security Perimeters and additional evidence to demonstrate that the escorted access process was implemented, such as visitor logs.

CIP-006-7~~6~~ Table R2 – Visitor Control Program

Part	Applicable Systems	Requirements	Measures
2.2	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; and 2. PCS~~A~~ Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; and 2. PCS~~A~~	Require manual or automated logging of visitor entry into and exit from the Physical Security Perimeter that includes date and time of the initial entry and last exit, the visitor's name, and the name of an individual point of contact responsible for the visitor~~, except during CIP Exceptional Circumstances~~.	An example of evidence may include, but is not limited to, language in a visitor control program that requires continuous escorted access of visitors within Physical Security Perimeters and additional evidence to demonstrate that the escorted access process was implemented, such as dated visitor logs that include the required information.
2.3	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; and 2. PCS~~A~~ Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; and 2. PCS~~A~~	Retain visitor logs for at least ninety calendar days.	An example of evidence may include, but is not limited to, documentation showing logs have been retained for at least ninety calendar days.

R3. Each Responsible Entity shall implement one or more documented Physical Access Control System maintenance and testing program(s) that collectively include each of the applicable requirement parts in *CIP-006-7~~6~~ Table R3 – Maintenance and Testing Program*.

M3. Evidence must include each of the documented Physical Access Control System maintenance and testing programs that collectively include each of the applicable requirement parts in *CIP-006-7~~6~~ Table R3 – Maintenance and Testing Program* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-006-7~~6~~ Table R3 – Physical Access Control System Maintenance and Testing Program			
Part	**Applicable Systems**	**Requirement**	**Measures**
3.1	Physical Access Control Systems (PACS) associated with: • High Impact BES Cyber Systems, or • Medium Impact BES Cyber Systems with External Routable Connectivity Locally mounted hardware or devices at the Physical Security Perimeter associated with: • High Impact BES Cyber Systems, or • Medium Impact BES Cyber Systems with External Routable Connectivity	Maintenance and testing of each Physical Access Control System and locally mounted hardware or devices at the Physical Security Perimeter at least once every 24 calendar months to ensure they function properly.	An example of evidence may include, but is not limited to, a maintenance and testing program that provides for testing each Physical Access Control System and locally mounted hardware or devices associated with each applicable Physical Security Perimeter at least once every 24 calendar months, Also, ~~and~~ additional evidence such as dated maintenance records or other documentation ~~to demonstrate that this testing was done, such as dated maintenance records, or other documentation~~ to demonstrate that ~~showing~~ testing and maintenance has been performed on each applicable device or system at least once every 24 calendar months.

C. Compliance

1. Compliance Monitoring Process:

1.1. Compliance Enforcement Authority:

As defined in the NERC Rules of Procedure, “Compliance Enforcement Authority” (CEA) means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

1.2. Evidence Retention:

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the CEA may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Responsible Entity shall keep data or evidence to show compliance as identified below unless directed by its CEA to retain specific evidence for a longer period of time as part of an investigation:

- Each Responsible Entity shall retain evidence of each requirement in this standard for three calendar years.
- If a Responsible Entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.
- The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Investigations

Self-Reporting

Complaints

1.4. Additional Compliance Information:

The Background, VRF/VSLs, and Guidelines and Technical Basis Sections have been removed for this informal posting. The Project 2016-02 is seeking comments around the concept of the Requirement/Measure language at this time. All other sections will be modified prior to the initial posting.

A. Introduction

1. **Title:** Cyber Security — System Security Management
2. **Number:** CIP-007-7
3. **Purpose:** To manage system security by specifying select technical, operational, and procedural requirements in support of protecting BES Cyber Systems against compromise that could lead to misoperation or instability in the Bulk Electric System (BES).
4. **Applicability:**
   - **4.1. Functional Entities:** For the requirements in this standard, the following list of functional entities will be collectively referred to as "Responsible Entities." For requirements in this standard where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are explicitly specified.
     - **4.1.1. Balancing Authority**
     - **4.1.2. Distribution Provider** that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:
       - **4.1.2.1.** Each underfrequency Load shedding (UFLS) or undervoltage Load shedding (UVLS) system that:
         - **4.1.2.1.1.** is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and
         - **4.1.2.1.2.** performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.
       - **4.1.2.2.** Each Remedial Action Scheme (RAS) where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.
       - **4.1.2.3.** Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.1.3. Generator Operator

4.1.4. Generator Owner

4.1.5. Reliability Coordinator

4.1.6. Transmission Operator

4.1.7. Transmission Owner

4.2. Facilities: For the requirements in this standard, the following Facilities, systems, and equipment owned by each Responsible Entity in 4.1 above are those to which these requirements are applicable. For requirements in this standard where a specific type of Facilities, system, or equipment or subset of Facilities, systems, and equipment are applicable, these are explicitly specified.

4.2.1. Distribution Provider: One or more of the following Facilities, systems and equipment owned by the Distribution Provider for the protection or restoration of the BES:

4.2.1.1. Each UFLS or UVLS System that:

4.2.1.1.1. is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.2.1.1.2. performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.2.1.2. Each RAS where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.2.2. Responsible Entities listed in 4.1 other than Distribution Providers: All BES Facilities.

4.2.3. Exemptions: The following are exempt from Standard CIP-007-7:

4.2.3.1. Cyber Assets at Facilities regulated by the Canadian Nuclear Safety Commission.

4.2.3.2. Cyber Assets associated with communication networks and data communication links between BES Cyber Systems' Logical Isolation Zones (LIZ).

4.2.3.3. Cyber Assets associated with communication networks and data communication links used to extend a Logical Isolation Zone to more than one geographic location.

4.2.3.4. The systems, structures, and components that are regulated by the Nuclear Regulatory Commission under a cyber security plan pursuant to 10 C.F.R. Section 73.54.

4.2.3.5. For Distribution Providers, the systems and equipment that are not included in section 4.2.1 above.

4.2.3.6. Responsible Entities that identify that they have no BES Cyber Systems categorized as high impact or medium impact according to the CIP-002-5.1 identification and categorization processes.

5. Effective Dates: See Implementation Plan for CIP-007-7.

B. Requirements and Measures

R1. Each Responsible Entity shall implement one or more documented process(es) to mitigate the risk posed by uncontrolled logical and physical connectivity that collectively include each of the applicable requirement parts in *CIP-007-7 Table R1 – Connectivity*.

M1. Evidence must include the documented processes that collectively include each of the applicable requirement parts in *CIP-007-7 Table R1 – Connectivity* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-007-7 Table R1– Connectivity			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.1	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS	Use one or a combination of the following methods (per system capability) excluding serial port connectivity such as RS-232 and RS-485: • Configure each system to provide only essential logical connectivity; • Detect and alert on malicious communication within systems; • Baseline system logical connectivity, and alert on deviation from baseline; or • Other method(s) to mitigate the risk posed by uncontrolled logical connectivity. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	Examples of evidence may include, but are not limited to: • Documentation of the need for all enabled logical ports. • Listings of logical listening ports on the applicable systems, individually or by group, from either the device configuration files, command output (such as netstat), or network scans of open ports; or • Configuration files of host-based firewalls or other device level mechanisms that only allow needed ports and deny all others. • Documentation that malicious communications detection methods (e.g. intrusion detection system, application layer firewall, privileged introspection, etc.) are implemented within systems. • Any necessary combination of configuration files of system connectivity, storage connectivity, or network connectivity.

CIP-007-7 Table R1– Connectivity			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.2	High Impact BES Cyber Systems and their associated: 1. PCS; and 2. Nonprogrammable communication components located inside both a PSP and a LIZ. Medium Impact BES Cyber Systems at Control Centers and their associated: 1. PCS; and 2. Nonprogrammable communication components located inside both a PSP and a LIZ.	Protect against the use of unnecessary physical input/output ports used for network connectivity, console commands, or Removable Media.	An example of evidence may include, but is not limited to, documentation showing types of protection of physical input/output ports, either logically through system configuration or physically using a port lock or signage.

R2. Each Responsible Entity shall implement one or more documented process(es) to mitigate the risk posed by unmanaged software that collectively include each of the applicable requirement parts in *CIP-007-7 Table R2 – Software Management*.

M2. Evidence must include each of the applicable documented processes that collectively include each of the applicable requirement parts in *CIP-007-7 Table R2 – Software Management* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-007-7 Table R2 – Software Management			
Part	**Applicable Systems**	**Requirements**	**Measures**
2.1	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS	Use one or a combination of the following methods (per system capability) to allow only essential software execution, as determined by the Responsible Entity: • Configure each system with intentionally installed essential software and executable scripts; • Baseline currently installed software and executable scripts and alert on any newly installed software or executable scripts; • Implement application whitelisting; • Use read-only bootable media; or • Other methods to mitigate the risk posed by unmanaged software. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	An example of evidence may include, but is not limited to: • Documentation of essential software and executable scripts; • Application whitelisting rule sets; • Documentation of read-only bootable media configuration; or • Documentation of other methods.

R3. Each Responsible Entity shall implement one or more documented process(es) to mitigate the risk posed by malicious code that collectively include each of the applicable requirement parts in *CIP-007-7 Table R3 – Malicious Code Prevention*.

M3. Evidence must include each of the documented processes that collectively include each of the applicable requirement parts in *CIP-007-7 Table R3 – Malicious Code Prevention* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-007-7 Table R3 – Malicious Code Prevention			
Part	**Applicable Systems**	**Requirements**	**Measures**
3.1	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS	Deploy method(s) to deter, detect, or prevent malicious code. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	An example of evidence may include, but is not limited to, records of the Responsible Entity's performance of these processes (e.g., through traditional antivirus, system hardening, policies, etc.).

CIP-007-7 Table R3 – Malicious Code Prevention			
Part	**Applicable Systems**	**Requirements**	**Measures**
3.2	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS	Mitigate the threat of detected malicious code. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	Examples of evidence may include, but are not limited to: • Records of response processes for malicious code detection • Records of the performance of these processes when malicious code is detected.
3.3	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS	For those methods identified in Part 3.1 that use signatures or patterns, have a process for the update of the signatures or patterns. The process must address testing and installing the signatures or patterns.	An example of evidence may include, but is not limited to, documentation showing the process used for the update of signatures or patterns.

R4. Each Responsible Entity shall implement, except during CIP Exceptional Circumstances, one or more documented process(es) to monitor security events to mitigate the risk posed by detectable security incidents that collectively include each of the applicable requirement parts in *CIP-007-6 Table R4 – Security Event Monitoring*.

M4. Evidence must include each of the documented processes that collectively include each of the applicable requirement parts in *CIP-007-7 Table R4 – Security Event Monitoring* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-007-6 Table R4 – Security Event Monitoring			
Part	**Applicable Systems**	**Requirements**	**Measures**
4.1	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS	Log events (per system capability) for identification and subsequent investigations of Cyber Security Incidents that include each of the following types of events: 4.1.1. Detected successful login attempts; 4.1.2. Detected failed access attempts and failed login attempts; 4.1.3. Detected malicious code. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	Examples of evidence may include, but are not limited to, a paper or system generated listing of event types that the BES Cyber System can detect and, for generated events, is configured to log. This listing must include the required types of events.

CIP-007-6 Table R4 – Security Event Monitoring			
Part	**Applicable Systems**	**Requirements**	**Measures**
4.2	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; 2. PACS; and 3. PCS	Generate alerts for security events that the Responsible Entity determines need an alert, that include, as a minimum, each of the following types of events (per system capability): 4.2.1. Detected malicious code from Part 4.1; and 4.2.2. Detected failure of Part 4.1 event logging. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	Examples of evidence may include, but are not limited to, paper or system-generated lists of security events that the Responsible Entity determined need alerts, including paper or system generated lists showing how alerts are configured.

CIP-007-6 Table R4 – Security Event Monitoring			
Part	**Applicable Systems**	**Requirements**	**Measures**
4.3	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems at Control Centers and their associated: 1. EACS; 2. PACS; and 3. PCS	Retain applicable event logs identified in Part 4.1 per system capability for at least the last 90 consecutive calendar days.	Examples of evidence may include, but are not limited to, documentation of the event log retention process and paper or system generated reports showing log retention configuration set at 90 days or greater.
4.4	High Impact BES Cyber Systems and their associated: 1. EACS; and 2. PCS	Review a summarization or sampling of logged events as determined by the Responsible Entity at intervals no greater than 15 calendar days to identify undetected Cyber Security Incidents.	Examples of evidence may include, but are not limited to, documentation describing the review, findings from the review (if any), and dated documentation showing the review occurred.

R5. Each Responsible Entity shall implement one or more documented process(es) to mitigate the risk posed by unauthorized electronic access that collectively include each of the applicable requirement parts in *CIP-007-7 Table R5 – System Access Controls*.

M5. Evidence must include each of the applicable documented processes that collectively include each of the applicable requirement parts in *CIP-007-7 Table 5 – System Access Controls* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-007-7 Table R5 – System Access Controls

Part	Applicable Systems	Requirements	Measures
5.1	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems at Control Centers and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; 2. PACS; and 3. PCS	Have a method(s) to enforce authentication of interactive user access, per system capability. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	An example of evidence may include, but is not limited to, documentation describing how access is authenticated.

CIP-007-7 Table R5 – System Access Control			
Part	**Applicable Systems**	**Requirements**	**Measures**
5.2	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS	Identify and inventory all known enabled default or other generic account types, either by system, by groups of systems, by location or by system type(s). NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	An example of evidence may include, but is not limited to, a listing of accounts by account types showing the enabled or generic account types in use for the BES Cyber System.
5.3	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; 2. PACS; and 3. PCS	Identify individuals who have authorized access to shared accounts.	An example of evidence may include, but is not limited to, listing of shared accounts and the individuals who have authorized access to each shared account.

CIP-007-6 Table R5 – System Access Control			
Part	**Applicable Systems**	**Requirements**	**Measures**
5.4	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS	Change known default passwords, per system capability	Examples of evidence may include, but are not limited to: • Records of a procedure that passwords are changed when new devices are put in production; or • Documentation in system manuals or other vendor documents showing default vendor passwords were generated pseudo-randomly and are thereby unique to the device.
5.5	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS	For password-only authentication for interactive user access, either technically or procedurally enforce the following password parameters: 5.5.1. Password length that is, at least, the lesser of eight characters or the maximum length supported by the system; and 5.5.2. Minimum password complexity that is the lesser of three or more different types of characters (e.g., uppercase alphabetic, lowercase alphabetic, numeric, non-alphanumeric) or the maximum complexity supported by the system.	Examples of evidence may include, but are not limited to: • System-generated reports or screen-shots of the system-enforced password parameters, including length and complexity; or • Attestations that include a reference to the documented procedures that were followed.

		NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	

CIP-007-7 Table R5 – System Access Control			
Part	**Applicable Systems**	**Requirements**	**Measures**
5.6	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EACS; 2. PACS; and 3. PCS	Per system capability, for password-only authentication for interactive user access, either technically or procedurally enforce password changes or an obligation to change the password at least once every 15 calendar months. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	Examples of evidence may include, but are not limited to: - System-generated reports or screen-shots of the system-enforced periodicity of changing passwords; or - Attestations that include a reference to the documented procedures that were followed.
5.7	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems at Control Centers and their associated: 1. EACS; 2. PACS; and 3. PCS	Per system capability, either: - Limit the number of unsuccessful authentication attempts; or - Generate alerts after a threshold of unsuccessful authentication attempts. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	Examples of evidence may include, but are not limited to: - Documentation of the account-lockout parameters; or Rules in the alerting configuration showing how the system notified individuals after a determined number of unsuccessful login attempts.

C. Compliance

1. **Compliance Monitoring Process:**

1.1. Compliance Enforcement Authority: As defined in the NERC Rules of Procedure, "Compliance Enforcement Authority" (CEA) means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

1.2. Evidence Retention: The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the CEA may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

- The Responsible Entity shall keep data or evidence to show compliance as identified below unless directed by its CEA to retain specific evidence for a longer period of time as part of an investigation:
- Each Responsible Entity shall retain evidence of each requirement in this standard for three calendar years.
- If a Responsible Entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.
- The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes:

- Compliance Audits
- Self-Certifications
- Spot Checking
- Compliance Violation Investigations
- Self-Reporting
- Complaints

1.4. Additional Compliance Information:

None.

D. Regional Variances

None.

E. Interpretations

None.

F. Associated Documents

None.

Version History

Version	Date	Action	Change Tracking
1	1/16/06	R3.2 — Change “Control Center” to “control center.”	3/24/06
2	9/30/09	Modifications to clarify the requirements and to bring the compliance elements into conformance with the latest guidelines for developing compliance elements of standards. Removal of reasonable business judgment. Replaced the RRO with the RE as a responsible entity. Rewording of Effective Date. Changed compliance monitor to Compliance Enforcement Authority.	
3	12/16/09	Updated Version Number from -2 to -3 In Requirement 1.6, deleted the sentence pertaining to removing component or system from service in order to perform testing, in response to FERC order issued September 30, 2009.	
3	12/16/09	Approved by the NERC Board of Trustees.	
3	3/31/10	Approved by FERC.	
4	1/24/11	Approved by the NERC Board of Trustees.	

Version	Date	Action	Change Tracking
5	11/26/12	Adopted by the NERC Board of Trustees.	Modified to coordinate with other CIP standards and to revise format to use RBS Template.
5	11/22/13	FERC Order issued approving CIP-007-5.	
6	11/13/14	Adopted by the NERC Board of Trustees.	Addressed two FERC directives from Order No. 791 related to identify, assess, and correct language and communication networks.
6	2/15/15	Adopted by the NERC Board of Trustees.	Replaces the version adopted by the Board on 11/13/2014. Revised version addresses remaining directives from Order No. 791 related to transient devices and low impact BES Cyber Systems.
6	1/21/16	FERC order issued approving CIP-007-6. Docket No. RM15-14-000	

The Background, VRF/VSLs, and Guidelines and Technical Basis Sections have been removed for this informal posting. The Project 2016-02 is seeking comments around the concept of the Requirement/Measure language at this time. All other sections will be modified prior to the initial posting.

A. Introduction

1. **Title:** Cyber Security — System Security Management

2. **Number:** CIP-007-7~~6~~

3. **Purpose:** To manage system security by specifying select technical, operational, and procedural requirements in support of protecting BES Cyber Systems against compromise that could lead to misoperation or instability in the Bulk Electric System (BES).

4. **Applicability:**

   4.1. Functional Entities: For the ~~purpose of the~~ requirements in this standard~~contained herein~~, the following list of functional entities will be collectively referred to as "Responsible Entities." For requirements in this standard where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are explicitly specified.~~ explicitly.~~

   4.1.1. Balancing Authority

   4.1.2. Distribution Provider that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:

   4.1.2.1. Each underfrequency Load shedding (UFLS) or undervoltage Load shedding (UVLS) system that:

   4.1.2.1.1. is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

   4.1.2.1.2. performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

   4.1.2.2. Each ~~Special Protection System (SPS) or~~ Remedial Action Scheme (RAS) where the~~ SPS or~~ RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

   4.1.2.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.1.3. Generator Operator

4.1.4. Generator Owner~~Interchange Coordinator or Interchange Authority~~

4.1.5. Reliability Coordinator

4.1.6. Transmission Operator

4.1.7. Transmission Owner

4.2. Facilities: For the ~~purpose of the~~ requirements in this standard~~contained herein~~, the following Facilities, systems, and equipment owned by each Responsible Entity in 4.1 above are those to which these requirements are applicable. For requirements in this standard where a specific type of Facilities, system, or equipment or subset of Facilities, systems, and equipment are applicable, these are explicitly specified.~~ explicitly.~~

4.2.1. Distribution Provider: One or more of the following Facilities, systems and equipment owned by the Distribution Provider for the protection or restoration of the BES:

4.2.1.1. Each UFLS or UVLS System that:

4.2.1.1.1. is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.2.1.1.2. performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.2.1.2. Each ~~SPS or~~ RAS where the ~~SPS or~~ RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.2.2. Responsible Entities listed in 4.1 other than Distribution Providers: All BES Facilities.

4.2.3. Exemptions: The following are exempt from Standard CIP-007-7~~6~~:

4.2.3.1. Cyber Assets at Facilities regulated by the Canadian Nuclear Safety Commission.

4.2.3.2. Cyber Assets associated with communication networks and data communication links between BES Cyber Systems’ Logical Isolation Zones (LIZ).~~discrete Electronic Security Perimeters.~~

4.2.3.3. Cyber Assets associated with communication networks and data communication links used to extend a Logical Isolation Zone to more than one geographic location.

~~4.2.3.3.~~4.2.3.4. The systems, structures, and components that are regulated by the Nuclear Regulatory Commission under a cyber security plan pursuant to 10 C.F.R. Section 73.54.

~~4.2.3.4.~~4.2.3.5. For Distribution Providers, the systems and equipment that are not included in section 4.2.1 above.

~~4.2.3.5.~~4.2.3.6. Responsible Entities that identify that they have no BES Cyber Systems categorized as high impact or medium impact according to the CIP-002-5.1 identification and categorization processes.

5. **Effective Dates:** See Implementation Plan for CIP-007-7~~6~~.

B. Requirements and Measures

R1. Each Responsible Entity shall implement one or more documented process(es) to mitigate the risk posed by uncontrolled logical and physical connectivity that collectively include each of the applicable requirement parts in *CIP-007-7~~6~~ Table R1 – ~~Ports and Services~~Connectivity*.

M1. Evidence must include the documented processes that collectively include each of the applicable requirement parts in *CIP-007-7~~6~~ Table R1 – ~~Ports and Services~~Connectivity* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-007-7~~6~~ Table R1– ~~Ports and Services~~Connectivity			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.1	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~ Medium Impact BES Cyber Systems ~~with External Routable Connectivity~~ and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~	~~Where technically feasible, enable only logical network accessible ports that have been determined to be needed by the Responsible Entity, including port ranges or services where needed to handle dynamic ports. If a device has no provision for disabling or restricting logical ports on the device then those ports that are open are deemed needed.~~ Use one or a combination of the following methods (per system capability) excluding serial port connectivity such as RS-232 and RS-485: - Configure each system to provide only essential logical connectivity; - Detect and alert on malicious communication within systems; ~~or~~ - Baseline system logical connectivity, and alert on deviation from baseline; or - Other method(s) to mitigate the risk posed by uncontrolled logical connectivity. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	Examples of evidence may include, but are not limited to: - Documentation of the need for ~~all enabled ports on~~ all enabled logical ports. ~~applicable Cyber Assets and Electronic Access Points, individually or by group.~~ - Listings of logical ~~the~~ listening ports on the ~~Cyber Assets~~ applicable systems, individually or by group, from either the device configuration files, command output (such as netstat), or network scans of open ports; or - Configuration files of host-based firewalls or other device level mechanisms that only allow needed ports and deny all others. - Documentation that malicious communications detection methods (e.g. intrusion detection system, application layer firewall, privileged introspection, etc.) are implemented within systems. - Any necessary combination of configuration files of system connectivity, storage connectivity, or network connectivity.

CIP-007-7~~6~~ Table R1– ~~Ports and Services~~Connectivity

Part	Applicable Systems	Requirements	Measures
1.2	High Impact BES Cyber Systems and their associated: 1. PCS~~A~~; and 2. Nonprogrammable communication components located inside both a PSP and a~~n~~ ~~ESP~~LIZ. Medium Impact BES Cyber Systems at Control Centers and their associated: 1. PCS~~A~~; and 2. Nonprogrammable communication components located inside both a PSP and a~~n~~ ~~ESP~~LIZ.	Protect against the use of unnecessary physical input/output ports used for network connectivity, console commands, or Removable Media.	An example of evidence may include, but is not limited to, documentation showing types of protection of physical input/output ports, either logically through system configuration or physically using a port lock or signage.

R2. Each Responsible Entity shall implement one or more documented process(es) to mitigate the risk posed by unmanaged software that collectively include each of the applicable requirement parts in *CIP-007-7~~6~~ Table R2 – ~~Security Patch~~ Software Management*.

M2. Evidence must include each of the applicable documented processes that collectively include each of the applicable requirement parts in *CIP-007-~~6~~7 Table R2 – ~~Security Patch~~Software Management* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-007-7~~6~~ Table R2 – ~~Security Patch~~Software Management			
Part	Applicable Systems	Requirements	Measures

2.1	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~ Medium Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~	~~A patch management process for tracking, evaluating, and installing cyber security patches for applicable Cyber Assets. The tracking portion shall include the identification of a source or sources that the Responsible Entity tracks for the release of cyber security patches for applicable Cyber Assets that are updateable and for which a patching source exists.~~ Use one or a combination of the following methods (per system capability) to allow only essential software execution, as determined by the Responsible Entity: • Configure each system with intentionally installed essential software and executable scripts; • Baseline currently installed software and executable scripts and alert on any newly installed software or executable scripts; • Implement application whitelisting; ~~or~~ • Use read-only bootable media; or • Other methods to mitigate the risk posed by unmanaged software. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	An example of evidence may include, but is not limited to:~~, documentation of a patch management process and documentation or lists of sources that are monitored, whether on an individual BES Cyber System or Cyber Asset basis.~~ • Documentation of essential software and executable scripts; • Application whitelisting rule sets; • Documentation of read-only bootable media configuration; or • Documentation of other methods.

R3. Each Responsible Entity shall implement one or more documented process(es) to mitigate the risk posed by malicious code that collectively include each of the applicable requirement parts in *CIP-007-7~~6~~ Table R3 – Malicious Code Prevention*.

M3. Evidence must include each of the documented processes that collectively include each of the applicable requirement parts in *CIP-007-7~~6~~ Table R3 – Malicious Code Prevention* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-007-7~~6~~ Table R3 – Malicious Code Prevention

Part	Applicable Systems	Requirements	Measures
3.1	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~ Medium Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~	Deploy method(s) to deter, detect, or prevent malicious code. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	An example of evidence may include, but is not limited to, records of the Responsible Entity's performance of these processes (e.g., through traditional antivirus, system hardening, policies, etc.).

CIP-007-7~~6~~ Table R3 – Malicious Code Prevention

Part	Applicable Systems	Requirements	Measures
3.2	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~ Medium Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~	Mitigate the threat of detected malicious code. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	Examples of evidence may include, but are not limited to: - Records of response processes for malicious code detection - Records of the performance of these processes when malicious code is detected.
3.3	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~ Medium Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~	For those methods identified in Part 3.1 that use signatures or patterns, have a process for the update of the signatures or patterns. The process must address testing and installing the signatures or patterns.	An example of evidence may include, but is not limited to, documentation showing the process used for the update of signatures or patterns.

R4. Each Responsible Entity shall implement, except during CIP Exceptional Circumstances, one or more documented process(es) to monitor security events to mitigate the risk posed by detectable security incidents that collectively include each of the applicable requirement parts in *CIP-007-6 Table R4 – Security Event Monitoring*.

M4. Evidence must include each of the documented processes that collectively include each of the applicable requirement parts in *CIP-007-7~~6~~ Table R4 – Security Event Monitoring* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-007-6 Table R4 – Security Event Monitoring			
Part	**Applicable Systems**	**Requirements**	**Measures**
4.1	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~ Medium Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~	Log events ~~at the BES Cyber System level~~ (per ~~BES Cyber S~~system capability~~) or at the Cyber Asset level (per Cyber Asset capability~~) for identification ~~of,~~ and ~~after-the-fact~~ subsequent investigations of~~,~~ Cyber Security Incidents that include~~s, as a minimum,~~ each of the following types of events: 4.1.1. Detected successful login attempts; 4.1.2. Detected failed access attempts and failed login attempts; 4.1.3. Detected malicious code. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	Examples of evidence may include, but are not limited to, a paper or system generated listing of event types that the ~~for which the~~ BES Cyber System ~~is capable of~~can detect~~ing -~~and, for generated events, is configured to log. This listing must include the required types of events.

CIP-007-6 Table R4 – Security Event Monitoring			
Part	**Applicable Systems**	**Requirements**	**Measures**
4.2	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~ Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~	Generate alerts for security events that the Responsible Entity determines need ~~necessitates~~ an alert, that include~~s~~, as a minimum, each of the following types of events (per ~~Cyber Asset or BES Cyber S~~system capability): 4.2.1. Detected malicious code from Part 4.1; and 4.2.2. Detected failure of Part 4.1 event logging. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	Examples of evidence may include, but are not limited to, paper or system-generated lists~~ing~~ of security events that the Responsible Entity determined need~~cessitate~~ alerts, including paper or system generated lists showing how alerts are configured.

CIP-007-6 Table R4 – Security Event Monitoring			
Part	**Applicable Systems**	**Requirements**	**Measures**
4.3	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCSA~~A~~ Medium Impact BES Cyber Systems at Control Centers and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCSA~~A~~	~~Per system capability~~ ~~Where technically feasible, r~~Retain applicable event logs identified in Part 4.1 per system capability for at least the last 90 consecutive calendar days. ~~except under CIP Exceptional Circumstances.~~	Examples of evidence may include, but are not limited to, documentation of the event log retention process and paper or system generated reports showing log retention configuration set at 90 days or greater.
4.4	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; and 2. PCSA~~A~~	Review a summarization or sampling of logged events as determined by the Responsible Entity at intervals no greater than 15 calendar days to identify undetected Cyber Security Incidents.	Examples of evidence may include, but are not limited to, documentation describing the review, ~~any~~ findings from the review (if any), and dated documentation showing the review occurred.

R5. Each Responsible Entity shall implement one or more documented process(es) to mitigate the risk posed by unauthorized electronic access that collectively include each of the applicable requirement parts in *CIP-007-7~~6~~ Table R5 – System Access Controls*.

M5. Evidence must include each of the applicable documented processes that collectively include each of the applicable requirement parts in *CIP-007-~~6~~7 Table 5 – System Access Controls* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-007-7~~6~~ Table R5 – System Access Controls

Part	Applicable Systems	Requirements	Measures
5.1	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~ Medium Impact BES Cyber Systems at Control Centers and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~ Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~	Have a method(s) to enforce authentication of interactive user access, ~~where technically feasible.~~ per system capability. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	An example of evidence may include, but is not limited to, documentation describing how access is authenticated.

Part	**Applicable Systems**	**Requirements**	**Measures**
5.2	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~ Medium Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~	Identify and inventory all known enabled default or other generic account types, either by system, by groups of systems, by location~~,~~ or by system type(s). NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	An example of evidence may include, but is not limited to, a listing of accounts by account types showing the enabled or generic account types in use for the BES Cyber System.
5.3	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~ Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~	Identify individuals who have authorized access to shared accounts.	An example of evidence may include, but is not limited to, listing of shared accounts and the individuals who have authorized access to each shared account.

CIP-007-6 Table R5 – System Access Control			
Part	**Applicable Systems**	**Requirements**	**Measures**
5.4	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~ Medium Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~	Change known default passwords, per ~~Cyber Asset~~system capability	Examples of evidence may include, but are not limited to: - Records of a procedure that passwords are changed when new devices are put in production; or - Documentation in system manuals or other vendor documents showing default vendor passwords were generated pseudo-randomly and are thereby unique to the device.
5.5	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~ Medium Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~	For password-only authentication for interactive user access, either technically or procedurally enforce the following password parameters: 5.5.1. Password length that is, at least, the lesser of eight characters or the maximum length supported by the ~~Cyber Asset~~system; and 5.5.2. ~~5.5.2~~ Minimum password complexity that is the lesser of three or more different types of characters (e.g., uppercase alphabetic, lowercase alphabetic, numeric, non-alphanumeric) or the maximum complexity supported by the ~~Cyber Asset~~system.	Examples of evidence may include, but are not limited to: - System-generated reports or screen-shots of the system-enforced password parameters, including length and complexity; or - Attestations that include a reference to the documented procedures that were followed.

		NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	

CIP-007-7~~6~~ Table R5 – System Access Control

Part	Applicable Systems	Requirements	Measures
5.6	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~ Medium Impact BES Cyber Systems with External Routable Connectivity and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~	~~Where technically feasible~~Per system capability, for password-only authentication for interactive user access, either technically or procedurally enforce password changes or an obligation to change the password at least once every 15 calendar months. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	Examples of evidence may include, but are not limited to: - System-generated reports or screen-shots of the system-enforced periodicity of changing passwords; or - Attestations that include a reference to the documented procedures that were followed.
5.7	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~ Medium Impact BES Cyber Systems at Control Centers and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~	~~Where technically feasible~~Per system capability, either: - Limit the number of unsuccessful authentication attempts; or - Generate alerts after a threshold of unsuccessful authentication attempts. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	Examples of evidence may include, but are not limited to: Documentation of the account-lockout parameters; or - Rules in the alerting configuration showing how the system notified individuals after a determined number of unsuccessful login attempts.

C. Compliance

1. **Compliance Monitoring Process:**

1.1. Compliance Enforcement Authority: As defined in the NERC Rules of Procedure, "Compliance Enforcement Authority" (CEA) means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

1.2. Evidence Retention: The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the CEA may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

- The Responsible Entity shall keep data or evidence to show compliance as identified below unless directed by its CEA to retain specific evidence for a longer period of time as part of an investigation:
- Each Responsible Entity shall retain evidence of each requirement in this standard for three calendar years.
- If a Responsible Entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.
- The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes:

- Compliance Audits
- Self-Certifications
- Spot Checking
- Compliance Violation Investigations
- Self-Reporting
- Complaints

1.4. Additional Compliance Information:

Version History

Version	Date	Action	Change Tracking
1	1/16/06	R3.2 — Change “Control Center” to “control center.”	3/24/06
2	9/30/09	Modifications to clarify the requirements and to bring the compliance elements into conformance with the latest guidelines for developing compliance elements of standards. Removal of reasonable business judgment. Replaced the RRO with the RE as a responsible entity. Rewording of Effective Date. Changed compliance monitor to Compliance Enforcement Authority.	
3	12/16/09	Updated Version Number from -2 to -3 In Requirement 1.6, deleted the sentence pertaining to removing component or system from service in order to perform testing, in response to FERC order issued September 30, 2009.	
3	12/16/09	Approved by the NERC Board of Trustees.	
3	3/31/10	Approved by FERC.	
4	1/24/11	Approved by the NERC Board of Trustees.	

Version	Date	Action	Change Tracking
5	11/26/12	Adopted by the NERC Board of Trustees.	Modified to coordinate with other CIP standards and to revise format to use RBS Template.
5	11/22/13	FERC Order issued approving CIP-007-5.	
6	11/13/14	Adopted by the NERC Board of Trustees.	Addressed two FERC directives from Order No. 791 related to identify, assess, and correct language and communication networks.
6	2/15/15	Adopted by the NERC Board of Trustees.	Replaces the version adopted by the Board on 11/13/2014. Revised version addresses remaining directives from Order No. 791 related to transient devices and low impact BES Cyber Systems.
6	1/21/16	FERC order issued approving CIP-007-6. Docket No. RM15-14-000	

The Background, VRF/VSLs, and Guidelines and Technical Basis Sections have been removed for this informal posting. The Project 2016-02 is seeking comments around the concept of the Requirement/Measure language at this time. All other sections will be modified prior to the initial posting.

A. Introduction

1. **Title:** Cyber Security — Configuration Change Management and Vulnerability Management

2. **Number:** CIP-010-4

3. **Purpose:** To prevent and detect unauthorized changes to BES Cyber Systems by specifying configuration change management and vulnerability management requirements in support of protecting BES Cyber Systems from compromise that could lead to misoperation or instability in the Bulk Electric System (BES).

4. **Applicability:**

4.1. Functional Entities: For the requirements in this standard, the following list of functional entities will be collectively referred to as “Responsible Entities.” For requirements where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are explicitly specified.

4.1.1. Balancing Authority

4.1.2. Distribution Provider that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:

4.1.2.1. Each underfrequency Load shedding (UFLS) or undervoltage Load shedding (UVLS) system that:

4.1.2.1.1. is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.1.2.1.2. performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.1.2.2. Each Remedial Action Scheme (RAS) where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.1.3. Generator Operator

4.1.4. Generator Owner

4.1.5. Reliability Coordinator

4.1.6. Transmission Operator

4.1.7. Transmission Owner

4.2. Facilities: For the requirements in this standard, the following Facilities, systems, and equipment owned by each Responsible Entity in Section 4.1 above are those to which these requirements are applicable. For requirements where a specific type of Facilities, systems, or equipment or subset of Facilities, systems, and equipment are applicable, these are explicitly specified.

4.2.1. Distribution Provider: One or more of the following Facilities, systems and equipment owned by the Distribution Provider for the protection or restoration of the BES:

4.2.1.1 Each UFLS or UVLS System that:

4.2.1.1.1 is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.2.1.1.2 performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.2.1.2 Each RAS where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.3 Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.4 Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.2.2. Responsible Entities listed in 4.1 other than Distribution Providers:

All BES Facilities.

4.2.3. Exemptions: The following are exempt from Standard CIP-010-4:

4.2.3.1. Cyber Assets at Facilities regulated by the Canadian Nuclear Safety Commission.

4.2.3.2. Cyber Assets associated with communication networks and data communication links between BES Cyber Systems' Logical Isolation Zones (LIZ)..

4.2.3.3. Cyber Assets associated with communication networks and data communication links used to extend a Logical Isolation Zone to more than one geographic location.

4.2.3.4. The systems, structures, and components that are regulated by the Nuclear Regulatory Commission under a cyber security plan pursuant to 10 C.F.R. Section 73.54.

4.2.3.5. For Distribution Providers, the systems and equipment that are not included in section 4.2.1 above.

4.2.3.6. Responsible Entities that identify that they have no BES Cyber Systems categorized as high impact or medium impact according to the CIP-002-5 identification and categorization processes.

5. Effective Date:

See Implementation Plan for CIP-010-4.

B. Requirements and Measures

R1. Each Responsible Entity shall implement one or more documented process(es) to mitigate the risk posed by insecure system configuration that collectively include each of the applicable requirement parts in *CIP-010-4 Table R1 – Secure Configuration Management*.

M1. Evidence must include each of the applicable documented processes that collectively include each of the applicable requirement parts in *CIP-010-4 Table R1 – Secure Configuration Management* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-010-4 Table R1 – Secure Configuration Management			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.1	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS	Control change to the Secure Configuration implemented on systems through: 1.1.1. Authorization; 1.1.2. Prior to the change, determine required cyber security controls in the Secure Configuration that could be impacted by the change; 1.1.3. Implementation; and 1.1.4. Following the change, verify that required cyber security controls determined in 1.1.2 are not adversely affected and document the results. The process requirements of Parts 1.1.1 through 1.1.4 and timeline are based on the analysis of the risk to BES reliability and the risk posed by the change to the system(s).	Examples of evidence may include, but are not limited to: • Records of authorization • Records of controls impact evaluation; • Records of implementation; and • Records of verification.

1.2	High Impact BES Cyber Systems	For each change that deviates from the implemented Secure Configuration, perform the following, per system capability, except during CIP Exceptional Circumstances: 1.2.1. Prior to implementing any change in the production environment, test the changes in a test environment; or test the changes in a production environment where the test is performed in a manner that minimizes adverse effects, that models the Secure Configuration to ensure that required cyber security controls in CIP-005 and CIP-007 are not adversely affected; and 1.2.2. Document the results of the testing and, if a test environment was used, the differences between the test environment and the production environment, including a description of the measures used to account for any differences in operation between the test and production environments.	An example of evidence may include, but is not limited to, a list of tested cyber security controls, test dates, successful test results, and a list of differences between the production and test environments including descriptions of how any differences in the test and production environments were accounted for.

CIP-010-4 Table R1 – Secure Configuration Management			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.3	High Impact BES Cyber Systems Medium Impact BES Cyber Systems Note: Implementation does not require the Responsible Entity to renegotiate or abrogate existing contracts (including amendments to master agreements and purchase orders). Additionally, the following issues are beyond the scope of Part 1.3: (1) the actual terms and conditions of a procurement contract; and (2) vendor performance and adherence to a contract.	Prior to a change that deviates from the existing Secure Configuration associated with installing or updating operating system, firmware, and software and when the method to do so is available to the Responsible Entity from the software source: 1.3.1. Verify the identity of the software source; and 1.3.2. Verify the integrity of the software obtained from the software source.	An example of evidence may include, but is not limited to a change request record that demonstrates the verification of identity of the software source and integrity of the software was performed prior to the Secure Configuration change or a process which documents the mechanisms in place that would automatically ensure the identity of the software source and integrity of the software.

R2. Each Responsible Entity shall implement one or more documented process(es) to mitigate the risk posed by unauthorized change to Secure Configurations that collectively include each of the applicable requirement parts in *CIP-010-4 Table R2 – Secure Configuration Monitoring.*

M2. Evidence must include each of the applicable documented processes that collectively include each of the applicable requirement parts in *CIP-010-4 Table R2 – Secure Configuration Monitoring* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-010-4Table R2 – Secure Configuration			
Part	**Applicable Systems**	**Requirements**	**Measures**
2.1	High Impact BES Cyber Systems and their associated: 1. EACS; and 2. PCS	Use one or a combination of the following methods to monitor the implemented Secure Configuration (per system capability): • Hash monitoring; • Configuration monitoring; • Configuration auditing; or • Other method(s) to mitigate the risk posed by unauthorized change to Secure Configurations. The process requirements of Part 2.1 and timeline are based on the analysis of the risk to BES reliability and the impact rating of the applicable system(s).	An example of evidence may include, but is not limited to, logs from a system that is monitoring the configuration along with records of investigation for any unauthorized changes that were detected.
2.2	High Impact BES Cyber Systems and their associated: 1. EACS; and 2. PCS	Investigate and remediate detected unauthorized changes to the implemented Secure Configuration found through implementation of Requirement R2 Part 2.1.	An example of evidence may include, but is not limited to, records of unauthorized change investigations and remediating activities.

CIP-010-4Table R2 – Secure Configuration			
Part	**Applicable Systems**	**Requirements**	**Measures**
		The process requirements of Part 2.2 and timeline are based on the analysis of the risks to BES reliability and the risks posed by the detected unauthorized change to the implemented Secure Configuration	

R3. Each Responsible Entity shall implement one or more documented process(es) to mitigate the risk posed by system vulnerabilities that collectively include each of the applicable requirement parts in *CIP-010-4 Table R3– Vulnerability Management*.

M3. Evidence must include each of the applicable documented processes that collectively include each of the applicable requirement parts in *CIP-010-4 Table R3 – Vulnerability Management* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-010-4 Table R3 – Vulnerability Management			
Part	**Applicable Systems**	**Requirements**	**Measures**
3.1	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS	At least once every 15 calendar months, conduct a paper or active vulnerability assessment.	Examples of evidence may include, but are not limited to: • A document listing the date of the assessment (performed at least once every 15 calendar months), the controls assessed for each BES Cyber System along with the method of assessment; or • A document listing the date of the assessment and the output of any tools used to perform the assessment.

CIP-010-4 Table R3 – Vulnerability Management			
Part	**Applicable Systems**	**Requirements**	**Measures**
3.2	High Impact BES Cyber Systems	Per system capability, at least once every 36 calendar months: 3.2.1 Perform an active vulnerability assessment in a test environment, or perform an active vulnerability assessment in a production environment where the test is performed in a manner that minimizes adverse effects, that models the Secure Configuration of the BES Cyber System in a production environment; and 3.2.2 Document the results of the testing and, if a test environment was used, the differences between the test environment and the production environment, including a description of the measures used to account for any differences in operation between the test and production environments.	An example of evidence may include, but is not limited to, a document listing the date of the assessment (performed at least once every 36 calendar months), the output of the tools used to perform the assessment, and a list of differences between the production and test environments with descriptions of how any differences were accounted for in conducting the assessment.

CIP-010-4 Table R3 – Vulnerability Management			
Part	**Applicable Systems**	**Requirements**	**Measures**
3.3	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PCS	Prior to adding a new Cyber Asset to a production environment, perform an active vulnerability assessment of the new Cyber Asset, except for CIP Exceptional Circumstances and like replacements and additions of the same type of Cyber Asset with a Secure Configuration that models an existing Secure Configuration of the previous or other existing Cyber Asset.	An example of evidence may include, but is not limited to, a document listing the date of the assessment (performed prior to the commissioning of the addition) and the output of any tools used to perform the assessment.
3.4	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS	Document the results of the assessments conducted according to Parts 3.1, 3.2, and 3.3 and the action plan to remediate or mitigate vulnerabilities identified in the assessments including the planned date of completing the action plan and the execution status of any remediation or mitigation action items.	An example of evidence may include, but is not limited to, a document listing the results or the review or assessment, a list of action items, documented proposed dates of completion for the action plan, and records of the status of the action items (such as minutes of a status meeting, updates in a work order system, or a spreadsheet tracking the action items).

CIP-010-4 Table R3 – Vulnerability Management			
Part	**Applicable Systems**	**Requirements**	**Measures**
3.5	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS	Identify software vulnerabilities using one or more of the following methods: • Vulnerability database monitoring; • Patch source monitoring; • Vulnerability scanning; or • Other method(s) to identify software vulnerabilities. The process of Part 3.5 shall include the periodicity for identifying software vulnerabilities based on the risk to BES reliability and the impact rating of the applicable system(s).	An example of evidence may include, but is not limited to: • Records of vulnerability database monitoring; • Records of patch source monitoring; or • Records of vulnerability scanning.

CIP-010-4 Table R3 – Vulnerability Management			
Part	**Applicable Systems**	**Requirements**	**Measures**
3.6	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS	Create or update a plan to mitigate the identified software vulnerabilities from Part 3.5, through one or more of the following: • Implementing security patches; • Applying compensating controls; • System hardening; or • Other method(s) to mitigate software vulnerabilities. The plan for Part 3.6 must include the timeline for mitigating the software vulnerability based on the analysis of the risk posed by the software vulnerability to the applicable systems. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	An example of evidence may include, but is not limited to: • Records of implemented security patches; • Records of applied compensating controls; • Records of system hardening; or • Records of other methods.

R4. Each Responsible Entity, for its high impact and medium impact BES Cyber Systems and associated Protected Cyber Systems, shall implement, except under CIP Exceptional Circumstances, one or more documented plan(s) for Transient Cyber Assets and Removable Media that include the sections in Attachment 1.

M4. Evidence shall include each of the documented plan(s) for Transient Cyber Assets and Removable Media that collectively include each of the applicable sections in Attachment 1 and additional evidence to demonstrate implementation of plan(s) for Transient Cyber Assets and Removable Media. Additional examples of evidence per section are located in Attachment 2. If a Responsible Entity does not use Transient Cyber Asset(s) or Removable Media, examples of evidence include, but are not limited to, a statement, policy, or other document that states the Responsible Entity does not use Transient Cyber Asset(s) or Removable Media.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- Each applicable entity shall retain evidence of each requirement in this standard for three calendar years.
- If an applicable entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.
- The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

D. Regional Variances

None.

E. Associated Documents

CIP-010-4 - Attachment 1

Required Sections for Plans for Transient Cyber Assets and Removable Media

Responsible Entities shall include each of the sections provided below in their plan(s) for Transient Cyber Assets and Removable Media as required under Requirement R4.

Section 1. Transient Cyber Asset(s) Managed by the Responsible Entity.

1.1. Transient Cyber Asset Management: Responsible Entities shall manage Transient Cyber Asset(s), individually or by group: (1) in an ongoing manner to ensure compliance with applicable requirements at all times, (2) in an on-demand manner applying the applicable requirements before connection to a BES Cyber System, or (3) a combination of both (1) and (2) above.

1.2. Transient Cyber Asset Authorization: For each individual or group of Transient Cyber Asset(s), each Responsible Entity shall authorize:

1.2.1. Users, either individually or by group or role;

1.2.2. Locations, either individually or by group; and

1.2.3. Uses, which shall be limited to what is necessary to perform business functions.

1.3. Software Vulnerability Mitigation: Use one or a combination of the following methods to achieve the objective of mitigating the risk of vulnerabilities posed by unpatched software on the Transient Cyber Asset (per Transient Cyber Asset capability):

- Security patching, including manual or managed updates;
- Live operating system and software executable only from read-only media;
- System hardening; or
- Other method(s) to mitigate software vulnerabilities.

1.4. Introduction of Malicious Code Mitigation: Use one or a combination of the following methods to achieve the objective of mitigating the introduction of malicious code (per Transient Cyber Asset capability):

- Antivirus software, including manual or managed updates of signatures or patterns;
- Application whitelisting; or
- Other method(s) to mitigate the introduction of malicious code.

1.5. Unauthorized Use Mitigation: Use one or a combination of the following methods to achieve the objective of mitigating the risk of unauthorized use of Transient Cyber Asset(s):

- Restrict physical access;
- Full-disk encryption with authentication;
- Multi-factor authentication; or
- Other method(s) to mitigate the risk of unauthorized use.

Section 2. Transient Cyber Asset(s) Managed by a Party Other than the Responsible Entity.

2.1 Software Vulnerabilities Mitigation: Use one or a combination of the following methods to achieve the objective of mitigating the risk of vulnerabilities posed by unpatched software on the Transient Cyber Asset (per Transient Cyber Asset capability):

- Review of installed security patch(es);
- Review of security patching process used by the party;
- Review of other vulnerability mitigation performed by the party; or
- Other method(s) to mitigate software vulnerabilities.

2.2 Introduction of malicious code mitigation: Use one or a combination of the following methods to achieve the objective of mitigating malicious code (per Transient Cyber Asset capability):

- Review of antivirus update level;
- Review of antivirus update process used by the party;
- Review of application whitelisting used by the party;
- Review use of live operating system and software executable only from read-only media;
- Review of system hardening used by the party; or
- Other method(s) to mitigate malicious code.

2.3 For any method used to mitigate software vulnerabilities or malicious code as specified in 2.1 and 2.2, Responsible Entities shall determine whether any additional mitigation actions are necessary and implement such actions prior to connecting the Transient Cyber Asset.

Section 3. Removable Media

3.1. Removable Media Authorization: For each individual or group of Removable Media, each Responsible Entity shall authorize:

3.1.1. Users, either individually or by group or role; and

3.1.2. Locations, either individually or by group.

3.2. Malicious Code Mitigation: To achieve the objective of mitigating the threat of introducing malicious code to high impact or medium impact BES Cyber Systems and their associated Protected Cyber System, each Responsible Entity shall:

3.2.1. Use method(s) to detect malicious code on Removable Media using a Cyber Asset other than a BES Cyber System or Protected Cyber System; and

3.2.2. Mitigate the threat of detected malicious code on Removable Media prior to connecting the Removable Media to a high impact or medium impact BES Cyber System or associated Protected Cyber System.

CIP-010-4 - Attachment 2

Examples of Evidence for Plans for Transient Cyber Assets and Removable Media

Section 1.1: Examples of evidence for Section 1.1 may include, but are not limited to, the method(s) of management for the Transient Cyber Asset(s). This can be included as part of the Transient Cyber Asset plan(s), part of the documentation related to authorization of Transient Cyber Asset(s) managed by the Responsible Entity or part of a security policy.

Section 1.2: Examples of evidence for Section 1.2 may include, but are not limited to, documentation from asset management systems, human resource management systems, or forms or spreadsheets that show authorization of Transient Cyber Asset(s) managed by the Responsible Entity. Alternatively, this can be documented in the overarching plan document.

Section 1.3: Examples of evidence for Section 1.3 may include, but are not limited to, documentation of the method(s) used to mitigate software vulnerabilities posed by unpatched software such as security patch management implementation, the use of live operating systems from read-only media, system hardening practices or other method(s) to mitigate the software vulnerability posed by unpatched software. Evidence can be from change management systems, automated patch management solutions, procedures or processes associated with using live operating systems, or procedures or processes associated with system hardening practices. If a Transient Cyber Asset does not have the capability to use method(s) that mitigate the risk from unpatched software, evidence may include documentation by the vendor or Responsible Entity that identifies that the Transient Cyber Asset does not have the capability.

Section 1.4: Examples of evidence for Section 1.4 may include, but are not limited to, documentation of the method(s) used to mitigate the introduction of malicious code such as antivirus software and processes for managing signature or pattern updates, application whitelisting practices, processes to restrict communication, or other method(s) to mitigate the introduction of malicious code. If a Transient Cyber Asset does not have the capability to use method(s) that mitigate the introduction of malicious code, evidence may include documentation by the vendor or Responsible Entity that identifies that the Transient Cyber Asset does not have the capability.

Section 1.5: Examples of evidence for Section 1.5 may include, but are not limited to, documentation through policies or procedures of the method(s) to restrict physical access; method(s) of the full-disk encryption solution along with the authentication protocol; method(s) of the multi-factor authentication solution; or documentation of other method(s) to mitigate the risk of unauthorized use.

Section 2.1: Examples of evidence for Section 2.1 may include, but are not limited to, documentation from change management systems, electronic mail or procedures that document a review of installed security patch(es); memoranda, electronic mail, policies or contracts from parties other than the Responsible Entity that identify the security patching process or vulnerability mitigation performed by the party other than the Responsible Entity; evidence from change management systems, electronic mail, system documentation or contracts that identifies acceptance by the Responsible Entity that the practices of the party other than the Responsible Entity are acceptable; or documentation of other method(s) to mitigate software vulnerabilities for Transient Cyber Asset(s) managed by a party other than the Responsible Entity. If a Transient Cyber Asset does not have the capability to use method(s) that mitigate the risk from unpatched software, evidence may include documentation by the Responsible Entity or the party other than the Responsible Entity that identifies that the Transient Cyber Asset does not have the capability.

Section 2.2: Examples of evidence for Section 2.2 may include, but are not limited to, documentation from change management systems, electronic mail or procedures that document a review of the installed antivirus update level; memoranda, electronic mail, system documentation, policies or contracts from the party other than the Responsible Entity that identify the antivirus update process, the use of application whitelisting, use of live of operating systems or system hardening performed by the party other than the Responsible Entity; evidence from change management systems, electronic mail or contracts that identifies the Responsible Entity’s acceptance that the practices of the party other than the Responsible Entity are acceptable; or documentation of other method(s) to mitigate malicious code for Transient Cyber Asset(s) managed by a party other than the Responsible Entity. If a Transient Cyber Asset does not have the capability to use method(s) that mitigate the introduction of malicious code, evidence may include documentation by the Responsible Entity or the party other than the Responsible Entity that identifies that the Transient Cyber Asset does not have the capability.

Section 2.3: Examples of evidence for Section 2.3 may include, but are not limited to, documentation from change management systems, electronic mail, or contracts that identifies a review to determine whether additional mitigations are necessary and that they have been implemented prior to connecting the Transient Cyber Asset managed by a party other than the Responsible Entity.

Section 3.1: Examples of evidence for Section 3.1 may include, but are not limited to, documentation from asset management systems, human resource management systems, forms or spreadsheets that shows authorization of Removable Media. The documentation must identify Removable Media, individually or by group of Removable Media, along with the authorized users, either individually or by group or role, and the authorized locations, either individually or by group.

Section 3.2: Examples of evidence for Section 3.2 may include, but are not limited to, documented process(es) of the method(s) used to mitigate malicious code such as results of scan settings for Removable Media, or implementation of on-demand scanning. Documented process(es) for the method(s) used for mitigating the threat of detected malicious code on Removable Media, such as logs from the method(s) used to detect malicious code that show the results of scanning and that show mitigation of detected malicious code on Removable Media or documented confirmation by the entity that the Removable Media was deemed to be free of malicious code.

The Background, VRF/VSLs, and Guidelines and Technical Basis Sections have been removed for this informal posting. The Project 2016-02 is seeking comments around the concept of the Requirement/Measure language at this time. All other sections will be modified prior to the initial posting.

A. Introduction

1. **Title:** Cyber Security — Configuration Change Management and Vulnerability ~~Assessments~~ Management

2. **Number:** CIP-010-4~~3~~

3. **Purpose:** To prevent and detect unauthorized changes to BES Cyber Systems by specifying configuration change management and vulnerability ~~assessment~~ management requirements in support of protecting BES Cyber Systems from compromise that could lead to misoperation or instability in the Bulk Electric System (BES).

4. **Applicability:**

4.1. Functional Entities: For the ~~purpose of the~~ requirements in this standard~~contained herein~~, the following list of functional entities will be collectively referred to as “Responsible Entities.” For requirements ~~in this standard~~ where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are explicitly specified.~~ explicitly.~~

4.1.1. Balancing Authority

4.1.2. Distribution Provider that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:

4.1.2.1. Each underfrequency Load shedding (UFLS) or undervoltage Load shedding (UVLS) system that:

4.1.2.1.1. is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.1.2.1.2. performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.1.2.2. Each Remedial Action Scheme (RAS) where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.1.3. Generator Operator

~~**4.1.4.**~~ **Generator Owner**

~~**4.1.5.**~~**4.1.4.** ~~**Interchange Coordinator or Interchange Authority**~~

~~**4.1.6.**~~**4.1.5. Reliability Coordinator**

~~**4.1.7.**~~**4.1.6. Transmission Operator**

~~**4.1.8.**~~**4.1.7. Transmission Owner**

4.2. Facilities: For ~~the purpose of~~ the requirements ~~contained herein~~in this standard, the following Facilities, systems, and equipment owned by each Responsible Entity in Section 4.1 above are those to which these requirements are applicable. For requirements ~~in this standard~~ where a specific type of Facilities, systems, or equipment or subset of Facilities, systems, and equipment are applicable, these are explicitly specified. ~~explicitly.~~

4.2.1. Distribution Provider: One or more of the following Facilities, systems and equipment owned by the Distribution Provider for the protection or restoration of the BES:

4.2.1.1 Each UFLS or UVLS System that:

4.2.1.1.1 is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.2.1.1.2 performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.2.1.2 Each RAS where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.3 Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.4 Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.2.2. Responsible Entities listed in 4.1 other than Distribution Providers:

All BES Facilities.

4.2.3. Exemptions: The following are exempt from Standard CIP-010-4~~3~~:

4.2.3.1. Cyber Assets at Facilities regulated by the Canadian Nuclear Safety Commission.

4.2.3.2. Cyber Assets associated with communication networks and data communication links between~~-~~ BES Cyber Systems' Logical Isolation Zones (LIZ).~~discrete Electronic Security Perimeters~~.

~~4.2.3.2.~~4.2.3.3. Cyber Assets associated with communication networks and data communication links used to extend a Logical Isolation Zone to more than one geographic location.

~~4.2.3.3.~~4.2.3.4. The systems, structures, and components that are regulated by the Nuclear Regulatory Commission under a cyber security plan pursuant to 10 C.F.R. Section 73.54.

~~4.2.3.4.~~4.2.3.5. For Distribution Providers, the systems and equipment that are not included in section 4.2.1 above.

~~4.2.3.5.~~4.2.3.6. Responsible Entities that identify that they have no BES Cyber Systems categorized as high impact or medium impact according to the CIP-002-5 identification and categorization processes.

5. Effective Date:

See Implementation Plan for ~~Project 2016-03~~CIP-010-4.

B. Requirements and Measures

R1. Each Responsible Entity shall implement one or more documented process(es) to mitigate the risk posed by insecure system configuration that collectively include each of the applicable requirement parts in *CIP-010-4~~3~~ Table R1 – Secure Configuration ~~Change~~ Management*.

M1. Evidence must include each of the applicable documented processes that collectively include each of the applicable requirement parts in *CIP-010-~~3~~ 4 Table R1 – Secure Configuration ~~Change~~ Management* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-010-4~~3~~ Table R1 – Secure Configuration ~~Change~~ Management			
Part	**Applicable Systems**	**Requirements**	**Measures**
~~1.1~~	~~High Impact BES Cyber Systems and their associated:~~ ~~1. EACMS;~~ ~~2. PACS; and~~ ~~3. PCA~~ ~~Medium Impact BES Cyber Systems and their associated:~~ ~~1. EACMS;~~ ~~2. PACS; and~~ ~~3. PCA~~	~~Develop a baseline configuration, individually or by group, which shall include the following items:~~ ~~1.1.1. Operating system(s) (including version) or firmware where no independent operating system exists;~~ ~~1.1.2. Any commercially available or open-source application software (including version) intentionally installed;~~ ~~1.1.3. Any custom software installed;~~ ~~1.1.4. Any logical network accessible ports; and~~ ~~1.1.5. Any security patches applied.~~	~~Examples of evidence may include, but are not limited to:~~ ~~• Documentation A spreadsheet identifying the required items of the baseline secure configuration for each Cyber Assetsystem, individually or by group.; or~~ ~~A record in an asset management system that identifies the required items of the baseline configuration for each Cyber Asset, individually or by group.~~

1.1~~2~~	High Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~ Medium Impact BES Cyber Systems and their associated: 1. EAC~~M~~S; 2. PACS; and 3. PCS~~A~~	Control change to the S~~s~~ecure C~~c~~onfiguration ~~described in CIP-010 Requirement R1 Part 1.1~~ implemented on systems through: ~~Authorize and document changes that deviate from the existing baseline configuration.~~ ~~1.1.1.~~ 1.1.1. Authorization; 1.1.2. Prior to the change, determine required cyber security controls in the Secure Configuration that could be impacted by the change; 1.1.3. Implementation; and 1.1.4. Following the change, verify that required cyber security ~~controls determined~~controls determined in 1.1.2 are not adversely affected~~;~~ and document the results. ~~.~~ The process requirements of Parts 1.1.1 through 1.1.4 and timeline are based on the analysis of the risk to BES reliability and the risk posed by the change to the system(s).	Examples of evidence may include, but are not limited to: • ~~A change request record and~~ R~~r~~ecords ~~for~~of authorization~~associated electronic authorization (performed by the individual or group with the authority to authorize the change) in a change management system for each change; or~~ • Records of ~~testing~~controls impact ~~evaluaton~~evaluation; • Records of implementation; and • Records of ~~evaluation~~verification. ~~Documentation that the change was performed in accordance with the requirement.~~

CIP-010-4~~3~~ Table R1 – Secure Configuration ~~Change~~ Management

3.6	High Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS Medium Impact BES Cyber Systems and their associated: 1. EACS; 2. PACS; and 3. PCS	Create or update a plan to mitigate the identified software vulnerabilities from Part 3.5, through one or more of the following: • Implementing security patches; • Applying compensating controls; • System hardening; or • Other method(s) to mitigate software vulnerabilities. The plan for Part 3.6 must include the timeline for mitigating the software vulnerability based on the analysis of the risk posed by the software vulnerability to the applicable systems. NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.	An example of evidence may include, but is not limited to: • Records of implemented security patches; • Records of applied compensating controls; • Records of system hardening; or • Records of other methods.

R4. Each Responsible Entity, for its high impact and medium impact BES Cyber Systems and associated Protected Cyber ~~Assets~~Systems, shall implement, except under CIP Exceptional Circumstances, one or more documented plan(s) for Transient Cyber Assets and Removable Media that include the sections in Attachment 1.

M4. Evidence shall include each of the documented plan(s) for Transient Cyber Assets and Removable Media that collectively include each of the applicable sections in Attachment 1 and additional evidence to demonstrate implementation of plan(s) for Transient Cyber Assets and Removable Media. Additional examples of evidence per section are located in Attachment 2. If a Responsible Entity does not use Transient Cyber Asset(s) or Removable Media, examples of evidence include, but are not limited to, a statement, policy, or other document that states the Responsible Entity does not use Transient Cyber Asset(s) or Removable Media.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: “Compliance Enforcement Authority” means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- Each applicable entity shall retain evidence of each requirement in this standard for three calendar years.
- If an applicable entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.
- The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, “Compliance Monitoring and Enforcement Program” refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

D. Regional Variances

None.

E. Associated Documents

None.

Required Sections for Plans for Transient Cyber Assets and Removable Media

Responsible Entities shall include each of the sections provided below in their plan(s) for Transient Cyber Assets and Removable Media as required under Requirement R4.

Section 1. Transient Cyber Asset(s) Managed by the Responsible Entity.

1.1. Transient Cyber Asset Management: Responsible Entities shall manage Transient Cyber Asset(s), individually or by group: (1) in an ongoing manner to ensure compliance with applicable requirements at all times, (2) in an on-demand manner applying the applicable requirements before connection to a BES Cyber System, or (3) a combination of both (1) and (2) above.

1.2. Transient Cyber Asset Authorization: For each individual or group of Transient Cyber Asset(s), each Responsible Entity shall authorize:

1.2.1. Users, either individually or by group or role;

1.2.2. Locations, either individually or by group; and

1.2.3. Uses, which shall be limited to what is necessary to perform business functions.

1.3. Software Vulnerability Mitigation: Use one or a combination of the following methods to achieve the objective of mitigating the risk of vulnerabilities posed by unpatched software on the Transient Cyber Asset (per Transient Cyber Asset capability):

- Security patching, including manual or managed updates;
- Live operating system and software executable only from read-only media;
- System hardening; or
- Other method(s) to mitigate software vulnerabilities.

1.4. Introduction of Malicious Code Mitigation: Use one or a combination of the following methods to achieve the objective of mitigating the introduction of malicious code (per Transient Cyber Asset capability):

- Antivirus software, including manual or managed updates of signatures or patterns;
- Application whitelisting; or
- Other method(s) to mitigate the introduction of malicious code.

1.5. Unauthorized Use Mitigation: Use one or a combination of the following methods to achieve the objective of mitigating the risk of unauthorized use of Transient Cyber Asset(s):

- Restrict physical access;
- Full-disk encryption with authentication;
- Multi-factor authentication; or
- Other method(s) to mitigate the risk of unauthorized use.

Section 2. Transient Cyber Asset(s) Managed by a Party Other than the Responsible Entity.

2.1 Software Vulnerabilities Mitigation: Use one or a combination of the following methods to achieve the objective of mitigating the risk of vulnerabilities posed by unpatched software on the Transient Cyber Asset (per Transient Cyber Asset capability):

- Review of installed security patch(es);
- Review of security patching process used by the party;
- Review of other vulnerability mitigation performed by the party; or
- Other method(s) to mitigate software vulnerabilities.

2.2 Introduction of malicious code mitigation: Use one or a combination of the following methods to achieve the objective of mitigating malicious code (per Transient Cyber Asset capability):

- Review of antivirus update level;
- Review of antivirus update process used by the party;
- Review of application whitelisting used by the party;
- Review use of live operating system and software executable only from read-only media;
- Review of system hardening used by the party; or
- Other method(s) to mitigate malicious code.

2.3 For any method used to mitigate software vulnerabilities or malicious code as specified in 2.1 and 2.2, Responsible Entities shall determine whether any additional mitigation actions are necessary and implement such actions prior to connecting the Transient Cyber Asset.

Section 3. Removable Media

3.1. Removable Media Authorization: For each individual or group of Removable Media, each Responsible Entity shall authorize:

3.1.1. Users, either individually or by group or role; and

3.1.2. Locations, either individually or by group.

3.2. Malicious Code Mitigation: To achieve the objective of mitigating the threat of introducing malicious code to high impact or medium impact BES Cyber Systems and their associated Protected Cyber ~~Assets~~System, each Responsible Entity shall:

3.2.1. Use method(s) to detect malicious code on Removable Media using a Cyber Asset other than a BES Cyber System or Protected Cyber ~~Assets~~System; and

3.2.2. Mitigate the threat of detected malicious code on Removable Media prior to connecting the Removable Media to a high impact or medium impact BES Cyber System or associated Protected Cyber ~~Assets~~System.

CIP-010-4~~3~~ - Attachment 2

Examples of Evidence for Plans for Transient Cyber Assets and Removable Media

Section 1.1: Examples of evidence for Section 1.1 may include, but are not limited to, the method(s) of management for the Transient Cyber Asset(s). This can be included as part of the Transient Cyber Asset plan(s), part of the documentation related to authorization of Transient Cyber Asset(s) managed by the Responsible Entity or part of a security policy.

Section 1.2: Examples of evidence for Section 1.2 may include, but are not limited to, documentation from asset management systems, human resource management systems, or forms or spreadsheets that show authorization of Transient Cyber Asset(s) managed by the Responsible Entity. Alternatively, this can be documented in the overarching plan document.

Section 1.3: Examples of evidence for Section 1.3 may include, but are not limited to, documentation of the method(s) used to mitigate software vulnerabilities posed by unpatched software such as security patch management implementation, the use of live operating systems from read-only media, system hardening practices or other method(s) to mitigate the software vulnerability posed by unpatched software. Evidence can be from change management systems, automated patch management solutions, procedures or processes associated with using live operating systems, or procedures or processes associated with system hardening practices. If a Transient Cyber Asset does not have the capability to use method(s) that mitigate the risk from unpatched software, evidence may include documentation by the vendor or Responsible Entity that identifies that the Transient Cyber Asset does not have the capability.

Section 1.4: Examples of evidence for Section 1.4 may include, but are not limited to, documentation of the method(s) used to mitigate the introduction of malicious code such as antivirus software and processes for managing signature or pattern updates, application whitelisting practices, processes to restrict communication, or other method(s) to mitigate the introduction of malicious code. If a Transient Cyber Asset does not have the capability to use method(s) that mitigate the introduction of malicious code, evidence may include documentation by the vendor or Responsible Entity that identifies that the Transient Cyber Asset does not have the capability.

Section 1.5: Examples of evidence for Section 1.5 may include, but are not limited to, documentation through policies or procedures of the method(s) to restrict physical access; method(s) of the full-disk encryption solution along with the authentication protocol; method(s) of the multi-factor authentication solution; or documentation of other method(s) to mitigate the risk of unauthorized use.

Section 2.1: Examples of evidence for Section 2.1 may include, but are not limited to, documentation from change management systems, electronic mail or procedures that document a review of installed security patch(es); memoranda, electronic mail, policies or contracts from parties other than the Responsible Entity that identify the security patching process or vulnerability mitigation performed by the party other than the Responsible Entity; evidence from change management systems, electronic mail, system documentation or contracts that identifies acceptance by the Responsible Entity that the practices of the party other than the Responsible Entity are acceptable; or documentation of other method(s) to mitigate software vulnerabilities for Transient Cyber Asset(s) managed by a party other than the Responsible Entity. If a Transient Cyber Asset does not have the capability to use method(s) that mitigate the risk from unpatched software, evidence may include documentation by the Responsible Entity or the party other than the Responsible Entity that identifies that the Transient Cyber Asset does not have the capability.

Section 2.2: Examples of evidence for Section 2.2 may include, but are not limited to, documentation from change management systems, electronic mail or procedures that document a review of the installed antivirus update level; memoranda, electronic mail, system documentation, policies or contracts from the party other than the Responsible Entity that identify the antivirus update process, the use of application whitelisting, use of live of operating systems or system hardening performed by the party other than the Responsible Entity; evidence from change management systems, electronic mail or contracts that identifies the Responsible Entity's acceptance that the practices of the party other than the Responsible Entity are acceptable; or documentation of other method(s) to mitigate malicious code for Transient Cyber Asset(s) managed by a party other than the Responsible Entity. If a Transient Cyber Asset does not have the capability to use method(s) that mitigate the introduction of malicious code, evidence may include documentation by the Responsible Entity or the party other than the Responsible Entity that identifies that the Transient Cyber Asset does not have the capability.

Section 2.3: Examples of evidence for Section 2.3 may include, but are not limited to, documentation from change management systems, electronic mail, or contracts that identifies a review to determine whether additional mitigations are necessary and that they have been implemented prior to connecting the Transient Cyber Asset managed by a party other than the Responsible Entity.

Section 3.1: Examples of evidence for Section 3.1 may include, but are not limited to, documentation from asset management systems, human resource management systems, forms or spreadsheets that shows authorization of Removable Media. The documentation must identify Removable Media, individually or by group of Removable Media, along with the authorized users, either individually or by group or role, and the authorized locations, either individually or by group.

Section 3.2: Examples of evidence for Section 3.2 may include, but are not limited to, documented process(es) of the method(s) used to mitigate malicious code such as results of scan settings for Removable Media, or implementation of on-demand scanning. Documented process(es) for the method(s) used for mitigating the threat of detected malicious code on Removable Media, such as logs from the method(s) used to detect malicious code that show the results of scanning and that show mitigation of detected malicious code on Removable Media or documented confirmation by the entity that the Removable Media was deemed to be free of malicious code.

CIP Definitions

Project 2016-02 Modifications to CIP Standards
October 29, 2018, Informal Posting

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Table 1: Retired, Modified, or Newly Proposed Definitions

NERC Glossary Term	**Currently Approved Definition**	**CIP SDT Proposed New or Revised**
Cyber Asset (CA)	Programmable electronic devices, including the hardware, software, and data in those devices.	A p~~P~~rogrammable electronic device~~s~~, including the physical or virtual hardware, software, and data in th~~os~~e device~~s~~.
BES Cyber System (BCS)	One or more BES Cyber Assets logically grouped by a responsible entity to perform one or more reliability tasks for a functional entity.	Any combination of hardware (including virtual hardware), software (including application virtualization), and data, regardless of redundancy, performing one or more reliability tasks that if rendered unavailable, degraded, or misused would result in adverse impact to one or more BES Facilities within 15 minutes.

Table 1: Retired, Modified, or Newly Proposed Definitions		
NERC Glossary Term	**Currently Approved Definition**	**CIP SDT Proposed New or Revised**
BES Cyber Asset (BCA)	A Cyber Asset that if rendered unavailable, degraded, or misused would, within 15 minutes of its required operation, misoperation, or non-operation, adversely impact one or more Facilities, systems, or equipment, which, if destroyed, degraded, or otherwise rendered unavailable when needed, would affect the reliable operation of the Bulk Electric System. Redundancy of affected Facilities, systems, and equipment shall not be considered when determining adverse	Retired

Table 1: Retired, Modified, or Newly Proposed Definitions

NERC Glossary Term	Currently Approved Definition	CIP SDT Proposed New or Revised
Transient Cyber Asset (TCA)	A Cyber Asset that is: 1. capable of transmitting or transferring executable code, 2. not included in a BES Cyber System, 3. not a Protected Cyber Asset (PCA) associated with high or medium impact BES Cyber Systems, and 4. directly connected (e.g., using Ethernet, serial, Universal Serial Bus, or wireless including near field or Bluetooth communication) for 30 consecutive calendar days or less to a: • BES Cyber Asset, • network within an Electronic Security Perimeter (ESP) containing high or medium impact BES Cyber Systems, or • PCA associated with high or medium impact BES Cyber Systems. Examples of Transient Cyber Assets include, but are not limited to, Cyber Assets used for data transfer, vulnerability assessment, maintenance, or troubleshooting purposes.	A Cyber Asset that is: 1. capable of transmitting or transferring executable code, 2. not included in a BES Cyber System, 3. not a Protected Cyber ~~Asset~~ System (PCS~~A~~) associated with high or medium impact BES Cyber Systems, and 4. directly connected (e.g., using Ethernet, serial, Universal Serial Bus, or wireless including near field or Bluetooth communication) for 30 consecutive calendar days or less to a: • BES Cyber ~~Asset~~System (BCS), • ~~network within an~~ A BES Cyber System Logical Isolation Zone ~~Electronic Security Perimeter (ESP)~~ containing high or medium impact BES Cyber Systems, or • PCS~~A~~ associated with high or medium impact BES Cyber Systems. Examples of Transient Cyber Assets include, but are not limited to, Cyber Assets used for data transfer, vulnerability assessment, maintenance, or troubleshooting purposes.

Table 1: Retired, Modified, or Newly Proposed Definitions

NERC Glossary Term	Currently Approved Definition	CIP SDT Proposed New or Revised
Physical Access Control Systems (PACS)	Cyber Assets that control, alert, or log access to the Physical Security Perimeter(s), exclusive of locally mounted hardware or devices at the Physical Security Perimeter such as motion sensors, electronic lock control mechanisms, and badge readers.	Cyber systems ~~Assets~~ that control~~, alert, or log~~ access to the Physical Security Perimeter(s), exclusive of locally mounted hardware or devices at the Physical Security Perimeter such as motion sensors, electronic lock control mechanisms, and badge readers.
Physical Access Monitoring Systems (PAMS)	N/A	Cyber systems that alert or log access to the Physical Security Perimeter(s), exclusive of locally mounted hardware or devices at the Physical Security Perimeter such as motion sensors, electronic lock control mechanisms, and badge readers.
Protected Cyber Asset (PCA)	One or more Cyber Assets connected using a routable protocol within or on an Electronic Security Perimeter that is not part of the highest impact BES Cyber System within the same Electronic Security Perimeter. The impact rating of Protected Cyber Assets is equal to the highest rated BES Cyber System in the same ESP.	Retired
Protected Cyber System (PCS)	N/A	Cyber systems that are able to communicate with a BES Cyber System from within the BES Cyber System's Logical Isolation Zone. The impact rating of Protected Cyber Systems is equal to the highest rated BES Cyber System within the Logical Isolation Zone.

Table 1: Retired, Modified, or Newly Proposed Definitions

NERC Glossary Term	Currently Approved Definition	CIP SDT Proposed New or Revised
Electronic Access Point (EAP)	A Cyber Asset interface on an Electronic Security Perimeter that allows routable communication between Cyber Assets outside an Electronic Security Perimeter and Cyber Assets inside an Electronic Security Perimeter.	Retired
Electronic Access Control or Monitoring Systems (EACMS)	Cyber Assets that perform electronic access control or electronic access monitoring of the Electronic Security Perimeter(s) or BES Cyber Systems. This includes Intermediate Systems.	RETIRED – Proposed Develop EAMS and EACS
Electronic Access Control System (EACS)	N/A	Cyber systems that provide electronic access control to BES Cyber Systems.
Electronic Access Monitoring Systems (EAMS)	N/A	Cyber systems that provide electronic access monitoring of BES Cyber Systems.
Electronic Security Perimeter (ESP)	The logical border surrounding a network to which BES Cyber Systems are connected using a routable protocol.	Retired
External Routable Connectivity (ERC)	The ability to access a BES Cyber System from a Cyber Asset that is outside of its associated Electronic Security Perimeter via a bi-directional routable protocol connection.	The ability to access a BES Cyber System from a Cyber Asset that is outside of its associated Logical Isolation Zone via a bi-directional routable protocol connection.

Table 1: Retired, Modified, or Newly Proposed Definitions		
NERC Glossary Term	**Currently Approved Definition**	**CIP SDT Proposed New or Revised**
Logical Isolation Zone (LIZ)	N/A	A logical security zone created by applying controls to communications to or from BES Cyber Systems and Protected Cyber Systems.
Intermediate Systems (IS)	A Cyber Asset or collection of Cyber Assets performing access control to restrict Interactive Remote Access to only authorized users. The Intermediate System must not be located inside the Electronic Security Perimeter.	A system acting as part of the protection applied to a logically isolated BCS that limits external user-initiated access to authorized users.
Interactive Remote Access (IRA)	User-initiated access by a person employing a remote access client or other remote access technology using a routable protocol. Remote access originates from a Cyber Asset that is not an Intermediate System and not located within any of the Responsible Entity's Electronic Security Perimeter(s) or at a defined Electronic Access Point (EAP). Remote access may be initiated from: 1) Cyber Assets used or owned by the Responsible Entity, 2) Cyber Assets used or owned by employees, and 3) Cyber Assets used or owned by vendors, contractors, or consultants. Interactive remote access does not include system-to-system process communications.	User-initiated access by a person employing a remote access client to a BES Cyber System or Protected Cyber System from outside of a Logical Isolation Zone. Interactive Remote Access does not include system-to-system process communications or access initiated from an Intermediate System.

Table 1: Retired, Modified, or Newly Proposed Definitions

NERC Glossary Term	Currently Approved Definition	CIP SDT Proposed New or Revised
Physical Security Perimeter (PSP)	The physical border surrounding locations in which BES Cyber Assets, BES Cyber Systems, or Electronic Access Control or Monitoring Systems reside, and for which access is controlled.	The physical border surrounding locations in which~~,~~ ~~BES Cyber Assets,~~ BES Cyber Systems~~,~~ or Electronic Access Control ~~or Monitoring~~ Systems reside~~,~~ and for which access is controlled.
Removable Media	Storage media that (i) are not Cyber Assets, (ii) are capable of transferring executable code, (iii) can be used to store, copy, move, or access data, and (iv) are directly connected for 30 consecutive calendar days or less to a BES Cyber Asset, a network within an ESP, or a Protected Cyber Asset. Examples include, but are not limited to, floppy disks, compact disks, USB flash drives, external hard drives, and other flash memory cards/drives that contain nonvolatile memory.	Storage media that (i) are not Cyber Assets, (ii) are capable of transferring executable code, (iii) can be used to store, copy, move, or access data, and (iv) are directly connected for 30 consecutive calendar days or less to a BES Cyber ~~Asset~~System, ~~a network within an ESP,~~ or a Protected Cyber ~~Asset~~System. ~~Examples include, but are not limited to, floppy disks, compact disks, USB flash drives, external hard drives, and other flash memory cards/drives that contain nonvolatile memory.~~
Secure Configuration	N/A	The implemented set of controls supporting the security objectives found within the CIP Reliability Standards where the following text exists within the requirement language: “NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.”

Unofficial Comment Form

Project 2016-02 Modifications to CIP Standards | Virtualization

Do not use this form for submitting comments. Use the Standards Balloting and Commenting System to submit comments on the **Virtualization Updates for CIP-004, CIP-005, CIP-006, CIP-007, CIP-010, and Associated Definitions**. Comments must be submitted by **8 p.m. Eastern, Tuesday, December 18, 2018**

Additional information is available on the project page. If you have questions, contact Standards Developer Jordan Mallory (via email) or at (404) 446-2589.

Background Information

Project 2016-02 (1) addresses the Federal Energy Regulatory Commission (Commission) directives contained in Order No. 822 and (2) considers the Version 5 Transition Advisory Group (V5TAG) issues identified in the CIP V5 Issues for Standard Drafting Team Consideration (V5TAG Transfer Document).

The V5TAG, which consisted of representatives from NERC, Regional Entities and industry stakeholders, was formed to issue guidance regarding possible methods to achieve compliance with the CIP Version 5 standards and to support industry's implementation activities. During the V5TAG's activities, it identified certain issues with the CIP Reliability Standards that would be better addressed by a standard drafting team (SDT) for the CIP Reliability Standards. The V5TAG developed the CIP Version 5 Transition Advisory Group Issues for Consideration document to formally recommend that the SDT address these issues and consider modifications to the standard language during the standards development process. Among other issues, the V5TAG stated "The CIP Version 5 standards do not specifically address virtualization. However, because of the increasing use of virtualization in industrial control system environments, questions around treatment of virtualization within the CIP Standards are due for consideration. The SDT should consider revisions to CIP-005 and the definitions of Cyber Asset and Electronic Access Point that make clear the permitted architecture and address the security risks of network, server and storage virtualization technologies."

As the SDT investigated these issues, it found that virtualization affects most of the technical definitions used within CIP from the foundational "Cyber Asset" to the technical CIP standards (CIP-005, CIP-007, and CIP-010 in particular). This is due to virtualization changing fundamental assumptions, such as the standards having an "electronic device" basis and focusing on routable protocol level only, perimeter-based security. The SDT found virtualization to be not only a driver of change, but a symptom of a larger issue with the standard's ability to adapt to current and future technology innovation. The SDT concluded these more technical standards could benefit from removing inherent prescription of certain architectures and moving requirements to an objective or results-oriented level that do not make assumptions about architecture. In other words, the standards should not go further and prescribe how to secure today's newer architectures but should require that certain security objectives be met and "get out of the way" of virtualization and future innovations that can increase reliability, resiliency, and security of our BES Cyber Systems.

The SDT has been addressing these issues and is at a point where enough work has been accomplished to post the SDT's work in progress and get industry feedback on the direction. The SDT has progressed from a general direction of "cyber system orientation and objective-level requirements" to now having many of these concepts drafted into these standards. During this informal comment period, the SDT recognizes that this is a work in progress and is not ready for a formal posting and ballot and is seeking industry feedback on the direction and concepts of these definitions and requirements.

The remaining CIP standards are not directly affected by virtualization or technology changes and the SDT believes only conforming changes will be required in those standards. As part of our Standard Authorization Request, the SDT also addressed the addition of CIP Exceptional Circumstances allowances where needed. Therefore, the SDT is also posting CIP-004 and CIP-006 for three reasons:

- to show what the conforming changes from the SDT's virtualization work may look like;
- to begin to show how the EACMS split into EACS and EAMS would affect these standards;
- to show the new CIP Exceptional Circumstances additions within these standards.

Summary of Definition Changes

The following provides rationale and updates the associated definitions.

Term to be retired	Rationale for Retirement
BES Cyber Asset	This term is proposed for retirement and the foundational definition is established at the system level.
Electronic Access Control or Monitoring Systems	Term is proposed for retirement and split into two new proposed terms; Electronic Access Control Systems (EACS); and Electronic Access Monitoring Systems (EAMS).
Protected Cyber Asset	This term is proposed for retirement and the concepts of the term are incorporated into the proposed definition of Protected Cyber System (PCS). This change takes advantage of the more objective-based requirements at the system level.
Electronic Access Point	With the proposed retirement of CIP-005-6 Part 1.2 this definition is no longer required. The isolation concepts in proposed requirement Part 1.1 address the necessary controls previously defined in the concept of an identified Electronic Access Point.
Electronic Security Perimeter	This term is proposed for retirement. The concepts of the ESP have been incorporated into the definition of a Logical Isolation Zone (LIZ)

The CIP SDT Proposed new or revised definitions to incorporate virtualization and future technology. The bullet points below provide rationale for a number of the definitions. Please see the CIP Definitions document for all new and revised definitions.

- **Cyber Asset –** The SDT is proposing to retain the Cyber Asset definition with updates to incorporate virtual hardware. With the proposed updates, it is only used in places where it did not make sense to upgrade the term to cyber system. Cyber Asset can be located in the TCA and Removable Media definitions and in a small number of locations in the CIP-010 standard. The goal is to limit the use of 'Cyber Asset' to areas where the upgraded term 'Cyber System does not apply.
- **BES Cyber System –** This term was updated to accommodate the cyber system concept. The hardware portions of the new definition were incorporated from the Cyber Asset definition and qualifying language (15 mins, etc.) included from the BES Cyber Asset definition. The term no longer relies on the word "programmable" and uses new language to classify devices.
- **EACMS to EACS and EAMS –** To support wider correlation of events and data sharing with government agencies and other security vendors to more quickly detect cyber-attacks, the SDT is proposing to split off cyber systems that do electronic access monitoring but perform no electronic access control. The new terms, EACS and EAMS will allow changes within the applicability for the monitoring portion to allow third party monitoring systems. This allows adjustments to the applicability of requirements that are appropriate to the different risks associated with EACS and EAMS.
- **Physical Access Control System (PACS) –** During the process of evaluating the split in applicability for EACMS the SDT determined that the PACS definition would need the same considerations to ensure consistency for monitoring systems. The alerting and logging definition parts were removed from the definition and moved to a new proposed term, Physical Access Monitoring Systems (PAMS). The SDT is seeking input from industry on whether or not having PACS and PAMS as two separate definitions is a positive path for the future.
- **Logical Isolation Zone (LIZ) –** The SDT is proposing this new term which transitions to a new zone-based protection model to control communications to and from BES Cyber Systems and Protected Cyber Systems taking advantage of advances in cyber security. The SDT intends for this concept to be backwards compatible with the ESP while also being non-prescriptive to the communications protocol and layer of the Open Systems Interconnection (OSI) model in which they are implemented.
- **Physical Security Perimeter (PSP) –** In concert with the changes to EACMS and PACS, the SDT is proposing the removal of the requirement for monitoring systems to be kept inside of a PSP. This change would allow flexibility for security monitoring services to be outsourced where these types of controls are currently not available.

Summary of CIP-005 Changes

For a detailed explanation of these changes, please refer to the *CIP-005 Technical Rationale* document.

- **ESP transition to Logical Isolation Zone –** To accommodate advances in network security that go beyond routable protocol address filtering at perimeters, the SDT is proposing a transition to the zone concept while retaining backward compatibility with ESPs.

- **Super ESP, 4.2.3.2 and 4.2.3.3 Exemptions, and R1.2 –** As it addresses virtualization, the SDT is concurrently addressing the V5TAG issue known as the "Super ESP," where BES Cyber Systems may be split across different geographic locations within a single ESP.
- **Management Plane isolation –** Virtualization allows BES cyber systems with a 15 minute impact to share infrastructure with systems that do not share that time constraint (e.g., a control system and its historian). The SDT has added a new requirement (R3) to bring the management plane and its isolation controls into scope of the CIP standards.

Summary of CIP-007 Changes

For a detailed explanation of these changes, please refer to the *CIP-007 Technical Rationale* document.

- Made conforming changes to applicable systems column: (PCS, EACS, etc.)
- Made conforming changes to ensure the requirements are at the system level (per system capability, remove references to Cyber Asset, etc.)
- Added security objectives to the "Big R" main requirements. Example: Each Responsible Entity shall implement one or more documented process(es) *to mitigate the risk posed by uncontrolled logical and physical connectivity* that collectively include each of the applicable requirement parts in…"
- Modified R1.1 (ports/services) to be more objective oriented. Permits use of east/west IDS, baselining logical connectivity, etc. in addition to documenting required network accessible ports.
- Introduced new requirement for installing only essential software and executable scripts on high and medium impact BES Cyber Systems, EACS, PACS, and PCAs.
- Moved CIP-007 R2 patching requirement to CIP-010 vulnerability management program requirement
- Added CIP Exceptional Circumstances language to apply to all of Requirement 4 (Security Event Monitoring)

Summary of CIP-010 Changes

For a detailed explanation of these changes, please refer to the *CIP-010 Technical Rationale* document.

- Made conforming changes to applicable systems column (PCS, EACS, etc.)
- Made conforming changes to ensure the requirements are at the system level (per system capability, remove references to Cyber Asset, etc.)
- Added security objectives to the "Big R" main requirements. Example: Each Responsible Entity shall implement one or more documented process(es) *to mitigate the risk posed by insecure system configuration* that collectively include each of the applicable requirement parts in…"
- Removed the requirement to develop a baseline configuration
- Introduced the concept of a secure configuration. This new concept requires the collective identification of the methods used to comply with the security requirements in CIP-005 R1, CIP-007 R1, R2, R3, R4, R5, and CIP-010 R3.
- Replaced prescriptive timeframes with a risk based evaluation for entity determined timeframes.

- Added specification to the configuration monitoring requirement for hash monitoring, configuration monitoring, or configuration auditing.
- Split obligation to investigate detected unauthorized changes to its own requirement part. Added obligation to remediate detected unauthorized changes.
- Moved patch management requirement from CIP-007 to the CIP-010 Vulnerability Management program. Rephrased requirement in terms of identifying and mitigating software vulnerabilities. Added risk-based entity defined timeframes for implementation.
- Added CIP Exceptional Circumstances to apply to testing of changes prior to implementation

Questions

1. The proposed BCS definition no longer relies on the term Cyber Asset. The SDT asserts that the proposed BES Cyber System definition describes the BCS adequately without the use of the word "programmable" in the definition. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

   ☐ Yes

   ☐ No

   Comments:

2. The SDT asserts that the proposed Cyber Asset definition provides clarity around virtual hardware. (Cyber Assets revised definition: Programmable electronic devices, including the physical or virtual hardware, software, and data in those devices.) Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

   ☐ Yes

   ☐ No

   Comments:

3. The SDT asserts that the term Cyber Asset should continue to be used within the NERC Glossary of Terms for: Removable Media and Transient Cyber Asset. Due to the nature of that type of hardware, these devices do not lend themselves to the systems approach. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

   ☐ Yes

   ☐ No

   Comments:

4. The SDT is proposing to retire EACMS and develop two new terms: EACS and EAMS. These terms will allow changes within the applicability for the monitoring portion to allow third party monitoring systems. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

☐ Yes

☐ No

Comments:

5. The SDT realized through the process of splitting EACMS that the same considerations apply to PACS, which will allow changes within the applicability for alerting and logging (PAMS is not reflected within the applicability section at this time). The SDT is considering splitting the PACS term into PACS and PAMS to allow third party monitoring or event correlation to be performed without carrying the PACS classification. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

   ☐ Yes

   ☐ No

   Comments:

6. The SDT is proposing to move away from the more prescriptive ESP/EAP model to logical isolation through the higher level objectives provided by the BES Cyber System concept and its Logical Isolation Zone. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

   ☐ Yes

   ☐ No

   Comments:

7. The SDT is considering taking qualitative language out of the Intermediate System definition and using it to clarify requirements. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

   ☐ Yes

   ☐ No

   Comments:

8. The SDT is considering changes to the ERC and IRA definitions to address V5TAG issues (see the CIP-005 Technical Rationale document for detailed information). ERC will have conforming changes only and will continue its use as a scoping mechanism. The proposed modifications to IRA will apply to certain non-routable to routable protocol conversion scenarios. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

   ☐ Yes

   ☐ No

   Comments:

9. To the extent possible, the SDT intends its modifications to permit approaches to compliance that are “backwards compatible” with compliance approaches within the currently approved versions of the CIP standards. (Notable exceptions include CIP-005 R3, CIP-007 R2, and Secure Configurations –

CIP-010). Do you agree the modifications are backwards compatible? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

☐ Yes

☐ No

Comments:

10. The SDT has not yet determined a proposed timeframe to include in the Implementation Plan. How long would you as an entity need to implement the proposed modifications? Please provide your implementation timeframe and justification for why that amount of time would be needed.

Comments:

11. The SDT is proposing conforming modifications to CIP-004. Do you agree with these changes? Please provide comments to support your response. In particular, the SDT seeks stakeholder feedback on:

    a. Modifications related to CIP Exceptional Circumstances

    b. Use of newly proposed terms EACS and EAMS in the Applicable Systems column

    c. Addition of PCS to the Applicable System column for Parts in CIP-004 to mitigate security risks associated with individuals not needing authorization or PRAs when granted access to systems inside the Logical Isolation Zone

☐ Yes

☐ No

Comments:

12. The SDT is proposing modifications to CIP-005 (see the CIP-005 Technical Rationale document for detailed information). Do you agree with these changes? Please provide comments to support your response. In particular, the SDT seeks stakeholder feedback on:

    a. The replacement of the ESP concept with Logical Isolation Zone (LIZ).

    b. Is the backward compatibility clear as existing ESPs and EAPs move to the new LIZ concept?

    c. The addition of the 4.2.3.3 exemption in the standard along with the addition of Requirement part R1.2 to address the V5TAG concern of “Super ESPs” or single networks within or between BES Cyber Systems that span more than one geographic location.

    d. As differing forms of shared infrastructure come into play with virtualization, Requirement R3 has been added to include the management plane and its isolation controls as a part of the CIP standards. Is this concept clearly and widely understood?

☐ Yes

☐ No

Comments:

13. The SDT is proposing conforming modifications to CIP-006. Do you agree with these changes? Please provide comments to support your response. In particular, the SDT seeks stakeholder feedback on:
    a. Modifications related to CIP Exceptional Circumstances
    b. Use of newly proposed term EACS in the Applicable Systems column

    ☐ Yes

    ☐ No

    Comments:

14. The SDT is proposing modifications to CIP-007 (see the CIP-007 Technical Rationale document for detailed information.). Do you agree with these changes? Please provide comments to support your response. In particular, the SDT seeks stakeholder feedback on:
    a. The SDT is proposing adding the security objectives throughout the Requirements in CIP-007. Do you agree that the proposed security objectives add clarity to the reason the requirement exists?
    b. The SDT is proposing the security objective in CIP-007 R1, "to mitigate the risk posed by uncontrolled logical and physical connectivity". Do you agree that the modifications to CIP-007 R1 Part 1.1 fulfill this security objective for systems where connectivity is not limited to TCP/IP port service combinations, as in virtualized systems and SAN based storage?
    c. Do you agree that the modifications to CIP-007 R1 Part 1.1 add necessary flexibility to fulfill the security objective of CIP-007 R1 for virtualized systems and provides a degree of future proofing?

    ☐ Yes

    ☐ No

    Comments:

15. The SDT is proposing modifications to CIP-010 (see the CIP-010 Technical Rationale document for detailed information.). Do you agree with these changes? Please provide comments to support your response. In particular, the SDT seeks stakeholder feedback on:
    a. The SDT is proposing adding the security objectives throughout the Requirements in CIP-010. Do you agree that the proposed security objectives add clarity to the reason the requirement exists?
    b. The SDT is proposing to modify the referenced baseline configuration from CIP-010-3 R1 Part 1.1 to a 'Secure Configuration' which is made up of the implemented controls that fulfill requirements within CIP-005 and CIP-007. Do you agree that this set of controls supports managing change under CIP-010 R1 Part 1.1?
    c. The SDT is proposing to modify the current CIP-007 R2 requirements and move them to CIP-010 R3. The SDT believes that the software vulnerability management found within this set of requirements fits logically within the security objective of CIP-010 R3 "to mitigate the risk posed by system vulnerabilities" and has moved it there. Do you agree?

d. The SDT is proposing CIP-010 R3 Parts 3.5 and 3.6 to replace the current CIP-007 R2 Parts 2.1 – 2.4. Do you agree that the proposed CIP-010 R3 Parts 3.5 and 3.6 offer the additional flexibility needed when implementing virtualized systems that can be dormant for a period, and for which security patches have become available?

☐ Yes

☐ No

Comments:

16. Provide any additional comments for the SDT to consider, if desired.

Introduction

This document explains the technical rationale and justification for the proposed Reliability Standard CIP-005-7. The Standard Drafting Team (SDT) is proposing changes to CIP-005-6 as it updates the standards based on technology innovation and changes such as the increasing use of virtualization.

CIP-005 - From ESP's to "Logical Isolation" – The Case for Change

In previous versions of the CIP standards, CIP-005 required declarations of Electronic Security Perimeters (ESP) based on OSI layer 3 routable protocols. All BES Cyber Assets (BCA) that were connected to a network with routable protocols had to reside inside a declared ESP. Any External Routable Connectivity (ERC) to the BES Cyber Assets inside the ESP had to enter and exit via an Electronic Access Point (EAP). This limited the traffic entering or leaving the ESP to only that which was needed. It denied all other traffic by default.

This "castle and moat with drawbridge" protection, where the castle is the BES Cyber Systems (BCS), the moat is the ESP, and the drawbridge is the EAP, has been in place for many years. For a number of situations, it still offers sufficient protection. This protection configuration, however, drives certain network architecture decisions that may hinder the adoption of newer and in some cases more secure designs. Network access control is expanding beyond perimeter-based security at routable protocol address levels into other levels, with security present within the network fabric itself. The entire network is becoming "the firewall." As infrastructure components become smarter, entities can describe network policy at layers other than that of a routable protocol address, and the infrastructure itself can enforce these access policies at multiple levels.

The nature of virtualization is driving much of this as workloads are dynamically created, moved, and destroyed to meet changing demand. With virtualization, what resides in an ESP might be very dynamic, and rulesets in any EAPs will need to be dynamic as well. This is driving solutions more towards policy-based user access controls for workloads that the infrastructure then dynamically applies within the environment. EAPs themselves are also dynamic, and as network access controls become embedded into the infrastructure, we may go from a few designated EAPs to thousands of dynamic locations where access controls are enforced.

This is the reason the CIP standards are changing from "perimeters" to "zones" and why the ESP has been replaced with the Logical Isolation Zone (LIZ). A perimeter typically implies an outer boundary; something you can draw a rectangle around on a network diagram. As network security becomes more integrated into the network fabric, or is virtualized and dynamic, it is no longer a perimeter that you can draw a box around. This is driving us to employ the zone construct for the future. An ESP is one form of logical isolation zone making it backward compatible, but a logical isolation zone can be broader than the layer 3, routable protocol subnet.

As firewalls continue to evolve, IP addresses and port numbers, which are simply protocol data, will become less common methods of identifying and filtering communications. What needs to be secured are the processes behind those layer 3 network addresses and the actual communications they are processing. IP addresses and ports have traditionally been filtered at the network layer to ensure communications include only what is needed. As technology continues to evolve, more secure future architectures may not be based on routable protocol addressing schemes.

Logical Isolation – What Does It Mean?

ESPs deal only with layer 3 routable protocol addressing. Virtualization and its accompanying shared infrastructure has other characteristics such as shared computing hosts, shared storage, shared virtual networks and switches, all of which posing new security concerns. To adapt to these changes, CIP-005 includes a requirement that high and medium impact BES Cyber Systems be “logically isolated” from all other systems (regardless of protocol) to replace the routable protocol-based ESP requirement.

If a BCS is executing on a virtual host along with another related virtual machine that may not have a 15-minute impact, (e.g. a control system and its data historian), the entity must either consider all these workloads as part of a single system or declare the system with the 15-minute impact as a BCS and the historian as a separate system. If the latter is chosen, the entity will need to prove that the two systems are logically isolated and that every communication between the two is limited to only what is necessary.

Logical isolation is also relevant to other layers of a computing stack. Imagine in a virtualized data center where you are looking at a BES Cyber System architecture “from the side”. You can see the different layers of the system, from the storage on a Storage Area Network (SAN) through the virtual networks, switches, and firewalls at the virtual network layer, up to the virtual hosts that are executing the application workloads. If you rotate the view until you are looking down at the system from above, you should be able to see the touch points of all these layers to other systems. Logical isolation refers to this top-down view. An entity needs to be able to show that only necessary data flows are allowed through any of these layers that have an interface to another system. For example, at a storage layer, BCS systems should have their storage logically isolated from other systems that are not part of the BCS. At a networking layer, there should be no communications channels that allow the BCS to talk to any other system that is not controlled. At a virtual machine level, there should be logical isolation between VMs. As you “look down” through the computing stack, you should only see interface points that are controlled and locked down to a least-privilege position.

Logical isolation does not mean complete isolation. It means that only known, controlled communications can occur between a system and anything outside of its Logical Isolation Zone, and that all other communication is blocked. Serial communications such as RS-232 or RS-485 are logically isolated communications methods as well. These types of communications move data from the TX pin on one end of a cable to the RX pin on the other end of the cable. There is no addressing scheme or routing/firewall capability, so it meets the intent of logical isolation.

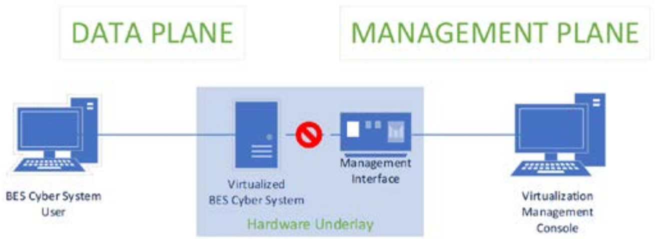
Management and Data Planes and CIP-005 R3

As the SDT considered virtualization, it identified a risk though not unique to virtualized infrastructures, is amplified by it. As virtualized servers, networks, switches, firewalls, and storage are logical constructs, controlling access and communications to the management plane of these systems becomes imperative. Access to the management plane (interface/console/etc.) allows a user to create, modify, or delete these objects or entire infrastructures from one place, or move objects from one zone or network to another. Administrative level or “management plane” access to the hypervisors is therefore absolutely critical to the security and reliability of the hosted systems and must be brought into the scope of CIP standards if hosting BES Cyber Systems.

Another example from a networking perspective is virtual LANs (VLANs) which are a method of logical isolation that can be used to meet CIP-005 R1. However, such logical isolation is critically dependent upon proper configuration of the isolation and management of access to those logical controls within the management plane of the switch or other network device. CIP-005 R3 brings that management plane of the switch into scope of the CIP standards, requiring that entities restrict access to the management functionality of these systems and isolate that access from the data plane (the normal, operational, non-administrative access).

Examples of this separation of the management plane and data plane can be accomplished in several different ways:

- A hypervisor can put its management interface IP address on a physical port or in a logical interface connected to a VLAN that is trunked to an upstream switch.
- Many hardware vendors include "integrated lights-out" or dedicated management interfaces that allow you to power on/off a cyber system.
- Physically isolated out-of-band network for management interfaces.
- Logically isolated out-of-band network (where logical constructs like VLAN, VXLAN, MPLS, VRF's (logical routers) are used to maintain logical isolation)



"Super-ESPs", CIP-005 R1.2, and the 4.2.3.3 Exemption

One of the issues with the ESP construct carried forward into the logical isolation model is the situation where entities have BES Cyber Systems that include components at separate locations. For example, if an entity has a need to replicate data at high speed between two databases in two different geographic locations to improve the resilience and reliability of BES Cyber Systems, the entity may have issues with the 4.2.3.2 exclusion in the standards that exempts the network and communications gear that is "between discrete ESPs." If this replication protocol is not a routable protocol, then no ESP can be created. The entity needs to be able to have a "Super-ESP" that can span more than one location.

The ESP model, along with the 4.2.3.2 exclusion within the CIP standards applicability does not lend itself to this construct. As technology evolves, there will be many more instances where a BES Cyber System may need to span locations. Another example could be the protection of a Transmission line consisting of digital devices at each end of the line with an IEC 61850 high speed network between them. This type of system, even with its components located in two geographically separate substations, can be shown to be logically isolated from other systems. The issue is that the 4.2.3.2 exclusion for limiting the scope of the involved communications gear between the sites does not apply. It is no longer "between" two ESP's or two logical isolation zones but is now completely "inside" a single BES Cyber System or a single logical isolation zone. Traditionally this situation could be addressed by installing an EAP at each site as an ESP boundary that would then allow the communications equipment between the sites to be subject to the exemption. There are issues however, such as:

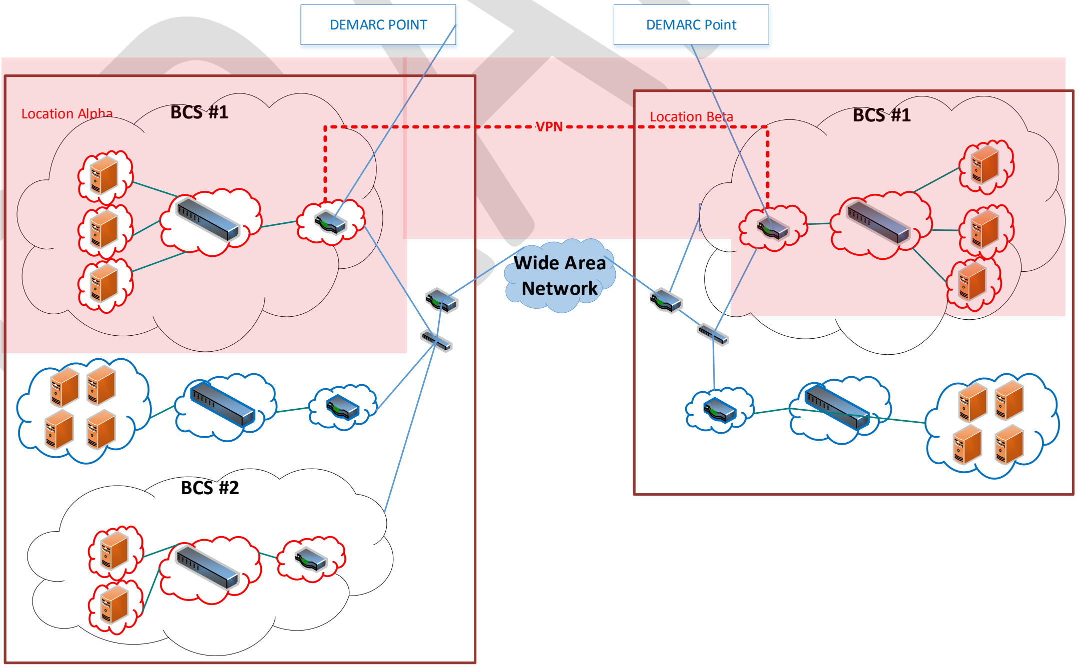
- Installing a firewall at each end of an essentially point to point circuit with rules allowing devices at either end to talk to the other adds complexity, single points of failure, and provides little security benefit.
- Some of these scenarios are extremely time sensitive and the devices need to communicate at very high speed to perform their asset protection function. Going through layers of security could cause latency and reliability issues that could hamper the asset protection function of the system.

This ‘Super ESP’ construct has been addressed with a new exclusion and a new requirement part in CIP-005 R1. The new exclusion in 4.2.3.3 allows communication networks and data communication links used by an isolated BES Cyber System that spans more than one geographic location to be exempt from the standards. The new R1.2 in CIP-005 pairs with this exemption and requires that the data over this exempted communication be protected to preserve its integrity and confidentiality, with the exception in R1.2 for those time sensitive protection functions.

“SUPER-ESP” EXCLUSION

Entity has 2 BCS with “BCS 1” having components in two locations. A VPN has been established between the components of BCS 1 at each location to logically isolate that BCS across the locations. Further logical isolation occurs at other touch points to other networks or out of scope systems. The entity chooses an appropriate demarcation point at each location and the networks between those points are excluded unless CIP-012 is applicable.

(NOTE: Red Cloud icons only denote some form of logical isolation for the BCS, Blue Cloud icons denote some form of logical isolation for the non-BCS)



External Routable Connectivity and Interactive Remote Access

External Routable Connectivity (ERC) is used in the CIP standards for different purposes, including:

1. Establishing when EAPs are required
2. Limiting scope of ~38 requirement parts to those locations that have a high enough level of remote connectivity to support the requirement

The move to the more objective-based logical isolation concept shifts the requirement to an obligation that shows the system is logically isolated with controlled communications at any interface point or shared infrastructure. This can be accomplished without dictating any architecture or access control method. ERC is still needed as a scoping mechanism due to the vast scale of systems and their components within a geographically distributed BES. Many requirement parts should be scoped based on whether the system has ERC for the following reasons:

- The risk is increased for systems with ERC. The requirement should apply to those systems with an increased attack surface and risk due to their connectivity/accessibility.
- Locations that have legacy connectivity such as non-routable serial leased circuits should not have to increase their level of remote connectivity and attack surface to meet security requirements. For example, it would not be advisable to put in an IP network into a site to get SNMP traps out for alerts if a serial circuit with reduced attack surface is all that is needed for operations.

One issue with the ERC definition from the V5TAG transfer document has been that of BES Cyber Assets (BCA) that only speak non-routable protocols over a serial port. These BCAs are not in an ESP and therefore can be considered to not have ERC because it is defined in terms of an "associated ESP." These BCAs, however, can have Interactive Remote Access through an upstream serial-to-IP conversion. The SDT has kept ERC as-is with only conforming changes in order to not disrupt its scoping function as noted above. However, the IRA definition has been modified so that a device with only a serial, non-routable connection could now have IRA and be subject to CIP-005 R2. Appropriate controls (CIP-005 R2) are now required for these Interactive Remote Access sessions without regard to ERC.

The following diagrams show different scenarios and whether ERC and/or IRA exist in the situation.

EACMS Changes to EACS and EAMS

As technologies and attacks have advanced and become more complex, entities are becoming more interested in partnering with outside and government security services. These includes services like NERC's Cyber Security Risk Information Sharing Program (CRISP), Cybersecurity for the Operational Technology (OT) Environment (CYOTE), and those of other external security services and internal monitoring centers. Going forward, these types of service and providers will become more cloud based. Security service providers have visibility into emerging threats and trends that come through their extensive collections of information. Analysis of this information can then be shared more broadly, improving the overall cybersecurity posture and reliability of the BES through early detection of compromise and the ability to monitor for threats and indicators of compromise (IOCs) at machine speeds.

Under the current body of CIP Standards, using the types of services that include electronic access monitoring data (not involved in the actual control of electronic access) may bring all Cyber Assets involved into scope as an EACMS. This may discourage or even preclude entities from using these services based on the cyber asset level requirements of an EACMS. These limitations affect personnel, physical security, patching, baselines, and other requirements that focus on a Cyber Asset. Entities may also be discouraged from providing and correlating security events across enterprise and control networks, even though most cyber-attacks against control systems today enter through business networks. There is great value in correlating security events seen across enterprise and OT networks that may be discouraged or precluded through the "M" in EACMS growing to include much an enterprise's other monitoring only Cyber Assets.

The cyber systems that do perform electronic access control will remain as they are today in the standards. Those cyber systems, such as firewalls and routers with ACLs and other systems that do perform access control and actively protect the networks to which BES Cyber Systems are connected should not change. However, the monitoring and logging aspect of EACMS presents a different though lesser risk. The creation of two different defined terms recognizes this. EACS represents those systems that do control electronic access and will essentially be a drop-in replacement for today's EACMS.

CIP-007-7 Technical Rationale

Project 2016-02: Modifications to CIP Standards

CIP-007-7 R1

The original technical rationale for CIP-007-6 Requirement R1 described the existence of Requirement R1 as being needed "…to reduce the attack surface of Cyber Assets by requiring entities to disable known unnecessary ports." The reasoning remains the same for Requirement R1 with the new objective language "to mitigate the risk posed by uncontrolled logical and physical connectivity." The changes in Requirement R1 language continue the move from Cyber Asset up to the BES Cyber System and supports the secure configuration implemented within CIP-010-3 Requirement R1.

CIP-007 Requirement R1 is intended to limit the ability of an attacker to move laterally throughout the secure environment.

CIP-007 R1 Part 1.1

The move to logical connectivity supports the proliferation of additional connectivity options found in modern technology stacks such as virtualization. With SAN connectivity over Fiber Channel delivering storage to virtualized systems without the use of IP or a "network," the limitation of network based controls becomes more clear. Additionally, the connectivity of a local hypervisor based configuration manager to the VM likewise does not go through a "network accessible port" in the strict sense.

By moving the control to "logical connectivity" the requirement can be applied in both the original "logical network accessible port" model as well as in the virtualized system to apply access controls to the network and storage "fabric" and hypervisor supporting a virtualized BES Cyber System.

CIP-007-7 R2

The original technical rationale for CIP-007-6 Requirement R2 included the intent "to require entities to know, track, and mitigate the known software vulnerabilities associated with their BES Cyber Assets." This intent was determined to logically fit within the intent of CIP-010-2 R3 associated with vulnerability assessment and management. Accordingly, the SDT moved the related requirements from CIP-007-6 Requirement R2, with modifications supporting virtualization, to CIP-010-4 Requirement R3 Parts 3.5 and 3.6.

The SDT is including a replacement requirement related to controlling software that is allowed to execute on applicable BES Cyber Systems with the inclusion of the objective "to mitigate the risk posed by unmanaged software". This clarifies one of the implied requirements of the original CIP-007-6 Requirement R2 for a list of software, and supports the secure configuration implemented within CIP-010-4 Requirement R1.

CIP-007 R2 Part 2.1

The inclusion of the objective in Requirement R2 Part 2.1, “to allow only essential software execution” further clarifies the intent of CIP-007 Requirement R2 to limit what software can execute on a system. This requirement helps ensure that entities control software execution, which limits the attack vectors, and limits the scope of required software vulnerability management efforts in CIP-010-3 R3 Parts 3.5 & 3.6.

NERC
NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

CIP-010-4 Technical Rationale

Project 2016-02

Requirement R1

The SDT proposes to retire the CIP-010 R1, Part 1.1 baseline configuration requirement and introduce a new related definition describing a Secure Configuration. This Secure Configuration consists of the security control methods implemented to comply with other requirement parts contained in CIP-005, CIP-007, and CIP-010. To avoid creating a long list of requirements in either the definition or in CIP-010 R1 itself, it states within each pertinent requirement part that it is part of the Secure Configuration. This was done by including the statement "The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system."

One reason for retiring the baseline configuration is that while the baseline requirement is applicable to BES Cyber Systems, its implementation tended to drive Responsible Entities into creating a 1-to-1 relationship between BES Cyber Assets and BES Cyber Systems. This was partially due to uncertainty in how to document a baseline where multiple disparate BES Cyber Assets were included in a single BES Cyber System. The question was how to reference multiple Operating Systems on a single BES Cyber System. On a list of installed software, what indicates that the software may be installed only on a single virtual machine or that there may be multiple copies of it across multiple virtual machines? These challenges didn't exist in a 1 to 1 BCA-BCS relationship. That relationship effectively limited the adoption of the system approach and ignored a fundamental aspect in the application of virtualization and emerging technologies to the CIP standards.

The existing baseline configuration serves as a list creating a requirement for implementing change control processes for these configuration items. The proposed Secure Configuration definition then ensures that this scoping for the change control process includes required security controls implemented to protect the BES Cyber System. This is an expansion over the scope of items that must go through change control under the existing CIP standards. The rationale for expanding the scope comes from risks associated with virtualization and emerging technologies. Specifically in virtualization, a few clicks can dramatically change your system architecture and the resources on which your applications are executing. Given this unique risk, change control for security settings was an essential element for mitigation. While this risk is greater for virtualized systems, the risk of inadvertently modifying security controls also exists in physical and traditional systems. For these reasons, this expanded scope should apply to all Medium and High Impact BES Cyber Systems.

Moving the baseline configuration from a requirement to a Secure Configuration definition should reduce the administrative overhead required to comply with CIP-010. Along with creating the Secure Configuration definition and removing the requirement to maintain a list of baseline configurations for all BES Cyber Systems, there is a new proposed requirement in CIP-007 (specifically the new CIP-007 R2) and modifications to CIP-007 R1. By creating related controls and removing list-making requirements, these changes collectively provide an increase in security and reduce the CIP standards' administrative overhead.

Only conforming changes based on newly modified definitions and the new Secure Configuration concept were made to the remaining requirement parts in CIP-010 R1.

Requirement R2

There are only minor adjustments to Requirement R2. The primary modification was to split the requirement into two parts based on the 'monitor' and 'investigate' obligations that were specified in Requirement R2. Changes to the structure of the requirement part added some examples of how to perform configuration monitoring. Input from regulatory staff indicated that they had observed some Responsible Entities implementing configuration monitoring, but not in an effective manner. The examples provide additional context on how to effectively meet the security objective of this requirement part.

Requirement R3

The primary change made to R3 was the addition of the vulnerability management (formerly patch management) requirement that was previously located in CIP-007 R2. The relocation of the requirement better acknowledges that patching is one component of an overall vulnerability management program that includes ongoing analysis, mitigation, and periodic vulnerability assessments. It is generally recognized that the existing patch management requirement is very prescriptive. As part of this prescriptiveness, the assessment of risk, a fundamental element of vulnerability management, was left out entirely – all vulnerabilities were treated exactly the same. In a virtualization context, a risk-based view of vulnerability management becomes even more important. It is essential that the requirements provide enough flexibility to recognize that some patches are critical and must be dealt with urgently while others could reasonably wait for implementation or may be better mitigated through other means.

Entity Identified Timeframes

Modifications to CIP-010 propose a new concept regarding the timeframes that currently prescribe actions required at least every 35 days or similar. These prescriptive requirements, while useful reference points for completing certain tasks, may also have a number of unintended consequences. Primarily, these prescriptive timelines discourage any risk analysis to determine when activities should be completed. In certain instances, the risk is so great that 35 days may be too long. In others, 35 days is much too short. A prescriptive 35-day requirement prevents Responsible Entities from allocating their resources to address the highest risks first. Consider the patching requirement. Responsible Entities are currently required to identify and evaluate security patches at least every 35 days. Some equipment has never had an applicable security patch released, while some software may regularly have patches released monthly or more frequently. The criticality of the patch is also not considered in today's requirements. Current requirements prescribe that we treat all of those examples the same. This is an increasingly important topic in the context of virtualization. In virtualization, a single vulnerability in the underlying infrastructure may impact all of your systems. This could be through a single patch causing all of your systems to fail, or a single vulnerability that could create security risk across all of your systems.

In either case, virtualization requires extra care from both security and functional perspectives.

Responsible Entities need greater flexibility regarding timelines for when activities are performed. In particular, additional risk analysis is needed when determining how to proceed. CIP-010 permits Responsible Entities to perform a risk analysis to determine the most appropriate timeframe for their unique environment. There are several forms of this language in CIP-010 depending on the objective of the requirement and the analysis that needs to take place. Some examples include:

> *From Part 1.1:* "The process requirements of Parts 1.1.1 through 1.1.4 and timeline are based on the analysis of the risk to BES reliability and the risk posed by the change to the system(s)."
>
> *From Part 2.1:* "The process requirements of Part 2.1 and timeline are based on the analysis of the risk to BES reliability and the impact rating of the applicable system(s)."
>
> *From Part 3.6:* "The plan for Part 3.6 must include the timeline for mitigating the software vulnerability based on the analysis of the risk posed by the software vulnerability to the applicable systems."

Each example specifies what the risk analysis needs to include. For example, in Part 3.6, it is important to evaluate the risk of the specific vulnerability when determining how quickly it needs to be mitigated. In Part 1.1, timelines should be based on the risk posed by the change itself.

These changes are not entirely backwards compatible. This flexibility, however, should increase security by shifting the focus to risk-based vulnerability management and should reduce administrative compliance violations when the risk of taking an action does not change from day 35 to day 36.

Standards Announcement

2016-02 Modifications to CIP Standards Virtualization

Informal Comment Period Open through December 18, 2018

Now Available

An informal comment period for **Virtualization Updates for CIP-004, CIP-005, CIP-006, CIP-007, CIP-010, and Associated Definitions** is open through **8 p.m. Eastern, Tuesday, December 18, 2018**.

Commenting

Use the Standards Balloting and Commenting System (SBS) to submit comments. If you experience Issues using the SBS, contact Wendy Muller. An unofficial Word version of the comment form is posted on the project page.

- *If you are having difficulty accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out, contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern).*
- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*
- *Please be mindful of ballot and comment period closing dates. We ask to **allow at least 48 hours** for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts **prior to the last day** of a comment/ballot period.*

Next Steps

The drafting team will review all responses received and determine the next steps of the project.

For more information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Standards Developer, Jordan Mallory (via email) or at 404-446-2589.

Comment Report

Project Name:	2016-02 Modifications to CIP Standards | Virtualization Updates for CIP-004, CIP-005, CIP-006, CIP-007, CIP-010, and Associated Definitions
Comment Period Start Date:	11/2/2018
Comment Period End Date:	12/18/2018
Associated Ballots:	

There were 76 sets of responses, including comments from approximately 199 different people from approximately 132 companies representing 10 of the Industry Segments as shown in the table on the following pages.

Questions

1. The proposed BCS definition no longer relies on the term Cyber Asset. The SDT asserts that the proposed BES Cyber System definition describes the BCS adequately without the use of the word “programmable” in the definition. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

2. The SDT asserts that the proposed Cyber Asset definition provides clarity around virtual hardware. (Cyber Assets revised definition: Programmable electronic devices, including the physical or virtual hardware, software, and data in those devices.) Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

3. The SDT asserts that the term Cyber Asset should continue to be used within the NERC Glossary of Terms for: Removable Media and Transient Cyber Asset. Due to the nature of that type of hardware, these devices do not lend themselves to the systems approach. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

4. The SDT is proposing to retire EACMS and develop two new terms: EACS and EAMS. These terms will allow changes within the applicability for the monitoring portion to allow third party monitoring systems. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

5. The SDT realized through the process of splitting EACMS that the same considerations apply to PACS, which will allow changes within the applicability for alerting and logging (PAMS is not reflected within the applicability section at this time). The SDT is considering splitting the PACS term into PACS and PAMS to allow third party monitoring or event correlation to be performed without carrying the PACS classification. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

6. The SDT is proposing to move away from the more prescriptive ESP/EAP model to logical isolation through the higher level objectives provided by the BES Cyber System concept and its Logical Isolation Zone. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

7. The SDT is considering taking qualitative language out of the Intermediate System definition and using it to clarify requirements. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

8. The SDT is considering changes to the ERC and IRA definitions to address V5TAG issues (see the CIP-005 Technical Rationale document for detailed information). ERC will have conforming changes only and will continue its use as a scoping mechanism. The proposed modifications to IRA will apply to certain non-routable to routable protocol conversion scenarios. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

9. To the extent possible, the SDT intends its modifications to permit approaches to compliance that are “backwards compatible” with compliance approaches within the currently approved versions of the CIP standards. (Notable exceptions include CIP-005 R3, CIP-007 R2, and Secure Configurations – CIP-010). Do you agree the modifications are backwards compatible? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

10. The SDT has not yet determined a proposed timeframe to include in the Implementation Plan. How long would you as an entity need to implement the proposed modifications? Please provide your implementation timeframe and justification for why that amount of time would be needed.

11. The SDT is proposing conforming modifications to CIP-004. Do you agree with these changes? Please provide comments to support your response. In particular, the SDT seeks stakeholder feedback on:

a. Modifications related to CIP Exceptional Circumstances

b. Use of newly proposed terms EACS and EAMS in the Applicable Systems column

c. Addition of PCS to the Applicable System column for Parts in CIP-004 to mitigate security risks associated with individuals not needing authorization or PRAs when granted access to systems inside the Logical Isolation Zone

12. The SDT is proposing modifications to CIP-005 (see the CIP-005 Technical Rationale document for detailed information). Do you agree with these changes? Please provide comments to support your response. In particular, the SDT seeks stakeholder feedback on:

a. The replacement of the ESP concept with Logical Isolation Zone (LIZ).

b. Is the backward compatibility clear as existing ESPs and EAPs move to the new LIZ concept?

c. The addition of the 4.2.3.3 exemption in the standard along with the addition of Requirement part R1.2 to address the V5TAG concern of “Super ESPs” or single networks within or between BES Cyber Systems that span more than one geographic location.

d. As differing forms of shared infrastructure come into play with virtualization, Requirement R3 has been added to include the management plane and its isolation controls as a part of the CIP standards. Is this concept clearly and widely understood?

13. The SDT is proposing conforming modifications to CIP-006. Do you agree with these changes? Please provide comments to support your response. In particular, the SDT seeks stakeholder feedback on:

a. Modifications related to CIP Exceptional Circumstances

b. Use of newly proposed term EACS in the Applicable Systems column

14. The SDT is proposing modifications to CIP-007 (see the CIP-007 Technical Rationale document for detailed information.). Do you agree with these changes? Please provide comments to support your response. In particular, the SDT seeks stakeholder feedback on:

a. The SDT is proposing adding the security objectives throughout the Requirements in CIP-007. Do you agree that the proposed security objectives add clarity to the reason the requirement exists?

b. The SDT is proposing the security objective in CIP-007 R1, “to mitigate the risk posed by uncontrolled logical and physical connectivity". Do you agree that the modifications to CIP-007 R1 Part 1.1 fulfill this security objective for systems where connectivity is not limited to TCP/IP port service combinations, as in virtualized systems and SAN based storage?

c. Do you agree that the modifications to CIP-007 R1 Part 1.1 add necessary flexibility to fulfill the security objective of CIP-007 R1 for virtualized systems and provides a degree of future proofing?

15. The SDT is proposing modifications to CIP-010 (see the CIP-010 Technical Rationale document for detailed information.). Do you agree with these changes? Please provide comments to support your response. In particular, the SDT seeks stakeholder feedback on:

a. The SDT is proposing adding the security objectives throughout the Requirements in CIP-010. Do you agree that the proposed security objectives add clarity to the reason the requirement exists?

b. The SDT is proposing to modify the referenced baseline configuration from CIP-010-3 R1 Part 1.1 to a ‘Secure Configuration’ which is made up of the implemented controls that fulfill requirements within CIP-005 and CIP-007. Do you agree that this set of controls supports managing change under CIP-010 R1 Part 1.1?

c. The SDT is proposing to modify the current CIP-007 R2 requirements and move them to CIP-010 R3. The SDT believes that the software vulnerability management found within this set of requirements fits logically within the security objective of CIP-010 R3 “to mitigate the risk posed by system vulnerabilities” and has moved it there. Do you agree?

d. The SDT is proposing CIP-010 R3 Parts 3.5 and 3.6 to replace the current CIP-007 R2 Parts 2.1 – 2.4. Do you agree that the proposed CIP-010 R3 Parts 3.5 and 3.6 offer the additional flexibility needed when implementing virtualized systems that can be dormant for a period, and for which security patches have become available?

16. Provide any additional comments for the SDT to consider, if desired.

1. The proposed BCS definition no longer relies on the term Cyber Asset. The SDT asserts that the proposed BES Cyber System definition describes the BCS adequately without the use of the word “programmable” in the definition. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

APPA does not believe the removal of “programmable” adequately scopes the applicable device types with the current definition. APPA believes that the new definition would include devices that have been previously excluded, such as electro-mechanical relays, since “any combination of” would include hardware only, and there is no scope placed on the hardware to eliminate these devices.

In any case, because “programmable” remains in the legacy definition of “cyber asset,” the issue about its meaning—to the degree that remains an issue—has not been eliminated.

Additionally, APPA does not believe the proposed BES Cyber System definition describes the BCS appropriately. The new definition is attempting to combine many definitions into one. Public power recommends using the language below:

A BES Cyber System includes any combination of programmable hardware (including virtual hardware), software (including application virtualization), and data, where:

1. It/they performs one or more reliability tasks; and

2. If rendered unavailable, degraded, or misused, the situation would result in adverse impact to one or more BES Facilities within 15 minutes. Redundancy is not a factor, in the sense of considering the activation of different, redundant BES Cyber Systems.

The language “regardless of redundancy,” as used in the proposed definition, is unclear. Does “regardless of redundancy” apply to all items (hardware, software, and data)? It seems that the redundancy being introduced is intended to address the BES Cyber Asset definition, but the language structure makes this difficult to decipher. We understand that redundancy in determining systems is based on the language in CIP-002-5.1a as it relates to Real-Time Operations:

“This time window must not include in its consideration the activation of redundant BES Cyber Assets or BES Cyber Systems: from the cyber security standpoint, redundancy does not mitigate cyber security vulnerabilities.” In this regard, revisions to the core BCS definition will require some Entities to re-work their CIP-002-5.1a process to address the Real-time Operations decision at a different point in the process to identify BES Cyber Systems.

The recommended revised definition above attempts to incorporate these concepts.

Response

David Rivera - New York Power Authority - 1,3,5,6

Answer	No
Document Name	

Comment

NYPA supports comments submitted by NPCC / TFIST.

The current BCS definition has the potential to increase the scope / applicability of the CIP standards. The BCS definition should include a reference to Cyber Asset definitions, and further define what is meant by hardware, software, data, etc. As currently written, it seems “hardware” that do not satisfy the definition of Cyber Asset could be brought in under the BCS definition.

In addition, any changes to existing terminology or definitions should provide a security benefit considering the extent of administrative changes that will be required to implement these changes (policies, procedures, tools, asset management systems, device labeling, updated training materials, implementing staff training, etc.). It seems the current proposed change does not provide a security benefit.

Lana Smith - San Miguel Electric Cooperative, Inc. - 5

Answer	No
Document Name	

Comment

SMEC does not support the changes made to the term BES Cyber System (BCS) or the retirement of BES Cyber Asset (BCA). This proposed change would require entities to re-evaluate what is in scope under CIP-002 and could cause non-programmable devices to be included. The changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs. SMEC is concerned that this magnitude of change to the CIP standards would be too disruptive to non-virtualization compliance.

N&ST believes that for the sake of avoiding arguments during audits, the word, “programmable” should be retained. Suggest rewording: “A programmable combination of physical and/or virtual hardware, software and data, performing or supporting one or more reliability tasks that if rendered unavailable, degraded, or misused would result in adverse impact to one or more BES Facilities within 15 minutes. Redundancy shall not be considered when identifying BES Cyber Systems.”

We believe the the new definition of BES Cyber System should contain the term Cyber Asset, like: "Any combination of Cyber Assets, regardless of redundancy, performing one or more reliability tasks that if rendered unavailable, degraded, or misused would result in adverse impact to one or more BES Facilities within 15 minutes." Additionally, we believe the new definition, without the use of "programmable" will bring into scope electronic devices that are not capable of being updated and have no means to update the software or firmware within them (not field updateable). These devices currently do not meet the “programmable” electronic device definition and are thus out of scope for NERC CIP.

ITC is in agreement with the comments submitted by EEI:	

"EEI does not support the changes made to the term BES Cyber System (BCS) or the retirement of BES Cyber Asset (BCA). While we understand the SDT's desire to move from the current asset focused model to a systems approach, the changes being proposed within the body of revised and retired definitions appears to go well beyond what we understand was intended within the currently approved SAR. EEI believes that the SDT should retain the defined terms "BES Cyber Assets (BCA)" and BES Cyber System (BCS) as currently written. We also believe that given the proposed revisions made to the term "Cyber Asset," which clarify that physical or virtual hardware, software and data are allowed, obviates the need to revise the other definitions."

Exelon does not support the changes made to the term BES Cyber System (BCS) or the retirement of BES Cyber Asset (BCA). While we understand the SDT's desire to move from the current device-focused model to a systems approach, the changes being proposed involve fundamental definitions and appear to go well beyond what we understand was intended within the currently approved SAR. The proposed change represents a major overhaul of the CIP Standards, including impacts on CIP-002 methodologies, assessment methods, and many current CIP Program processes and procedures. These changes would be better addressed in a separate and comprehensive major CIP version upgrade effort.

Susan Sosbe - Wabash Valley Power Association - 3

Answer	No
Document Name	

Comment

Covering all items without consideration of the difference between programmable and non-programmable devices introduces significant complications for physical security and for configuration management. Should an auditor independently determine that communications cabling, electrical wiring, or non-programmable devices such as electro-mechanical relays are part of the system, the scope of CIP-006 could grow drastically. This could have a tremendous impact on medium impact generation assets.

While “programmable” or a suitable variation of the term is needed, the issues with the current non-definition of programmable need to be addressed. The definition is based on programmable, the various types of programmability needs to be addressed: (1) Remotely programmable; (2) requires physical access and interruption of operation to change device programming; Electromechanical devices (including devices such as electromechanicable breakers and physical hardware such as communications cabling and electrical wiring).

Davis Jelusich - Public Utility District No. 1 of Chelan County - 1,3,5,6, Group Name Public Utility District No. 1 of Chelan County

Answer	No
Document Name	

Comment

CHPD disagrees with the removal of Cyber Asset from the definition. The new language will expand the current scope of the definition by bringing any electro-mechanical BES device into scope due to “Any combination…” language and the lack of a tie to the “Programmable” term defined in the Cyber Asset definition.

CHPD suggests using the new Cyber Asset definition (already scopes virtual systems) with the following BES Cyber System definition:

“A combination of one or more Cyber Assets performing one or more reliability tasks, including redundant members that support a reliability task, that if rendered unavailable, degraded, or misused would result in adverse impact to one or more BES Facilities within 15 minutes.”

Response

Kevin Salsbury - Berkshire Hathaway - NV Energy - 5

Answer	No
Document Name	

Comment

NV Energy does not support the changes made to the term BES Cyber System (BCS) or the retirement of BES Cyber Asset (BCA). While we understand the SDT’s desire to move from the current asset focused model to a systems approach, the changes being proposed within the body of revised and retired definitions appears to go well beyond what we understand was intended within the currently approved SAR. In addition, the revisions will create a significant change to existing processes, and documentation, due to revising the foundation of the identification of CIP Assets.

With the removal of the term, Cyber Asset, the SDT will be removing the necessary tie to BCS, and in turn, revising the current filtering system that Entities use to identify their CIP Assets. Additionally, with the removal of BCA, there is no explicit language within CIP Glossary Terms that address non-programmable devices as non-CIP applicable assets.

NV Energy believes that the SDT should retain the defined terms “BES Cyber Assets (BCA)” and BES Cyber System (BCS) as currently written. We also believe that given the proposed revisions made to the term “Cyber Asset,” which clarify that physical or virtual hardware, software and data are allowed, obviates the need to revise the other definitions.

NV Energy also believes that the revisions to the definition provide no improvement to reliability and security, and mainly address possible confusions found during auditing of the standards.

Comment	
Please clarify “regardless of redundancy” with respect to the “combination of hardware, software, and date.” Redundancy in this context appears to relate more to the BCA definition. With respect to redundancy, as stated in CIP-002-5.1a, relative to Real-Time Operations, “…redundancy does not mitigate cyber security vulnerabilities.” Revisions to the BCS definition may cause entities the burden of redefining and modifying their classification process, as well as subsequent processes/workflows that are intertwined. Not all BCS include virtualization. The retirement of the use of the term BCA affects how audit evidence in currently proposed in “CIP Version 5 Evidence Request v2.0”. In v1.0, there were tabs for both virtual systems and BCS, in v2.0, both are eliminated. How will device sampling be handled?

By removing the term “programmable” and the tie to “BES Cyber Asset” (which removes the tie to “Cyber Asset”), the term BES Cyber System does not provide a clear means to exclude devices that are hardware with built-in programmable read-only memory (PROM) or can only be interacted with through a push-button interface (or similar physical interaction). Including these devices in CIP cyber security scope creates administrative burden with no clear benefit to cyber risk. Previously, these could be excluded by an entity using internal definition/clarification of “programmable” to indicate programmable through an electronic interface and without disassembly of the device (i.e. replacing a PROM chip). Suggested options: Cyber Asset: A programmable electronic device, including the hardware (physical or virtual), software (including application virtualization), and data in these devices. BES Cyber System: Any combination of Cyber Assets, regardless of redundancy, performing one or more reliability tasks that if rendered unavailable, degraded, or misused, would result in adverse impact to one or more BES Facilities within 15 minutes.

Comments: PacifiCorp’s approach to this informal comment period was to provide the SDT with constructive feedback related to the proposed revisions to the terms, standards and concepts presented. With that said, PacifiCorp has additional comments and concerns that will be covered in question #16.

Not using Cyber Asset in the definition of BES Cyber Systems removes the necessary ties between the two terms. The terms should be used as a filtering mechanism to scope the assets subject to the CIP standards. Starting with Cyber Asset being the largest population of devices, followed by a filtering process to determine whether the Cyber Assets are part of a BES Cyber System. PAC suggests adding either Cyber Asset or programmable into the proposed BCS definition.

Option 1: BES Cyber System - Any combination of [Cyber Assets, that includes] hardware (including virtual hardware), software (including application virtualization), and data, regardless of redundancy, performing one or more reliability tasks that if rendered unavailable, degraded, or misused would result in adverse impact to one or more BES Facilities within 15 minutes.

Option 2: BES Cyber System - Any combination of [programmable electronic devices, that includes] hardware (including virtual hardware), software (including application virtualization), and data, regardless of redundancy, performing one or more reliability tasks that if rendered unavailable, degraded, or misused would result in adverse impact to one or more BES Facilities within 15 minutes.

Comment

Overall, the NSRF does not agree with the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry's programs. Originally, there was the Version 5 Transition Advisory Group, made up of 6 Entities to test our current suite of Standards. There are also multiple registered groups who can write and submit to NERC, Implementation Guidance for ERO deference. Any radical change to the CIP Standards should be practiced and tested BEFORE any Standard is recommended for change. The NSRF also believes that there are Entities who are currently compliant (via an audit) by incorporating virtualization practices under our current set of Standards. All Standards are written to "what to do" not how to incorporate a certain or new technology. The NSRF has attempted to answer the SDT questions but still does not agree with this Project. Here are some specific examples of what a small change to a Standard will do to the industry.

The new definition expands the scope of devices that would fall into CIP regulation if the Cyber Asset term is removed by removing the BCA component. Currently only programmable electronic devices are in scope. The new definition would bring into scope electronic devices that are not capable of being updated; no means to update the software or firmware within them (not field updateable). These devices currently do not meet the "programmable" electronic device definition and are thus out of scope for NERC CIP.

The NSRF recommends leaving the BES Cyber Asset and, BES Cyber Systems definitions and accepting the proposed Cyber Asset definition. We feel this allows for virtualization and significantly reduces the documentation changes that would be required by the elimination of the BCA definition.

Comment

We disagree with the proposed BCS definition. The NERC CIP requirements are generally device-centric, which are working well for both physical and virtual CIP Cyber Assets in registered entities' CIP compliance programs. In our virtual environment, we have no issue for continuously using the device-centric approach for the CIP compliance. For instance, we have identified the VM and SAN as a distinct virtual programmable device. CIP Version 5 previously introduced the concept of BES Cyber Systems to assist registered entities performing and documenting compliance actions by reducing the amount of required compliance documentation, and in some cases, to allow one BES Cyber Asset in a BES Cyber System to perform required actions on behalf of other BES Cyber Assets in the BES Cyber System. These BCA and BCS terms used in the registered entities' CIP compliance process today work fairly smoothly. In addition, the new term BES that breaks down from the Cyber Asset level to the hardware and software level is not manageable and auditable, and it would create additional identification workload that has no value for the registered entities. Based on the above rationale, there is no need for redefining the BCS from a compliance and security perspective. We disagree with the PCS definition for the same reason.

Due to the proposed retirement of the BCA definition and because the designation of the new Cyber Asset term is intentionally limited to TCA, Removable Media, and CIP-010 we believe the proposed BES Cyber System definition needs further clarification. As an example, the term “programmable” in the BCA definition currently excludes certain BCS Elements, such as Current Transformers [CT] and Potential Transformers [PT] for transmission protection BCS. Since these devices, if rendered unavailable, degraded, or misused, could cause failure of the host transmission protection BCS, the new definition of BCS could be interpreted to include all such nonprogrammable elements within a given BCS as part of the specific combination of hardware, software, and data.

Richard Jackson - U.S. Bureau of Reclamation - 1,5	
Answer	No
Document Name	

Comment

Reclamation does not support retiring the term BES Cyber Asset. Reclamation recommends the term BES Cyber Asset be retained and used as it is currently defined in all applicable definitions in the NERC Glossary of Terms.

Reclamation also does not support the proposed definition of BES Cyber System. Defining BES Cyber System without using the term “BES Cyber Asset” (to include the term “programmable”) could bring equipment like PTs, CTs, pressure sensors, temperature sensors, and other hardware devices for BES functionality into scope.

If the above recommendation is not adopted, Reclamation proposes the following definition of BES Cyber System:

BES Cyber System – One or more BES Cyber Assets logically grouped by a responsible entity to perform one or more reliability tasks that if rendered unavailable, degraded, or misused would, within 15 minutes of its required operation, misoperation, or non-operation, adversely impact one or more Facilities, systems, or equipment, which would affect the reliable operation of the Bulk Electric System. Redundancy of affected Facilities, systems, and equipment shall not be considered when determining adverse impact.

Comment

Eliminating the word “programmable” blurs the line between a cyber asset and complex electrical or electronic hardware, such as non-programmable relays. It opens the door to enforcement on many more assets that don’t make sense, such as integrated appliances or complex semiconductor switching devices that do not have field-changeable firmware.

The important nuance provided by the word “programmable” is that it is possible for the executable code to be modified in the field, other than just changing settings in a faceplate menu. That makes the CIP Standards relevant as protections against the device being a target for attackers (BCS) or being reconfigured for use in an intrusion or attack (EACMS, PACS, PCA). There may be value in adding a defined term for “Programmable.” A possible definition could be “containing executable code, including binaries and scripts, that can be modified after manufacture or creation. This is an intrinsic characteristic, not a situational one, which does not change with respect to whether the end user connects, secures, removes, or blocks any access paths that can used to modify executable code. This does not include the ability to modify basic configuration data that are not executed sequentially as scripts, such as a setpoint or IP address.”

Comment

We do not support the changes made to the term BES Cyber System (BCS) or the retirement of BES Cyber Asset (BCA). While we understand the SDT's desire to move from the current asset focused model to a systems approach, the changes being proposed within the body of revised and retired definitions appears to go well beyond what we understand was intended within the currently approved SAR.

We believe that the SDT should retain the defined terms "BES Cyber Assets (BCA)" and BES Cyber System (BCS) as currently written. We also believe that given the proposed revisions made to the term "Cyber Asset," which clarify that physical or virtual hardware, software and data are allowed, obviates the need to revise the other definitions.

We recommend returning the "programmable" language to the BCS definition, as well as maintaining a definition of BES Cyber Asset as a component of the BCS. We believe these changes improve backward compatibility.

This proposed change ripples into CIP-002 because Entities will need to re-evaluate their CIP-002 what is IN vs OUT. For example, some ROM devices may fall under CIP-002. This subtle change may force a new version of CIP-002 assessment - the new definition would bring in more devices that would not be considered programmable and the changes would not be backward compatible.

New definition will bring in more devices (ROM, firmware, etc.) that are typically not considered programmable

Since the Standard should be technically agnostic, we recommend not calling out virtual hardware (virtualization).

Comment

MEC does not support the changes made to the term BES Cyber System (BCS) or the retirement of BES Cyber Asset (BCA). The changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs too soon after the last one. Some entities have not had the chance for an audit on the last round of changes. Other revisions, such as CIP-003-7 sections 2, 3 and 5 have yet to become effective. MEC has compliantly implemented virtual servers within the existing CIP standards structure. We have been audited on CIP-005 and CIP-007 as well as CIP-004 and CIP-006. We have self-certified CIP-002, -003, -008 and -011. And are preparing evidence for an audit on CIP-009 and CIP-010 in 2019 and have not identified issues.

It is not clear how this magnitude of changes will create a corresponding improvement to reliability and security. Perhaps the "how to comply" with the existing standards when virtualization is involved could best be addressed using other tools such as ERO-endorsed implementation guidance or readiness reviews for the segment of Responsible Entities who are operating or plan to operate with virtualization.

MEC believes that the SDT should retain the defined terms “BES Cyber Assets (BCA)” and BES Cyber System (BCS) as currently written. We also believe that given the proposed revisions made to the term “Cyber Asset”, which clarify that physical or virtual hardware, software and data are allowed, obviates the need to revise the other definitions.

Comment

Dominion Energy has comments on the following proposed definitions:

- PAMS – It is unclear if the intent is to collect visitor logs (paper or substation voice system).
- LIZ – 1) It is unclear if an entity has multiple VLANs behind the firewall that the entity could claim it’s in a single ESP under the proposed definition. In addition, it is unclear if an entity can mix logical isolation zones in virtual environments on a single piece of hardware. Additional clarity should be added around which entity actually defines the LIZ (either the ERO or the Entity). Finally, it is unclear on whether the communication links mentioned in 4.2.3.3apply only if the ERO determines it extends one or more geographic locations.
- IRA – Additional clarity needs to be added on what “remote access client” means. It could be interperted to be either protocol or client.
- RM – Please clarify the first bullet. Would this apply to flash drives that are smart/have chips in them? We recommend adding the examples back for clarity.

AZPS does not agree with the proposed change in the BCS definition, unless the new Cyber Asset term is added to the definition of BCS to maintain the reference to/inclusion of the term “programmable.” Specifically, the revisions to BCS do not adequately describe the Cyber Assets that would comprise a BCS without the use of the word “programmable” because the fact that a Cyber Asset is “programmable” sets the foundational criteria by which assets and/or BCS are considered for CIP categorization. Without a reference to the term “programmable,” an inconsistency between the term Cyber Assets and BCS is introduced as is the potential that the scope of assets to be considered under the BCS classification will be unclear. To ensure consistency and reduce the potential for confusion, AZPS requests that the term “programmable” be included in the new BCS – either directly or indirectly through replacement of “hardware (including virtual hardware), software (including application virtualization), and data” with “Cyber Assets”.

Further, AZPS notes that the Standards Authorization Request form for this Project (“the SAR”) outlined that the SDT would be responding to the V5TAG Transfer Document request for clarification of “the intent of ‘programmable’ in Cyber Asset, and a focus on the definition of ‘BES Cyber Asset’ so that it does not subsume all other cyber asset types.” AZPS notes that this draft does not provide the necessary clarity regarding the intent of “programmable” and may go beyond the scope of the SAR by retiring the term BES Cyber Asset and fundamentally changing definitions and the requirements in which they are utilized across all CIP Standards.

For these reasons, AZPS requests the rationale for how the retirement of the term BES Cyber Asset and the modifications to BCS meet the intent of the SAR as well as clarification on the reasoning (generally) behind the retirement of the term BES Cyber Asset and the removal of references to “programmable” that results from the proposed revisions to the two foundational definitions associated with the CIP reliability standards (BES Cyber Asset and BCS). As discussed above, AZPS suggests additional revisions to recapture the term “programmable.” An alternative approach could be to develop a new definition and/or classification for virtualized assets, which definition/classification would then be added to the applicability tables, as appropriate.

NPPD does not support the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry’s programs. The changes being proposed present a risk of unintended consequences for what is the vast majority of systems that are not in virtualized environments. NPPD provides our comments in the spirit of identifying some of the risks and unintended consequences for moving forward in this direction; and in the final comment on this form our recommendations.

The new definition expands the scope of devices that would fall into CIP regulation if the Cyber Asset term is removed by removing the BCA component. Currently only programmable electronic devices are in scope. The new definition would bring into scope electronic devices that are not capable of being updated; no means to update the software or firmware within them (not field updateable). These devices currently do not meet the “programmable” electronic device definition and are thus out of scope for NERC CIP.

We recommend leaving the BES Cyber Asset and, BES Cyber Systems definitions and accepting the proposed Cyber Asset definition. We feel this allows for virtualization and significantly reduces the documentation changes that would be required by the elimination of the BCA definition

The new BCS definition exludes the use of the term “Cyber Asset”. “Cyber Asset” was also redefined and used in other defined terms such as TCA’s, etc. To be consistent, we suggest the following definition for BCS “A single or combination of Cyber Assets, regardless of redundancy, performing one or more….” Since the new definition of Cyber Asset is inclusive of the hardware (physical or virtual), software and data in the devices, it makes sense to utilize the term consistently in other new/revised definitions since not all devices lend themselves to be “systems”. (i.e. stand-alone assets or components of a system).

By excluding the term programmable from the proposed BCS definition, the SDT risks bringing into scope devices that were previously excluded from BCSs due to not being programmable. In the guidelines and technical basis of CIP-007-6, an unmanaged switch is listed as an example of a nonprogrammable device. As a nonprogrammable device, an unmanaged switch did not meet the definition of a Cyber Asset and therefore could not meet the definition of a BES Cyber Asset. Under the proposed BCS definition, an unmanaged switch meets the BCS definition. An unmanaged switch is hardware, it contains software (the firmware the switch is running), and it contains data (the MAC address table). If this proposed change is implemented in its current form then entities may need to re-evaluate the criteria used to determine what devices should be included in BES Cyber Systems.

SRP does not agree that the BCS definition describes the BCS appropriately. The new definition is attempting to combine many definitions into one. SRP suggests using the language below:	

A BES Cyber System includes any combination of programmable hardware (including virtual hardware), software (including application virtualization), and data, regardless of redundancy, where:

1. It/they performs one or more reliability tasks; and
2. If rendered unavailable, degraded, or misused, the situation would result in adverse impact to one or more BES Facilities within 15 minutes.

Additionally, the term ”programmable” should remain in the definition of a BES Cyber System. “Programmable” excludes certain IT network components such as patch panels, patch cables, etc. which should not be in scope.

SRP also agrees with APPA’s comments.

Duke Energy requests further clarification on the proposal for BCS definition. The proposed definition indicates that there should be a “combination of hardware, software, and data”. Is it the drafting team’s intent there must be a combination of any of those elements (hardware, software, data), or can something be considered as a BCS if it contains only one of those elements (software)? Without the use of the term “programmable” can an entity infer that an asset that is hardware only, not be considered a BCS?

Pamela Hunter - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - SERC, Group Name Southern Company	
Answer	No
Document Name	
Comment	
Southern Company is concerned that ultimately, this will depend on the audit methodology. If the objective of the requirement is measured to see if it is met on the BCS as a whole, then this should work. If the objective is measured on every physical device in the system, then it will fail. The term "Programmable" may still be needed as a scoping mechanism if the audit approach does not change to match the system approach.	

Southern Company is also concerned that in using the phrase “adverse impact to one or more BES Facilities”, auditors may interpret this as a considerable expansion of the scope of what is encompassed by the definition.

We understand that the F in Facility has been capitalized by the SDT intentionally and in this definition, means:

“A set of electrical equipment that operates as a single Bulk Electric System Element (e.g., a line, a generator, a shunt compensator, transformer, etc.)”

Therefore, it appears to Southern that this is **not** intended by the SDT to expand the scope of what is currently included, out to systems such as Fire Protection Systems, HVAC and other systems which do not have a direct impact upon the BES. Southern Company also believes that the way in which it is written will not change the scope of the Standard in respects to the inclusion of Control Centers and their associated Data Centers. As noted in CIP-002-5.1a,

“Responsible Entity may designate the group of Facilities by location, with qualifications on the group of Facilities that supports reliable operation of the BES, as the Facilities that are subject to the criteria for categorization of BES Cyber Systems. Generation Facilities are separately discussed in the Generation section below. In CIP-002-5.1a, these groups of Facilities, systems, and equipment are sometimes designated as BES assets. For example, an identified BES asset may be a named substation, generating plant, or Control Center. Responsible Entities have flexibility in how they group Facilities, systems, and equipment at a location.”

As long as the intent behind the quote above from CIP-002 does not change in future revisions, Southern feels the intent remains the same with the proposed wording of the definition of Cyber Asset as it relates to “BES Facilities”.

Southern Company is concerned that unless the SDT finds a way to ensure that the current scope remains unchanged, our Operations groups will suffer an undue compliance burden, spending an inordinate amount of time providing evidence of minutiae while likely seeing little of the direct benefits of virtualization.

That said, Southern Company would like to see additional clarity provided in future revisions of this proposed change regarding maintaining the scope of the Standards to what is *currently* in scope. This will allow us to balance implementing the benefits of virtualization while also providing reasonable proof demonstrating a secure implementation.

Comment

Because the concept of “programmable” is retained in the defined term “Cyber Asset” (which is an element of a BES Cyber System), industry needs guidance on what constitutes a “programmable” electronic device. Additionally, the new definition for BES Cyber System includes electronic devices that are not capable of being updated (i.e, no means to update the software or firmware within them (not field updateable)). Therefore, because these devices currently do not meet the “programmable” electronic device definition, such devices should be out of scope for NERC CIP.

Finally, for consistency with the revised definition of Cyber Asset, the definition of BES Cyber System should read: “Any combination of physical or virtual hardware (including virtual hardware), software…”

Mark Gray - Edison Electric Institute - NA - Not Applicable - NA - Not Applicable

Answer	No
Document Name	

Comment
EEI members who participated in the development of these comments do not support the changes made to the term BES Cyber System (BCS) or the retirement of BES Cyber Asset (BCA). However, we understand that other members are more supportive of the changes. As a result, these comments do not represent a consensus, but we offer them for the SDT to consider. EEI understands the SDT's desire to move from the current asset focused model to a systems approach, but the changes being proposed within the body of revised and retired definitions appears to go well beyond the EEI members' understanding of the scope and intention of the currently approved SAR. EEI recommends that the SDT retain the defined terms "BES Cyber Assets (BCA)" and BES Cyber System (BCS) as currently written. Further, EEI observes that the proposed revisions made to the term "Cyber Asset," which clarify that physical or virtual hardware, software and data are allowed, obviate the need to retain the other definitions.

Comment

NRG asserts that the proposed definition of BCS would include the SCADA traffic itself (not just the data that exists within the hardware). Therefore, change control would need to include source control. This could be a challenge for the industry. NRG recommends that NERC SDT work to include definition delineation and classification delineation of data at rest versus data while in transit as critical relating to the definition of Cyber Asset and BES Cyber System. Expanding the definition beyond data on devices, could cause entities to have to re-define BES Cyber Systems.

Comment

The proposed definition does not address the issues and interpretations that have been raised by not having a definition of programmable. Furthermore, the definition uses the phrase “Any combination of hardware (including virtual hardware), software (including application virtualization), and data.” The term “combination” does not mean a combination including at least one of each. Instead, a combination could have a null element in a set. For instance, you could have a combination of only hardware, no software, and no data as a valid combination set. So, if you look at the definition with that in mind you could have hardware “performing one or more reliability tasks that if rendered unavailable, degraded, or misused would result in adverse impact to one or more BES Facilities within 15 minutes.” This could easily be a breaker or some other item in a station that is made of only hardware. This has now opened a Pandora’s box of compliance issues and need for clarification rather than help resolve anything.

We would propose that the definition say something like, "Any combination of Cyber Assets, regardless of redundancy, performing one or more reliability tasks that if rendered unavailable, degraded, or misused would result in adverse impact to one or more BES Facilities within 15 minutes." We would also prefer the term "programmable" in the definition of Cyber Asset be further clarified.

Comment	
Programmability is a fundamental concept that sets the scope of applicability for the current CIP standards. While many standards will not apply, there are a number of requirements that aren't obviously tied to the ability of a device to be programmed. Including non-programmable hardware fundamentally changes the landscape of the CIP standards (i.e. breakers and motor-operated switches could now be in scope). Simply inserting "programmable" in front of the first instance of "hardware" in the definition would at least give the same scope as we have today (although the term "programmable" would still be fundamentally undefined and subject to individual interpretation).

2. The SDT asserts that the proposed Cyber Asset definition provides clarity around virtual hardware. (Cyber Assets revised definition: Programmable electronic devices, including the physical or virtual hardware, software, and data in those devices.) Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

Jamie Monette - Allete - Minnesota Power, Inc. - 1

Duke Energy requests further clarification on the use of the phrase “virtual hardware”. For example, if an entity sets up a virtual switch in the “virtual hardware”, would this be considered a separate asset? Futher examples of what the drafting team considers “virtual hardware” would be beneficial to the industry.

Public power is concerned that the new definition will require new evidence and will not work with the existing approach structured around the CIP Evidence Request Spreadsheet (v2.0). Public power is also concerned that the list of BES Cyber Assets used for sampling will no longer be feasible, therefore it is not clear what approach auditors may require. In addition, documentation of the virtual host and virtual guests will only be a snapshot in time making it difficult to demonstrate compliance for individual cyber asset level security controls. APPA believes it would be clearer to maintain the BCA definition for physical devices, while providing new definitions for virtual devices (Virtual Cyber Asset), or consider a dual-definition approach (see response to Question 3).

The proposed definition of cyber asset just adds the words “or virtual” to the definition, but continues to leave known issues with the current definition unaddressed. Most of these issues are related to the use of the term programmable. It is recommended that the team further evaluate the definition and consider migrating from the term programmable to a less ambiguous term. While “programmable” or a suitable variation of the term is needed, the issues with the current non-definition of programmable need to be addressed. The definition is based on programmable, the various types of programmability needs to be addressed: (1) Remotely programmable; (2)	

requires physical access and interruption of operation to change device programming; Electromechanical devices (including devices such as electromechanicable breakers and physical hardware such as communications cabling and electrical wiring)

The definition only helps address virtualization to the level of discrete virtual machines. It does not adequately cover more advanced edge cases that blur the lines between virtual machines. Examples of edge cases could include collections of machines like supercomputing clusters that share resources such as memory, or (more commonly) network storage. Examples could also use containerized assets, which may share a substantial amount of the OS and software without duplication, running specific software within walled containers.

The virtual hardware is vague and causes confusion. We suggest using the previous revised Cyber Asset definition as follows:

"A programmable electronic physical or virtual device, including the hardware, software, and data in the device. Each virtual machine and host is a distinct device." Given that the virtual device can be captured separately using this previously proposed definition, additional requirements that may be developed only apply to the virtual devices if the current requirements don't fit them.

While the revision provides some clarity around virtual hardware, “programmable” remains a debated topic that should have more clarity regarding what is programmable and what isn’t because component changes are required. The definition does not address application virtualization which is another virtualization technology that can be employed. In relation to the BCS comment, Cyber Asset needs to remain a component of BCS because otherwise how does an entity define what the composition of the System is?

What is “virtual hardware”? The SSRG recommends the SDT define virtual hardware to ensure consistent application across industry and in audit situations. Likewise, due to the programmable aspect of a Cyber Asset, “virtual” software is delivered by a vendor (rather than coded by the responsible entity) and, therefore, is not a physical programmable device (ie., hardware). Given this, how does programmable apply to virtualization software?

Comments: MRO supports the intent to accommodate virtualization within the NERC Glossary terminology, but the term “device” is generally understood to be a hardware specific physical term and cannot be grammatically supported to also represent something that is virtual as has been attempted in the proposed redefinition of Cyber Asset. This grammatical conflict may yield to extensive interpretation which may hamper consistent CMEP implementation by the ERO. One option for incorporating virtual components into the Cyber Asset term could be to add a layer beneath the Cyber Asset term so that the programmable electronic devices language can remain (representing physical hardware devices), and a new defined peer term like “Virtual Programmable Asset (VPA)” or “Cyber Element” could be added to identify VPAs that have no physical form. We recommend consideration of the following terms (organized like a schema - includes hierarchy), which permit the incorporation of VPAs while insulating impact to existing NERC CIP glossary terms:

- PED (programmable electronic device) – this can remain undefined, but we understand it to be hardware based. A device is a physical thing and can’t be virtual itself but can host other Virtual Programmable Assets
- Virtual Programmable Asset (VPA – more basic than a Cyber Asset): Includes software and data, but does not include physical hardware
  - Cyber Asset: PEDs and VPAs, including hardware, software, and associated data
    - BES Cyber Asset – (remains as defined)
    - BES Cyber System – (remains as defined)
    - PCA (Protected Cyber Asset) – (remains as defined)
    - EACMS – (remains as defined)
    - PACS – (remains as defined)

CHPD agrees that the term Cyber Asset should continue to be used within the NERC Glossary of Terms for: Removable Media and Transient Cyber Asset.

Additionally, consider how this same issue applies to traditional non-virtual hardware-based BES Cyber Assets. If an exception is being granted for specific existing hardware device types, then perhaps the problem should be flipped to instead consider the virtual systems to be the exception to the rule. Using this thinking, it may make more sense to instead develop separate virtualization language that is then referenced in the existing Cyber Asset and BES Cyber System definition. This would enable the language to expand scope to allow virtual environments without throwing out the existing scoping language for existing non-virtual Cyber Assets.

This could be accomplished with something like the following:

Virtual Cyber Asset (VCA) – Programmable virtual system that is comprised of a virtual operating system and the host hardware and software that hosts the virtual operating system.

BES Cyber System (BCS) - A combination of one or more Cyber Assets or Virtual Cyber Assets performing one or more reliability tasks, including redundant members that support a reliability task, that if rendered unavailable, degraded, or misused would result in adverse impact to one or more BES Facilities within 15 minutes.

The NSRF agrees that the term Cyber Asset should continue to be used within the NERC Glossary Terms for: Removable Media and Transient Cyber Asset. The NSRF does not agree with making other changes to the Removable Media and Transient Cyber Asset definitions. Overall, the NSRF does not agree with the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry's programs. Originally, there was the Version 5 Transition Advisory Group, made up of 6 Entities to test our current suite of Standards. There are also multiple registered groups who can write and submit to NERC, Implementation Guidance for ERO deference. Any radical change to the CIP Standards should be practiced and tested BEFORE any Standard is recommended for change. The NSRF also believes there are Entities who are currently compliant (via an audit) by incorporating virtualization practices under our current set of Standards. All Standards are written to "what to do" not how to incorporate a certain or new technology. The NSRF has attempted to answer the SDT questions but still does not agree with this Project.

MEC agrees that the term Cyber Asset should remain in the Glossary of Terms but do not believe it should be limited to Removeable Media and Transient Cyber Asset. Rather, we believe that the term should continue throughout the CIP standards utilized in its current form. The changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs too soon after the last one. Some entities have not had the chance for an audit on the last round of changes. Other revisions, such as CIP-003-7 sections 2, 3 and 5 have yet to become effective. MEC has compliantly implemented virtual servers within the existing CIP standards structure. We have been audited on CIP-005 and CIP-007 as well as CIP-004 and CIP-006. We have self-certified CIP-002, -003, -008 and -011. And are preparing evidence for an audit on CIP-009 and CIP-010 in 2019 and have not identified issues.

It is not clear how this magnitude of changes will create a corresponding improvement to reliability and security. Perhaps the "how to comply" with the existing standards when virtualization is involved could best be addressed using other tools such as ERO-endorsed implementation guidance or readiness reviews for the segment of Responsible Entities who are operating or plan to operate with virtualization.

Southern believes the retirement of the term BES Cyber Asset accomplishes the purpose and the generic Cyber Asset is still appropriate for those areas in the standard where a device level is appropriate, such as TCAs. Due to the nature in which they are used, Transient Cyber Assets should continue to be viewed as individual assets that can be grouped for compliance and reporting reasons. The proposed changes reflect this.

Comment	

Texas RE suggests the term Cyber Asset should continue to be used in defining all system definitions, such as Removable Media, Transient Cyber Assets, and BES Cyber System. A system is one to many Cyber Assets, regardless of whether the Cyber Asset is physical or virtual. Removing the term Cyber Asset from the system definition loses the hierarchy that is in place.

Texas RE is concerned there will be a gap because not every cyber asset in the system will be protected under the new definition. Treating the virtual machine and its host as separate Cyber Assets may result in mixed-trust virtual environments, which exacerbates vulnerabilities as the host runs CIP and corporate virtual machines. CIP controls are only being applied to the CIP virtual machine and not its host; even though the host "if rendered unavailable, degraded, or misused" can affect the CIP and corporate virtual machines. In addition to certain assets not being protected, Texas RE is concerned these changes could lead to an increased effort for entities to provide evidence of their identification of BES Cyber Systems and for Regional Entities to audit.

If the SDT elects to eliminate the term Cyber Asset, Texas RE recommends the following BES Cyber System (BCS) definition:

One or more Cyber Assets, regardless of redundancy, performing one or more reliability tasks that if rendered unavailable, degraded, or misused would result in adverse impact to one or more BES Facilities within 15 minutes.

Jack Cashin - American Public Power Association - 4	
Answer	
Document Name	
Comment	

APPA believes the SDT should consider the concept of two (parallel) definitions, at least for a time, and a sort of "virtualization overlay" for the CIP Standards. Instead of replacing the definitions and Standards, create options whereby an entity can select, for any particular cyber system, to use the existing V5-6 definitions and Standards, or new virtualization definitions and Standards. It is up to the entity to make clear in advance which approach they choose for each cyber system.

As a practical matter, it is anticipated that there would be a single Standard in each case, but that it would include all the existing Parts as well as all the new proposed Parts (as modified by comments) to accommodate virtualization, with language directing an entity to select, for each cyber system, which of the two sets they will adhere to.

In this way the extensive changes to allow virtualization can be piloted by those entities most involved, while other entities can continue their CIP practices as at present, which accommodates the backwards compatibility concept. Over time, industry can learn whether the changes represent a real advance or introduce a large number of unintended consequences, and work to improve the Standards.

As such, all existing definitions would be retained in parallel to the new ones proposed in this effort.

This concept might be considered somewhat analogous to that used for the transition from PRC-005-2 to PRC-005-6, modified for use in virtualized and non-virtualized environments.

Comment

Cyber Assets are still discrete parts of a BCS either physical or virtual and must remain a term across the standards. Limiting the use of Cyber Asset to TCA and RM becomes problematic when looking at the way a Cyber Asset that is included in a BCS is disposed of as a part of CIP-011 R2.1 and R2.2. Either the language in CIP-011 must be changed or this question needs to be rewritten to clarify the impacts to CIP-011 as well.

The "systems" approach is flexible and has value when used for any CIP Cyber Assets. The "system" grouping can be applied arbitrarily and applicability only relies on an entities approach. In one context, the use of "Cyber Asset" versus "Cyber System" is valuable to be able to distinguish a single "device" that is included in a Cyber System. The entity just needs to be diligent in how they define their "Cyber Assets" and "Cyber Systems" to ensure they effectively provide value. We agree that Removable Media does not lend itself well to the "systems" approach. Unlike a Transient Cyber Asset (example, a laptop) that includes a combination of hardware, software, data, etc., the typical Removable Media is only media used for transferring and/or storing code and/or data.

PacifiCorp's approach to this informal comment period was to provide the SDT with constructive feedback related to the proposed revisions to the terms, standards and concepts presented. With that said, PacifiCorp has additional comments and concerns that will be covered in question #16. No changes to proposed Removable Media. PAC is suggesting some minor adjustments to the TCA definition:	

Transient Cyber Asset - A Cyber Asset that is: 1) capable of transmitting or transferring executable code, 2) not included in a BES Cyber System, 3) not [included in] a Protected Cyber System (PCS) associated with high or medium impact BES Cyber Systems, and 4) directly connected (e.g., using Ethernet, serial, Universal Serial Bus, or wireless including near field or Bluetooth communication) for 30 consecutive calendar days or less to a: 1) BES Cyber System (BCS), 2) network within a BES Cyber System Logical Isolation Zone containing high or medium impact BES Cyber Systems, or 3) PCS associated with high or medium impact BES Cyber Systems. [delete the remaining examples text] Examples of Transient Cyber Assets include, but are not limited to, Cyber Assets used for data transfer, vulnerability assessment, maintenance, or troubleshooting purposes.

BPA believes that a more effective approach would roll up the requirements that currently depend upon that term for applicability and retire the term Cyber Asset itself. Security controls for removable media can easily be a subset of controls applied to any transient device. Rather than a defined term "Cyber Asset" which then has "Transient" pre-pended, either TCA (including removable media) can be a defined term with requirements applied to it, or the requirement can simply apply to transient devices with no special term required.

Transient Cyber Assets could be better considered as Transient Cyber Systems. There may be virtualized systems that blur the line between individual or multiple assets. It may be possible to “virtually” change a Transient Cyber System’s location from inside the Logical Isolation Zone to outside, allowing it to transit. Depending on how virtualization is implemented, it may make sense to manage multiple or blurred assets on a Transient Cyber System level. The key elements of a Transient Cyber System are that the entire system is either inside the LIZ (for 30 days or less) or outside at any one time, but never both at the same time. Operating by this definition would still make asset-level management appropriate where discrete Cyber Assets such as laptops are used.

BPA suggests adding the following clarification to this question regarding security requirements for EAMS: “Under the proposed new definition EAMS can safely exist outside of a Logical Isolation Zone, under a reduced set of applicable requirements that allow entities to use additional methods to monitor and correlate access log entries.” This may require modification to CIP-004 R4.2 to allow the entity to accept verification of electronic access authorization for third parties other than at the individual level, perhaps based upon contract statements of work (SOW) or service level agreements (SLA).”

Button respons should be "No". Editing of the button isn't possible. PacifiCorp’s approach to this informal comment period was to provide the SDT with constructive feedback related to the proposed revisions to the terms, standards and concepts presented. With that said, PacifiCorp has additional comments and concerns that will be covered in question #16. PAC believes that this can still be accomplished by maintaining the EACMS term and altering the existing definition. It will allow entities the flexibility to define the different devices that are EACMS and what duties they perform. Third party monitoring still fits into the scope of the original definition of EACMS. Based on the current proposal of EAMS and EACS, systems like SEIM and IDS would be categorized as EAMS. EAMS does not show up in any of the current draft versions of the Standards, it is unclear if this was the SDT’s intent. Proposed change to existing definition for EACMS: **EACMS** - Cyber Assets or [systems] that [delete – perform] [provide] electronic access control or electronic access monitoring of [delete - the Electronic Security Perimeter(s) or] BES Cyber Systems. This includes Intermediate Systems.

Pamela Hunter - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - SERC, Group Name Southern Company

Answer	Yes
Document Name	

Comment

Southern Company believes that this change is one that will allow for more granular scoping and grouping of systems so that protections can be consistently applied at appropriate levels. Along with the proposed term PAMS, the additional flexibility that this change will provide opens up the possibility to use security and analysis services that cannot currently be used while preserving backward compatibility.

Southern agrees with this direction and believes it will greatly help with the sharing of logging information for detection of cyber-attacks and indicators of compromise. It is a big step towards allowing correlation of events with non-CIP network activity and the sharing of information with entities or agencies that may have classified intel for use in the analysis of log data. Southern requests that as the SDT considers this area and its relationship to BCSI, that the SDT consider the implications to “off premise repositories” of this log information that is shared with external parties for further analysis. Southern believes the risks of this should be covered contractually with NDA's for example, and not covered by system level requirements on the off-premise systems on which this data resides. With that in mind, Southern suggests the SDT consider the need for EAMS and PAMS definitions.

Also, while CIP-011-2 was not included in this round of informal comments, the scope within CIP-011-2 will need to be refined to accommodate the new terms but we understand that this further refinement is planned.

With respect to the proposed EAMS definition, what is meant by “Cyber systems that provide electronic access monitoring”? Is the term intended to refer to systems that are monitoring the “electronic access”? Or does the term mean that EAMS are performing electronic monitoring of the BCS (such as Tripwire, patch management solutions, SIEM tools, etc.)? The EACS definition is clear that a device/system is controlling electronic access to the BCS. Guidance on EAMS should include what systems are anticipated to be considered EAMS. Currently, EAMS are only applicable under CIP-004. In the event of a third-party service monitoring EAMS and PAMS, it may be extremely difficult to authorize access and revoke access in a timely fashion for individual employees at said third-party service. This requirement will need further compliance guidance. As written now, the Standard introduces for EAMS and PAMS the same unresolved challenge as exists the use of third-party cloud providers for BCS storage. The EACMS vs. EAC/EAM definition discussion presents the same possibility for two parallel definitions as discussed above in response to Question 3. Why not retain the EACMS definition and introduce the new option for EAC/EAM definitions as well? Entities must state which definition they use for each applicable cyber system. There is no security necessity at this time to force all to change to accommodate virtualization, when only some entities are pursuing such approaches. Both options are feasible at present.

Rachel Coyne - Texas Reliability Entity, Inc. - 10	
Answer	No
Document Name	
Comment	

Texas RE does not agree that separating EACMS into two separate terms is necessary. It appears that separating EACMS into EACS and EAMS and updating the applicability of various requirements based on this new distinction is acting to remove the applicability of some requirements, including security, from purely monitoring systems. This would decrease cyber security and the defense in depth posture. Based on the changes in the applicability to EAMS that were proposed, such as CIP-004-7 R3 regarding PRAs, it appears as though we would be allowing for third party monitoring by removing requirements that are difficult for entities to impose on third parties.

In regards to the language of the proposed ECMS and EAMS definitions, the SDT uses “cyber system”. This is not consistent with the language used in the proposed BES Cyber System definition. Entities also use virtualization for their EACMS. Texas RE proposes that the EACMS definition also use the Cyber Asset term, and the Cyber Asset term will allow for virtualization.

Rather than breaking EACMS into two terms, Texas RE recommends the following revised EACMS definition:

Cyber Assets that perform authentication, monitoring and logging, access control, interactive remote access, or alerting of the Electronic Security Perimeter(s) or BES Cyber Systems. This includes Intermediate Systems.

This recommendation is based on FERC’s description of EACMs in Order 848, paragraph 54: “*With regard to identifying EACMS for reporting purposes, NERC’s reporting threshold should encompass the functions that various electronic access control and monitoring technologies provide. Those functions must include, at a minimum: (1) authentication; (2) monitoring and logging; (3) access control; (4) interactive remote access; and (5) alerting*.”

The only place EAMS is used is in CIP-004 R4 relative to granting physical and electronic access. Please clarify the definition of EAMS. Do EAMS monitor “electronic access” to a BCS or Cyber Asset within a BCS, or does it refer to event monitoring and network inventory discovery tools like SIEMs and Tripwire, Spiceworks, etc? If third party monitoring is allowed, how can the entity timely handle revocation of access? Logging and alerting in CIP-007 R4 refer to EACS however; the proposed definitions do not apply to those terms and are better suited for EAMS.

Kevin Salsbury - Berkshire Hathaway - NV Energy - 5

Answer	No
Document Name	

Comment

NV Energy agrees with the SDT that there are potential future benefits in separating the control and monitoring functions of EACMS; however, we do not agree these changes should be pursued at this time. It is our view that the changes being considered by the SDT go well beyond the intended scope as provided within the approved SAR. The changes provided by this separation of functions by device, at this time, will again represent another overhaul of existing Entity's CIP programs, processes, and documentation.

Additionally, the current SAR simply asked the SDT to consider how the increased use of virtualization in industry control systems might impact the CIP V5 Standards, along with assessing the security risks associated with virtualization. We do not believe this should be interpreted to mean that the SDT should as a first step recraft the body of CIP Standards in ways that fundamentally change the current BES Cyber System security philosophy. While that may ultimately be what is necessary, we do not believe that is what is required at this time. We are also concerned that the proposed changes may have many unknown and unintended impacts that could diminish BES Cyber System security rather than improve it.

For this reason, we recommend that the SDT take a more conservative approach through the 1) identification of the security risks introduced by virtualization, 2) consideration of how virtualization might be utilized within the current CIP Reliability Standards structure, and 3) consideration of how guidance might be developed to assist Responsible Entities who are considering the implementation of virtualization.

Additionally of note, that there are no Parts within the revisions to the Standards that are applicable to EAMS, which would question the need for splitting the EACMS definition versus revising the definition to accommodate the SDT's intent.

Comment

CenterPoint Energy Houston Electric, LLC (CenterPoint Energy) does not support a major overhaul of the standards at this time. However, if the SDT continues to make revisions, CenterPoint Energy recommends the following:

The intent of the new EACS and EAMS terms need to be clarified. The SDT should consider adding “access monitoring, alerting, and logging” to the EAMS definition to be consistent with the approach for PACS and PAMS. The definition should also clarify that the alert is coming from the system generating the alert.

This change will require all existing non-third party systems that perform both operations to be re-classified under two Cyber Asset definitions, rather than one. Consider retaining the existing EACMS classification and adding new split classifications that can optionally be used for those systems that only perform half of the functional activities.

Nicholas Lauriat - Network and Security Technologies - 1

Answer	No
Document Name	

Comment

Although N&ST appreciates the desire to allow the use of 3rd party monitoring systems in CIP environments, N&ST strongly opposes the idea of allowing “monitoring only” devices to be assigned to a new definition and subject to only CIP-004 requirements. N&ST believes this proposal suggests the SDT considers detective security controls to be of lesser importance than preventative controls, which in our opinion is contrary to generally accepted best practices for layered and multi-faceted cyber security. N&ST notes that the SANS / E-ISAC analysis of the Ukraine power grid attack cites a lack of ICS network monitoring as a likely factor in the attack’s success. N&ST further notes that in FERC Order 850, in which the Commission directs NERC to add EACMS devices to the applicable systems for Supply Chain Standards, the Commission specifically argues against the idea that monitoring may be a less important security function (Paragraph 57).

Response

Robert Ganley - Long Island Power Authority - 1

Answer No

Document Name

Comment

By separating EACMS into EAMS and EACS, it will allow entities to place "monitoring systems" (EAMS) outside of a PSP and be treated similarly to BCSI. While this concept makes sense from an information protection perspective, it dramatically increases risk to the safe and reliable operation of the BES. EAMSs are more than just BCSI containers - they may also perform alerting to potential/actual cyber attacks. Permitting them to reside outside of a defined PSP (refer to EAMS removal in CIP-006-7 Redline) increases the risk of their physical impairment by an attacker. Furthermore, the implementation of EAMSs in either a corporate enterprise or 3rd party environment, potentially outside of a PSP and/or DMZ associated with a LIZ, extends the surface area for a cyber attack and increases the number of potential attack vectors. As a result, it would place BCSs/PCSs at greater risk of an undetected attack.

Since CIP-004-7 continues to include EAMSs in requirements associated with granting and revoking electronic access, the use of 3rd party providers to support EAMSs will become increasingly difficult to manage. 3rd party providers would also have to agree to requirements in other CIP standards such as “disposal of cyber assets containing BCSI”.

If EAMS and EACS functionality cannot be split from a device, it’s unclear as to how it should be categorized. Recommendation: These changes are not impacted by virtualization and should be left as-is.

Comment	
The changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs too soon after the last one. Some entities have not had the chance for an audit on the last round of changes. Other revisions, such as CIP-003-7 sections 2, 3 and 5 have yet to become effective. MEC has compliantly implemented virtual servers within the existing CIP standards structure. We have been audited on CIP-005 and CIP-007 as well as CIP-004 and CIP-006. We have self-certified CIP-002, -003, -008 and -011. And are preparing evidence for an audit on CIP-009 and CIP-010 in 2019 and have not identified issues. It is not clear how this magnitude of changes will create a corresponding improvement to reliability and security. Perhaps the “how to comply” with the existing standards when virtualization is involved could best be addressed using other tools such as ERO-endorsed implementation guidance or readiness reviews for the segment of Responsible Entities who are operating or plan to operate with virtualization.

Richard Jackson - U.S. Bureau of Reclamation - 1,5

Answer	No
Document Name	

Comment

Reclamation recommends NERC not retire EACMS. Reclamation does not support creating new terms EACS and EAMS. If EACMS must be retired, Reclamation recommends using existing, familiar industry terms (as defined in the National Institute of Standards and Technology (NIST) Glossary of Key Information Security Terms (NISTIR 7298)).

For example:

Replace **EACMS** with NIST's **Intrusion Detection and Prevention System (IDPS)** – Software that automates the process of monitoring the events occurring in a computer system or network and analyzing them for signs of possible incidents and attempting to stop detected possible incidents.

Replace **EACS** with NIST's **Intrusion Prevention System(s) (IPS)** – System(s) that can detect an intrusive activity and can also attempt to stop the activity, ideally before it reaches its targets.

Replace **EAMS** with NIST’s **Intrusion Detection Systems (IDS)** – System(s) that detect attacks by capturing and analyzing network packets. Listening on a network segment or switch, one network-based IDS can monitor the network traffic affecting multiple hosts that are connected to the network segment.

Dana Klem - MRO - 1,2,3,4,5,6 - MRO, Group Name MRO NSRF

Answer	No
Document Name	

Comment

Overall, the NSRF does not agree with the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry’s programs. Originally, there was the Version 5 Transition Advisory Group, made up of 6 Entities to test our current suite of Standards. There are also multiple registered groups who can write and submit to NERC, Implementation Guidance for ERO deference. Any radical change to the CIP Standards should be practiced and tested BEFORE any Standard is recommended for change. The NSRF also believes that there are Entities who are currently compliant (via an audit) by incorporating virtualization practices under our current set of Standards. All Standards are written to “what to do” not how to incorporate a certain or new technology. The NSRF has attempted to answer the SDT questions but still does not agree with this Project.

If the EAMS contains BCSI then how is third party monitoring allowed? A company still must protect BCSI. More guidance is required for how third party-managed EAMS containing BCSI can be done in a compliant manner. In addition, v5 has an assumption that BCS, PACS, and EACMS are always separate devices. However, they are not. Now we have split EACMS into two along with PACS. So, what is required of devices that have multiple associations? This needs to be address by the SDT.

5. The SDT realized through the process of splitting EACMS that the same considerations apply to PACS, which will allow changes within the applicability for alerting and logging (PAMS is not reflected within the applicability section at this time). The SDT is considering splitting the PACS term into PACS and PAMS to allow third party monitoring or event correlation to be performed without carrying the PACS classification. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

Sandra Shaffer - Berkshire Hathaway - PacifiCorp - 6

Answer	Yes
Document Name	

Comment

Button response should be "No". Editing option seems to be broken.

PacifiCorp's approach to this informal comment period was to provide the SDT with constructive feedback related to the proposed revisions to the terms, standards and concepts presented. With that said, PacifiCorp has additional comments and concerns that will be covered in question #16.

PAC believes this can still be accomplished by maintaining the PACS term and altering the proposed definition. It will allow entities the flexibility to define the different devices that are PACS and what duties they perform. Third party monitoring still fits into the scope of the original definition of PACS. Based on the current proposal of PAMS, there are no instances of the term used in the proposed Standards, it is unclear if this was the SDT's intent.

Proposed change to PACS:

PACS - Cyber Assets [or systems] that control, alert, or log access to the Physical Security Perimeter(s), exclusive of locally mounted hardware or devices at the Physical Security Perimeter such as motion sensors, electronic lock control mechanisms, and badge readers.

Southern enthusiastically agrees with separating the monitoring/logging aspects out of the access control systems. However, we suggest the SDT consider the need for EAMS and PAMS to exist at all. The monitoring and logging aspects of these systems make any risk they present a data disclosure risk and not a device or system-oriented risk. If the data is of concern, we can have requirements to protect the data without the need for device/system level terms at all. Also, please see our answer to question 4.

Please clarify how an entity would classify an asset that performs PACS and PAMS functionality. Would high-watermarking to the most restrictive be appropriate? Please clarify whether PAMS is to be treated as an applicable system subject device-type requirements (e.g. ports, patching, etc.) or if PAMS is to be treated similar to BCSI, which appears to be the case.

While public power is not sure of the need to separate the terms, if the terms are separated, they will require appropriate accompanying guidance. Consistent with our EAMS response in question 4, clarity regarding applicability of the terms would be needed. The SDT should consider the additional resources and costs associated with a registered entity adding the new applicability to existing CIP-004, R4, and R5 requirements. Moreover, the EAMS and PAMS would need to be incorporated into CIP-011 as designated storage locations. As indicated in the responses to questions 3 and 4, another option is to retain the existing definition while introducing the option to use the new bifurcated formulation, which may offer advantages to some. In this case, the existing PACS term might be re-named PACMS (in parallel with EACMS) so that PACS and PAMS are clear and also parallel to new terms. APPA would also request that the SDT consider the CIP controls appropriate for PAMS. As is the case for EAMS, if defined and scoped carefully, a PAMS may have no 15-minute impact and would not qualify for CIP controls at all, other than potentially as a BCS storage location

If an entity is using a single system for both PACS and PAMS, how should the system be identified within CIP-002 (as a PACS, PAMS or PACS / PAMS combination), and should the system be high-water marked within applicable standards and requirements? NYPA questions why PAMS is excluded from certain requirements, such as CIP-006 R1.7 (alarm or alert for detected unauthorized physical access) or R3.1 (Maintenance and Testing). If entities rely on PAMS for alerting and logging within CIP-006 R1, these systems should be subject to M&T processes. And if the new definition of PAMS focuses on alerting and logging, this system should be applicable to R1.7. Excluding PAMS from selected requirements is lowering the security bar. In addition, the SDT should justify why PAMS and EAMS are specifically called out within the requirement language of CIP-004 R4.1, 4.4, and 5.3. This approach is inconsistent throughout the standards and exclude other applicable device types listed within the ‘Applicable Systems’ column.

Similar to EACMS, this change will require all existing non-third party systems that perform both operations to be re-classified under two Cyber Asset definitions, rather than one. Consider retaining the existing PACS definition and adding new split classifications that can optionally be used for those systems that only perform half of the functional activities.

Kevin Salsbury - Berkshire Hathaway - NV Energy - 5

Answer	No
Document Name	

Comment

NV Energy agrees with the SDT that there are potential future benefits in separating the control and monitoring functions of PACS; however, we do not agree these changes should be pursued at this time. It is our view that the changes being considered by the SDT go well beyond the intended scope as provided within the approved SAR. The changes provided by this separation of functions by device, at this time, will again represent another overhaul of existing Entity's CIP programs, processes, and documentation.

Additionally, the current SAR simply asked the SDT to consider how the increased use of virtualization in industry control systems might impact the CIP V5 Standards, along with assessing the security risks associated with virtualization. We do not believe this should be interpreted to mean that the SDT should as a first step recraft the body of CIP Standards in ways that fundamentally change the current BES Cyber System security philosophy. While that may ultimately be what is necessary, we do not believe that is what is required at this time. We are also concerned that the proposed changes may have many unknown and unintended impacts that could diminish BES Cyber System security rather than improve it.

For this reason, we recommend that the SDT take a more conservative approach through the 1) identification of the security risks introduced by virtualization, 2) consideration of how virtualization might be utilized within the current CIP Reliability Standards structure, and 3) consideration of how guidance might be developed to assist Responsible Entities who are considering the implementation of virtualization.

Given there is no applicability for PAMS at this time, NV Energy would recommend the SDT address the reasoning for maintaining the Glossary Term if its existence is not applicable to the CIP Standards.

Dana Klem - MRO - 1,2,3,4,5,6 - MRO, Group Name MRO NSRF

Answer	No
Document Name	

Comment

Overall, the NSRF does not agree with the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry's programs. Originally, there was the Version 5 Transition Advisory Group, made up of 6 Entities to test our current suite of Standards. There are also multiple registered groups who can write and submit to NERC, Implementation Guidance for ERO deference. Any radical change to the CIP Standards should be practiced and tested BEFORE any Standard is recommended for change.   The NSRF also believes that there are Entities who are currently compliant (via an audit) by incorporating virtualization practices under our current set of Standards. All Standards are written to "what to do" not how to incorporate a certain or new technology. The NSRF has attempted to answer the SDT questions but still does not agree with this Project.

Response

Richard Jackson - U.S. Bureau of Reclamation - 1,5

Answer	No
Document Name	

Comment

Reclamation recommends the SDT apply the same considerations used for splitting EACMS to PACS. Specifically, Reclamation recommends the SDT consider creating the term PACMS to address existing systems that both control and monitor physical access. Reclamation proposes the existing definition for PACS be used for Physical Access Control and Monitoring Systems (PACMS).

Physical Access Control and Monitoring Systems (PACMS) – Cyber Assets that control, alert, or log access to the Physical Security Perimeter(s), exclusive of locally mounted hardware or devices at the Physical Security Perimeter such as motion sensors, electronic lock control mechanisms, and badge readers

Reclamation supports creating the new terms PACS and PAMS if the PACMS term is also adopted.

Reclamation also recommends changing the proposed definitions of PACS and PAMS to use the term “Cyber Assets” instead of “Cyber Systems,” as described in the response to Question 1,

from:

Physical Access Control Systems (PACS) – Cyber systems that control access to the Physical Security Perimeter(s), exclusive of locally mounted hardware or devices at the Physical Security Perimeter such as motion sensors, electronic lock control mechanisms, and badge readers.

and

Physical Access Monitoring Systems (PAMS) – Cyber systems that alert or log access to the Physical Security Perimeter(s), exclusive of locally mounted hardware or devices at the Physical Security Perimeter such as motion sensors, electronic lock control mechanisms, and badge readers.

to:

Physical Access Control Systems (PACS) – One or more Cyber Assets that control to the Physical Security Perimeter(s), exclusive of locally mounted hardware or devices at the Physical Security Perimeter such as motion sensors, electronic lock control mechanisms, and badge readers.

and

Physical Access Monitoring Systems (PAMS) – One or more Cyber Assets that alert or log access to the Physical Security Perimeter(s), exclusive of locally mounted hardware or devices at the Physical Security Perimeter such as motion sensors, cameras, and badge readers.

Comment	
There is no practical way to meet Requirements related to controlling authorized access without also monitoring whether access granted by the PACS is authorized. In this way, PACS must already be integrated with a form of the proposed PAMS. It is, however, possible for monitoring systems (the proposed PAMS) to go above and beyond the minimum Requirements for PACS. Such additional functionality, which may be helpful to support additional operating controls, should be encouraged. Inventing a new asset class for PAMS would increase the regulatory burden placed on these optional but encouraged systems. The change could have the undesired effect of deterring any monitoring beyond minimum compliance, rather than the desired effect of improving system security.

The changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs too soon after the last one. Some entities have not had the chance for an audit on the last round of changes. Other revisions, such as CIP-003-7 sections 2, 3 and 5 have yet to become effective. MEC has compliantly implemented virtual servers within the existing CIP standards structure. We have been audited on CIP-005 and CIP-007 as well as CIP-004 and CIP-006. We have self-certified CIP-002, -003, -008 and -011. And are preparing evidence for an audit on CIP-009 and CIP-010 in 2019 and have not identified issues. It is not clear how this magnitude of changes will create a corresponding improvement to reliability and security. Perhaps the "how to comply" with the existing standards when virtualization is involved could best be addressed using other tools such as ERO-endorsed implementation guidance or readiness reviews for the segment of Responsible Entities who are operating or plan to operate with virtualization.

We agree with the concept, however LIZ and PCS are defined by their own terms, for example "Logication Isolation Zone: A logicial security zone...." The definitions should be worked on furhter so to avoid this circular definition. This choice of defining also makes 4.2.3.2 and 4.2.3.3 in CIP-010-4 difficult to understand.

While we agree with the proposal to move in this direction, we feel that much more detailed information will be needed in the definitions to fill the void by eliminating the GTB sections. Also, we feel that this approach would benefit from an actual definition for “Logical Security Zone”. This phrase is used in the Logical Isolation Zone definition, but is not itself defined.

This is a good move. However, more clarity is needed on the LIZ language to define what the boundaries of an LIZ are. A communication boundary may not be an accurate way to describe the boundary of an LIZ. Traditional definitions of communication do not take into account virtualized systems that share components; information, hardware, and executable code may exist in a location that bridges the communicating boundary of an LIZ. The definition of PCA may need to be expanded to include any asset, such as a hypervisor, that is able to access the internals of an LIZ. For example, if an LIZ includes virtual machines on a VMware host, the host would be a PCA. If an LIZ is containerized, the host OS would be a PCA. If the virtualized assets are on a SAN, then the SAN would be a PCA. The LIZ would need defined limits which are protected by LIZ design. CIP-005 R1.1 would remain necessary and would specify that all applicable BCS must reside within a defined LIZ. The issue would have to be addressed: How to use inclusive language that covers both routable networked devices and components of a virtualized environment, but exclude devices that are neither.

Sandra Shaffer - Berkshire Hathaway - PacifiCorp - 6	
Answer	Yes
Document Name	
Comment	
Button response should be "No". Editing option seems to be broken. PacifiCorp's approach to this informal comment period was to provide the SDT with constructive feedback related to the proposed revisions to the terms, standards and concepts presented. With that said, PacifiCorp has additional comments and concerns that will be covered in question #16. This term captures the intent, but PAC suggests not using the same words from the term to describe the zone in its definition (i.e. logical security zone = logical isolation zone): Logical Isolation Zone – [delete - A logical] [Electronic] security zone created by applying [logical] controls to communications to or from BES Cyber Systems and Protected Cyber Systems.

We agree that this helps allow entities to provide more defense in depth. However, if an Entity has multiple LIZ nested within each other and has a violation of one of the inner LIZ then you have removed the motivation to do more. If an interior LIZ has a violation but is still fully protected by an outer LIZ, then the Violation Risk Factors should reflect that only a violation related to the outer most LIZ of a nested LIZ setup should result in a penalty. However, if all the BCS and PCAs were all protected by another LIZ then the entity should not be penalized for the outermost LIZ violation since they were all within another interior LIZ. This is because the risk to the BES remain unchanged.

The Technical Rationale document describes well how the Logical Isolation Zone (LIZ) concept will improve the security for virtual environments as well as clarify the serial communications. We recommend that the SDT consider adding clarification to the standard regarding DNP3 over Serial communications. Several questions remain. For example, will the SCADA communications from a front-end processor through a terminal services device to strip off IP communications for DNP3 over serial also be considered as logical isolation? Also, it is not clear why “with External Routable Connectivity” was removed from CIP-005 R2. Given that the CIP-005 Technical Rationale indicates the serial connectivity generally provides logical isolation (p.4), the “with ERC” clarifier should be retained. The LIZ concept represents another dual-definition opportunity, if ESP is retained. An entity would be able select between either concept, on a cyber-system by cyber-system basis, based on which concept makes the most sense for security and operations in its particular environment.

Rachel Coyne - Texas Reliability Entity, Inc. - 10	
Answer	No
Document Name	
Comment	
Texas RE does not see a need to retire the term ESP and introduce the new term, Logical Isolation Zone. The current definition of ESP provides entities the flexibility to implement ESP(s) based on network environment and technology used. ESP(s) can be established using VLANs, IP ranges, **network zones**, demilitarized zone (DMZ), etc. Changing the definition to Logical Isolation Zone means entities would need to implement “network zones”, which would not allow for the same flexibility as the ESP concept. This could result in potential un-needed upgrades. Texas RE does not agree with retiring the EAP definition. Since network traffic from Logical Isolation Zones will need to pass through an interface, the definition of EAP should be retained and protected how it is currently being protected. Texas RE does agree with moving the concept of PCA to PCS, however, Texas RE recommends using the current definition of PCA and simply change the term to PCS. This is consistent with Texas RE’s recommendation for the BCS definition.

Kevin Salsbury - Berkshire Hathaway - NV Energy - 5	
Answer	No
Document Name	
Comment	

NV Energy does not support the proposed retirement of the terms Electronic Security Perimeter (ESP) or Electronic Access Point (EAP), nor do we support their replacement with the newly proposed term Logical Isolation Zone (LIZ). While there may be future benefits to such a change, and NV Energy currently deploys this method of Zone identification within its system, NV Energy does not believe that this is the right time, nor do we agree that the changes being considered will improve an entity's reliability, security and compliance efforts through the higher-level objectives set forth by the SDT. Responsible Entities have broadly built their cybersecurity programs around proven concepts, objectives, and programs. The proposed changes will undoubtedly create significant disruption to those systems and efforts. We also question the need for such broad changes when there are changes within the body of CIP Reliability Standards that will not be enforceable until the year 2020 (e.g., CIP-005-6).

NV Energy is also concerned that the level of change being contemplated by the SDT is too great and represents a very steep learning curve for the industry. For this reason, we ask the SDT to narrow their focus to providing clear requirements for the protection of CIP systems in virtualized environment, without the broader overhaul of terms and definitions as proposed in this informational posting.

Lan Nguyen - CenterPoint Energy Houston Electric, LLC - 1 - Texas RE

Answer	No
Document Name	

Comment

CenterPoint Energy does not support a major overhaul of the standards at this time. However, if the SDT continues to make revisions, CenterPoint Energy recommends the following:

The Logical Isolation Zone (LIZ) concept does not address host firewalls or other technology limiting logical connections to an asset. The SDT should revise the LIZ definition to clarify that the LIZ controls are external to the controls applied by the BES Cyber System itself.

Response

Susan Sosbe - Wabash Valley Power Association - 3

Answer	No
Document Name	

Comment

Introduction of a new term logical isolation zone rather than ESP introduces confusion in the definition and with backward compatibility. For example, the definition would now be applicable to serial communications. This is an example of a definition that will be debated for several years in the industry. Continue with our current industry standard definition or ESP and adjust the standards language to address issues or adopt standard NIST terms. SuperESPs can be accommodated by changes to requirements rather than definitions as the current definition of an ESP does not prevent multi-site ESPs.

Douglas Webb - Great Plains Energy - Kansas City Power and Light Co. - 1,3,5,6 - MRO, Group Name Westar-KCPL

Answer	No
Document Name	

Comment

Westar | Kansas City Power & Light Company incorporate by reference Edison Electric Institute’s response to Question 6.

Additionally, Westar | Kansas City Power & Light Company share the following observations:

Retiring the Electronic Access Point Glossary Term removes critical identification of the ingress and egress points.

The concept of a Logical Isolation Zone does not relieve the expectation of documented ingress and egress points, especially for network diagramming.

Identify LIZ Data Flow. Related to concerns regarding retirement of the EAP Glossary Term, we believe it is critical that the Logical Isolation Zone considers the ingress and egress flow of data at the zone.

LIZ Residing within a PSP. Considering the Logical Isolation Zone concept, at first glance, it would be expected the LIZ is protected within a Physical Security Perimeter. The LIZ concept is strengthened by an affirmative statement the zone is located within a PSP.

Chris Scanlon - Exelon - 1,3,5,6

Answer	No
Document Name	

Comment

Exelon does not support the proposed retirement of the terms Electronic Security Perimeter (ESP) or Electronic Access Point (EAP), nor do we support their replacement with the newly proposed term Logical Isolation Zone (LIZ) as part of this effort.

We do agree there may be future benefits to such a change but see this being handled more appropriately within a separate, comprehensive CIP version overhaul effort. Even with the proposed backward compatibility, this change will be disruptive to current CIP programs in place, requiring documentation, compliance tool/technology and process changes. Such a change also brings with it a very steep learning curve for the industry.

We would prefer for the SDT to narrow their focus to providing clear requirements for the protection of CIP systems in virtualized environment, without the broader overhaul of terms and definitions as proposed in this informational comment period.

SMEC believes the proposed changes to the CIP standards goes beyond the intent of the SAR. The proposed new term LIZ, if approved, should only apply to the virtual devices in which managing access may not use the layer 3 routable protocol while keep the existing requirements the same as before. The changes as proposed will bring BES Cyber Sytems with serial conections, no erc and no dial up into scope for a number of requirements with no benefit. SMEC is concerned that this magnitude of change to the CIP standards and definitions would be too disruptive to non-virtualization compliance.

NYPA supports comments submitted by NPCC / TFIST. We stress that the SDT must better define the term “communications” used throughout the standards / requirements, and whether this expands the scope beyond routable communications. SDT should also differentiate between a logical and physical environment. The current proposed change does not provide a security benefit and will lead to costly administrative changes (governance documents, asset management systems, diagrams, evidence, etc.). NYPA supports maintaining the ESP / EAP, and routable communication model. In addition, the SDT should consider reverting to the previous CIP-005 R1.1 that required identification (boundaries) of the Electronic Security Perimeter (or Logical Isolation Zone in this case). Entities must define / develop a LIZ before applying required security controls.

Comment	
The exclusion of "Routable Protocol" in the LIZ definition, along with the technical guidance, helps address the use of serial comms and its inherent isolation ability. Note: To achieve this, on CIP-005-7 Part R 1.1, the sub Parts should be bulleted and the “and” between sub Part 1.1 and 1.2 should be an “or”. In addition, it would be preferable to put some specific language in this definition and requirements in lieu of referring to technical guidance. The redaction of EAP from the definition is detracting from the ability to easily identify what connections lead to BCSs/PCSs. Recommendation: Restate EAP definition in new terms that coincide with the implementation of a LIZ. (I.e. Entities can identify “Virtual” EAP’s by name/lable).

Comment

NPPD does not support the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry’s programs. The changes being proposed present a risk of unintended consequences for what is the vast majority of systems that are not in virtualized environments. NPPD provides our comments in the spirit of identifying some of the risks and unintended consequences for moving forward in this direction; and in the final comment on this form our recommendations.

This will require unnecessary additional documentation for serial connected devices. We do not see an issue with the current ESP/EAP model. We support keeping the “are connected using a routable protocol” language.

Comment

MEC does not support the proposed retirement of the terms Electronic Security Perimeter (ESP) or Electronic Access Point (EAP), nor do we support their replacement with the newly proposed term Logical Isolation Zone (LIZ). The changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs too soon after the last one. Some entities have not had the chance for an audit on the last round of changes. Other revisions, such as CIP-003-7 sections 2, 3 and 5 have yet to become effective. MEC has compliantly implemented virtual servers within the existing CIP standards structure. We have been audited on CIP-005 and CIP-007 as well as CIP-004 and CIP-006. We have self-certified CIP-002, -003, -008 and -011. And are preparing evidence for an audit on CIP-009 and CIP-010 in 2019 and have not identified issues.

It is not clear how this magnitude of changes will create a corresponding improvement to reliability and security. Perhaps the “how to comply” with the existing standards when virtualization is involved could best be addressed using other tools such as ERO-endorsed implementation guidance or readiness reviews for the segment of Responsible Entities who are operating or plan to operate with virtualization.

Recommend changing the label to clarify this is a security label . . . possibly Logical Security Zones

Audit interpretations of this new, more flexible label are a concern

Concern that this does not enhance cyber security, this is not backwards compatible and forces to re-evaluate what is in scope (ie, microwave communications, serial communications, third party communications, etc). Need better clarification on communications demarcation – what is in scope vs out of scope? Concerned that the current CIP-005 R1.1 has not translated well – need more clarity on establishing boundaries and guidance on how to document

We do not support the proposed retirement of the terms Electronic Security Perimeter (ESP) or Electronic Access Point (EAP), nor do we support their replacement with the newly proposed term Logical Isolation Zone (LIZ). While there may be future benefits to such a change, we do not believe that this is the right time, nor do we agree that the changes being considered will improve an entity's reliability, security and compliance efforts through the higher-level objectives set forth by the SDT. Richard Jackson - U.S. Bureau of Reclamation - 1,5

Answer	No
Document Name	

Comment

Reclamation does not support the proposed term Logical Isolation Zone (LIZ). “Logical isolation” in computer networking is when two sets of devices, which share a physical network infrastructure, are prevented from being able to communicate with each other. The proposed definition implies that a LIZ is a created by *controlling* the communications to and from BES Cyber Systems and Protected Cyber Systems. This is the opposite of isolation.

Logical isolation must distinguish between BES and non-BES. A Logical Isolation Zone could become a risk to BES Cyber Systems when stretched to corporate business enclaves through virtual machine hyper jumping from a lower trust business network. Mixed trust environments on common hardware between CIP Applicable Systems and corporate business networks could also introduce risk to the BES.

Reclamation recommends retaining the existing ESP/EAP model. If the ESP/EAP model must be modified, Reclamation recommends using existing, familiar industry terms (as defined in the National Institute of Standards and Technology (NIST) Glossary of Key Information Security Terms (NISTIR 7298)).

For example:

Replace **ESP** with NIST's **Enclave** – A set of system resources that operate in the same security domain and that share the protection of a single, common, continuous security perimeter.

Replace **EAP** with NISTS's **Enclave Boundary** – Point at which an enclave's internal network service layer connects to an external network's service layer, i.e., to another enclave or to a wide area network (WAN).

Reclamation recommends the following term be added to the NERC Glossary of Terms instead of LIZ:

Electronic Security Enclave (ESE) – One or more Cyber Assets logically connected by one or more internal communication control(s) of a single authorizing security policy for BES Cyber Systems and Protected Cyber Systems. The logically connected Cyber Assets may be structured by physical proximity or by function, independent of location.

Mike Smith - Manitoba Hydro - 1,3,5,6, Group Name Manitoba Hydro

Answer	No
Document Name	

Comment

We disagree to use LIZ to replace the term ESP/EAP that is commonly understood and widely accepted by the registered entities. Given that currently the majority of CIP Cyber Assets (more than 99%) are physical devices and the ESP/EAP compliance process today works fairly smoothly by implementing ESP/EAP requirements that are appropriately prescribed, it doesn't make sense to change ESP to LIZ that is only for sufficing a very small percentage of the virtual devices while ignoring the fact that the majority of physical CIP devices are working very well for the ESP/EAP.

We suggest the proposed new term LIZ should only apply to the virtual devices in which managing access may not use the layer 3 routable protocol while keep the existing requirements the same as before. Resulting from our suggestions, it would be beneficial for all registered entities as follows:

- For the entities that have no any virtual CIP Cyber Assets, they don't need to do anything.
- For the entities that have some virtual CIP Cyber Assets, they may need to use the new term LIZ to resolve the CIP compliance issues unless they could resolve them before.

Dana Klem - MRO - 1,2,3,4,5,6 - MRO, Group Name MRO NSRF

Answer	No
Document Name	

Comment

Overall, the NSRF does not agree with the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry's programs. Originally, there was the Version 5 Transition Advisory

Group, made up of 6 Entities to test our current suite of Standards. There are also multiple registered groups who can write and submit to NERC, Implementation Guidance for ERO deference. Any radical change to the CIP Standards should be practiced and tested BEFORE any Standard is recommended for change. The NSRF also believes that there are Entities who are currently compliant (via an audit) by incorporating virtualization practices under our current set of Standards. All Standards are written to “what to do” not how to incorporate a certain or new technology. The NSRF has attempted to answer the SDT questions but still does not agree with this Project. Here are some specific examples of what a small change to a Standard will do to the industry.

This will require unnecessary additional documentation for serial connected devices. The NSRF does not see an issue with the current ESP/EAP model. The NSRF supports keeping the “are connected using a routable protocol” language.

Kara White - NRG - NRG Energy, Inc. - 3,4,5,6 - FRCC,MRO,WECC,Texas RE,NPCC,SERC,RF

Answer	No
Document Name	

Comment

This potential standard change has a broad implication than higher level objectives provided by BES Cyber System concept (and its Logical Isolation Zone). This could cause a re-definition of Interactive Remote Access. This adds a broader compliance burden to the standards than presently required under the non ERC BCA category. The secure configuration now includes serial configuration data. NRG asserts that this potential change would broadly expand confituration data requirements and the controls on configuration of serial ports. Beyond serial implications, it could also impact the 4-20 mA inputs (currently in the standard, implications are for routable communications).

Russel Mountjoy - Midwest Reliability Organization - 10

Answer	No
Document Name	

Comment

MRO concludes that surface area protection architectures such as the Logical Isolation Zone are not necessarily equivalent or a security improvement when compared to existing perimeter protections. Zone or system level protections such as microsegmentation can enhance the protections provided by perimeter protections, but they are not in conflict with each other and can coexist within the same currently defined CIP environment.

The virtualization changes that are proposed will likely permit mixed some trust applications but it isn't yet clear how logical isolation zones will provide better or equivalent protections to that of an ESP.

WAPA does not support the proposed term Logical Isolation Zone (LIZ). "Logical isolation" in computer networking is when two sets of devices, which share a physical network infrastructure, are prevented from being able to communicate with each other. The proposed definition implies that a LIZ is a created by controlling the communications to and from BES Cyber Systems and Protected Cyber Systems. This is the opposite of isolation.

Logical isolation must distinguish between BES and non-BES. A Logical Isolation Zone could become a risk to BES Cyber Systems when stretched to corporate business enclaves through virtual machine hyper jumping from a lower trust business network. Mixed trust environments on common hardware between CIP Applicable Systems and corporate business networks could also introduce risk to the BES.

WAPA recommends using existing, familiar industry terms (as defined in the National Institute of Standards and Technology (NIST) Glossary of Key Information Security Terms (NISTIR 7298)).

- Replace ESP with NIST's Enclave – A set of system resources that operate in the same security domain and that share the protection of a single, common, continuous security perimeter.
- Replace EAP with NISTS's Enclave Boundary – Point at which an enclave's internal network service layer connects to an external network's service layer, i.e., to another enclave or to a wide area network (WAN).

WAPA recommends the following term be added to the NERC Glossary of Terms instead of LIZ:

Electronic Security Enclave (ESE) – One or more Cyber Assets logically connected by one or more internal communication control(s) of a single authorizing security policy for BES Cyber Systems and Protected Cyber Systems. The logically connected Cyber Assets may be structured by physical proximity or by function, independent of location.

Sandra Shaffer - Berkshire Hathaway - PacifiCorp - 6

Answer	Yes
Document Name	

Comment

Button response should be "No". Editing option seems to be broken.

PacifiCorp's approach to this informal comment period was to provide the SDT with constructive feedback related to the proposed revisions to the terms, standards and concepts presented. With that said, PacifiCorp has additional comments and concerns that will be covered in question #16.

This term captures the intent, PAC suggests edits to provide additional scoping keeping Intermediate Systems outside of the Logical Isolation Zone they are designed to help protect:

Intermediate Systems - A [cyber] system acting as part of the protection applied [externally] to a logically isolated BCS that limits external user-initiated access to authorized users.

Public Power is not sure if this changes the function of the Intermediate System. For example, does the Intermediate System still include the, “jump host concept?” Also, it is not clear if the concept extends to management planes or the actual hypervisor. Clarity on these points would be appreciated.

Consider retaining the definition and option to use Intermediate System for entities not pursuing virtualization at this time, and to pilot the new approach with those interested in applying it. This approach will minimize the spread of unanticipated consequences and allow industry and auditors to more gradually learn about the new definitions.

NYPA supports comments submitted by NPCC / TFIST. The Intermediate System definition should use “Cyber System” (which needs to be defined) rather than “system.” System is a very broad term and can bring in many devices / equipment currently excluded. In addition, the proposed definition change enables IS to be within the LIZ, which we view as lowering the security bar.

The change to Intermediate System brings into question if the authentication servers used to limit access should be Intermediate Systems as well. Additionally, this language appears to make the location (e.g., inside or outside of the firewall) of the IS ambiguous, whereas the existing definition explicitly states that the IS should be located outside of the ESP.

The existing definition is fairly clear and auditors have a clear approach. Consider retaining the existing Intermediate System definition and add a new “Virtual Intermediate System” definition for those entities that wish to pursue that sort of access.

Dana Klem - MRO - 1,2,3,4,5,6 - MRO, Group Name MRO NSRF	
Answer	No
Document Name	
Comment	
Overall, the NSRF does not agree with the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry's programs. Originally, there was the Version 5 Transition Advisory Group, made up of 6 Entities to test our current suite of Standards. There are also multiple registered groups who can write and submit to NERC, Implementation Guidance for ERO deference. Any radical change to the CIP Standards should be practiced and tested BEFORE any Standard is recommended for change. The NSRF also believes that there are Entities who are currently compliant (via an audit) by incorporating virtualization practices under our current set of Standards. All Standards are written to "what to do" not how to incorporate a certain or new technology. The NSRF has attempted to answer the SDT questions but still does not agree with this Project. Here are some specific examples of what a small change to a Standard will do to the industry. The NSRF does not see the value in changing the definition. We are concerned that by removing the language, "The Intermediate System must not be located inside the Electronic Security Perimeter." could be construed that an Intermediate System could reside inside an ESP or a LIZ.

Based on our comments on the above, we disagree with the IS definition revisions. The current IS definition is clear and can be applied to the virtual devices as well. As we suggested in the above question 6, the proposed new term LIZ should only apply to the virtual devices in which managing access may not use the layer 3 routable protocol. If SDT wants the IS to apply to LIZ, we suggest revising the IS definition to read (**bold**):

"*A Cyber Asset or collection of Cyber Assets performing access control to restrict Interactive Remote Access to only authorized users. The Intermediate System must not be located inside the Electronic Security Perimeter* ***or LIZ****.*"

Steven Rueckert - Western Electricity Coordinating Council - 10

Answer	No
Document Name	

Comment

The language 'acting as part of the protection applied to a logically isolated BCS…' too broadly scopes the Intermediate System and appears to encompass the definition of an EACS.

Consider changing the proposed Intermediate System (IS) definition to, *A system that limits external user-initiated access to logically isolated BES Cyber Systems for authorized users.* If the SDT does not concur, then BCS to BES Cyber system in the Intermediate System definition should be spelled out.

An Intermediate System is not an applicable system of any CIP requirement. Currently, the EACMS definition includes an Intermediate System in its definition. With the proposed retirement of EACMS the new EACS definition should now say 'this includes Intermediate Systems' in the last sentence of the definition.

Also, the new definition appears to remove the jump-host control from the definition.

Terry Harbour - Berkshire Hathaway Energy - MidAmerican Energy Co. - 1,3

Answer	No
Document Name	

Comment

MEC does not support the changes being proposed to the term “Intermediate System”, which moves the term from being Cyber Asset based to systems based. The changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs too soon after the last one. Some entities have not had the chance for an audit on the last round of changes. Other revisions, such as CIP-003-7 sections 2, 3 and 5 have yet to become effective. MEC has compliantly implemented virtual servers within the existing CIP standards structure. We have been audited on CIP-005 and CIP-007 as well as CIP-004 and CIP-006. We have self-certified CIP-002, -003, -008 and -011. And are preparing evidence for an audit on CIP-009 and CIP-010 in 2019 and have not identified issues.

It is not clear how this magnitude of changes will create a corresponding improvement to reliability and security. Perhaps the “how to comply” with the existing standards when virtualization is involved could best be addressed using other tools such as ERO-endorsed implementation guidance or readiness reviews for the segment of Responsible Entities who are operating or plan to operate with virtualization.

Duke Energy disagrees with the removal of the sentence “The Intermediate System must not be located inside the ESP” from the definition of Intermediate Systems. Was it the drafting team’s intent to remove this phrase, if so, can the team provide its rationale? The concept of Intermediate System has always been understood to mean outside the ESP, but the removal of the language makes this unclear. Also, the proposed definition no longer uses the term “Cyber Asset”, instead uses the term “system”, which seems vague. Can the drafting team clarify what it means by its use of the term “system”?

The Intermediate System definition "A system acting as part of the protection applied to a logically isolated BCS..." What kind of "protection?" I think it should specify "logical" or "electronic", etc.

Also, we have concerns about the removal of an “Intermediate System must not be located inside the Electronic Security Perimeter” from the definition of Intermediate System. Does this mean we can have an IS inside an ESP?

The more prescriptive language in the current definition does a better job defining an Intermediate System. We recommend keeping the current definition.

While we agree with taking qualitative language of the definition and relocating it to the requirements, we do not believe that the current draft clarifies anything. Instead more questions are raised. For example, an Intermediate System used to have to exist outside the ESP, any ESP. However, can an Intermediate System now exist within a LIZ if it isn't the LIZ of the BCS that it is accessing? Or is this no longer the case and an Intermediate System can now reside within a LIZ? Or, since the Intermediate System is defined as "A system acting as part of the protection applied to a logically isolated BCS that limits external user-initiated access to authorized users," does it mean that the BCS at the end of the remote access connection is actually part	

of the Intermediate System and is thus itself part of an Intermediate System? Especially if the BCS had a host-based firewall acting as a LIZ that helped to limit external user-initiated access to authorized users.

8. The SDT is considering changes to the ERC and IRA definitions to address V5TAG issues (see the CIP-005 Technical Rationale document for detailed information). ERC will have conforming changes only and will continue its use as a scoping mechanism. The proposed modifications to IRA will apply to certain non-routable to routable protocol conversion scenarios. Do you agree? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

Jamie Monette - Allete - Minnesota Power, Inc. - 1	
Answer	Yes
Document Name	
Comment	
It is agreed that the revised definition includes the additional intended scope. The changes to the IRA definition state "...does not include… access initiated from an Intermediate System." It should be made clear in the Intermediate Systems definition that the Intermediate System is an Electronic Access Control System since there is no other clear statement of this. A suggested modification to the Intermediate Systems definition: "An Electronic Access Control System acting as part of the protection applied to a logically isolated BCS that limits external user-initiated access to authorized users."

CHPD agrees that changes may be needed, but the proposed definition is contradictory to CIP-005 R2, which Part 2.1 specifies that it applies to Interactive Remote Access, but the definition of Interactive Remote Access specifies that sessions from the Intermediate System are not considered Interactive Remote Access. Either this is a misunderstanding of the definition and requirement, which means it is confusing, or a mistake in the definition and requirement. Consider removing “or access initiated from an Intermediate System” from the new IRA definition.

SMEC disagrees with the revisions to ERC and IRA definitions. By removing “with ERC” from the applicable systems column of the requirement tables, multiple requirements will be added to the audit scope that were previously not applicable if there was no ERC. The existence or lack of ERC is fundamental to the current application of CIP Standatrds and removing it will result in additional documentation to prove compliance with no added benefit or reduction in risk.

Regarding the proposal to modify the definition of ERC, Duke Energy recommends that the drafting team take this opportunity to provide needed clarity to the concept of routable protocol (i.e. Would serial to IP convertors be included?). The ambiguity around this topic has led to differing interpretations between entities and regulators. Also, modifications to the term IRA, should include some type of clarification on the concept of system to system communications. This continues to be an issue with varying interpretations.

LCRA is satisfied with the ERC definition. The IRA definition is contradictory and confusing. CIP-005-7 R2.1 states 'Have one or more methods to ensure that Interactive Remote Access to applicable systems is through an Intermediate System that is isolated from the BES Cyber System and restricts Interactive Remote Access to only authorized users. The definition of IRA states 'User-initiated access by a person employing a remote access client to a BES Cyber System or Protected Cyber System from outside of a Logical Isolation Zone. Interactive Remote Access does not include system-to-system process communications or access initiated from an Intermediate System.' LCRA would also like clarification on the statement 'remote access client…from outside of a Logical Isolation Zone'. Is this intended to mean access from a client outside of any LIZ or only the LIZ that the destination device is associated with? The previous definition of IRA clarified this issue by stating 'not located within any of the RE's ESPs'. The CIP standard states that IRA must be through an Intermediate System, but the definition of IRA states that it does not include access initiated from an Intermediate System.

MEC does not support the creation of the new Logical Isolation Zone at this time. Therefore, MEC does not support the proposed changes to the ERC and IRA definitions. The changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs too soon after the last one. Some entities have not had the chance for an audit on the last round of changes. Other revisions, such as CIP-003-7 sections 2, 3 and 5 have yet to become effective. MEC has compliantly implemented virtual servers within the existing CIP standards structure. We have been audited on CIP-005 and CIP-007 as well as CIP-004 and CIP-006. We have self-certified CIP-002, -003, -008 and -011. And are preparing evidence for an audit on CIP-009 and CIP-010 in 2019 and have not identified issues.

It is not clear how this magnitude of changes will create a corresponding improvement to reliability and security. Perhaps the “how to comply” with the existing standards when virtualization is involved could best be addressed using other tools such as ERO-endorsed implementation guidance or readiness reviews for the segment of Responsible Entities who are operating or plan to operate with virtualization.

Recommend changing from Logical Isolation Zone to Logical Security Zone

Concern that this change may bring more Cyber Assets into scope

Request more clarity

Likes 0	
Dislikes 0	

Response

Richard Jackson - U.S. Bureau of Reclamation - 1,5

Answer	No
Document Name	

Comment

Reclamation does not support replacing the term Electronic Security Perimeter with the term Logical Isolation Zone (LIZ). Reclamation does not support removing the term Electronic Access Point from the definition of Interactive Remote Access.

If a new term for logical isolation is adopted, Reclamation recommends the following be added to the NERC Glossary of Terms:

Electronic Security Enclave (ESE) – One or more Cyber Assets logically connected by one or more internal communication control(s) of a single authorizing security policy for BES Cyber Systems and Protected Cyber Systems. The logically connected Cyber Assets may be structured by physical proximity or by function, independent of location.

Recommend the SDT remove the word ‘connection’ from the ERC definition to ensure it addresses bi-directional routable protocol access opposed to connection. This is consistent with the SDT’s departure from LERC to ‘using a routable protocol’ in CIP-003-7, Section 3.1, ii.

Comment	

Based on our comments on the above, we disagree with revisions of the ERC and IRA definitions. The current ERC and IRA definitions are clear and can be applied to the virtual devices as well. As we suggested in the above question 6, the proposed new term LIZ should only apply to the virtual devices in which managing access may not use the layer 3 routable protocol. If SDT wants the IRA to apply to non-routable for the LIZ, we suggest revising the IRA as follows (**bold**):

“User-initiated access by a person employing a remote access client or other remote access technology using a routable protocol **to pass through ESP or non-routable protocol to pass through LIZ**. Remote access originates from a Cyber Asset that is not an Intermediate System and not located within any of the Responsible Entity’s Electronic Security Perimeter(s), LIZ or at a defined Electronic Access Point (EAP). Remote access may be initiated from: 1) Cyber Assets used or owned by the Responsible Entity, 2) Cyber Assets used or owned by employees, and 3) Cyber Assets used or owned by vendors, contractors, or consultants. Interactive remote access does not include system-to-system process communications.”

If SDT wants the ERC to apply to LIZ, we suggest revising the ERC as follows (**bold**):

The ability to access a BES Cyber System from a Cyber Asset that is outside of its associated Electronic Security Perimeter **or LIZ** via a bi-directional routable protocol connection.

Dana Klem - MRO - 1,2,3,4,5,6 - MRO, Group Name MRO NSRF	
Answer	No
Document Name	
Comment	

Overall, the NSRF does not agree with the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry’s programs. Originally, there was the Version 5 Transition Advisory Group, made up of 6 Entities to test our current suite of Standards. There are also multiple registered groups who can write and submit to NERC, Implementation Guidance for ERO deference. Any radical change to the CIP Standards should be practiced and tested BEFORE any Standard is recommended for change. The NSRF also believes that there are Entities who are currently compliant (via an audit) by incorporating virtualization practices under our current set of Standards. All Standards are written to “what to do” not how to incorporate a certain or new technology. The NSRF has attempted to answer the SDT questions but still does not agree with this Project. Here are some specific examples of what a small change to a Standard will do to the industry.

The non-routable definition is fundamental to the current understanding and application of CIP standards.

Comment

BPA proposes changing the ERC definition:

Current Proposed: “External Routable Connectivity” is the ability to access a BES Cyber System from a Cyber Asset that is outside of its associated Logical Isolation Zone via a bi-directional routable protocol connection.

BPA Proposed: “External Addressability” is the ability to direct communications traffic to a BES Cyber System from cyber systems external to an entity’s Logical Isolation Zone.

BPA believes this change adequately mitigates the risk of what was formerly known as ERC and allows the scope of controls to exclude communications between secure Logical Isolation Zones. Communications originating inside an LIZ and proceeding to another LIZ are already protected and do not pose additional risk to applicable systems. BPA’s proposed change provides better alignment with IRA requirements and retains better backward compatibility with the current ESP model.

Sandra Shaffer - Berkshire Hathaway - PacifiCorp - 6

Answer	No
Document Name	

Comment

PacifiCorp’s approach to this informal comment period was to provide the SDT with constructive feedback related to the proposed revisions to the terms, standards and concepts presented. With that said, PacifiCorp has additional comments and concerns that will be covered in question #16.

This term captures the intent, seems that the access initiated from the Intermediate System is treated as similar to system to system access. In adding certain non-routable to routable protocol conversion scenarios into the concept, the SDT should consider this brings in a huge amount of work for entities. PAC would request a 24 to 36 months implementation period for the changes proposed by these revisions.

Lynn Goldstein - PNM Resources - Public Service Company of New Mexico - 1,3	
Answer	No
Document Name	
Comment	
The conforming changes for ERC appear to be acceptable. However, if nested LIZ are allowed then consider changing "Logical Isolation Zone" to "Logical Isolation Zone(s)". As for IRA, the proposed changes had setup a dichotomy regarding the protection paradigm of CIP. If user-initiated access by a person employing a remote access client to a BCS or PCA from outside a LIZ, then it appears any access initiated from any LIZ regardless of impact level is acceptable. However, the drafted CIP-005 R3 proposes that further restriction between the data plane and management plane is required. So why is it acceptable to allow any LIZ to LIZ traffic and yet restrict the management plane and data plane? It appears the CIP-005 R3 is accomplished with a LIZ around the management plane. Yet IRA allows LIZ to LIZ traffic, so a CIP paradox has been created and more ambiguity regarding what is allowed and not. This would make the proposed IRA change and proposed requirement changes difficult to audit.

Kara White - NRG - NRG Energy, Inc. - 3,4,5,6 - FRCC,MRO,WECC,Texas RE,NPCC,SERC,RF

Answer No

Document Name

Comment

When you remove ERC, you eliminate a threat vector to the ESP. Therefore, the controls required in that situation should reflect that. This proposed standards change reinstates a lot of the controls that were not required under the current version of the standards, which could cause a compliance burden to the industry that may exceed the risk mitigation acheived. NRG asserts that the proposed definition changes to IRA may contradict the requirements relating to CIP-005. The new IRA definition specifically describes that IRA does not include sessions initiated from an intermediate system. As written, registered entities using an Intermediate System, are excluded from CIP-005 R2.

Comment

User-initiated access by a person employing a remote access client to a BES Cyber System or Protected Cyber System from outside of a Logical Isolation Zone. Interactive Remote Access does not include system-to-system process communications or access initiated from an Intermediate System. Southern requests the SDT consider adding “or other remote access technology using a routable protocol” back in to the definition to retain proper scoping. We do not want KVMs and similar “dumb devices” to be unintentionally scoped in.

Southern would also like clarification on the definition for Interactive Remote Access. While the inclusion of “by a person employing a remote access client” helps clarify that we are discussing people using accounts, this is also implicitly stated later in the definition. Also, including “remote access client” implies that the remote access software be client based and we feel that excluding this will help clarify the scope of the definition.

We propose the following as an alternate IRA definition:

“User-initiated access to a BES Cyber System or Protected Cyber System from outside of a Logical Isolation Zone. Interactive Remote Access does not include system-to-system process communications or access initiated from an Intermediate System.”

9. To the extent possible, the SDT intends its modifications to permit approaches to compliance that are “backwards compatible” with compliance approaches within the currently approved versions of the CIP standards. (Notable exceptions include CIP-005 R3, CIP-007 R2, and Secure Configurations – CIP-010). Do you agree the modifications are backwards compatible? If you do not agree, please provide your recommendation and, if appropriate, technical or procedural justification.

The “ERC” qualifier has been removed from CIP-007 R1.1. This could dramatically increase burden on some entities, where the intended effect could be achieved instead with a virtualization-ready definition of “PCA” and “ERC.” CIP-007 R1.4 also seems to shift from requiring intrusion protection on an ESP level to requiring it on a BCS level. This will be onerous and may not be technical feasible in many cases, unless BCS are defined over-broadly (i.e., the entire LIZ is a single BCS). There is a meaningful distinction in keeping the BCS definition separate as a subcomponent of the LIZ. The appropriate shift would be from EAP to LIZ, not from EAP to BCS.

Because of the extensive changes to both definitions and Standards, and as a yet-to-be- determined audit approaches, it is not possible, at this time, to be certain that the modifications are indeed backwards compatible. As an alternative that better assures backwards compatibility, consider the option to retain the existing definitions and requirements along with instituting the new definitions and requirements, and then direct entities to select among these two options, on a cyber system basis. This option could be planned to sunset after a set number of years.

SMEC appreciates the intent of backwards compatibililty, but the proposed changes will not be backwards compatible for existing compliance documentation. The proposed changes (i.e., removing ESP/EAP, removing BES Cyber Asset definition, etc.) will require entities to change documented processes and compliance evidence for multiple CIP standards. As suggest before, the proposed new term LIZ should only apply to the virtual devices while keeping the existing requirements the same as before. Another alternative would be a new standard which applies only to virtualized systems to address related concerns, thus adding no burden to those entities without virtualization.

For the most part the current draft presents a systematic approach which is backwards compatible, but Cyber Assets are discrete objects which cannot be systematically removed unless replacing the entire Cyber System. Further CIP-011 contains the term Cyber Asset for disposal and reuse. CIP-011 needs to be modified or further delineation in the BCS definition due to the fact that Cyber Assets, virtual or physical, are still discrete parts of a BCS and cannot be handled systematically.

Chris Scanlon - Exelon - 1,3,5,6

Answer No

Document Name

Comment

Even with the “proposed backward compatibility,” this change will be disruptive to current CIP programs in place, requiring documentation, compliance tool/technology and process changes. Major changes to our CIP program would be required just to address the foundational definition changes, CIP-002 methodology and assessments, device and asset inventory, patching and change management tools, as well as the entire suite of program, process and procedural documents.

We cannot say with confidence (within this comment period) that the modifications proposed are clearly backward compatible and do not create unintended problems that might compromise BES reliability and security. The proposed changes bring with them a very steep learning curve for the industry.

The timing and scope of these changes is concerning, as they represent a major overhaul of the CIP Standards. We would prefer for the SDT to narrow their focus to providing clear requirements for the protection of CIP systems in virtualized environment, without the broader overhaul of terms and definitions as proposed in this informational posting.

Douglas Webb - Great Plains Energy - Kansas City Power and Light Co. - 1,3,5,6 - MRO, Group Name Westar-KCPL

Answer No

Document Name

Comment

Westar | Kansas City Power & Light Company incorporate by reference Edison Electric Institute’s response to Question 9.

Additionally, Westar | Kansas City Power & Light Company share the following concerns.

Recognizing the issue that is being addressed, the strategy “backwards compatible” is ripe with compliance ambiguity and confusion.

The Standards or their revisions are approved and effective at a point in time. That required certainty as to when a Standard is effective is fundamental to compliance and, for that matter, auditability.

Any compelling need to consider “backwards compatibility” can be addressed in Implementation Plans or revisions to the specific Standard. Attempting to address globally will not serve compliance and, in turn, reliability.

Comment

The extensive changes to definitions significantly interferes with practical implementation of the standard in a backward compatible manner.

While on the surface, the changes appear to be capable of being backwards compatible, significant research through a detailed study program is required. Unfortunately, this requires time and the standards are far behind the technology and the increased reliability the new technology provides. A certain component of the backward compatibility will need to be taken on faith. This will need to include modified definitions and guidance that is publicly accepted by NERC as valid.

Clear guidance needs to be created that virtualization that is not mixed mode continues to meet the requirements.

CHPD is concerned with how this question is asked. The question essentially asks "other than the proposed changes, is the SDT's proposal backwards compatible?" The Secure Configuration concept is such a large deviation from the existing standards that we believe is not valid to exclude it from a question like this. No entity would be able to carry their existing program forward given the sweeping changes proposed, even if they do not intend to virtualize.

The changes to EACMS (splitting into EACS and EAMS) do seem to be largely backwards compatible, so long as you exclude the proposed Secure Configuration concept.

Lan Nguyen - CenterPoint Energy Houston Electric, LLC - 1 - Texas RE

Answer	No
Document Name	

Comment

CenterPoint Energy does not support a major overhaul of the standards at this time. However, if the SDT continues to make revisions, CenterPoint Energy recommends the following:

The proposed CIP-010 language does not address a compliant way to authorize changes after the fact. Previous Requirement R1.2 required change authorization without requiring a timeframe, after the change if necessary. This could be due to operational necessity or minor administrative delay. The new language does not have this flexibility.

The new CIP-007 language requires baselining of all executable scripts. Scripts and "custom" software have been a poorly defined area, but the language in the new standard is broad and therefore difficult to implement or enforce given that any user can enter, execute, and delete scripted commands at a shell prompt. The underlying intent of CIP-007 is a good one, but entities must have the flexibility to automate administrative processes on their own systems, planned or ad-hoc. Furthermore, while installed software or packages are recognized by the OS and can therefore be monitored, scripts are not installed and may not even exist as files. Baselining or alerting on scripts is not practicable.

The new CIP-007 language also requires provision of only "essential" logical access and "essential" software. This is a strong and undefined term. Entities must flexibility to determine what is needed and to revise their determination as their system, or understanding of the system, evolves over time. Language in the new CIP-007 Requirements R1.1 and R2.1 provides no flexibility in revising what is "essential" in a compliant way. CenterPoint Energy recommends that the SDT provide clarification and more context around the term "essential."

Malicious code deterent, detective, or preventative controls may be external to a BCS that cannot run host-based anti-malware controls and therefore cannot be part of the Secure Configuration of the BCS. The NOTE about Secure Configuration should read "The implemented configuration, where implemented on the applicable System, in support of this Part becomes part of the Secure….."

Dana Klem - MRO - 1,2,3,4,5,6 - MRO, Group Name MRO NSRF

Answer	No
Document Name	

Comment

Overall, the NSRF does not agree with the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry's programs. Originally, there was the Version 5 Transition Advisory Group, made up of 6 Entities to test our current suite of Standards. There are also multiple registered groups who can write and submit to NERC, Implementation Guidance for ERO deference. Any radical change to the CIP Standards should be practiced and tested BEFORE any Standard is recommended for change. The NSRF also believes that there are Entities who are currently compliant (via an audit) by incorporating virtualization practices under our current set of Standards. All Standards are written to "what to do" not how to incorporate a certain or new technology. The NSRF has attempted to answer the SDT questions but still does not agree with this Project. Here are some specific examples of what a small change to a Standard will do to the industry.

The NSRF feels there will be significant changes to required documentation.

The MRO NSRF has further concerns the proposed revisions change how to comply but don't improve system reliability or security.

The relatively quick timeframe in which these significant proposed changes were made presents the risk of many unintended consequences for what is the vast majority of systems that are not in virtualized environments. The NSRF agrees that there is a need to take a different approach to Cyber and Physical Security of the Bulk Electric System, however with the continuous state of change and adjustments being made to NERC CIP requirements we do not feel that this is the proper project to take on a larger transformational change.

There are two types of "backwards compatible" – technological and documentational. For entities not employing virtualization, there should be no need to update either the documents or the technologies that refer to ESP and other existing terms. The proposed changes (i.e., removing ESP/EAP, removing BES Cyber Asset definition, changes to EACMS/EACS/EAMS/PAMS/PACS, etc.) will require *all* entities to change their documented processes and compliance evidence for the entire suite of CIP standards.

Answer	No
Document Name	
Comment	

We do not agree that the changes are backwards compatible since existing policies / procedures (system changes, patch management, re-labeling equipment, etc) may need to be re-written and staff will need new training. One example is changing EAP to Logical Security Zone.

Fundamental changes to protection controls which were established CIP Standards version 3.

We are concerned with the broad changes being contemplated by the SDT. While we applaud the SDT's effort to make these changes "backward compatible" with existing systems not operating within a virtualized environment, the proposed changes system approach introduces new risk to security. We are also concerned that the changes being considered do not take into consideration that the vast majority of systems do not operate within a virtualized environment and are unlikely to be moved in that direction anytime soon. The industry needs more time to better assess the potential disruptive impacts given there are no pressing needs for such changes. Terry Harbour - Berkshire Hathaway Energy - MidAmerican Energy Co. - 1,3

Answer	No
Document Name	

Comment

We appreciate the intent of backwards compatibility, but are not convinced this will work with the security objective-based requirements subject to different interpretations by Responsible Entities and auditors. The changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs too soon after the last one. Some entities have not had the chance for an audit on the last round of changes. Other revisions, such as CIP-003-7 sections 2, 3 and 5 have yet to become effective. MEC has compliantly implemented virtual servers within the existing CIP standards structure. We have been audited on CIP-005 and CIP-007 as well as CIP-004 and CIP-006. We have self-certified CIP-002, -003, -008 and -011. And are preparing evidence for an audit on CIP-009 and CIP-010 in 2019 and have not identified issues.

It is not clear how this magnitude of changes will create a corresponding improvement to reliability and security. Perhaps the "how to comply" with the existing standards when virtualization is involved could best be addressed using other tools such as ERO-endorsed implementation guidance or readiness reviews for the segment of Responsible Entities who are operating or plan to operate with virtualization.

Leonard Kula - Independent Electricity System Operator - 2

Answer	No
Document Name	

Comment

We disagree that the changes are fully backwards compatible in compliance approach as CIP-004 now includes an access control program for PCS (PCA). There may be many PCA devices within a substation that must be added to the access control program which may require changes to the compliance approach. This may require changes to PCS/PCA controls to bring them into the CIP user authorization program

We do agree that the majority of the changes are backwards compatible from a compliance/ controls approach, but will require extensive documentation changes.

Comment

AZPS does not agree that all changes are "backwards compatible" as the proposed modifications are expansive and it is, therefore, difficult to determine with certainty if the changes will generally be backwards compatible. It is also likely that changing definitions that are used throughout all CIP standards will have impacts beyond those immediately obvious, and could affect internal controls.

As an example, AZPS believes the following changes will not be "backwards compatible" and may require extensive changes to internal programs:

- Removal of the term BCA. AZPS has structured its CIP environment to be processed at the BES Cyber Asset level. While AZPS agrees that moving to a BES Cyber System level is appropriate, it will require extensive changes for AZPS to conform its program approach, associated documentation and work processes, associated technology, etc.
- Removal of "routable protocol" from the definition of IRA. This will increase the scope of devices for which compliance with the CIP reliability standards is applicable. Further, this change creates inconsistency by continuing to use "routable protocol" in the applicability tables.

For these reasons, there is a high likelihood that the proposed changes are not wholly backwards compatible and would require a significant effort to revise and implement.

Comment	

SRP does not agree the modifications are backwards compatible due to the expansion of applicability for various requirements. For example, under the proposed requirement updates, the applicability for CIP-004 R3, R4, and R5 would extend to PCS. If the requirement did not previously apply to certain systems, and the SDT is not following a FERC Order to expand the scope, then SRP does not see a need to expand the applicability of the requirements. In addition CIP-005 R1.2.1 is not backwards compatible as it brings serial port connectivity in scope of the standard and also may indirectly imply encryption on the connections.

Additionally, SRP believes removing the term 'routable protocol' from the definition may bring serial connections in scope, which are currently excluded. Not excluding serial connection does not allow for backwards compatibility.

SRP also agrees with the comments by APPA.

It is difficult to answer the question of backwards compatibility without gaining the necessary clarity on some of the definition proposals. Having said that, it appears at first glance, that certain programmable devices that are considered non-CIP devices (Variable Frequency Drive), would now be considered CIP based on some of the proposed changes. If that is the case, we fail to see how this would equate to backwards compatibility.

1.) On its face, the SSRG believes the proposal will require significant documentation and system changes to implement and is concerned the modifications are not truly backwards compatable with the current baseline. The SSRG requests the drafting team clarify or explain what the Secure Configuration includes that is not part of the original baseline configuration.

2.) Does the standard drafting team intend the "baseline" paradigm of CIP-010-3 R1.1 to be congruent (i.e., "backwards compatable") with the new "Secure Configuration" paradigm documented in the proposed CIP-010-4 R1.1? In addition, are the controls as documented in CIP-010-4 R1.1.2 indended to be the same as controls as documented in CIP-010-4 R1.2.1. If yes, to avoid confusion and provide specificity to the requirements, the SSRG suggests utilizing corresponding or parallel language in each section where appropriate.

We do not agree that the changes are backwards compatible since existing policies / procedures (system changes, patch management, re-labeling equipment, etc) may need to be re-written and staff will need new training. One example is changing EAP to Logical Security Zone. Fundamental changes to protection controls which were established CIP Standards version 3.

Answer	No
Document Name	
Comment	
While the changes appear to be relatively backwards compatible, the items that are required to be part of the Secure Configuration in effect expand the scope of what is required for change control (per CIP-010 R1) in a non-virtual environment. For this reason, we believe the modifications do not appear to be entirely backwards compatible. Tri-State would like to request additional guidance to include an example and a graphic of how backwards compatibility would look for each of the changes.

EEI members who participated in the development of these comments are concerned with the broad changes being contemplated by the SDT. These members applaud the SDT's effort to make these changes "backward compatible" with existing systems not operating within a virtualized environment; however, the proposed changes may introduce new risk to security. There is concern that the changes being considered may not take into consideration the vast majority of systems that do not operate within a virtualized environment and are unlikely to be moved into such an environment soon. For these reasons, more time may be needed to better assess the potential disruptive impacts given there are no pressing needs for such changes. As stated earlier, it is not clear that the modifications proposed are clearly backward compatible and concern that the proposed modifications do not create unintended problems and consequences that might compromise BES reliability and security.

To address these concerns, EEI recommends that the SDT focus first on providing clear implementation guidance to protect BES Cyber Systems within virtualized environments under the existing framework already in place.

NRG disagrees with this proposed change because it would cause registered entities to re-assess all aspects of their current NERC CIP compliance programs. An entity cannot be backwards compatible and also achieve the newly proposed requirements. The new secure configuration definition mandates malware monitoring within BES Cyber Systems which implies AV on the BCS and not at the system level (which is the only requirement of the current standard). This proposed change could also imply needing network access control, whitelisting, and/or needing host based intrusion detection.

We appreciate the SDTs effort to make the updated requirements backwards compatible but even for an entity that has no virtualization the updated requirements and terms will necessitate re-evaluation of assets, updates to policies and procedures, and implementation of new controls and concepts (for example, the Secure Configuration concept). Based on this alone, we believe that 24 months would be the minimum timeframe required to implement the proposed modifications.

18 to 24 months at a minumum. There is great deal of change that will have to be considered, created, and then implemented. The idea presented by some others on phased implementation similar to what was done for V5 also has some merit if it can explained clearly how it can be used and the Regions are willing to accept it.

Susan Sosbe - Wabash Valley Power Association - 3	
Answer	
Document Name	
Comment	
Not only will this implementation require adaptation to the new standard, but also restructuring of existing systems with new terminology and re-evaluation of BES Cyber System categorization. This is a widely variable time period depending on size of company. An appropriate implementation plan must allow some type of flexible adoption of the revisions depending on the network and systems considered. For example, an entity not using virtualization may choose to adopt the new standard at a single point in time when language in their systems have been changed. Other entities that are currently using virtualized systems may adopt the new compliance standard at various times for each logical isolation zone that contains virtualized systems. At a minimum, two years will be required at large entities. The radical changes in the standard will cause smaller entities to delay work until the standard is approved by FERC, unless FERC provides some kind of feedback that approval is expected. Again, two years would be the minimum time frame to consider.

Answer	
Document Name	

Comment

Westar | Kansas City Power & Light Company incorporate by reference Edison Electric Institute’s response to Question 10.

Additionally, Westar | Kansas City Power & Light Company supplements the EEI response with the following detail:

A minimum of three years, likely longer in some instances, to implement the proposed strategy.

To address the proposed revisions / additions to the CIP Standards will require:

- complete review of all systems;
- likely investment in additional or upgraded cyber assets;
- training;
- potentially adding or contracting scarce cyber security engineering expertise; and
- wholesale revision to the company’s CIP processes and procedures.

The proposed strategy will be a substantial undertaking regardless of an entity's size.

SRP recommends including an additional 36 to 48 months in the Implementation Plan because the new terminology and retired terminology are now in more requirements creating a review and revision administration burden. This will allow Responsible Entities time for planning, budgeting, and evaluating new tools, hardware, software, professional services, architectural changes, and encryption.

Additionally, the suggested changes increase the scope substantially by including serial connectivity and applicable devices into requirements they were not previously in. This is an overhaul of the CIP standards just as with version 3. SRP also requests the time frame between the current standards and the standards with the revised methodology be treated as the CIPv3 to v5 transition.

SRP also agrees with APPA's comment regarding a pilot program.

If NERC and FERC approve such wide-sweeping changes, industry will need at least as much implementation time as was provided for CIP version 5 to overhaul all CIP programs and retrain personnel and practice on all standards before the effective date. The changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs too soon after the last one. Some entities have not had the chance for an audit on the last round of changes. Other revisions, such as CIP-003-7 sections 2, 3 and 5 have yet to become effective. MEC has compliantly implemented virtual servers within the	

existing CIP standards structure. We have been audited on CIP-005 and CIP-007 as well as CIP-004 and CIP-006. We have self-certified CIP-002, -003, -008 and -011. And are preparing evidence for an audit on CIP-009 and CIP-010 in 2019 and have not identified issues.

It is not clear how this magnitude of changes will create a corresponding improvement to reliability and security. Perhaps the “how to comply” with the existing standards when virtualization is involved could best be addressed using other tools such as ERO-endorsed implementation guidance or readiness reviews for the segment of Responsible Entities who are operating or plan to operate with virtualization.

Joseph Pride - Trans Bay Cable LLC - 1 - WECC

Answer	
Document Name	

Comment

Two years. As described elsewhere in this response, the proposed changes blur the line between what constitutes a Logical Isolation Zone and a BES Cyber System, now applying Requirements at the BCS level that previously applied only to an EAP or an ESP with ERC. Depending on the system, these changes could require a combination of major technical enhancements on a BCS level and the administrative burden of restructuring what constitutes a BCS. The changes could be more backward-compatible, and therefore faster to implement in most cases, if network-level protections are applied to the Logical Isolation Zone while system-level protections are applied to the BCS. The proposed isolation of the Management Plane from the Data Plane could be more backward-compatible if its application scope is refined to only those assets where the Management Plane would be capable of changing the isolation limits or accessing internal data from outside of a Logical Isolation Zone, for which we propose the new term “Zone Boundary System.”

Dana Klem - MRO - 1,2,3,4,5,6 - MRO, Group Name MRO NSRF

Answer	
Document Name	

Comment

Overall, the NSRF does not agree with the direction of this Project. There are other ways of applying and testing of new directions. Originally, there was the Version 5 Transition Advisory Group, made up of 6 Entities to test our current suite of Standards. There is also multiple registered groups who can write and submit to NERC, Implementation Guidance. Any radical change to the CIP Standards should be practiced and tested BEFORE any Standard is recommended for change. The NSRF also believes that there are Entities who are currently compliant (via an audit) by incorporating virtuazation practices under our current set of Standards. All Standards are written to “what to do” not how to incorporate a certain or new technology. The NSRF has attempted to answer the SDT questions but still do not agree with this Project. Here are some specific examples of what a small change to a Standard will do to the industry.

We do not agree with most of the changes, especially the removal of BCA and ESP.

Industry needs 4 calendar years or 48 months to adequately design, spec, budget, build, implement, rewrite program documents and train on all of the new requirements. Each one of these phases takes time to implement.

2-5 years due to small public entities with limited staff and resources. These entities must first budget through the approved budget that is not as fexible as larger agencies. This includes public meetings and voting by publicly elected officials. Typically, one FTE is a significant expense and must be well supported. Additonal systems, equipment and processes take considerable resources in small organiztions. Repetative work loads must also me considered for staffing purposes at smaller agencies. Physical and Cyber Security has been one of the single bigest cost drivers in small agencies and has begun to negatively impact rural ratepayers, especially in depressed economies that still struggle to get basic services.

Recommend at least 36 months to perform architecture redesign, documentation updates, and documentation reviews.

Dial-up is employed at many locations throughout our company and a significant amount of work will need to be completed to meet the requirements in the Standard especially with the removal of ERC, BCA, and ESP from the Standards. In addition, budgets are completed annually so if additional equipment is required it would need to be included in annual budget cycles.

Because of the extensive amount of changes currently proposed we recommend a NERC sponsored pilot program similar to what was done for CIP Version 5.

Three years because this change is similar in scope to upgrading from CIP version 3 to 5.

We suggest borrowing from that earlier implementation plan, where each Entity had the option of which version to adhere to and by BES Cyber Asset / BES Cyber System (instead of wholesale conversion).

Given that these changes will require Responsible Entities to review internal program documentation and potentially make signification changes to their programs, 36 months is a reasonable timeframe for successful implementation of the necessary changes. The changes required for internal program documentation and coordination of these changes across large enterprises will take time to develop and implement. For Registered entities that choose to shift from an asset-based CIP philosophy to a system-based one, the change of alignment will be a significant program change. Changing configuration management from our current methodology (logical to system or system to logical) will take significant time to change and also what and how we gather the required evidence to demonstrate compliance. Enumerating the change will require new processes. New processes will take time to implement.

At a minimum, APPA recommends that the timeline for the Implementation Plan be 24 months. Public power companies believe Virtualization will be a challenge that will exceed the transition from CIP Version 3 to Version 5. Implementation will require significant time and resources. Consequently, sufficient time and an appropriate compliance approach will be needed to ensure successful implementation.
Because of the extensive, untried nature of the changes, we strongly urge a NERC-sponsored pilot program with volunteer entities, analogous to that undertaken for the CIP v5 changes.

The implementation timeline might be minimized under a “virtualization overlay” approach, in which entities can elect to stay with existing definitions and requirements or move to the new ones (on a cyber-system by cyber-system basis). Perhaps 12 or 18 months might suffice in such a case, which would allow interested entities to exploit as soon as possible the possibilities of virtualization.

11. The SDT is proposing conforming modifications to CIP-004. Do you agree with these changes? Please provide comments to support your response. In particular, the SDT seeks stakeholder feedback on:

a. Modifications related to CIP Exceptional Circumstances

b. Use of newly proposed terms EACS and EAMS in the Applicable Systems column

c. Addition of PCS to the Applicable System column for Parts in CIP-004 to mitigate security risks associated with individuals not needing authorization or PRAs when granted access to systems inside the Logical Isolation Zone

Lana Smith - San Miguel Electric Cooperative, Inc. - 5

Answer	Yes
Document Name	

Comment

SMEC agrees with modifications related to CIP Exceptional Circumstances. SMEC believes further guidance should be provided to define the split of EACMS.

Comment

We are in agreement with the changes related to CIP Exceptional Circumstances, the use of the newly proposed terms EACS and EAMS, and the addition of PCS. However, we believe it would also be prudent to include PCS under CIP-004 R2. Individuals who have access to PCS have access to systems inside the LIZ and should be trained on the security risks accordingly.

a. The modification to CEC is appropriate for CIP-004. b. There are concerns around revocation of access in a timely fashion if a third party service is used for monitoring of EAMS and PAMS. c. The definitions for Protected Cyber Systems and Logical Isolation Zone lose the "routable" distinction for communications. This is somewhat addressed in CIP-005-7 1.2.1, but recomend it remain in the definition. Also, the LIZ definition doesn't define "communications" or "controls," so exactly what will define this zone? A modem can be said to "control communications." The definition of LIZ is too vague.

Button response should be "No". Button selection wasn't allowed. PacifiCorp's approach to this informal comment period was to provide the SDT with constructive feedback related to the proposed revisions to the terms, standards and concepts presented. With that said, PacifiCorp has additional comments and concerns that will be covered in question #16. The SDT did a good job here. PAC disagrees with EACMS and PACS changes and believe we can accomplish the same without the new terms. If the PCS is going to be added to the R3 applicability is should be added consistently to CIP-004 and be added to R2.

Response	
Jack Cashin - American Public Power Association - 4	
Answer	
Document Name	
Comment	

APPA believes the modifications to CIP Exceptional Circumstances (CEC) are appropriate. However, the SDT needs to verify that standards being balloted separately (CIP-008 for example) are considered and included appropriately for CEC. This is especially important for CIP-008 given that the definition of CEC includes language on Cyber Security Incidents.

The only place that EAMS and PAMS appear in the revised standards is under requirement language in CIP-004 R4 and R5. Public power believes that the CIP-004 update does not alleviate third party provider concerns with PAMS and EAMS. See discussion under Question 4.

Public power does not agree with the expansion of applicability for CIP-004 R3, R4, and R5 to include PCS. Changes in these Applicability Systems are not consistent with this Standard’s Purpose statement.

If PCAs were not included originally and the SDT is not following a FERC order to do so, then there is no reason to make them applicable. In CIP-004, R4, and R5 the terms EAMS and PAMS are selectively included in the Requirement language.

In general, the necessity to expand the scope of CIP Standards to address new vulnerabilities introduced by virtualization can be minimized or eliminated by use of the dual-definition/parallel requirement “virtualization overlay” approach discussed above.

Tho Tran - Oncor Electric Delivery - 1 - Texas RE	
Answer	No
Document Name	
Comment	

Please clarify if EAMS and PAMS are to be treated as an applicable system subject device-type requirements (e.g. ports, patching, etc.) or if EAMS and PAMS are to be treated similar to BCSI, which appears to be the case. If they are intended to be treated similar to BCSI, they should not be included in the applicable systems column. They should only be in the requirements column. The periodic review requirements need to be clarified based on the intent. As written, you are requiring quarterly review of BCSI-like repositories. You are also requiring two different types of access reviews every 15 months. This seems duplicative and inappropriate. The same issues are present with the access revocation tasks under Requirement R5.

Susan Sosbe - Wabash Valley Power Association - 3

Answer	No
Document Name	
Comment	

Yes – CIP Exceptional Circumstances

No – EAMS and EACS

Yes – Addition of PCS

Disagree with the use of EAMS and PAMS in the applicable systems column. One significant issue that is being studied is the use of cloud storage and the use of remote monitoring by professional services firms that have higher levels of security skill than many entities. By including EAMS and PAMS in CIP-004 requirement part 4.1, this difficulty is perpetuated.

In its place, Wabash Valley recommends a new CIP-004 requirement part governing for access to EACS, EAMS, PACS, PAMS, governing electronic access, physical access, and BCSI Storage location access to:

Identify and demonstrate that access controls have been implemented by the entity or through implementation of a widely accepted independently audited certification such as ISO 27001, FEDRAMP, <Canadian Equivalent to FEDRAMP> or <Mexican Equivalent to FEDRAMP>.

May need to add an additional part or language to address the case of a withdrawn certification.

Aaron Cavanaugh - Bonneville Power Administration - 1,3,5,6 - WECC	
Answer	No
Document Name	
Comment	
If the stated intent of the creation of EAMS is “to allow third party monitoring systems” and PAMS is “to allow third party monitoring or event correlation”, BPA believes this is not specifically supported in the requirements CIP-004 R4.1/4.2 since CIP-004 R4.2 directs “Verify at least once each calendar quarter that individuals with active electronic access or unescorted physical access have authorization records.” If the intent is to allow third part monitoring, there needs to be a way to allow authorization on a vendor or provider basis. BPA suggests this could be done via contract language or grant to that company. This exists in CIP-004 R5.1, 5.2, 5.3 and anywhere else action on an individual basis is required.

Dana Klem - MRO - 1,2,3,4,5,6 - MRO, Group Name MRO NSRF	
Answer	No
Document Name	
Comment	
Overall, the NSRF does not agree with the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry's programs. Originally, there was the Version 5 Transition Advisory Group, made up of 6 Entities to test our current suite of Standards. There are also multiple registered groups who can write and submit to NERC, Implementation Guidance ERO deference. Any radical change to the CIP Standards should be practiced and tested BEFORE any Standard is recommended for change. The NSRF also believes that there are Entities who are currently compliant (via an audit) by incorporating virtualization practices under our current set of Standards. All Standards are written to "what to do" not how to incorporate a certain or new technology. The NSRF has attempted to answer the SDT questions but still does not agree with this Project

Richard Jackson - U.S. Bureau of Reclamation - 1,5	
Answer	No
Document Name	
Comment	

a. Reclamation agrees with the modifications related to CIP Exceptional Circumstances. CIP Exceptional Circumstances are necessary during emergencies for first responders.

b. Reclamation disagrees with the proposed terms EACS and EAMS in the Applicable Systems column. Reclamation recommends the SDT use Intrusion Prevention System (IPS) and Intrusion Detection System (IDS) instead, as stated in the response to Question 4.

c. Reclamation agrees with the addition of PCS in the Applicable Systems column for CIP-004; however, Reclamation does not agree with the proposed PCS definition. The system wide approach does not allow for the detail needed to properly address all security issues.

Reclamation recommends changing the PCS definition

from:

Cyber systems that can communicate with a BES Cyber System from within the BES Cyber System's Logical Isolation Zone. The impact rating of Protected Cyber Systems is equal to the highest rated BES Cyber System within the Logical Isolation Zone.

to:

One or more Cyber Assets that can communicate with a BES Cyber System from within the BES Cyber System's Electronic Security Enclave. The impact rating of Protected Cyber Systems is equal to the highest rated BES Cyber System within the Electronic Security Enclave.

MEC does agree with some of the modifications related to CIP Exceptional Circumstances, such as adding it back to CIP-004-6 R3, but we do not agree with the conforming changes resulting from the retirement of EACMS, ESP, EAP, etc. The changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs too soon after the last one. Some entities have not had the chance for an audit on the last round of changes. Other revisions, such as CIP-003-7 sections 2, 3 and 5 have yet to become effective. MEC has compliantly implemented virtual servers within the existing CIP standards structure. We have been audited on CIP-005 and CIP-007 as well as CIP-004 and CIP-006. We have self-certified CIP-002, -003, -008 and -011. And are preparing evidence for an audit on CIP-009 and CIP-010 in 2019 and have not identified issues.

It is not clear how this magnitude of changes will create a corresponding improvement to reliability and security. Perhaps the “how to comply” with the existing standards when virtualization is involved could best be addressed using other tools such as ERO-endorsed implementation guidance or readiness reviews for the segment of Responsible Entities who are operating or plan to operate with virtualization.

Southern Company agrees with the CEC additions and with the addition of PCS to the applicability of these requirements. However, we disagree with the inclusion of EAMS and PAMS throughout R4 and R5. Southern asserts that retaining EAMS and PAMS on these requirements prevents the results the SDT has stated as reasons for splitting these terms. Entities will still not be able to utilize vendor or government agency services that can enhance reliability and security and help detect cyber-attack activity early in the kill chain if we shackle the entities with requirements on the personnel or devices/systems at those outside entities. We suggest the SDT consider the need for these terms at all. Can government “cloud service” certification (FedRAMP, etc.) help achieve the same data security end goal when external parties are involved? If the three letter government agencies can certify against a government body (FedRAMP), we assert that we should be able to do the same.

In agreement with BPAs comment - If the stated intent of the creation of EAMS is "to allow third party monitoring systems" and PAMS is "to allow third party monitoring or event correlation", BPA believes this is not specifically supported in the requirements CIP-004 R4.1/4.2 since CIP-004 R4.2 directs "Verify at least once each calendar quarter that individuals with active electronic access or unescorted physical access have authorization records." If the intent is to allow third part monitoring, there needs to be a way to allow authorization on a vendor or provider basis. BPA suggests this could be done via contract language or grant to that company. This exists in CIP-004 R5.1, 5.2, 5.3 and anywhere else action on an individual basis is required.

Please clarify if EAMS and PAMS are to be treated as an applicable system subject device-type requirements (e.g. ports, patching, etc.) or if EAMS and PAMS are to be treated similar to BCSI, which appears to be the case. If they are intended to be treated similar to BCSI, they should not be included in the applicable systems column. They should only be in the requirements column. The periodic review requirements need to be clarified based on the intent. As written, quarterly review of BCSI-like repositories are required. As are two different types of access reviews every 15 months. This seems duplicative and inappropriate. The same issues are present with the access revocation tasks under Requirement R5.

We still have concerns about the splitting of EACMS and PACS into two different types. As mentioned before, has the drafting team considered when a device performs both functions what role it will have?   We agree with the modifications related to CIP Exceptional Circumstances. For CIP-004 R5.3, it is unclear why EAMS and PAMS are called out in the requirement when they are also in the applicability column. A BCS by its very nature has BCSI on it. EACMS and PACS (classical definition) may also have BCSI on it. If the SDT still believes that EAM and PAMS need to be called out in the requirement, then we recommend the following modification: "designated storage locations, including EAMS and PAMS, for BES Cyber System Information, whether physical or electronic (unless already revoked according to Requirement R5.1), by the end..." Furthermore, CIP-004 R5.3 continues to be broken because technically it only applies to the applicable systems. There is not such concept as a BES Cyber System Information Repository, or storage, either physical or electronic, that contains BES Cyber System Information. All of CIP-011 also only applies to applicable systems. While most companies are applying BCSI protections to those items not listed in the applicable systems, technically they do not have to. However, this appears to be outside the SAR for this effort.

12. The SDT is proposing modifications to CIP-005 (see the CIP-005 Technical Rationale document for detailed information). Do you agree with these changes? Please provide comments to support your response. In particular, the SDT seeks stakeholder feedback on:

a. The replacement of the ESP concept with Logical Isolation Zone (LIZ).

b. Is the backward compatibility clear as existing ESPs and EAPs move to the new LIZ concept?

c. The addition of the 4.2.3.3 exemption in the standard along with the addition of Requirement part R1.2 to address the V5TAG concern of "Super ESPs" or single networks within or between BES Cyber Systems that span more than one geographic location.

d. As differing forms of shared infrastructure come into play with virtualization, Requirement R3 has been added to include the management plane and its isolation controls as a part of the CIP standards. Is this concept clearly and widely understood?

Michael Johnson - Consultant - NA - Not Applicable - NA - Not Applicable

Answer	Yes
Document Name	

Comment

I beleive item "a" for LIZ will need more examples to help entities better understand how it can be identified and then documented to help ease any audit concerns.

CIP-005 needs to be renamed. In general, we support the SDTs new definitions and terminology retirements. However, the structure of CIP-005 R1 requires mitigating risk of unauthorized communications, this seems to imply a requirement to authorize communication. Compliance with the new R1 and auditing could be problematic.

Regarding c: Encryption should be in place between the two end-points shown in the diagram. Also, the same level of firewall controls should be enabled within both environments. However, there really doesn't seem to be a logical alternative to encryption to allow for disparate LIZs. Regarding d: The management planes should reside in completely isolated layer 3 networks that are not accessible by other workloads or layer stacks from the other LIZs and/or mixed mode environments. VLANS and VXLANS should not be used to isolate the management planes. Additionally, multi-factor authentication should be used along with separate authentication domains. These management planes, if compromised, would provide the “keys to the kingdom.”

Button response should be "No". Button selection wasn't allowed.

PacifiCorp's approach to this informal comment period was to provide the SDT with constructive feedback related to the proposed revisions to the terms, standards and concepts presented. With that said, PacifiCorp has additional comments and concerns that will be covered in question #16.

The SDT did a good job here.

{C}a) Comments above in #6 cover the LIZ

{C}b) Yes

{C}c) PAC appreciates the exception language related to the implementation of the super ESP.

{C}d) In CIP-005-7 the SDT capitalized the two terms Management Plane and Data Plane. Was this intentional? PAC understands the concepts presented.

Response

Rachel Coyne - Texas Reliability Entity, Inc. - 10

Answer	
Document Name	

Comment

a. Texas RE does not agree the ESP concept should be replaced with Logical Isolation Zone (LIZ), since LIZ currently can exist within the current ESP concept. Please see Texas RE's response to #6.

b. Registered Entities may or may not be "backward compatible" with the LIZ concept. The LIZ concept would require network zoning, where ESP concept currently does not. If registered entities do not having network zoning, they would not be backward compatible. Texas RE notes that the LIZ concept can currently be done within the ESP concept.

c. Texas RE maintains ESP and EAP do nit need to change, so the exemption in CIP-005 Part 4.2.3.3 exemption is not needed.

Texas RE agrees with CIP-005 Part 1.2 but it should say "Protect the data traversing communication networks used to provide connectivity between **ESPs** that spans multiple geographic locations to preserve confidentiality and integrity."

c. Texas RE agrees with CIP-005 Part 3.1 and acknowledges that it does address virtualization. Texas RE recommends the following in the Applicable Systems column:

- EACS and PCS should be replaced with EACMS and PCA
- There appears to be a typo: "*Medium Impact BES Cyber Systems and their associated* ***PCS***"; "PCS" should be removed.

Russel Mountjoy - Midwest Reliability Organization - 10

Answer

Document Name

Comment

The virtualization changes that are proposed will likely permit some mixed trust applications but it isn’t yet clear how logical isolation zones will provide better or equivalent protections to that of an ESP.

12.c. MRO supports the concept of a “Super ESP” that leverages encryption or equivalent logical protections initiated and terminated inside geographically separated ESP locations. The Logical Isolation Zone described in the 4.2.3.3 exemption however is not yet understood to be an equivalent or superior security protection.

Response

Jack Cashin - American Public Power Association - 4

Answer

Document Name

Comment

a. APPA agrees with the replacement of the ESP concept with Logical Isolation Zone (LIZ). Still better might be the overlay approach, in which both ESP and LIZ are options for an entity. Under such an option the existing definitions of EACMS and ERC might need to be updated to include “…Electronic Security Perimeter or Local Isolation Zone…” (i.e., add LIZ concept) to allow appropriate flexibility.

b. No. See discussion under Question 6.

c. Unclear. There is also concern that new approach to “Super-ESPs” is not backwards compatible as regards to communications among serially-connected BCS without ERC, and for relay tele-protection systems. For serial connected BCS, the new approach appears to expand the scope and treat communications for these cases the same as if there was ERC, which is not the way such cases are audited now. At present, a communication “demarcation” is identified for the non-ERC BCS at each end, and communications outside this demarcation are exempted, and no encryption or other security is required. For relay tele-protection, it appears to extend the BCS to include both ends, thereby raising to Medium any otherwise Low-impact rated substation connected by tele-protection to a Medium rated substation. Again, this expands the scope. In general, as a guiding principle, any expansion of scope to accommodate new vulnerabilities introduced by virtualization should be limited in applicability only to virtualized BCS.

d. Public power generally agrees with the addition of 4.3.3.3 and the addition of R1.2 to clarify Cyber System geographic spans. However, these additions do have several aspects that raise questions. For example, Requirement R3 regarding management plane concept will require implementation to understand the implications. Will there be a need to “future proof” the language related to the R1 exclusion? How will registered entities document the exclusion of time-sensitive protection or control functions?

(a) LIZ may be better understood once additional clarity on logical security zone is provided. (b) Backward compatability is dependent upon previous questions asked and their results. (c) Yes (d) We believe there are too many dependencies at this stage to determine “clear and understood” status. CIP-005-7 R1.2: Duke Energy requests clarification on the differences between, or how R1.2 interrelates with CIP-006-7 R1.10. On its face, these two appear to be redundant. Additional language distinguishing one from the other, or perhaps Implementation Guidance on these would be helpful. CIP-005-7 R3: Is it the SDT’s intent for proposed R3 to be more expansive than what is currently protected? Is the SDT intending to bring in for example, the management interface of a firewall for the EACS?

MISO requests that the SDT:

Unify the terminology between LIZ and “Super-ESP”

Provide clarity on the encrypted/protected data requirement. In particular does this requirement only apply if the data is leaving a PSP and is out in public spaces between the separate parts of the “Super-ESP?” If the requirement applies even when the data is still within a PSP that may require significant network complexity for minimal risk avoidance.

Devin Shines - PPL - Louisville Gas and Electric Co. - 3,5,6 - SERC, Group Name Louisville Gas and Electric Company and Kentucky Utilities Company

Answer	No
Document Name	

Comment

While we do not have specific comments on questions a-b, we do have a comment on questions c and d and some concerns about certain updates within CIP-005.

c. We would like for the SDT to provide some examples within IG of how ESP would meet the definition of LIZ. We do have some concerns that auditors will need to have additional training to be able to audit the new LIZ.

d. We agree that in a mixed-mode virtual environment, isolation between the management plane and data plane becomes imperative (with mixed-mode meaning, for example, high/medium BES Cyber Systems, BES Cyber Systems/EACS, or CIP/non-CIP). However, if an entity sets up separate virtual environments (i.e. a high impact BES Cyber System virtual environment and a separate associated High Impact EACS environment) we believe that isolation between the management plane and the data plane will require a significant amount of extra work that will result in elevated compliance risk and zero benefit. The SDT should continue to consider that not all virtual environments that involve CIP will be mixed-mode. It should be clear in the requirements that if you protect the management plane as a part of the BES Cyber Systems the isloations requirements of Part 3.1 become nothing more than an exercise for compliance.

Other Comments:

Part 1.4 lists PCS as an applicable system and refers back to groupings under 1.1. However, Part 1.1 does not include PCS. Was this intentional by the SDT? To be consistent, we believe that PCS need to be added to 1.1 or removed from 1.4.

Additionally, the Secure Configuration concept is found throughout CIP-005. Please see our comment relating to Secure Configuration under question 15.

Finally, can the SDT provide information on the difference between CIP-005 R1.2 and CIP-006 R1.10? Under CIP-006 you can use physical protections and/or encryption to protect data that runs between LIZ, this seems to be duplicated under the new requirement of CIP-005 R1.2. We realize that CIP-005 talks about protecting data and CIP-006 discusses the physical protection of the cable, but both requirements are completeing basically the same function. This could result in double jeapory.

Response

Kevin Salsbury - Berkshire Hathaway - NV Energy - 5

Answer	No
Document Name	

Comment

NV Energy does not support all the changes being considered by the SDT for CIP-005 because we do not agree that the CIP Standards should be upended in order to accommodate a very small number of virtualized systems currently operated or being considered.

NV Energy does support the revisions to R1.2 for a “Super ESP”. As an Entity that currently deploys this type of ESP, the inclusion of defining this ESP would improve the existing Auditing practices for this type of system.

NV Energy also asks the SDT to consider the broad impacts and risk that the proposed wholescale replacement of the existing defined terms will have on Responsible Entities, who have worked to ensure the security of their BES Cyber Systems through the currently approved requirements. While we do not dispute that over time “zone” type security will replace the current “perimeter” type solutions, we disagree that this is the right time for such broad and sweeping changes. Instead, the SDT should take a less aggressive posture toward virtualization and narrow this effort to less complicated steps that might assist Responsible Entities in their efforts to virtualize portions of their BES Cyber Systems. Moreover, working within the current CIP structure will allow Responsible Entities to take smaller, less risky steps that will also reduce security and compliance issues for the industry.

Additionally, while the SDT proceeds with this effort, we respectfully ask them to consider providing more time for the industry to review, analyze, and determine where there might be issues related to proposed solutions to virtualization in order to ensure SMEs can thoughtfully assess, with greater confidence, that the proposed solutions will not create unintended disruptions while ensuring backward compatibility with existing BES Cyber Systems.

Lan Nguyen - CenterPoint Energy Houston Electric, LLC - 1 - Texas RE

Answer	No
Document Name	

Comment

CenterPoint Energy does not support a major overhaul of the standards at this time. However, if the SDT continues to make revisions, CenterPoint Energy recommends the following:

Do the proposed changes intend to include the EACS inside or outside the LIZ?

The concept of LIZ is not perimeter based and so it is not clear what or where an EACS is. Previous language was more clear that it was an Access Point, Intermediate System, or internal authentication system (e.g. LDAP inside the ESP).

In the proposed EACS concept, does a host-based firewall count as an EACS? Does a switch with an ACL count as an EACS? Does a network firewall inside an ESP implementing segmentation count as an EACS? Does a system's authorized users and authentication config count as its own EACS? Entities may define, in compliance with CIP-005-7 RequirementR1.1, their EACS protecting their BCS. However, there is compliance risk with the entities' choices because EACS is not well defined as being external to BCS/PCS in the LIZ or at the LIZ perimeter.

Additionally, access to a system using serial connection is allowed in CIP-005-7 Requirement R1.1, but not addressed much elsewhere. Is the intent that requirements for user restriction on IRA, encryption of connection to an intermediate system, and multi-factor authentication at an intermediate system apply to serial connections? This is unclear in the proposed standard.

Davis Jelusich - Public Utility District No. 1 of Chelan County - 1,3,5,6, Group Name Public Utility District No. 1 of Chelan County

Answer	No
Document Name	

Comment

CHPD is concerned about the overlap of CIP-005 R1 Part 1.2 and CIP-006 R1 Part 1.10. The protection of so-called "Super ESPs" seems to already be covered by the CIP-006 R1 Part 1.10. Only one of the requirements should be maintained, and given that CIP-006 R1 Part 1.10 is already in effect, it is CHPD's preference that it be maintained over CIP-005 R1 Part 1.2.

CHPD also has concerns about the ambiguity of the management plane. Many devices do not have dedicated management planes, such as a server with remote desktop enabled. While it is best practice to separate your management plane from your data plane, many devices either would not support that or their function would be greatly degraded by having to disable management capability that cannot be isolated. Additionally, this requirement would apply to EACS, bringing network connectivity requirements to a classification of assets that did not before have connectivity requirements.

The concept of the LIZ does not seem to work if CIP-005 R3 is not considered. Depending on the interpretation of what a management plane is, significant rework of the network may be needed to separate it from the data plane. Take, for example, a PC-based system that is managed using remote management software (RDP, SSH, VNC, etc…). These systems and protocols could easily be considered to be "management plane" without any specific definition or language to say otherwise. The problem with this is that there is no feasible method for separating these kinds of PC-based management services from the "data plane" like can be easily done for a switch, firewall or hypervisor. The current scope of R3 includes BCA, EACS and PCS, so Windows and other similar PC-based Cyber Assets would definitely fall under the requirement, as written. Without a definition for "management plane" that properly scopes devices that do support separation of a management plane (e.g., switches, firewalls, routers, hypervisors, etc…) there is little likelihood that any existing Medium of High Impact-owning entity could establish a method for achieving compliance with this language. One recommendation for fixing this problem is to specifically identify those system types, either by definition or within R3 itself, that require management plane separation.

Document Name	
Comment	
Introduction of a new term logical isolation zone rather than ESP introduces confusion in the definition and with backward compatibility. For example, the definition would now be applicable to serial communications. This is an example of a definition that will be debated for several years in the industry. Continue with our current industry standard definition or ESP and adjust the standards language to address issues or adopt standard NIST terms. SuperESPs can be accommodated by changes to requirements rather than definitions as the current definition of an ESP does not prevent multi-site ESPs.

Chris Scanlon - Exelon - 1,3,5,6	
Answer	No
Document Name	
Comment	
Exelon does not support the changes being considered by the SDT for CIP-005 because we do not agree that the CIP Standards should undergo this level of significant change for the purpose of accommodating the needs of a relatively small number of mixed virtual environments currently operated or being considered. The proposed change to move from a layer 3 "perimeter" to a "logical isolation zone" philosophy introduces a significant learning curve. There may be serious risks to security through misunderstandings of vulnerabilities and how to properly implement, by both Responsible Entities and auditors. Exelon also asks the SDT to consider the broad impacts and risk that the proposed wholescale replacement of the existing defined terms will have on Responsible Entities, who have worked to ensure the security of their BES Cyber Systems through the currently approved requirements. While we do not dispute that over time "zone" type security will replace the current "perimeter" type solutions, we disagree that this is the right time for such broad and sweeping changes. Instead, the SDT should take a less aggressive posture toward virtualization and narrow this effort to less complicated steps	

that might assist Responsible Entities in their efforts to virtualize portions of their BES Cyber Systems. Moreover, working within the current CIP structure will allow Responsible Entities to take smaller, less risky steps that will also reduce security and compliance issues for the industry.

Additionally, while the SDT proceeds with this effort, we respectfully ask them to consider providing more time during the standard development process for the industry to review, analyze, and determine where there might be issues related to proposed solutions to virtualization in order to ensure SMEs can thoughtfully assess, with greater confidence, that the proposed solutions will not create unintended disruptions while ensuring backward compatibility with existing BES Cyber Systems.

ITC is in agreement with the comments submitted by EEI:

"EEI does not support the changes being considered by the SDT for CIP-005 because we do not agree that the CIP Standards should be upended in order to accommodate a very small number of virtualized systems currently operated or being considered. Additionally, changes such as moving from a “perimeter” to a “zone” philosophy may result in serious risks to security through misunderstandings of what exactly that means by both Responsible Entities and auditors, which is not currently justified.

EEI also asks the SDT to consider the broad impacts and risk that the proposed wholescale replacement of the existing defined terms will have on Responsible Entities, who have worked to ensure the security of their BES Cyber Systems through the currently approved requirements. While we do not dispute that over time “zone” type security will replace the current “perimeter” type solutions, we disagree that this is the right time for such broad and sweeping changes. Instead, the SDT should take a less aggressive posture toward virtualization and narrow this effort to less complicated steps that might assist Responsible Entities in their efforts to virtualize portions of their BES Cyber Systems. Moreover, working within the current CIP structure will allow Responsible Entities to take smaller, less risky steps that will also reduce security and compliance issues for the industry.

Additionally, while the SDT proceeds with this effort, we respectfully ask them to consider providing more time for the industry to review, analyze, and determine where there might be issues related to proposed solutions to virtualization in order to ensure SMEs can thoughtfully assess, with greater confidence, that the proposed solutions will not create unintended disruptions while ensuring backward compatibility with existing BES Cyber Systems."

The note should not be used within requirement language in Part 1.1 and other requirements. As written, this is not an actual requirement. It is simply guidance in this format. The content should be moved to a more appropriate location.

Geographic location should be clarified on Part 1.2. It is unclear how this would apply to multiple buildings within a single campus. These buildings may have different PSPs while in the same campus.

For Part 1.4, consider using “per system capability” instead of “excluding serial port connectivity such as RS-232 and RS-485”.

For Part 2.2, consider the following, “Have one or more methods at the point of termination to mitigate the risks posed by unauthorized modification and unauthorized disclosure of data during all Interactive Remote Access sessions.”

For Part 2.3 consider the following, “Have one or more methods of multi-factor authentication for all Interactive Remote Access sessions.”

Although N&ST is supportive of the general concept of replacing the network-centric definition of “ESP” with a more flexible, “secure enclave” concept, we have a number of concerns:

>> N&ST believes the current proposed definition of “LIZ” needs to be clarified. Suggested re-wording: “A logical container, or enclave, that encloses one or more BES Cyber Systems and applies a common set of controls to all communications to or from those BES Cyber Systems.”

>> N&ST believes the desired “backward compatibility” needs to be made more clear. N&ST suggestions include (1) revising the definition of “LIZ,” as per above, (2) adding explicit language to R1 to the effect that applicable systems must be located with a “LIZ,” and (3) Cyber Asset(s) used to provide the necessary control of communications into and out of a “LIZ” must, if not already part of an applicable system, be identified as EACMS or EACS.

>> N&ST opposes the proposal to exempt Cyber Assets within a “LIZ” if they are associated with communications links between multiple geographic locations. N&ST believes such an exemption carries the risk of creating “soft spots” within logical boundaries that are supposed to be highly secure.

>> N&ST believes the concept of isolating the management and data planes of virtual systems is reasonably well understood, but we are concerned about the fact there are no further requirement statements about the management plane in any of the modified Standards. N&ST believes that at a minimum, the management plane(s) of virtual systems (e.g., Hypervisor) should be categorized as EACMS or EACS.

>> N&ST has an additional concern about the proposed changes to CIP-005: As written, R1 could, N&ST believes, be interpreted as applying to ALL high and medium impact BES Cyber Systems, regardless of whether or not they communicate using routable protocols.

NYPA supports comments submitted by NPCC / TFIST.

In addition, how is the proposed CIP-005 R1.2 different from CIP-006 R1.10? Seems there is overlap as it relates to encryption of data.

Also, SDT needs to explain the comment “Examples include physical protections and points where encryption initiates and terminates.” Is this suggesting physical protection must be applied to encryption points, or that this requiring both physical measures and encryption?

Need to better define communication networks. Which protocols are in scope vs. out of scope, and how are third-party networks treated?

Regarding CIP-005 R1.4, SDT needs to provide guidance / clarity on the term “privileged introspection.”

And generally speaking, needs to clarify the use of system or asset throughout the standards, as the current proposed revisions do not seem to be consistent, and using undefined terms will make it difficult to establish device applicability.

Regarding the Virtual Machine concept, the entire Virtual Machine / system, including the hypervisor, must be part of the BCS with CIP controls applied. If someone can comprise the hypervisor and disable or compromise the virtual machines / systems (BCS) that could have 15-minute impact, it should also be a BCS. High-water mark everything or require segmentation.

NPPD does not support the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry’s programs. The changes being proposed present a risk of unintended consequences for what is the vast majority of systems that are not in virtualized environments. NPPD provides our comments in the spirit of identifying some of the risks and unintended consequences for moving forward in this direction; and in the final comment on this form our recommendations.

-

    No. We do not think ESP needs to be changed.

    No. We think it will require additional documentation, especially for serial connected devices.

    Yes.

No. We question how this applies to technology such as the Dell DRAC or large network backplane systems.

More education is needed before implementing such changes. The changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs too soon after the last one. Some entities have not had the chance for an audit on the last round of changes. Other revisions, such as CIP-003-7 sections 2, 3 and 5 have yet to become effective. MEC has compliantly implemented virtual servers within the existing CIP standards structure. We have been audited on CIP-005 and CIP-007 as well as CIP-004 and CIP-006. We have self-certified CIP-002, -003, -008 and -011. And are preparing evidence for an audit on CIP-009 and CIP-010 in 2019 and have not identified issues.

It is not clear how this magnitude of changes will create a corresponding improvement to reliability and security. Perhaps the “how to comply” with the existing standards when virtualization is involved could best be addressed using other tools such as ERO-endorsed implementation guidance or readiness reviews for the segment of Responsible Entities who are operating or plan to operate with virtualization.

Changing from ESP to LIZ is unclear and requires a change in the fundamental understanding to the cyber security that is in place today

Also a scope change because Medium Impact had two variations. For certain Requirements, BES Cyber Assets had exceptions when there was no External Routable Connectivity

Part D we do not believe that the concept of isolated and control of the management plane is widely understood.

We do not support the changes being considered by the SDT for CIP-005 because we do not agree that the CIP Standards should be upended in order to accommodate a very small number of virtualized systems currently operated or being considered. Additionally, changes such as moving from a “perimeter” to a “zone” philosophy may result in serious risks to security through misunderstandings of what exactly that means by both Responsible Entities and auditors, which is not currently justified. We also ask the SDT to consider the broad impacts and risk that the proposed wholescale replacement of the existing defined terms will have on Responsible Entities, who have worked to ensure the security of their BES Cyber Systems through the currently approved requirements. While we do not dispute that over time “zone” type security will replace the current “perimeter” type solutions, we disagree that this is the right time for such broad and sweeping changes. Instead, the SDT should take a less aggressive posture toward virtualization and narrow this effort to less complicated steps that might assist Responsible Entities in their efforts to virtualize portions of their BES Cyber Systems. Moreover, working within the current CIP structure will allow Responsible Entities to take smaller, less risky steps that will also reduce security and compliance issues for the industry. Comment	
It appears that the intent of modification to CIP-005 R1.1 was to shift from an isolated ESP to an isolated LIZ. However, as drafted, it appears that this modification either (a) raises the burden by requiring firewalls on every BCS, or (b) uses the “system or group” term to refer to an LIZ. The language “applicable systems, either individually or as a group,” should be replaced with the term “LIZ.” The term “communication” could be augmented with “and access to internals and shared resources,” which would imply not only routable communication but also other mechanisms that could affect an LIZ. The proposed CIP-005 R1.2 may be redundant with CIP-006 R1.10. CIP-005 R3 needs additional clarification under “Applicable Systems” in order to be backward-compatible. It may need a new class of asset such as “Zone Boundary System” to apply to. The intent of the Requirement appears to be to prevent an attacker from breaking LIZ boundaries. Most BCS, when they do have a management plane, do not have a management plane that can be used to break an LIZ boundary. If all aspects of a BCS, including management plane and internal virtualized Cyber Assets, are contained entirely within the same LIZ, then no change to its topology can break out of the LIZ. Only an asset that contains some part of an LIZ, but that has some presence in a zone external to the LIZ, could be used to gain unauthorized entry. That would be a Zone Boundary System. An example would be a hypervisor that contains a virtual switch with BCS on it. Access to the management plane of a Zone Boundary System could be used maliciously to reconfigure the virtual isolation and connect those BCS to external systems. Therefore, the proposed R3.1 should apply to Zone Boundary Systems associated with a Medium-Impact LIZ. The management plane should be considered a PCA at the “high water mark” rating of the LIZs contained within and should itself be entirely contained within a LIZ.

Richard Jackson - U.S. Bureau of Reclamation - 1,5

Answer	No
Document Name	

Comment

a. No. Reclamation does not support replacing ESP with Logical Isolation Zone (LIZ) as stated in the response to question 6. Reclamation recommends the SDT use the term Enclave to meet FERC's intent.

If new terminology is needed, Reclamation recommends using existing definitions from the National Institute of Standards and Technology (NIST) Glossary of Key Information Security Terms (NISTIR 7298), specifically the NIST-defined terms "Enclave" and "Enclave Boundary."

Reclamation also recommends replacing the proposed Logical Isolation Zone (LIZ) term with the following term and adding it to the NERC Glossary of Terms:

Electronic Security Enclave (ESE) – One or more Cyber Assets logically connected by one or more internal communication control(s) of a single authorizing security policy for BES Cyber Systems and Protected Cyber Systems. The logically connected Cyber Assets may be structured by physical proximity or by function, independent of location.

b. No. Reclamation does not support the term LIZ and recommends the SDT adopt the term ESE as described above and in the response to question 6. The proposed LIZ definition seems to combine the ESP and EAP concepts but is not as well defined as the individual ESP and EAP definitions.

Logical isolation must distinguish between BES and non-BES. A Logical Isolation Zone could become a risk to BES Cyber Systems when stretched to corporate business enclaves through virtual machine hyper jumping from a lower trust business network. Mixed trust environments on common hardware between CIP Applicable Systems and corporate business networks could introduce risk to the BES.

c. No. As it is written, exemption 4.2.3.3 does not distinguish between entity-owned Cyber Assets and third party-owned Cyber Assets. Reclamation recommends the SDT clearly state the scope of the exemption.

Reclamation also recommends that Cyber Assets associated with communication networks and data communication links used to extend an Electronic Security Enclave to more than one geographic location be protected.

d. No. Requirement R3 seems to apply to Virtual Machines, but it is unclear what the "management plane" and "data plane" are relative to the Applicable Systems. Reclamation recommends the SDT align Requirement R3 to be backwards compatible with current configurations, or state that R3 specifically applies to Virtual Machine technology. Reclamation also recommends if the SDT does use the terms "Management Plane" and "Data Plane" in the standard, they should be defined in the NERC Glossary of Terms.

Mike Smith - Manitoba Hydro - 1,3,5,6, Group Name Manitoba Hydro

Answer	No
Document Name	

Comment

We disagree with these changes. For the bullet a & b, we have the same comments as the above question 6. For the bullet c, the communication components between ESP at Control Centres has been addressed in CIP-006-6 R1.10, if SDT wants to protect the communication components between ESPs outside the Control Centres, SDT only needs to develop an additional requirement in CIP-006-6 to address that. For the bullet d, given that the current CIP V5 requirements have addressed the management plane implicitly, where the management plane devices must have been identified as EACMS since they can add, delete or modify CIP VMs and entire infrastructures. In our virtual environment, the management plane devices were identified as Intermediate Systems and fully compliant by the existing requirements.

Dana Klem - MRO - 1,2,3,4,5,6 - MRO, Group Name MRO NSRF

Answer	No
Document Name	

Comment

Overall, the NSRF does not agree with the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry's programs. Originally, there was the Version 5 Transition Advisory Group, made up of 6 Entities to test our current suite of Standards. There are also multiple registered groups who can write and submit to NERC, Implementation Guidance for ERO deference. Any radical change to the CIP Standards should be practiced and tested BEFORE any Standard is recommended for change. The NSRF also believes that there are Entities who are currently compliant (via an audit) by incorporating virtualization practices under our current set of Standards. All Standards are written to "what to do" not how to incorporate a certain or new technology. The NSRF has attempted to answer the SDT questions but still does not agree with this Project. Here are some specific examples of what a small change to a Standard will do to the industry.

We do not think ESP needs to be changed.

a. No. The NSRF believes ESP replacement will require additional documentation, especially for serial connected devices.

b. No. The NSRF does not recommend replacing ESP with Logical Isolation Zone (LIZ).

c. No. The NSRF questions how this applies to technology such as the Dell DRAC or large network backplane systems.

Lynn Goldstein - PNM Resources - Public Service Company of New Mexico - 1,3

Answer	No
Document Name	

Comment

The replacement of ESP to LIZ is appealing, but its ramifications have yet to be fully understood. While an existing ESP/EAP model may be able to port to the LIZ, the problem is the drafted changes have introduced other LIZ that may need to be implemented to be compliant with regard to serial communications and management planes. Per previous comments, we are still concerned about the issue of nesting LIZ and Entities being penalized for defense in depth when a single control fails, yet all other controls were still protecting the applicable systems.

The concept of “span more than one geographic location” gives us pause. The issue is what defines a geographic location. Per https://sciencing.com/geographic-location-mean-8667.html, a “Geographic location refers to a position on the Earth. Your absolute geographic location is defined by two coordinates, longitude and latitude.” The issue is what is the difference in longitude and latitude that constitute one geographic location be separate from another? Longitude can vary depending on the latitude that it is measured at. So just looking at latitude, one degree of latitude can span about 69 miles, a minute of latitude can span about 1.15 mi, and a second of latitude can span about 101 feet. So technically if you have a big enough campus with an A and B datacenter at the campus then you could have a network spanning more than one geographic location when measured down to the second of latitude and longitude. We applaud the SDT for actually trying to tackle a V5TAG issue since this has not been done for the issues of “Clarify the intent of ‘programmable’ in Cyber Asset”, “Clarify and focus the definition of ‘BES Cyber Asset’” and its three sub concerns, the issue of "associated" in the ERC definition, the concept of “directly” within the ERC definition, and the issue of IRA definition with “using a routable protocol” and the Guidelines and Technical Basis contradiction of dial-up connectivity for IRA means that R2 also applies. These are all the items in the SAR not addressed by the SDT in this proposed draft.

The concept of requiring a LIZ for the management plane is not clearly understood. Some devices may inherently come with a separate management plane interface like baseboard management controller on a server (e.g. HP iLO, DELL iDRAC, Cisco CIMC). However, many do not. Servers acting as a hypervisor have Network Interface Cards (NIC) assigned to various functions. Best practice would have a split of the data plane, management plane, storage plane, and motion or migration plane. However, the data plane and management plane can be on the same set of NICs and separated by VLANs. Since this separation is a design choice and not an inherent property, then does that mean all other machines including workstations must be outfitted with a set of management plan NICs per device capability and thus dual-homing all machines to both the management and data plan? While we appreciate the SDT trying to avoid overly prescriptive requirements, the current draft regarding data plane and management plane remains vague and open to varying interpretations of what compliance looks like.

Response

Kara White - NRG - NRG Energy, Inc. - 3,4,5,6 - FRCC,MRO,WECC,Texas RE,NPCC,SERC,RF

Answer	No
Document Name	

Comment

NRG does not agree with the replacement of the ESP concept with Logical Isolation Zone (LIZ) because serial ports and potentially 4-20mA inputs would be included under EAC or EAPs. Therefore, it would be difficult for registered entities' NERC CIP subject matter experts to understand and potentially difficult to implement as it would take significant resources for registered entities to revamp their entire NERC CIP compliance programs to accommodate these changes, which could affect their existing reliability or security postures. These proposed changes include fundamental changes to NERC CIP ESP and BCS concepts.

No, NRG does not assert that backward compatibility is clear as existing ESPs and EAPs move to the new LIZ concept, because it is not technically explicit and not explicit in its technical definition (no clear logical boundaries "in or out" due to retired key terms that help to build the framework of an ESP boundary).   This could cause reduced security and less ability to achieve compliance because it requires registered entities to take a more interpretive stance on achieving compliance as the proposed language is less prescriptive.

No, NRG does not agree that the addition of the 4.2.3.3 exemption in the standard along with the addition of Requirement part R1.2 to address the V5TAG concern of "Super ESPs" or single networks within or between BES Cyber Systems that span more than one geographic location, because NRG takes the 4.2.3.3 exemption to relate to VLANS. Attackers could manipulate network gear in-between EACs to compromise VLAN security.

No, NRG does not agree that as differing forms of shared infrastructure come into play with virtualization, Requirement R3 has been added to include the management plane and its isolation controls as a part of the CIP standards concept is clearly and widely understood. Registered entities would likely need to form additional understanding of these concepts with their vendors which may be broader than the intent of the proposed standard change.

a. We do not agree with replacing the ESP concept with LIZ. Is it the intent of the SDT that existing ESPs simply convert to a LIZ, where virtual technology does not exist?

b. With all the additions, deletions, and revisions to so many terms and definitions it is not possible at this time to be sure of backwards compatibility.

c. Unclear

d. Also, in R3 Isolation of Management Plane and Data Plane, these terms are initially defined in footnotes, and then capitalized in M3, then lower case again in 3.1. These terms should be explicitly defined in the Glossary.

Pamela Hunter - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - SERC, Group Name Southern Company

Answer	No
Document Name	

Comment

Southern supports the direction of CIP-005 and logical isolation of systems. We have concerns regarding R3 as it applies to all high and medium impact systems and not just those that utilize shared infrastructure. It is not clear exactly what the management plane and the data plane is on every high or medium impact system in existence. The data plane for instance is defined as "part of the network that carries user traffic" per the footnote. It is not clear how an entity on a firmware-based system with one network port will isolate the management plane from "the part of the network that carries user traffic." We also believe R1.2 is not scoped correctly. The language scopes it to all data on any network (LAN or WAN) within the "components of a LIZ" if that LIZ happens to span geographic locations. It needs to be scoped to just those networks used to span the different geographic locations and not all components within the LIZ, such as two hosts in the same cabinet. For R1, Southern is concerned over the "Secure Configuration" and its interaction with a "method" of isolation and change management in CIP-010. Devices such as LAN/RAN serial converters and Dynastars (i.e. mixed serial and IP configurations) and how to implement them need additional clarity. If a particular device cannot support encryption but the rest of the devices can, will I be able to reasonably scope my secure configuration at the device level for components, but also have a separate secure configuration for the "rest of the system"? R3 does not fit non-virtualized environments well.

a. No. WAPA does not support replacing ESP with Logical Isolation Zone (LIZ) as stated in the response to question 6. WAPA strongly recommends the SDT use the term Enclave to meet FERC's intent.

WAPA recommends using existing definitions from the National Institute of Standards and Technology (NIST) Glossary of Key Information Security Terms (NISTIR 7298), specifically the NIST-defined terms "Enclave" and "Enclave Boundary."

WAPA also recommends replacing the proposed Logical Isolation Zone (LIZ) term with the following term and adding it to the NERC Glossary of Terms:

Electronic Security Enclave (ESE) – One or more Cyber Assets logically connected by one or more internal communication control(s) of a single authorizing security policy for BES Cyber Systems and Protected Cyber Systems. The logically connected Cyber Assets may be structured by physical proximity or by function, independent of location.

b. No. WAPA does not support the term LIZ and recommends the SDT adopt the term ESE as described above and in the response to question 6. The proposed LIZ definition seems to combine the ESP and EAP concepts but is not as well defined as the individual ESP and EAP definitions.

Logical isolation must distinguish between BES and non-BES. A Logical Isolation Zone could become a risk to BES Cyber Systems when stretched to corporate business enclaves through virtual machine hyper jumping from a lower trust business network. Mixed trust environments on common hardware between CIP Applicable Systems and corporate business networks could introduce risk to the BES.

c.	No. As it is written, exemption 4.2.3.3 does not distinguish between entity-owned Cyber Assets and third party-owned Cyber Assets. WAPA recommends the SDT clearly state the scope of the exemption.

WAPA also recommends that Cyber Assets associated with communication networks and data communication links used to extend an Electronic Security Enclave to more than one geographic location be protected.

No. Requirement R3 seems to apply to Virtual Machines, but it is unclear what the “management plane” and “data plane” are relative to the Applicable Systems. WAPA recommends the SDT align Requirement R3 to be backwards compatible with current configurations, or state that R3 specifically applies to Virtual Machine technology. WAPA also recommends if the SDT does use the terms “Management Plane” and “Data Plane” in the standard, they should be defined in the NERC Glossary of Terms..

13. The SDT is proposing conforming modifications to CIP-006. Do you agree with these changes? Please provide comments to support your response. In particular, the SDT seeks stakeholder feedback on:

a. Modifications related to CIP Exceptional Circumstances

b. Use of newly proposed term EACS in the Applicable Systems column

If a system that controls access to a BES Cyber System (EACS) is compromised, the real-time ability to operate or control the BPS could be reduced or severed altogether. For this reason, we are in agreement with the use of the newly proposed term EACS throughout CIP-006. Additionally, the modifications related to CIP Exceptional Circumstances bring continuity throughout. See comment in question 12 about CIP-006 R1.10.

These changes appear reasonable. Changes to CIP Exceptional Circumstances relieve controls on authorized persons but remove such relief for visitors during CIP Exceptional Circumstances. Relieving controls on authorized persons is consistent with the concept that authorized people may need to act outside of the normal controls. However, authorizing or controlling visitors remains important. Corresponding reliefs under CIP-004 make it possible to grant new authorizations without the lead time of a PRA process, allowing (but still requiring) rational management of emergency staff augments such as incident management consultants during CIP Exceptional Circumstances.

Button response should be "No".   Button selection wasn't allowed.

PacifiCorp’s approach to this informal comment period was to provide the SDT with constructive feedback related to the proposed revisions to the terms, standards and concepts presented. With that said, PacifiCorp has additional comments and concerns that will be covered in question #16.

The SDT did a good job here. PAC disagrees with EACMS and PACS changes and believe we can accomplish the same without the new terms.

Response

Jack Cashin - American Public Power Association - 4

Answer	
Document Name	

Comment

a. Public power agrees with the addition of the CIP to the requirement level for R2. It seems appropriate to maintain the CIP Exceptional Circumstances (CEC) for R1 related to access logs. However, we suggest NERC consider that alarm requirements in R1 could also be covered by CEC in the event of “an imminent or existing hardware, software, or equipment failure.”

b. APPA agrees with the change to use the EACS in the Applicable Systems column. We appreciate the fact that the EAMS are not included as we anticipate that they will be covered under other BCS-related standards. This provides another option to use the dual-definition approach and allow entities to select between either the existing EACM definition and requirements or use the new EAC/EAM definition and proposed new requirements.

CHPD is concerned about the overlap of CIP-005 R1 Part 1.2 and CIP-006 R1 Part 1.10. The protection of so-called "Super ESPs" seems to already be covered by the CIP-006 R1 Part 1.10. Only one of the requirements should be maintained, and given that CIP-006 R1 Part 1.10 is already in effect, it is CHPD's preference that it be maintained over CIP-005 R1 Part 1.2.

Dana Klem - MRO - 1,2,3,4,5,6 - MRO, Group Name MRO NSRF	
Answer	No
Document Name	
Comment	

Overall, the NSRF does not agree with the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry's programs. Originally, there was the Version 5 Transition Advisory Group, made up of 6 Entities to test our current suite of Standards. There are also multiple registered groups who can write and submit to NERC, Implementation Guidance for ERO deference. Any radical change to the CIP Standards should be practiced and tested BEFORE any Standard is recommended for change. The NSRF also believes that there are Entities who are currently compliant (via an audit) by incorporating virtualization practices under our current set of Standards. All Standards are written to "what to do" not how to incorporate a certain or new technology. The NSRF has attempted to answer the SDT questions but still does not agree with this Project. Here are some specific examples of what a small change to a Standard will do to the industry.

a. No. During an extreme weather event a CEC may be declared. For instance, if a tornado hit a substation and compromised the control building a CEC would be required for all of R1 not just the Parts in the proposed change. We recommend leaving the CEC at the R1 level.

b. No. We think that EAMS should also be afforded the same protections as EACS. It is a generally accepted security concept that if a person has physical access to a system it is difficult to prevent them from compromising that system. EAMS are an important part of providing security for BES Cyber Systems and should thus be afforded the same physical protections.

Response

Richard Jackson - U.S. Bureau of Reclamation - 1,5

Answer	No
Document Name	

Comment

a. Yes. Reclamation agrees with the modifications related to CIP Exceptional Circumstances. CIP Exceptional Circumstances are necessary during emergencies for first responders.

b. Reclamation supports adding systems that control access to the Applicable Systems column; however, Reclamation disagrees with the newly-proposed term EACS. Reclamation recommends the SDT use the term Intrusion Detection System (IPS) instead, as stated in the response to Question 4.

Reclamation recommends CIP-006 Requirement R1 Part 1.10 be changed

from:

Where physical access restrictions to such cabling and components are not implemented, the Responsible Entity shall document and implement one or more of the following:…

to:

Where physical access restrictions to such cabling, components, or Cyber Assets associated with communication networks and data communication links cannot be implemented, the Responsible Entity shall document and implement the following:…

Comment

MEC does not agree with the conforming changes. The changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs too soon after the last one. Some entities have not had the chance for an audit on the last round of changes. Other revisions, such as CIP-003-7 sections 2, 3 and 5 have yet to become effective. MEC has compliantly implemented virtual servers within the existing CIP standards structure. We have been audited on CIP-005 and CIP-007 as well as CIP-004 and CIP-006. We have self-certified CIP-002, -003, -008 and -011. And are preparing evidence for an audit on CIP-009 and CIP-010 in 2019 and have not identified issues.

Don Schmit - Nebraska Public Power District - 1,3,5

Answer	No
Document Name	

Comment

NPPD does not support the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry's programs. The changes being proposed present a risk of unintended consequences for what is the vast majority of systems that are not in virtualized environments. NPPD provides our comments in the spirit of identifying some of the risks and unintended consequences for moving forward in this direction; and in the final comment on this form our recommendations.

a) No. During an extreme weather event a CEC may be declared. For instance, if a tornado hit a substation and compromised the control building a CEC would be required for all of R1 not just the Parts in the proposed change. We recommend leaving the CEC at the R1 level.

b) No. We think that EAMS should also be afforded the same protections as EACS. Pamela Hunter - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - SERC, Group Name Southern Company	

Answer	No
Document Name	

Comment

Southern Company believes the CEC in CIP-006 R1.8 and R1.9, while helpful, only addresses logging failures. In a storm response mutual assistance situation, for example, you would still have to control, monitor, and alert on access, even if the entire PACS is lost, not just the logging function. With this situation, it seems that there are now less restrictions on visitors during a CEC in R2 than the employees who are on site repairing the system. Southern Company asserts that it will make more sense to move the CEC language to the higher level requirement level (R x) rather than the sub-requirement level (R x.y).

Document Name	

Comment

a. Agree with the addition of CEC for the reqiuirement level of R2. Recommend it be maintain at the requirement level for R1. In the event of a catastrophic event an entitiy may have to declare a CIP Exceptional Circumstance that may require CEC all parts of R1.

b. If EACMS is split into EAMS and EACS, what would be considered an EAMS? The camera systems or software used to perform electronic monitoring? CIP-006 only requires Electronic Control Systems (EACS) and no Electronic Monitoring Systems (EAMS). So an entity has to control access but does not have to monitor it, was this the intent of the SDT?

14. The SDT is proposing modifications to CIP-007 (see the CIP-007 Technical Rationale document for detailed information.). Do you agree with these changes? Please provide comments to support your response. In particular, the SDT seeks stakeholder feedback on:

a. The SDT is proposing adding the security objectives throughout the Requirements in CIP-007. Do you agree that the proposed security objectives add clarity to the reason the requirement exists?

b. The SDT is proposing the security objective in CIP-007 R1, “to mitigate the risk posed by uncontrolled logical and physical connectivity". Do you agree that the modifications to CIP-007 R1 Part 1.1 fulfill this security objective for systems where connectivity is not limited to TCP/IP port service combinations, as in virtualized systems and SAN based storage?

c. Do you agree that the modifications to CIP-007 R1 Part 1.1 add necessary flexibility to fulfill the security objective of CIP-007 R1 for virtualized systems and provides a degree of future proofing?

Jamie Monette - Allete - Minnesota Power, Inc. - 1

Answer	Yes
Document Name	

Comment

a) Yes, the additions help clarify intent. As with any compliance standard, it is important to integrate the intent with the method of auditing to allow the intent to be the focus and not prescriptive details. This also needs to be clearly and consistently communicated throughout the regions.

b) Yes.

c) Yes.

CIP-007-7, Requirement R1, Part 1.2 regarding the protection of unused physical ports. The Secure Configuration is not present in this Requirement and I believe it should be. The potential protections can be physical or logical, and a change could impact either one of these. For logical, it is easy to understand a change could change the logical setting of a port making it usable. For a physical change, a similar condition could occur of the change was the swap out of hardware and a physical port blocker was not re-installed or signage is not put back into place.

Lan Nguyen - CenterPoint Energy Houston Electric, LLC - 1 - Texas RE

Answer

Document Name

Comment

CenterPoint Energy does not support a major overhaul of the standards at this time. However, if the SDT continues to make revisions, CenterPoint Energy recommends the following:

The SDT should provide more clarity around scripts and installed software. In CIP 007-7 Requirement R2.1, how is “essential” defined? Is the intent of this requirement to prohibit authorized users from writing and executing scripts in the course of their work? Is there a timeframe for alerting on newly-installed software or executable scripts? What does installed mean? If an executable or script is copied to the system, is it considered installed? Is a for loop typed in a shell considered a script? Would a shell alias be considered a script?

Comment	
Button response should be "No". Button selection wasn't allowed. PacifiCorp's approach to this informal comment period was to provide the SDT with constructive feedback related to the proposed revisions to the terms, standards and concepts presented. With that said, PacifiCorp has additional comments and concerns that will be covered in question #16. The SDT did a good job here. PAC believes it allows the flexibility to develop the program based on the infrastructure and how the communications are managed. {C}a) The security objective concept isn't new to cyber security controls. However, the subjectiveness will make it hard to audit as entities develop different implementations. It could open up an issue when the auditors develop an approach that identifies certain methods are more desirable than others and suggest entities adhere to their opinions rather than the language of the standard. {C}b) Excluding serial communications works, PAC understands the reasoning behind the change. Concern here is on Ethernet capable devices that aren't being used (RTAC, SEL-411, etc.) "Configure each system to provide only essential logical connectivity" Will we need to disable and document the port on the Cyber Assets in the Medium BCS? {C}c) Yes.

APPA generally agrees that the proposed security objectives add clarity to the reason the requirement exists.	

Public power does have some general concerns with CIP-007. With the removal of the TFE language, is guidance anticipated on “per system capability?” The removal of the, “with External Routable Connectivity” makes this important for registered entities to understand. Also, there are concerns that the “Detect and alert on malicious communication within systems,” included within the Requirement Part on Connectivity.

A further public power concern is: will vendor supported applications be able to provide sufficient documentation related to the implementation of the multiple elements of the “Secure Configuration?” If this does not exist in an application, will companies have sufficient time to procure/develop such a system prior to compliance date?

Another potential issue for public power will be determining what is the intent of the note related to Secure Configuration for the CIP-007-7 R3 Part 3.2 “Mitigate the threat of detected malicious code.” We understand that we need to remove or isolate the detected malicious code, but how does the removal become part of the Secure Configuration of the BCS? The capability to detect the malicious code will exist in the antivirus solution. Where else is it likely to become part of the implemented configuration? How does it apply to virtual environments?

Proposed CIP-007 and CIP-010, have significant cross references and requirements related to the documentation of the Secure Configuration. APPA recognizes that this will require significant resource commitment to manage security controls in a traditional and virtual/cloud-based environment.

The new requirement introduced in part R2 should be limited in applicability to virtualized BCS and associated PCS. No technical basis is evident to justify the expansion of scope to include this new requirement for the existing approach to securing non-virtual BCS, etc. Although this practice might be a good security practice, CIP requirements are intended to provide a baseline of security practices not a collection of all good or best practices. Indeed, there exist many other good security practices that are not included in CIP requirements. It is not sufficient justification alone to add a new requirement just because it is a good practice; there should exist an overriding technical or security need. If this requirement is maintained, we recommend that it apply to virtualized BCS only.

Jonathan Robbins - Seminole Electric Cooperative, Inc. - 1,3,4,5,6 - FRCC

Answer	No
Document Name	

Comment

a. Yes

b. It appears that TFEs are being eliminated, is that true? Will guidance be provided to better clarify “per system capability” and the expected compliance documentation? How will this be audited if device capabilities within a system vary, or if a system is not capable? Specific guidance for Secure Configurations should be included. If entities are required to develop, this could be timely. “Detect and alert on malicious communication within a system” seems to be better suited for either R3 or R4.

c. Yes

Duke Energy believes that a response to question #8 (regarding IP/Serial Converter inclusion in BCS) to fully comment. Are Secure Configuration items required to be documented? We believe the fifth bullet in R2.1 is too vague (Other methods?) and will allow for interpretation differences between the auditor and the Registered Entity. Also, the new verbiage now says “per system capability” instead of “where technically feasible” in CIP-007…Does that mean that an entity can retire filed TFEs as long as they maintain evidence of system capability? i.e. the entity does not have to perform material change tasks with the regions anymore.

While we do not have specific comments on the questions proposed by the SDT, we do have concerns about certain updates within CIP-007. CIP-007 R1: For consistency, we suggest that the measure related to malicious commination under Part 1.1 be updated to include alerting or that alerting be removed from the requirement (“Detect and *alert* on malicious communication with systems”).	

CIP-007 R2: While we understand the reasoning behind the changes to R2, "controlling software that is allowed to execute on a BES Cyber Systems", there is some confusion on what the requirement means. For example, what does "essential software execution" mean? As tedious as it might sound, adding words such as "essential" into the requirements without explicitly expressing what the intent of the word is, causes issues with the entities and the regions. It would be prudent to get away from words that can be construed in different ways or that can change the execution of the requirement depending on how they are interpreted. Additionally, treating scripts the same as software, without further explaining what types of scripts, will cause undue burden on entities. For example, is it the SDT intent that read-only scripts be tracked? We believe that this could turn into a time-consuming task that will never be completed to an auditor or the requirements satisfaction.

Additionally, the Secure Configuration concept is found throughout CIP-007. Please see our comment relating to Secure Configuration under question 15.

Response

Kevin Salsbury - Berkshire Hathaway - NV Energy - 5

Answer	No
Document Name	

Comment

NV Energy would like to comment the SDT for the work done in CIP-007-6, as we believe a movement to a risk-based approach for security will allow the flexibility to develop the program based on the infrastructure and how the communications are managed. In addition, with the removal of the strict timelines for R2, this would alleviate the multiple violations of this Requirement due to missing the 35 day windows, versus the intent of a program in preventing any incident due to the lack of patching Cyber Assets.

a) NV Energy does recognize that this more flexible approach to security does have its difficulties. The increase in subjectiveness will make it hard to audit as entities develop different implementations. It could open up an issue when the auditors develop an approach that identifies certain methods are more desirable than others and suggest entities adhere to their opinions rather than the language of the standard.

b) Excluding serial communications works, NV Energy understands the reasoning behind the change. Concern here is on Ethernet capable devices that aren't being used (RTAC, SEL-411, etc.) "Configure each system to provide only essential logical connectivity" Will we need to disable and document the port on the Cyber Assets in the Medium BCS?

c) Yes.

CIP-007 R1 Part 1.1’s proposed wording appears ambiguous and confusing to us. The language of the requirement part does not contain the objective (where all of the other requirement parts in CIP-007 do contain the objective). Even though the security objective is present in the language of R1, it should be present in Part 1.1 as well, especially since R1.1 is after a page break.

Although adding security objectives does allow for flexibility in the technical approach taken to comply it also poses additional potential for disparate interpretations of the requirement between entities and auditors. An approach the entity feels addresses the objective adequately may be viewed by the auditor as unsatisfactory. A more prescriptive model lends to more concise interpretation of the requirements.

For Part 1.1, consider using “per system capability” instead of “excluding serial port connectivity such as RS-232 and RS-485.” Please clarify “Detect and alert on malicious communication within systems”. This basically calls for IDS at the hypervisor. Should this be in Requirement R3? Should this be something like limiting traffic? As written, Part 1.1 seems to imply that an entity would be required to implement all of the bulleted items if the system is capable. Please reconsider the wording of this. The note should not be used within requirement language in Part 1.1 and other requirements. As written, this is not an actual requirement. It is simply guidance in this format. The content should be moved to a more appropriate location. For Part 2.1, please provide clarification on executable scripts. This element continues to raise issues with disparate interpretations between entities and Regional Entities. A clear descriptor of this would aid in consistency of implementation across the industry. Consider using “available software” instead of “installed software”. There is software that can be usable without an actual installation process. Please clarify “essential”. Regarding Parts 3.1, 3.2, 4.1, 4.2, 5.1, 5.2, 5.5, 5.6, and 5.7, the note should not be used within requirement language in Part 1.1 and other requirements. As written, this is not an actual requirement. It is simply guidance in this format. The content should be moved to a more appropriate location.

N&ST supports the idea of adding security objectives to top-level (“R”) requirements, but believes, for R2, that the SDT needs to provide at least a working definition of “managed software” before establishing an objective of mitigation risks posed by “unmanaged” software. N&ST supports the goal of proposed R1 Part 1.1 modifications but believes that configuring applicable systems to permit only required logical/electronic communications should be mandatory, vs. only one of several acceptable options.

Response

David Rivera - New York Power Authority - 1,3,5,6

Answer	No
Document Name	

Comment

NYPA supports comments submitted by NPCC / TFIST and NPDD.

In addition, the following questions should be addressed or guidance provided to address some ambiguity:

- CIP-007 R1.1
    - “Excluding port connectivity such as RS-232 and RS-485.” Should other exemptions be provided, such as DNP3 using non-routable? Or instance when data is carried over a TCP/IP network that are serial at the end-point. Stated differently, remove the specific exemptions and state serial communications are exempted.
    - Explain why “ERC” was removed from the applicability.
- CIP-007 R2.1
    - Does “to allow only essential software execution” exclude firmware?
    - Are manual methods of alerting allowed? Can alerting be done on a periodic basis, or does this requirement require real-time alerting?
- CIP-007 R3.2
    - Are we required to identify and document the mitigation processes used on a BCS process, or is this requiring each mitigation activity be part of the Secure Configuration? Currently reads as the latter which is a CIP-008 issue. In addition, including response activities within the Secure Configuration does not provide any value to detecting cyber security incidents.
- CIP-007 R5.1
    - For Interactive User Access, it could be a process or technical control. How should a process be documented as part of the Secure Configuration, especially if the process allows for different approaches / solutions?
    - Adding administrative overhead to track this / could result in creation of numerous new CSI documents which poses a risk.
- CIP-007 R5.2
    - Adding administrative overhead to track this / could result in creation of numerous new CSI documents which poses a risk.

- CIP-007 R5.3-5.5
    - No comments
- CIP-007 R5.6
    - How should a process be documented as part of the Secure Configuration, especially if the process allows for different approaches / solutions?
    - Adding administrative overhead to track this / could result in creation of numerous new CSI documents which poses a risk

NPPD does not support the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry's programs. The changes being proposed present a risk of unintended consequences for what is the vast majority of systems that are not in virtualized environments. NPPD provides our comments in the spirit of identifying some of the risks and unintended consequences for moving forward in this direction; and in the final comment on this form our recommendations.

a) No.

b) No. We do not see a need to change R1. We also are concerned with adding the "detect and alert" language to Part 1.1. Adding the detecting and alerting seems to be duplicative with CIP-010 Part 2.1. Adding the "detect and alert" language increases compliance obligations for Medium Impact systems.

c) No. By adding this flexibility you also introduce auditor discretion into requirements that have very clear objectives. CIP-002-1 to CIP-002-3 required an entity to develop a Risk Based Assessment Methodology (RBAM) to determine Critical Assets. FERC did not agree with some entity assessments and requested the standard be changed to be more prescriptive. We now have the “Bright Line” criteria in CIP-002-5.1a. We think the risk assessment methodology provides the potential for relief of unnecessary burdensome work. The current requirements unintentionally require processes that do not make sense in certain circumstances but we think there is great risk of an auditor not completely understanding the entity’s risk and therefore issuing a PNC (Potential Non-Compliance).

Security objective-based requirements may be the right direction, but at the wrong time. Other non-NERC standards that are security objective-based are not subject to zero-defect compliance monitoring. In this case, security objective-based requirements may provide too much flexibility that could result in too much difference in interpretation between different Responsible Entities and auditors. The changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs too soon after the last one. Some entities have not had the chance for an audit on the last round of changes. Other revisions, such as CIP-003-7 sections 2, 3 and 5 have yet to become effective. MEC has compliantly implemented virtual servers within the existing CIP standards structure. We have been audited on CIP-005 and CIP-007 as well as CIP-004 and CIP-006. We have self-certified CIP-002, -003, -008 and -011. And are preparing evidence for an audit on CIP-009 and CIP-010 in 2019 and have not identified issues.

It is not clear how this magnitude of changes will create a corresponding improvement to reliability and security. Perhaps the “how to comply” with the existing standards when virtualization is involved could best be addressed using other tools such as ERO-endorsed implementation guidance or readiness reviews for the segment of Responsible Entities who are operating or plan to operate with virtualization.

The proposed changes make progress toward accomplishing this goal, but they may also increase the compliance burden for existing BCS. Comments under question 9 apply here as well: The “ERC” qualifier has been removed from CIP-007 R1.1. This could dramatically increase burden on some entities, where the intended effect could be achieved instead with a virtualization-ready definition of “PCA” and “ERC.” CIP-007 R1.4 also seems to shift from requiring intrusion protection on an ESP level to requiring it on a BCS level. This will be onerous and may not be technically feasible in many cases, unless BCS are defined over-broadly (i.e., the entire LIZ is a single BCS). There is a meaningful distinction in keeping the BCS definition separate as a subcomponent of the LIZ. The appropriate shift would be from EAP to LIZ, not from EAP to BCS.

We disagree with these changes. We still support the current result-based requirements with appropriately prescriptive language. Even though the proposed objective-based non-prescriptive requirements provide some flexibility for the CIP compliance, they are too broad and subjective. By virtue of lack of detailed measures and guidance, how do the registered entities know their processes have been implemented effectively? How will Auditors/Teams be accredited to evaluate effectiveness? What will be the effectiveness metric? Given that currently the majority of CIP Cyber Assets are physical and the CIP compliance process today works fairly smoothly by implementing the existing requirements that are appropriately prescribed, it doesn't make sense to modify any existing requirements that are only for sufficing a small percentage of the virtual devices but a waste of the registered entities' time and resources for making these changes.

Resulting from our comments in the above question 1, as long as the virtual devices are identified correctly and the device-centric approach would still work well for the virtual devices, where the CIP-007 R1 Part 1.1 will apply to them smoothly.

Dana Klem - MRO - 1,2,3,4,5,6 - MRO, Group Name MRO NSRF

Answer	No
Document Name	

Comment

Overall, the NSRF does not agree with the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry's programs. Originally, there was the Version 5 Transition Advisory Group, made up of 6 Entities to test our current suite of Standards. There are also multiple registered groups who can write and submit to NERC, Implementation Guidance for ERO deference. Any radical change to the CIP Standards should be practiced and tested BEFORE any Standard is recommended for change. The NSRF also believes that there are Entities who are currently compliant (via an audit) by incorporating virtualization practices under our current set of Standards. All Standards are written to "what to do" not how to incorporate a certain or new technology. The NSRF has attempted to answer the SDT questions but still does not agree with this Project. Here are some specific examples of what a small change to a Standard will do to the industry.

a. No.

b. No. The NSRF does not see a need to change R1. We also are concerned with adding the "detect and alert" language to Part 1.1. Adding the detecting and alerting seems to be duplicative with CIP-010 Part 2.1. Adding the "detect and alert" language increases compliance obligations for Medium Impact systems.

c. No. By adding this flexibility the SDT also introduces auditor discretion into requirements that have very clear objectives. CIP-002-1 to CIP-002-3 required an entity to develop a Risk Based Assessment Methodology (RBAM) to determine Critical Assets. FERC did not agree with some entity assessments and requested the standard be changed to be more prescriptive. We now have the "Bright Line" criteria in CIP-002-5.1a. We think the risk assessment methodology provides the potential for relief of unnecessary burdensome work. The current requirements unintentionally require processes that do not make sense in certain circumstances but we think there is great risk of an auditor not completely understanding the entity's risk and therefore issuing a PNC (Potential Non-Compliance).

We agree with some, but not all the modifications. We do agree that adding the security objectives in the requirements of CIP-007 is a step in the right direction. However, the requirements need to support defense in depth without penalty. For instance, in the modifications to CIP-007 R1.1, an entity can use a combination of four protections. If an entity employs two or more to an applicable system and one is found to have failed, then an Entity should not be found in violation if the other protection remained in place. The entity should only be found if violation if all protections for an applicable system related to R1.1 were not in place. Regarding modifications to CIP-007 R1.1, it is unclear if “Detect and alert on malicious communication within systems” actually meets the security objective of mitigating the risk posed by uncontrolled logical and physical connectivity. In addition, this is also a control for the security objective of mitigating the risk posed by malicious code in R3 and the security objective of monitoring security events to mitigate the risk posed by detectable security incidents in R4. So, if an entity chooses only this control for a system then they are potentially also in violation of R3.1 and R4.2.1. Either the mitigation measure needs to belong only to one security objective to avoid multiple violations if one fails, or the entire CIP-007 needs to be reworked to a program that addresses each risk and the entity has identified controls for each risk. Again, with the idea that an entity with multiple controls in place for a particular risk is not penalized when one control fails, but other controls remain in place. The proposed changes might provide a degree of future proofing, but per Master Yoda, “Difficult to see. Always in motion is the future.”

Kara White - NRG - NRG Energy, Inc. - 3,4,5,6 - FRCC,MRO,WECC,Texas RE,NPCC,SERC,RF	

Answer	No
Document Name	

Comment

No, NRG does not agree that adding the security objectives throughout the Requirements in CIP-007 adds clarity to the reason the requirement exists, because the new secure configuration definition mandates malware monitoring within BES Cyber Systems which implies AV on the BCS and not at the system level (which is the only requirement of the current standard). This proposed change could also imply needing network access control, whitelisting, and/or needing host based intrusion detection.

No, NRG does not agree that the proposed security objective in CIP-007 R1, "to mitigate the risk posed by uncontrolled logical and physical connectivity" because it expands the port control requirements. Registered entities that have used no ERC as a security measure,will now have additional compliance requirements. The security gained from these activities may not outweigh the additional compliance burden to the industry. NRG does not agree that the modifications to CIP-007 R1 Part 1.1 fulfill this security objective for systems where connectivity is not limited to TCP/IP port service combinations, as in virtualized systems and SAN based storage because The new secure configuration definition mandates malware monitoring within BES Cyber Systems which implies AV on the BCS and not at the system level (which is the only requirement of the current standard). This proposed change could also imply needing network access control, whitelisting, and/or needing host based intrusion detection.

No, NRG does not agree that the modifications to CIP-007 R1 Part 1.1 add necessary flexibility to fulfill the security objective of CIP-007 R1 for virtualized systems and provides a degree of future proofing because while the direction of the other version 7 standard revisions have shifted focus to a system, this requirement provides a vague approach with underlying expectation on cyber asset level protections. Many control system vendors do not currently support host-based firewalls and/or intrusion detection systems. The same protection could be realized at the system level through a combination of firewalls, intrusion detection, configurations monitoring, network access control, malware scanning, and TCA/RM controls.

For Part 1.1, consider using "per system capability" instead of "excluding serial port connectivity such as RS-232 and RS-485." Please clarify "Detect and alert on malicious communication within systems." This basically calls for IDS at the hypervisor. Should this be in Requirement R3? Should this be something like limiting traffic? As written, Part 1.1 seems to imply that an entity would be required to implement all of the bulleted items if the system is capable. Please reconsider the wording of this. The note should not be used within requirement language in Part 1.1, or in other requirements. As written, this is not an actual requirement. It is simply guidance in this format. The content should be moved to a more appropriate location.

For Part 2.1, please provide clarification on executable scripts. This element continues to raise issues with disparate interpretations between entities and Regional Entities. A clear descriptor of this would aid in consistency of implementation across the industry. Consider using "available software" instead of "installed software." There is software that can be usable without an actual installation process. Please clarify "essential."

Regarding Parts 3.1, 3.2, 4.1, 4.2, 5.1, 5.2, 5.5, 5.6, and 5.7, the note should not be used within requirement language in Part 1.1, or other requirements. As written, this is not an actual requirement. It is simply guidance in this format. The content should be moved to a more appropriate location.

In order to provide the necessary flexibility to fulfill the security objectives and to clarify ability to choose, please consider adding "or" at the end of each line of all bullet point lists providing options.

R1.1 recommended updated language reads:

• Configure each system to provide only essential logical connectivity; or

• Detect and alert on malicious communication within systems; or

• Baseline system logical connectivity, and alert on deviation from baseline; or

• Other method(s) to mitigate the risk posed by uncontrolled logical connectivity.

R2.1 recommended updated language reads:

• Configure each system with intentionally installed essential software and executable scripts; or

• Baseline currently installed software and executable scripts and alert on any newly installed software or executable scripts; or

• Implement application whitelisting; or

• Use read-only bootable media; or

• Other methods to mitigate the risk posed by unmanaged software.

We disagree with the removal of “with External Routable Connectivity” as an applicable system in CIP-007.

Is CIP-007 R1 1.1 only applicable to systems where there is virtual technology? If so shouldn't that be listed as the applicable system? R1 is to mitigate the risk posed by uncontrolled logical and physical connectivity; Part 1.1 doesn't address physical and logical connectivity.

In CIP-007 2.1 – How would this apply to a BES Cyber System that is a System Protection Relay?

Comment

a. The SSRG requests the Standard Drafting Team ensure the language is clear enough to allow the Reponsible Entity to have clear direction what consistutes the type of port that is included in the Secure Configuration. For example, unlike CIP-007-6 which utilizes more concise language such as "logical network accessible ports that have been determined to be needed by the Responsible Entity…", version 7 utilizes terminology such as "only essential logical connecticity" and "uncontrolled logical connectivity," and states the standard excludes serial port connectivity "such as RS-232 and RS-485." This language appears very broad and subjective to what is included.

b. The SSRG does not see a need to change R1. Adding the "detect and alert" language to Part 1.1 seems duplicative of CIP-010 Part 2.1 and increases compliance obligations for Medium Impact systems.

c. The SSRG is concerned that by adding the referenced flexibility, auditor discretion is introducted into requirements that have very clear objectives. CIP-002-1 to CIP-002-3 required an entity to develop a Risk Based Assessment Methodology ("RBAM") to determine Critical Assets, which includes the "Bright Line" criteria in CIP-002-5.1a. The SSRG believes the RBAM approach provides for relief from unnecessarily burdensome work and mitigates auditor discretion.

MRO does not agree with these changes because it is not clear how “Mitigate the Risk” language supports enforceable requirements for the system security management of BES Cyber Systems. “Mitigate the risk” could be interpreted as anything between “Eliminate the Risk” and “Detect the Risk”. This could lead to challenges in consistent CMEP implementation by the ERO.

Pamela Hunter - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - SERC, Group Name Southern Company

Answer	No
Document Name	

Comment

Southern Company requests clarification on the interplay between the objective in the overall requirement and the scoping of applicability in the table. As an example, CIP-007 R1 addresses mitigating the risk posed by uncontrolled logical and physical connectivity, yet the physical connectivity mitigation in the table is scoped to high impact control centers only. If an entity has only medium impact systems, what is the obligation of this requirement? The main requirement states they must implement a process that mitigates the risk posed by uncontrolled logical and physical security - and that plan(s) "collectively include" the requirement parts, but it does not state or clarify that it is *scoped* by those parts. This was not an issue previously as all the objectives and requirements were in the tables. It has changed now that the objective is in the overall requirement. Southern suggests the SDT consider this issue across all the standards and clarify how the high-level objectives work with the applicability column in the tables.

Logical connectivity in CIP-007 R1.1 – does this unintentionally alter the scope for ports and services? This is a backwards compatibility question. Southern would like to see additional clarity in the definition for logical connectivity. This terminology is used throughout these proposed changes and clarity in the application of this term can provide clarity in scoping.

Can this unintentionally scope in “anything connected to the system”? Will mounting a drive unintentionally scope in that logical connectivity? Do we have to start tracking (i.e. making lists) of everything that a system connects to? How might this extend into shared memory? Do we need to enumerate USB mice and keyboards?

15. The SDT is proposing modifications to CIP-010 (see the CIP-010 Technical Rationale document for detailed information.). Do you agree with these changes? Please provide comments to support your response. In particular, the SDT seeks stakeholder feedback on:

a. The SDT is proposing adding the security objectives throughout the Requirements in CIP-010. Do you agree that the proposed security objectives add clarity to the reason the requirement exists?

b. The SDT is proposing to modify the referenced baseline configuration from CIP-010-3 R1 Part 1.1 to a 'Secure Configuration' which is made up of the implemented controls that fulfill requirements within CIP-005 and CIP-007. Do you agree that this set of controls supports managing change under CIP-010 R1 Part 1.1?

c. The SDT is proposing to modify the current CIP-007 R2 requirements and move them to CIP-010 R3. The SDT believes that the software vulnerability management found within this set of requirements fits logically within the security objective of CIP-010 R3 "to mitigate the risk posed by system vulnerabilities" and has moved it there. Do you agree?

d. The SDT is proposing CIP-010 R3 Parts 3.5 and 3.6 to replace the current CIP-007 R2 Parts 2.1 – 2.4. Do you agree that the proposed CIP-010 R3 Parts 3.5 and 3.6 offer the additional flexibility needed when implementing virtualized systems that can be dormant for a period, and for which security patches have become available?

Regarding b: Entities will need to track the Secure Configurations in a similar way to current baselines (with OS, software, etc) to monitor for and react to potential incidents and vulnerabilities. Additionally, tracking this way will assist entities in identifying, isolating and/or patching potentially vulnerable physical or virtual BCS.

Regarding d: This will require an entity to provide a thorough explanation of their rationale behind the periodicity for identifying software vulnerabilities.

Comment

Button response should be "No". Button selection wasn't allowed.

PacifiCorp’s approach to this informal comment period was to provide the SDT with constructive feedback related to the proposed revisions to the terms, standards and concepts presented. With that said, PacifiCorp has additional comments and concerns that will be covered in question #16.

The SDT did a good job here. PAC believes it allows the flexibility to develop the program based on the infrastructure and how the communications are managed.

{C}a) The security objective concept isn’t new to cyber security controls. However, the subjectiveness will make it hard to audit as entities develop different implementations. It could open up an issue when the auditors develop an approach that identifies certain methods are more desirable than others and suggest entities adhere to their opinions rather than the language of the standard.

Secure Configuration (proposed) The implemented set of controls supporting the security objectives found within the CIP Reliability Standards where the following text exists within the requirement language: “NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system.” New “Baseline” = CIP-005 R1.1, CIP-007

{C}a) R1.1, R2.1, R3.1, R3.2, R4.1, R4.2, R5.1, R5.2, R5.5, R5.6, R5.7, CIP-010 R3.6. This concept makes sense, but would need further review as compared to the original CIP-010 Bassline and CIP-007 controls documentation to fully understand the impacts of the changes proposed.

{C}b) From the beginning of CIPv5 that Patch Management should be CIP-010, PAC agrees with this change. Not understanding the new phrase “The process requirements of Part X.X and timeline are based on the analysis of the risks to BES reliability and the risks posed by the …”. Is the SDT expecting a risk register and program with thresholds of when things need to be done? Seems like this could be a good thing if we embrace this idea, but it leaves the auditors to determine what they feel is reasonable too when checking whether the timelines indicated line up with the risk level identified. Are there plans for future development during the drafting that the SDT plans to add some timeframes into the standards like before (i.e. every 35 days, etc.)

{C}c) Yes, PAC believes the SDT did a good job moving this to CIP-010 and allowing for flexible schedules based on system activity. However, our concern with timelines and risk are the same as explained in item "C" above.

Response

Jack Cashin - American Public Power Association - 4

Answer	
Document Name	

Comment

Public power agrees with transferring the requirements from CIP-007 to CIP-010 as mitigating software vulnerabilities more closely relates to vulnerability management rather than system management. However, as the 4 parts of this question suggest, these modifications add complexity to the standard. For example, the definition of the new term Secure Configuration and its role is unclear, and stakeholders can envision the term taking on more significance in the future. While it seems appropriate to identify the security controls as part of the Secure Configuration, some Entities had implemented the requirements for the current CIP-010 security controls by evaluating changes against all CIP-005 and CIP-007 security controls. Consequently, it would be best for the SDT to list out what the Secure Configuration is composed of.

APPA does consider that the move of the CIP-007 R2 requirements to CIP-010 is an improvement by locating them in a single standard. They are logically part of the methods that industry uses to mitigate the risk of system vulnerabilities. Further, we agree that the proposed changes will provide flexibility for virtual systems.

Although the Secure Configuration concept is not fully understood, either in application or audit approach, there is reasonable concern that it expands the scope of requirements for non-virtualized BCS. See further discussion above in responses to Question 14. Under the principle that CIP scope generally should not be expanded in these revisions for non-virtualized systems, the dual-definition/dual-requirement "overlay" approach discussed in Question 3, above, may be warranted as a means for entities to remove the scope expansion for existing BCS, for which the existing baseline approach may be sufficient.

Comment

NYPA supports comments submitted by NPCC / TFIST.

In addition, the following questions should be addressed or guidance provided to address some ambiguity:

- CIP-010 R1.1
    - Need to provide guidance on how timelines should be developed and what the risk analysis needs to consider. Is the entity required to develop their own risk analysis or will guidance be released making this more prescriptive? Will the resulting entity risk assessment process / criteria be subject to auditors?
    - Why does the requirement exclude EAMS and PAMS? Security controls should be applied to these systems that log and monitor. Not doing so will reduce security posture and make it difficult to meet requirements under CIP-006, 7 and 8.
- CIP-010 R1.2
    - Why is R1.2 written to CIP-005 and CIP-007 controls, whereas R1.1 is written to the Secure Configuration? This seems to be an inconsistency that should be addressed, or at a minimum explained.
- CIP-010 R1.3

  - Is firmware and operating system exempted since it is not included within R1.3.1 and R1.3.2 requirement text?

- CIP-010 R2
  - Similar question on timelines. Also, why is impact rating called out in the bottom note when the only applicable impact rating is High Impact? How many different types of risk assessments need to be conducted across CIP-010?

- CIP-010 R3.5
  - Is software intended to include firmware and operating systems? Firmware and operating system is called-out in CIP-010 R1.3 but not here. Why the inconsistency?
  - Similar comment on conducting risk assessments. If 35-days was sufficient under CIPv5, is it also sufficient under this proposed revision, thereby not requiring a risk assessment?

- CIP-010 R3.6
  - Is software intended to include firmware and operating systems? Firmware and operating system is called-out in CIP-010 R1.3 but not here. Why the inconsistency?
  - Similar comment on conducting risk assessments. If 35-days was sufficient under CIPv5, is it also sufficient under this proposed revision, thereby not requiring a risk assessment?

N&ST supports the addition of various types of applicable system configuration data to what is presently referred to as a “baseline configuration.” However, N&ST opposes changing the name to “Secure Configuration,” as it would not, by itself, contribute to the goal of making BES Cyber Systems as resistant to attack as possible. What it would do, instead, would be to compel all Responsible Entities to overhaul their existing CIP-010 documentation.

>> N&ST supports moving the existing CIP-007 R2 (patch management) requirements to CIP-010. N&ST also supports the goal of moving away from a calendar-driven, “apply all security patches” approach to vulnerability management. However, N&ST is concerned that some entities may lack the expertise necessary to perform comprehensive vulnerability management on an ongoing basis, and that among those that lack such skills, they could face tough questioning from audit teams. N&ST recommends adding some “… using one or more of the following approaches” language to the requirement language. An example might be, “By assigning security patching or mitigation action schedule priorities based on vulnerability severity ratings assigned by agencies such as the U.S. CERT.” N&ST is also concerned that while attempting to make CIP requirements generally less prescriptive, the SDT may have moved the pendulum too far: N&ST believes that allowing entities to to establish their own timetables for performing vulnerability identification and mitigation tasks incurs the risk of wide variations across the industry. N&ST has similar concerns about proposed changes to configuration monitoring requirements.

The use of software throughout the Standard, like in 1.3, 3.5, and 3.6 is inconsistent with the requirements of R1.3 “operating system, firmware, and software”. Are we to assume that the term software actually means “operating system, firmware, and software”? Maybe a defined term is needed?

The Secure Configuration definition is challenging us. Our preference woudl be that the definition did not referencing a set of standards, rather it were just fully defined. Also, we find this “NOTE: The implemented configuration in support of this Part becomes part of the Secure Configuration of the applicable system” text in CIP-010 R3.6 and I can’t trace back from that what the definition is.

The parts of Requirement R1 could be improved by putting the parts in sequence with actual change control (eg, implement in test, security controls testing, approve for production, etc.). As written the requirement is difficult to follow. The last statement in Part 1.1 should be guidance. It is not written as an objective requirement.

The last statement in Parts 2.1 and 2.2 should be guidance. They are not written as an objective requirement.

Requirement R3 is a good change over the current approach to patching. However, these changes may require significant significant capital investment and process changes. Requirement Part 3.6 should include provisions for changing a mitigation plan, similar to the current requirement in CIP-007 R2. This would allow entities to address changes in their timeline without the risk of a violation.

Although adding security objectives does allow for flexibility in the technical approach taken to comply it also poses additional potential for disparate interpretations of the requirement between entities and auditors. An approach the entity feels addresses the objective adequately may be viewed by the auditor as unsatisfactory. A more prescriptive model lends to more concise interpretation of the requirements.

Westar | Kansas City Power & Light Company incorporate by reference Edison Electric Institute's response to Question 15.

Additionally, Westar | Kansas City Power & Light Company share the following concerns.

Proposed Glossary Term, Secure Configuration, is ripe with compliance ambiguity and confusion. The Glossary Term can be interpreted as without boundaries. Recognizing flexibility in Standards and definitions is desirable, there is a need to provide a parameter, a fence, in which to operate.

Also, propagating into each CIP Standard is not required. Secure Configuration is restating a basic precept of compliance--establish and implement controls. Reiterating a fundamental principle of compliance does not promote compliant behavior nor improve reliability of the BES.

Finally, compliance ambiguity creates inconsistency in the CMEP.

Agree with additions to adding security objectives to CIP-010.

The definition of secure configuration is not adequately stated. This will either need to be fully prescriptive or fully non-prescriptive to be successful. While the fully non-prescriptive route would be preferred, this may result in an unenforceable standard.

Agree with moving CIP-007 R2 to CIP-010.

While conceptually supporting the changes, the details of how to comply with CIP-010 R3.5-3.6 are not adequately defined. Please provide clear guidance how to meet the standard and consider language changes to support the intent.

Comment

In general, as proposed, the Secure Configuration concept seems problematic   The Secure Configuration now contains many new elements not previously tracked through the baseline configuration. Many of these additions are potentially difficult to inventory (for example, logging and alerting configuration may be distributed throughout multiple systems, such as local application configuration, AD Group Policy and SEIM configuration, which is spread across multiple asset classifications).   Particularly with CIP-007 R4 and the changes to EACMS, some of these Secure Configuration items may be changes to non-applicable Systems (as SEIMs will in general be out of scope for CIP-010 R1, but the BES Cyber System’s configuration for logging and alerting, which is required to be part of the Secure Configuration, will reside on this out of scope device).

Several of the requirements (CIP-007 R3.2 and the procedural aspects CIP-007 R5.5 and R5.6) are procedural in nature. It does not make sense to include these in a Secure Configuration, as the actual configuration of the associated system is not changing when a change to these procedures is made.

Additionally, some of the requirements (CIP-007 R5.1 and CIP-007 R5.2 marked to be part of the secure configuration seem at best redundant. These items rarely change, and usually not at the behest of the Responsible Entity, RE, (the methods of authentication rarely change from deployment; changes to the default account inventory are usually due to a vendor disclosure of an undocumented account). As such, it does not really make sense to include these in the Secure Configuration, requiring regular monitoring and inventory.

In CIP-010 R3.6, the requirement allows for other means to mitigate a vulnerability besides the installation of security patches. This would now require CIP-010 change control for changes that might be covered by other CIP requirements (requirement not already part of the secure configuration), or even outside the standards. This greatly increases the burden of CIP-010 R1 on REs.

Another problem with the current proposal is that the way the “Secure Configuration” tag is applied to the requirements can be ambiguous. For example CIP-010 R3.6, which requires the RE to “Create or update a plan to mitigate the identified software vulnerabilities…” includes the Secure Configuration tag. The question becomes is the plan part of the Secure Configuration, or the security patches/mitigations implemented? Once again, procedural methods may fall into the scope of the Secure Configuration.

Finally, the SDT suggests in the Rationale that the expansion the of Secure Configuration beyond the currently implemented items in CIP-010-2 R1 Part 1.1 is needed due to the greater risks posed by virtualization. Yet there is no accounting for risk for purely physical systems, and potentially the compliance burden might even be higher given the lack of a centralized management platform on physical systems. This would place an undue burden upon entities who choose to remain physical rather than adopt the complexities of virtualization

CHPD would like to see the removal of the Secure Configuration tag from CIP-007 Requirement Parts R3.2, R4.1, R4.2, R5.1, R5.2, R5.5, and R5.6. Additionally, CHPD would like the Secure Configuration to be made more granular to only apply to actual configuration on applicable systems for all requirements (such as installed patches for CIP-010 R3.6 or local configuration changes).

CHPD support the changes moving CIP-007 R2 to CIP-010 R3.5 and R3.6 as well as the changes made (with the exception of the Secure Configuration tag).

Lan Nguyen - CenterPoint Energy Houston Electric, LLC - 1 - Texas RE

Answer	No
Document Name	

Comment

CenterPoint Energy does not support a major overhaul of the standards at this time. However, if the SDT continues to make revisions, CenterPoint Energy recommends the following:

CenterPoint Energy supports the flexibility of the timeframes being determined by Entity. However, below are questions that need clarification:

- Where is the line between changes required for incident response and the change control process required in CIP 010-4 Requirement R1?
- Is authorization required prior to the remediation step in an incident response plan?
- The CIP 010-4 Requirement R1.1 requirements may have the inadvertent impact of slowing down incident response. Can IR policies be customized to pre-authorize remediation changes?

The removal of Requirement R1.2 requiring authorization without reference to timeframe may hinder timely incident response. With this new change, entities are tied to pre-authorization of any change and potentially penalized for acting in response to operational or security circumstances.

Changes to CIP-010 Requirement R1.3 do not exclude installation of signatures addressed in CIP-007 Requirement R3. While it is important to validate software, this requirement may impede timely implementation of signature based security controls even more than the current CIP-007 Requirement R3 requirements do. This entity recommends excluding signatures in this requirement to allow entities the flexibility to automate signature updates without retaining records of hash verifications for each transaction.

Response

Kevin Salsbury - Berkshire Hathaway - NV Energy - 5

Answer	No
Document Name	

Comment

NV Energy does recognize that this more flexible approach to security does have its difficulties. The increase in subjectiveness will make it hard to audit as entities develop different implementations. It could open up an issue when the auditors develop an approach that identifies certain methods are more desirable than others and suggest entities adhere to their opinions rather than the language of the standard.

NV Energy is unable to provide a effective evaluation for this question at this time, due to the extent of the “Secure Configuration” spanning multiple Requirements in CIP-005 and CIP-007. Further review will be needed to determine the impact of this new model.

NV Energy would like to comment the SDT for the work done in CIP-010, as we believe a movement to a risk-based approach for security will allow the flexibility to develop the program based on the infrastructure and how the communications are managed. In addition, with the removal of the strict timelines from CIP-007-6 R2, and moving to a risk based approach for review in CIP-010, this would alleviate the multiple violations of this Requirement due to missing the 35 day windows, versus the intent of a program in preventing any incident due to the lack of patching Cyber Assets.

NV Energy does agree with this approach for addressing virtualized systems in CIP-010 R3, P3.5 and P3.6

a. We agree that the proposed security objectives add clarity to the reason the requirement exists.

b. While we agree with the SDTs approach to not include the long list of requirements associated with Secure Configuration in the definition or in CIP-010, we do not agree with the concept of Secure Configuration. The move from Version 3 to CIP Version 5 saw the elimination of almost all of the “spaghetti requirements” with the expectation of CIP-010 R1, which, in essence, was just a documentation exercise. This was a welcome change and eliminated a lot of confusion. The addition of the Secure Configuration concept, and the combined 13+ parts, feels like the industry is going backwards and not forwards. In short, this is a documentation nightmare that has no benefit for the entities or the BPS. Furthermore, tracking and monitoring several of the items within the Secure Configuration seems time intensive or not feasible. We propose that the SDT continue to consider how CIP-010 could become a more objective-based reqruiement, instead of the currently proposed prescriptive-based requirement, and also focus on eliminatating the risk associated with creating “spaghetti requirements” and the administrative burden that comes with an inordinate amount of compliance documentation without a security benefit.

c. While we agree that focusing on software vulnerabilities is an improved approach, we believe that the requirement as written can cause additional confusion. For example, if an entity’s program is based on security patches and there is a software vulnerability that has been publicized and yet has no associated security patch, is the entity required or expected to implement a “plan to mitigate the identified software vulnerability”? We believe as written, the entity could say no to the question above (there is no patch therefore they have not identified a vulnerability) but an auditor could argue that they are out of compliance. Additionally, focusing on just software vulnerabilities could lead some entities to feel pressure to apply “hot fixes” to their environment which could cause severe reliability issues for the BPS.

It doesn’t appear there is a requirement to document the Secure Configuration. Is this the case? Is R1.1.1 requiring Authorization prior to the change being implemented? Should R1.3 be implemented Secure Configuration instead of existing? R2.1 – What is the difference between Configuration monitoring and Configuration auditing? R3.3 – R3.2 allows for “per Cyber Asset capability” but R3.3 does not. Without timeframe expectations in R3, the opportunity for interpretation differences between the auditor and RE may exist.

It makes sense to move CIP-007 R2 to CIP-010. The elimination of the 35-day timeframe requirement for patching and moving toward a risk-based assessment methodology, while makes sense, poses concerns about how this will be audited. The risk in allowing entities to manage vulnerabilities based solely on risk may alter accountability in assessing and applying patches in a timeframe viewed acceptable by auditors.

Leanna Lamatrice - AEP - 3,5	
Answer	No
Document Name	
Comment	
AEP is in agreement with the concept of raising the Requirements to an objective level. However, we have concern for the proposed movement of the vulnerability management requirements from CIP-007 to CIP-010. Our belief is that CIP-010, as it is today, is essentially a quality assurance standard	

established as a means for confirming all the vulnerabilities “have been managed” not for requirements “to manage” vulnerabilities. AEP requests that the SDT consider retaining CIP-010 in this role by returning proposed CIP-010-4 Requirement Parts 3.5 and 3.6 to their former place in CIP-007. And, AEP requests specific examples of the intended implementation of ‘Secure Configuration’ be included in the technical rationale to provide more clarity of how this concept will reduce administrative burden in complying with the CIP standards.

Dana Klem - MRO - 1,2,3,4,5,6 - MRO, Group Name MRO NSRF

Answer	No
Document Name	

Comment

Overall, the NSRF does not agree with the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry’s programs. Originally, there was the Version 5 Transition Advisory Group, made up of 6 Entities to test our current suite of Standards. There are also multiple registered groups who can write and submit to NERC, Implementation Guidance for ERO deference. Any radical change to the CIP Standards should be practiced and tested BEFORE any Standard is recommended for change.   The NSRF also believes that there are Entities who are currently compliant (via an audit) by incorporating virtualization practices under our current set of Standards. All Standards are written to “what to do” not how to incorporate a certain or new technology. The NSRF has attempted to answer the SDT questions but still does not agree with this Project. Here are some specific examples of what a small change to a Standard will do to the industry.

a. No.

b. Yes. However, this change will increase the number of Cyber Asset attributes that need to be tracked for what was previously baseline attributes and will increase the compliance risk for change control. For instance, if a new generic account is added to a Cyber Asset (common operator account), current requirements are to identify and inventory the account. The proposed requirement makes this part of the Secure Configuration which will require the addition of the account to follow CIP-010-4 Part 1.1 change control processes. Currently, following your CIP-010-2 change control process is a best practice; it is not a violation if you do not follow it when adding a new generic account. This is just one example. Creating the new Secure Configuration definition and tying the definition to CIP-010-4 will significantly increase compliance work and introduces concern with auditor discretion.

c. No. We don’t think it matters which standard, CIP-007 or CIP-010, the requirements reside. Moving the requirements will cause unnecessary documentation changes.

d. No. We think the new requirements add the ability for auditor discretion to requirements that were previously very clear. For instance, if an entity chooses to only monitor patch sources (Part 3.5), it would reason that if no security patches are released there would be no requirement to have a mitigation plan. However, if an entity chooses to monitor patch sources as well as monitor a vulnerability database (Part 3.5), a mitigation plan would be required if a vulnerability is discovered in the database even though there is no patch released for the vulnerability. An auditor may view this as a weak program and issue a PNC.

We disagree with these changes. We still support the current result-based requirements with appropriately prescriptive language. Even though the proposed objective-based non-prescriptive requirements provide some flexibility for the CIP compliance, they are too broad and subjective. By virtue of lack of detailed measures and guidance, how do the registered entities know their processes have been implemented effectively? How will Auditors/Teams be accredited to evaluate effectiveness? What will be the effectiveness metric? Given that currently the majority of CIP Cyber Assets are physical and the CIP compliance process today works fairly smoothly by implementing the existing requirements that are appropriately prescribed, it doesn't make sense to modify any existing requirements that are only for sufficing a small percentage of the virtual devices but a waste of the registered entities' time and resources for making these changes. Resulting from our comments in the above question 1, as long as the virtual devices are identified correctly and the device-centric approach would work well for the virtual devices, where all existing requirements of CIP-007 and CIP-010 will apply to them smoothly.

The new CIP-010 provides a logical configuration control framework that can be extended to cover future Requirements without requiring a revision of CIP-010. The proposed changes do significantly increase the scope of configuration change control. However, this increase in scope may not be entirely onerous; management controls corresponding to the Secure Configuration already need to be implemented in some form to ensure compliance with the corresponding Requirements. While the new language does provide flexibility, some of that flexibility comes with compliance uncertainty. Where process requirements and timeline are based on risk analysis, significant additional definition is needed around what is acceptable for a risk analysis and how it shall be determined; this language leaves the door wide open for entities to give themselves the broadest interpretation of the gray area internally, resulting in unresolvable disagreements upon audit. To provide reasonable assurance, a separate Requirement or even a separate Standard may be required for defining risk analysis, similar to how CIP-002 defines Impact Rating. A clear distinction may need to be drawn between Impact Rating and risk analysis. As an alternative, a collaborative process may need to be formally defined and required outside of the audit process, in which the risk analysis methodology is reviewed and approved by the RRO, and the analysis itself may require a form of interaction with the RRO.

Security objective-based requirements may be the right direction, but at the wrong time. Other non-NERC standards that are security objective-based are not subject to zero-defect compliance monitoring. In this case, security objective-based requirements may provide too much flexibility that could result in too much difference in interpretation between different Responsible Entities and auditors. The changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs too soon after the last one. Some entities have not had the chance for an audit on the last round of changes. Other revisions, such as CIP-003-7 sections 2, 3 and 5 have yet to become effective. MEC has compliantly implemented virtual servers within the existing CIP standards structure. We have been audited on CIP-005 and CIP-007 as well as CIP-004 and CIP-006. We have self-certified CIP-002, -003, -008 and -011. And are preparing evidence for an audit on CIP-009 and CIP-010 in 2019 and have not identified issues. It is not clear how this magnitude of changes will create a corresponding improvement to reliability and security. Perhaps the “how to comply” with the existing standards when virtualization is involved could best be addressed using other tools such as ERO-endorsed implementation guidance or readiness reviews for the segment of Responsible Entities who are operating or plan to operate with virtualization.

a. Agree b. Agree c. Agree d. Disagree. The question d) seems to indicate that the intention of the SDT is that patches must be applied to dormant systems. This might not be desired if dormant instances are serving as backups to a production instance (for CIP-009 purposes). Flexibility is needed to allow for dormant intances/ systems to remain as is and only apply patches if the dormant instance is reused as a production instance (CIP-010 R1.2).

SRP does not agree or disagree that the proposed security objectives add clarity to the reason the requirement exists. SRP agrees with transferring the requirements from CIP-007 to CIP-010 as mitigating software vulnerabilities more closely relates to vulnerability management rather than system management.

However, SRP asserts the Secure Configuration definition needs more clarification. To understand the components of Secure Configuration, Responsible Entities would need to sift through the requirements. It should be clearly stated in the definition what the Secure Configuration is composed of.

Pamela Hunter - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - SERC, Group Name Southern Company	
Answer	No

Document Name

Comment

Southern Company generally agrees with the direction, but has several concerns. One area in which we would like clarification is regarding the “analysis of risk to the BES” or the system.   Does this analysis need to be performed and documented on a per patch basis? On a vulnerability basis? Can entities create processes for system analysis with standard categories that have appropriate timeframes associated with them?

Southern is also concerned with the "Secure Configuration" which could end up being a vast number of methods on various systems and is no longer bound to five discrete software change categories. Proving proof of change management on every change to any kind of "method" throughout CIP-005 and CIP-007 will be challenging if not impossible.

For Part R3.6 Southern would like clarification stating that existing mitigations may be sufficient for the risk of a particular vulnerability and the entity may not have any further analysis or mitigation required because of these existing mitigations.   In other words, past applied compensating controls may also cover many future vulnerabilities. It needs to be clarified that this situation is either A) not an applicable vulnerability in part 3.5, or B) it is, but nothing FURTHER needs to be done in 3.6. Southern prefers option A.

Generally, it is not clear why the proposal is to move away from the concept of an undefined baseline configuration to the “Secure Configuration.” The new requirements in Parts 3.5 and 3.6 of CIP-010-4 are less prescriptive than what is being replaced from CIP-007, and appears to allow a more subjective approach for determining the timeline and periodicity for identifying vulnerabilities. The SSRG recommends the Standard Drafting Team review the draft to ensure its objectives are being met.

Specific to “b” - this change will increase the number of Cyber Asset attributes that need to be tracked from what was previously considered baseline, and will heighten the compliance risk for change control. For instance, when a new generic account is added to a Cyber Asset (common operator account) the current requirements provide for identification and inventory. The proposed requirement makes a new generic account part of the Secure Configuration and will require the CIP-010-4 Part 1.1 change control processes. Currently, following the CIP-010-2 change control process for a new generic account is a best practice but not a violation. This is just one example where the proposal is not backwards compatible. Creating the new Secure Configuration definition and tying the definition to CIP-010-4 will significantly increase compliance work and introduces auditor discretion.

Specific to “c” the SSRG doesn’t think it matters whether CIP-007 or CIP-010 houses the requriements. However, the real issue is the uneccesary documentation changes that will be required to move the language; therefore, the drafting team may consider whether moving the requirements to CIP-010 is the most efficient means to address the issues.

The introduction of the new term Secure Configuration and its role is unclear. The proposed security objective throughout the Requirements in CIP-010 does not offer any clarity. For example removing the 35 day requirement for patching leaves it open to an auditor's interpretation of what they think is appropriate. Also, in CIP-10 R3, 3.5 the following sentence needs clarification and guidance: "The process of Part 3.5 shall include the periodicity for identifying software vulnerabilities based on the risk to BES reliability and the impact rating of the applicable system(s)."

Response

Kjersti Drott - Tri-State G and T Association, Inc. - 1,3,5 - MRO,WECC

Answer	No
Document Name	

Comment

Regarding subquestion B, Tri-State requests clarification on the control change process outlined in CIP-010 R1.1, specifically the language in R1.1.2 "could be impacted by the change." Is the intention of this requirement for each entity to make a determination of what could be impacted, or is the intention that each of the Secure Configuration components throughout these changes in CIP-005, CIP-007, and CIP-010 are the universe that must be considered?

Additionally, in CIP-010 R1.2.1 would like clarification of what specifically is included as "required" in the language "to ensure that required cyber security controls in CIP-005 and CIP-007 are not adversely affected"

Regarding subquestion B and the components of Secure Configuration, Tri-State requests that CIP-007 R3.1. and R3.2 are updated with language to require these sub-parts only if the system is capable.

CIP-007 R3.1 recommended updated language reads: "Deploy method(s) per system capability to deter, detect, or prevent malicious code"

R3.2 recommended updated language reads: "Mitigate the threat of detected malicious code, per system capability."

Regarding subquestion C, Tri-State recomends adding "or" after each bullet (similar to recommendations in Question 14). This language will clarify the ability to choose from the list.

CIP-010 R3.5 recommended updated language reads:

• Vulnerability database monitoring; or

• Patch source monitoring; or

• Vulnerability scanning; or

• Other method(s) to identify software vulnerabilities.

The parts of Requirement R1 could be improved by putting the parts in sequence with actual change control (eg, implement in test, security controls testing, approve for production, etc.). As written the requirement is difficult to follow. The last statement in Part 1.1 should be guidance. It is not written as an objective requirement.

The last statement in Parts 2.1 and 2.2 should be guidance. They are not written as an objective requirement.

Requirement R3 is a good change over the current approach to patching. However, these changes may require significant significant capital investment and process changes. Requirement Part 3.6 should include provisions for changing a mitigation plan, similar to the current requirement in CIP-007 Requireemnt R2. This would allow entities to address changes in their timeline without the risk of a violation.

Kara White - NRG - NRG Energy, Inc. - 3,4,5,6 - FRCC,MRO,WECC,Texas RE,NPCC,SERC,RF

Answer	No
Document Name	

Comment

No, NRG does not agree that adding the security objectives throughout the Requirements in CIP-010 adds clarity to the reason the requirement exists because: The changes to CIP-010 change the understood intent of the standard from Change Control to a hybrid objective. A recommendation would be to change the standard to “Vulnerability Management” and realign the requirements with the new objective.

No NRG does not agree with the proposal to modify the referenced baseline configuration from CIP-010-3 R1 Part 1.1 to a ‘Secure Configuration’ which is made up of the implemented controls that fulfill requirements within CIP-005 and CIP-007 and that this set of controls supports managing change under CIP-010 R1 Part 1.1 NRG asserts that the requirement changes while reducing overall compliance burden, introduce a new “spaghetti” requirement. NRG recommends that a specific list of Secure Configuration, even as an addendum, would be helpful.

No, NRG does not agree with the proposal to modify the current CIP-007 R2 requirements and move them to CIP-010 R3 and does not believe that the software vulnerability management found within this set of requirements fits logically within the security objective of CIP-010 R3 “to mitigate the risk posed by system vulnerabilities" because the intent of CIP-007 patch management requirements were readily understood by the industry, while developing a risk based system is left to the interpretation of each Registered Entity. The result is going to be a large disparity in patching cycles between entities and even within the same entity. This will make auditing & benchmarking more difficult and could lead to industry difficulty with implementation of standards change.

No, NRG does not agree that the proposal of CIP-010 R3 Parts 3.5 and 3.6 to replace the current CIP-007 R2 Parts 2.1 – 2.4 offers the additional flexibility needed when implementing virtualized systems that can be dormant for a period, and for which security patches have become available because in relation to virtualized systems, NRG asserts that the proposed requirements do offer flexibility. However, there is no prescriptive criteria to manage the duration of dormant periods.

Comment

While we agree with adding the security objective to the requirements it appears that a security objective was not added to R4.

We believe that the relocation of CIP-007 R2 to CIP-010 R3 makes much more sense and allows for Entities to finally address vulnerabilities as part of compliance and not just potentially wasted effort on patches which are only a component of vulnerability management. In addition, Entities now can get compliance credit for addressing vulnerabilities when announced rather than waiting for patches which may lag the vulnerability announcement by months. However, the concept of revising a vulnerability mitigation plan in CIP-007 R2.4 does not appear to have been ported to the CIP-010 R3 modifications.

While we appreciate the SDT trying to revise CIP-010 R1 for the better, it is currently a chicken and the egg requirement. The requirement states, "Control change to the Secure Configuration" and "Prior to the change determine required cyber security controls in the Secure Configuration that could be impacted by the change." So, if we are to control change to the Secure Configuration then we need to know what will change and yet we are to take an educated guess as to what in the Secure Configuration COULD be changed. Also, the question is prior to what change? The previous requirement was changes to the Configuration Baseline. We would recommend that the impetus for change management should still be defined as a change to Operating System, or firmware where not OS exists, change to software versions, and the application of all patches not just security patches. Changes to logical network accessible ports should be dropped from the list of items that prompt a change given the modified CIP-007 R1.1 controls. If necessary, these change triggers could be defined as Configuration Change. However we believe the concept of Configuration Baseline can be dropped in favor of a Secure Configuration. Tracking the Configuration Baseline is no longer required when the modifications to CIP-007 R2 address the security objective of unmanaged software. Also, it is unclear when CIP-010 R1.3 would be triggered if the impetus is a change the Secure Configuration and not a Configuration Change. If an entity implemented application whitelisting for CIP-007 R2.1 then would CIP-010 R1.3 ever be triggered? The impetus is a change that deviates from the Secure Configuration. If application whitelisting remains implemented when the OS, firmware, software (or patch) is installed or updated then did the Secure Configuration ever change? If not, then an entity doesn't have to perform either of the verification tasks. Therefore, the impetus for any CIP-010 R1 change should be a Configuration Change like before, but without tracking the Configuration Baseline.

We have concerns regarding the monitoring of the implemented Secure Configuration in CIP-010 R2. First, we have implemented Device Specific Test Plans for many types of Cyber Assets for the current CIP-010 R1. While many aspects of the Secure Configuration can be monitored through configuration monitoring, many still require the inspection through configuration auditing which is more time consuming for personnel. In addition, unauthorized change to the Secure Configuration could be considered a system vulnerability and should potentially be managed under that security

objective. If it is managed under R3 then it should be only performed if monitoring of a Secure Configuration property has not occurred in X amount of time. This is because many of the Secure Configuration properties would be inspected throughout the year as part of the change management process.

16. Provide any additional comments for the SDT to consider, if desired.

Jamie Monette - Allete - Minnesota Power, Inc. - 1

Answer	
Document Name	

Comment

Clarification for the CIP-010-4 R1.2 term "models" would be valuable. This is an ambiguous term that in current standards provides confusion for what will satisfy expectations. We see this as possible via formalizing the term with definition, stating more clear aspects, or including specific guidance in the supporting documentation of the standard.

Comment

First, MISO would like to thank the SDT for their efforts in drafting these revisions. Revising existing CIP Standards is a difficult task and MISO appreciates the quality of the proposed changes and the effort put forth by the Team. MISO is encouraged by the work to modernize the standards and recognize that many modern software and hardware configurations are capable of safely and securely separating BES and non-BES workloads on the same physical hardware. The move to LIZ that is not focused on a subnet centric design is welcome. The changes to a risk based approach to patching instead of a hard time limit is also encouraging, however guidance will need to be provided on what will be required when audited to ensure that the risk criteria and decisions made around patching are appropriate and compliant.

The proposals do raise some questions with MISO around data protections for data in transit, as well as the definition of "secure configuration" and what may need to be demonstrated for that requirement.

The proposed changes do not yet tackle in any way the use of "cloud" or off-prem providers who would have continual management connectivity into the environment for CIP computational or storage workloads. They also do not yet address handling certain types of CIP data using Cloud storage providers.

Overall, we support changing from prescriptive-based requirements to objective-based requirements and most of the concepts presented to help clarify virtualization in the CIP environment. However, aside from the concerns mentioned throughout, we do have some concerns on how the updated requirements will be audited. Specifically, how will the auditors apply the requirements to entities that have no virtualization or entities that have their virtual environments segmented (i.e. one virtual environment for high impact BES Cyber Systems, one virtual environment for associated high impact EACs, one virtual environment for associated high impact PACS, etc.)?

We are also in support of EEI comments.

Kevin Salsbury - Berkshire Hathaway - NV Energy - 5

Answer	
Document Name	

Comment

In the development of NV Energy comments, we have struggled with trying to find some middle ground that acknowledges the hard work and laudable efforts made by the SDT, unfortunately, the structure of the comment format did not lend itself to such comments.

Nevertheless, NV Energy cannot support the level of change being proposed at this time, due to the recognition that virtualization remains a small piece implemented within the industry, and will continue as such for the foreseeable future. This has led us to the conclusion that SDT efforts need to focus more on the how virtualization might be effectively integrated into BES Cyber Systems, under the current standards, rather than trying to solve all these issues at an early stage of industry adoption.

NV Energy does not support the overly broad and sweeping change proposed by the SDT because it is premature. While there are aspects of what the SDT is considering that may have future benefit and utility, employing those changes at this time would prove to be too disruptive to existing efforts by the industry. Furthermore, there is limited acceptance of virtualized networks within the industry and efforts to try and tailor the current body of standards to accommodate this emerging security solution is likely to create needless security concerns. Instead the SDT should work toward addressing the more immediate needs of the industry such as clarifying how the security and management of BES Cyber Systems can be accomplished in a virtualized environment using the existing body of standards, as currently approved. We further believe that the level of change being considered by the SDT would be better addressed through a separate initiative spanning several years to allow more engagement by the industry.

NV Energy also notes that while the SDT has offered up some very interesting ideas to address virtualization within BES Cyber Systems, many Responsible Entities still feel there is a lack of overall clarity necessary to address the design, control, and protection of these systems in a virtualized environment.

NV Energy’s last concern centers on the auditability of the proposed approach. While the security objective-based approach does provide a friendlier environment for virtualization, we are concerned that from an audit perspective this approach may prove to be very difficult for Responsible Entities and auditors to demonstrate compliance leading to interpretations and judgements that could impact the security of BES Cyber Systems, while placing into question whether the proposed solution can be effective and consistently audited.

Lan Nguyen - CenterPoint Energy Houston Electric, LLC - 1 - Texas RE

Answer

Document Name

Comment

CenterPoint Energy supports EEI's comments and approach for the next steps to address virtualization. It is important to highlight that these revisions were not mandated by a FERC order. Furthermore, entities with virtual environments are already complying with the existing CIP standards. In order to address virtualization and other emerging technologies, CenterPoint recommends that the SDT focus its efforts in transferring these concepts to Implementation Guidance or through a separate inititive to allow more engagement by the industry

While the proposed revisions offer some flexibility for implementation, CenterPoint Energy is not in favor of the level of changes being proposed by the STD team at this time. The large fundamental changes proposed in this draft may introduce potential unintended consequences and challenges with auditability at a time when the industry is affirming compliance with the current version of the CIP standards.

If the SDT continues to proceed with these revisions, CenterPoint Energy recommends addressing the items commented above and conducting implementation pilots to surface implementation challenges, similar to what was done with the CIPv5 pilots.

Ginette Lacasse - Seattle City Light - 1,3,4,5,6 - WECC, Group Name Seattle City Light Ballot Body

Answer	
Document Name	

Comment

Seattle City Light recognizes the complex and difficult job the SDT had in drafting the proposed virtualization standards, and applauds the persistence and creativity shown in crafting the present proposal. We appreciate these efforts. Project 2016-02 provides best practices for security standards that strive to stay ahead of adversaries' efforts. The Project is groundbreaking and is the first step toward the next level of the best practices in security standards. We see this effort to date as significant progress.

Importantly, refining and implementing the virtualization standards will be a challenge for NERC and industry. Seattle suggests the following as general principles that might guide futher development of the the proposed virtualization changes:

We strongly support for direction of proposed changes, as very promising and necessary to accommodate technological change and increasing theats

That said, the changes proposed are more far-reaching than expected, likely have many unintended consequences, are in some areas complex and largely untried, and in other cases expand the CIP scope to address new vulnerabilities introduced by virtualization

Therefore, Seattle recommends consideration of a parallel "virtualization overlay" approach, in which the Standards are revised such that the existing definitions and existing requirements are retained, but the proposed new definitions and new requirements are also an option. An entity must identify which approach they choose, on a cyber-system by cyber-system basis. This approach ensures backwards compatibility, minimizes the impact on entities that do not employ virtual technology, and yet frees other entities to pursue the possibilities of virtualization.

The overlay approach might by designed to sunset after a time, or be reassessed at a certain point based on lessons learned. It might be considered as a sort of CIP version of the PRC-005-2 to PRC-005-6 trransition.

Expansion of CIP scope to address new vulnerabilities associated with virtualization should be restricted only to virtualized BCS. These changes should not increase scope for non-virtualized BCS.

Seattle strongly urges that NERC sponsor a pilot project with volunteer utilities, as happened with CIP v5 changes be utilized with virtualization.

Chris Scanlon - Exelon - 1,3,5,6

Answer	
Document Name	

Comment

Exelon appreciates the work and time that the SDT as put into this effort. We do see value in moving toward security objective-based requirements and being less technology dependent. We agree with many of the ideas, including splitting out lower risk monitoring from access control. However, we believe that the sweeping changings as now proposed are overly broad, including foundational definition changes, and these will radically impact current CIP programs.

As far as virtualization, Exelon has successfully implemented virtualization using a “conservative” architecture approach, while maintaining compliance with the current CIP requirements. We do see the potential of architecting virtualization and other technologies in new ways in the future to increase reliability and security while decreasing cost. CIP Standard changes to address new technologies and architectures are needed but are more appropriately addressed in a separate longer-term and comprehensive CIP version change effort. That effort should also take into consideration many other factors beyond virtualization that have surfaced since CIP V5 to improve the CIP Standards overall. Such an effort we could support.

We would prefer to see the current SDT address the more immediate needs of the industry such as clarifying how the security and management of BES Cyber Systems can be accomplished in a virtualized environment using the existing body of standards, as currently approved.

Todd Bennett - Associated Electric Cooperative, Inc. - 1,3,5,6, Group Name AECI

Answer	
Document Name	

Comment

In general AECI agrees with the revisions to address virtualization for the follow reasons:

*Not materially changing non-virtualization compliance

* Providing the explicit ability to demonstrate compliance while using virtualization

* Allows CIP compliance program concepts to mature as the BCA term is retired

Additionally AECI raises an additional concern that the standards may not adequately address the “shared responsibility” aspect of using cloud computing resources, such as Azure or AWS. This was a topic of discussion at a recent NERC CIPC meeting, FedRAMP requirements were explained as possibly being a good model for addressing the shared responsibility issues. Comment

In NPPD’s opinion the proposed changes are too wide sweeping and transformational in nature without adequately addressing the more immediate need to clarify how the security and management of CIP systems in virtualized environments (or any new emerging technology) can be accomplished. Changes of this magnitude should be accomplished under a separate initiative with an adequate timeframe that allows proper engagement with industry to develop an approach to CIP compliance that can better adjust to changes in technology and risk environments.

NPPD does encourage the drafting team to develop industry guidance for virtualization. However, as stated, the industry should have a focused (not rushed) effort to evaluate what is needed within the CIP Standards as changing or new technology emerge.

Continual overhaul of the NERC Standards means increased risk to the Bulk Power System, as resources are siphoned off to align entity programs to continual change to the Standards. NPPD encourages the drafting team to issue guidance to the industry on virtualization and, if necessary, develop a single separate NERC Standard for Virtualization. However, a larger overall solution must be attained for new/emerging technologies and risk without the continual overhaul of the CIP suite of Standards

MEC appreciates all the thoughtful hard work the SDT has put into this effort. That said, the changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs too soon after the last one. Some entities have not had the chance for an audit on the last round of changes. Other revisions, such as CIP-003-7 sections 2, 3 and 5 have yet to become effective. MEC has compliantly implemented virtual servers within the existing CIP standards structure. We have been audited on CIP-005 and CIP-007 as well as CIP-004 and CIP-006. We have self-certified CIP-002, -003, -008 and -011. And are preparing evidence for an audit on CIP-009 and CIP-010 in 2019 and have not identified issues.	

It is not clear how this magnitude of changes will create a corresponding improvement to reliability and security. Perhaps the “how to comply” with the existing standards when virtualization is involved could best be addressed using other tools such as ERO-endorsed implementation guidance or readiness reviews for the segment of Responsible Entities who are operating or plan to operate with virtualization.

Richard Jackson - U.S. Bureau of Reclamation - 1,5

Answer	
Document Name	

Comment

Each change to a standard creates additional work for an entity to evaluate its processes, revise where appropriate, implement the changes, and retrain employees, which is not cost-effective. The proposed changes to the CIP standards will have significant impacts on entities and will require substantial resources to implement. The proposed changes go beyond simply updating technology and/or documentation; they constitute a culture shift comparable to the CIP v5 transition. Entities must implement processes to achieve an understanding of new terms, buy in to their use, and change their the culture to employ new terms. Entities must be provided sufficient time to determine the effects of the revised requirements and definitions, develop adequate processes, and train personnel appropriately in order to implement quality practices that improve BES reliability. Reclamation recommends a minimum of 24 months for all entities to implement the proposed changes, with an additional 18 months for entities that use virtualization to achieve compliance.

Where possible, Reclamation recommends the SDT use the following existing industry terms:

Intrusion Detection and Prevention System (IDPS) – Software that automates the process of monitoring the events occurring in a computer system or network and analyzing them for signs of possible incidents and attempting to stop detected possible incidents.

Intrusion Prevention System(s) (IPS) – System(s) that can detect an intrusive activity and can also attempt to stop the activity, ideally before it reaches its targets.

Intrusion Detection Systems (IDS) – System(s) that detect attacks by capturing and analyzing network packets. Listening on a network segment or switch, one network-based IDS can monitor the network traffic affecting multiple hosts that are connected to the network segment.

Enclave – A set of system resources that operate in the same security domain and that share the protection of a single, common, continuous security perimeter.

Enclave Boundary – Point at which an enclave’s internal network service layer connects to an external network’s service layer, i.e., to another enclave or to a wide area network (WAN).

Reclamation recommends adding the following new terms to the NERC Glossary of Terms:

Physical Access Control and Monitoring System (PACMS) – Cyber Assets that control, alert, or log access to the Physical Security Perimeter(s), exclusive of locally mounted hardware or devices at the Physical Security Perimeter such as motion sensors, electronic lock control mechanisms, and badge readers.

Electronic Security Enclave (ESE) – One or more Cyber Assets logically connected by one or more internal communication control(s) of a single authorizing security policy for BES Cyber Systems and Protected Cyber Systems. The logically connected Cyber Assets may be structured by physical proximity or by function, independent of location.

Mike Smith - Manitoba Hydro - 1,3,5,6, Group Name Manitoba Hydro

Answer	
Document Name	

Comment

Given that as long as the virtual CIP Cyber Assets are identified appropriately, most of existing CIP V5 requirements worked with these virtual CIP Cyber Assets very well based on previously NERC and MRO's advices regarding virtualization. We disagree with these significant directional changes that are only for sufficing a very small percentage of the virtual devices while ignoring the fact that the majority of physical devices are working smoothly for the existing requirements. The major issue for the existing CIP V5 requirements is that the virtual Cyber Assets are not explicitly required in the current standard language. After revising the Cyber Asset definition to include the virtual devices, most of the compliance issues will be resolved. SDT's strategy for the virtualization should focus on developing few additional requirements that only apply to the virtual CIP Cyber Assets if the existing requirements cannot be addressed in the virtual environment. Resulting from we suggested strategy, it would be beneficial for all registered entities as follows:

•   For the registered entities that have no any virtual CIP Cyber Assets, they may not need to do anything.

•   For the registered entities that have some virtual CIP Cyber Assets, they would only need to address the additional requirements for their virtual CIP Cyber Assets unless they could resolve them using the existing requirements.

Overall, the NSRF does not agree with the direction of this Project. There are other ways of applying and testing of new directions without doing a complete overhaul of the existing standards and associated overhaul of industry's programs. Originally, there was the Version 5 Transition Advisory

Group, made up of 6 Entities to test our current suite of Standards. There are also multiple registered groups who can write and submit to NERC, Implementation Guidance for ERO deference. Any radical change to the CIP Standards should be practiced and tested BEFORE any Standard is recommended for change. The NSRF also believes that there are Entities who are currently compliant (via an audit) by incorporating virtualization practices under our current set of Standards. All Standards are written to “what to do” not how to incorporate a certain or new technology. The NSRF has attempted to answer the SDT questions but still does not agree with this Project. Here are some specific examples of what a small change to a Standard will do to the industry.

The MRO NSRF remains concerned with the subjectivity this will bring to meeting compliance. Auditors come from varying backgrounds and while one auditor may not have an issue with an entity’s risk based assessment, the next auditor may. This may even be true with an entity. The industry experienced this with the CIP-002 RBAM and then was later asked to change to a more prescriptive set of requirements.

We do not agree with the SDT direction at this time. The NSRF feels that the proposed changes are too wide sweeping and transformational in nature without adequately addressing the more immediate need to clarify how the security and management of CIP systems in virtualized environments can be accomplished. Changes of this magnitude should be accomplished under a separate initiative with an adequate multi-year timeframe that allows proper engagement with industry to develop a new approach to CIP compliance that can better adjust to changes in technology and risk environments.

In the meantime, we recommend that the SDT narrow their focus back to the issue at hand which should be clarified standards and guidance for systems that exist within a virtualized environment. One possible recommendation would be to look at the development of a new CIP Standard that solely addresses the base level controls, security and configuration requirements for virtualized CIP systems and modify other existing CIP Standards and Requirements to exempt virtualized systems when applicable. Taking this approach would provide the clarity that is needed today for entities currently utilizing or planning to utilize virtualization with their CIP systems without requiring yet another complete NERC CIP program overhaul

Leanna Lamatrice - AEP - 3,5

Answer	
Document Name	

Comment

AEP is concerned with the addition of veiled requirements to conduct "risk" analyses in proposed CIP-010-4 R3 Parts 3.5 and 3.6. Our understanding is that the "impact to the BES" is in fact the risk based on the equation used when the bright lines were established: Risk equals Threat times Vulverability times Impact, where Impact is the only variable and Threat and Vulnerability are defined as being equal to one. Also, sufficiency criteria for the risk analysis have not been established so this will likely become another source of contention when compliance is assessed. The work involved with assessing and documenting the "risk" for every component of every high and medium impact BCS across the BES will be enormous. AEP believes there should be an alternative to the "risk" analysis, stated in the Requirement, such as checking for patches and implementing/mitigating on the current 35 day cycles.

Sandra Shaffer - Berkshire Hathaway - PacifiCorp - 6

Answer	
Document Name	

Comment

PacifiCorp's approach to this informal comment period was to provide the SDT with constructive feedback related to the proposed revisions to the terms, standards and concepts presented. With that said, PacifiCorp has additional comments and concerns that will be addressed here.

PacifiCorp does not support the overly broad and sweeping change proposed by the SDT, feeling that the effort is premature. While there are aspects of what the SDT is considering that may have future benefit and utility, employing those changes at this time would prove to be too disruptive to existing efforts by the industry.

PacifiCorp's primary concern centers on the auditability of the proposed approach. While the security objective-based approach does provide a friendlier environment for virtualization, we are concerned that from an audit perspective this approach may prove to be very difficult for Responsible Entities and auditors to demonstrate compliance leading to interpretations and judgements that could impact the security of BES Cyber Systems, while placing into question whether the proposed solution can be effective and consistently audited.

The changes being proposed within the body of revised, retired and new definitions and the impact on the applicable systems represents another overhaul of the CIP standards and associated Responsible Entity compliance programs too soon after the last one. Other revisions, such as CIP-003-7 sections 2, 3 and 5 have yet to become effective.

It is not clear how the magnitude of changes will create a corresponding improvement to reliability and security. Perhaps the "how to comply" with the existing standards when virtualization is involved could best be addressed using other tools such as ERO-endorsed implementation guidance or readiness reviews for the segment of Responsible Entities who are operating or plan to operate with virtualization.

Rachel Coyne - Texas Reliability Entity, Inc. - 10

Answer	
Document Name	

Comment
It appears most of these changes are not specific to virtualization as the project indicates. Rather, the changes indicate a shift in the CIP Reliability Standards. As the industry recently implemented version 5 of the CIP standards, this puts an additional burden to comply with the proposed changes. Texas RE is not convinced a shift in the CIP standards is necessary. If the SDT feels it is necessary, the entire body of CIP Reliability Standards should be evaluated. Texas RE requests the SDT provide justification for the proposed changes by the V5 TAG, since that is what is referenced in the June 1, 2016 Standards Authorization Request.

PGE supports the direction that the drafting team is taking. The CIP standards framework should not serve to limit the use of new technologies that meet the security objectives and this poposed set of standards makes great strides in accomplishing that outcome. PGE encourages the continued engagement of FERC and the ERO enterprise to develop and document consistent approaches to implementing and auditing these new standards.

A concept not address in the concepts in a virtual TCA. So, in a virtualized environment if an entity spins up a new virtual machine, but the wrong base image was used, and it is deactivated within 30 days of creation is it now a TCA?

The creation of virtual machines should be addressed. Is cloning from a base virtual machine in the environment acceptable since it already has all the security controls applied? What about when a new base image needs to be created? Must it be created in a test bed first then moved to production. However, typically the security controls of policies and targets for systems managing backups, anti-malware, logging and other may be different. So, can a new virtual machine have only some security controls in place if they are applied in a reasonable time frame when connected to production? This is also a problem for new physical equipment as well.

As pointed out in another comment, some of the V5TAG items in the Standards Authorization Request are not addressed by these proposed revisions.

We appreciate the SDT's effort on this issue. While our comments may appear negative, they are only pointing out the problems and concerns we have identified. The revisions to CIP-010 R1, R3, and CIP-007 R2 are a step in the right direction when it comes to the current pains of CIP compliance. If the SDT focused on those changes and the V5TAG issues remaining, then we might be able to get to a better set of requirements. However, some of the overly broad and sweeping changes to both defined terms and requirements may be more than the industry can digest at this time. The SDT needs to focus on how virtualization fits into the current requirements. Furthermore, we like the idea of meeting security objectives with a selection of one or more protection elements to achieve the objective. This is much better than overly prescriptive controls that do not always fit. We prefer examining this path and not the other fork in the road with overly prescriptive requirements trying to tie an industry to best practices as they exist today. If the SDT wanted to future proof the requirements then the requirements should be reworked with the stated security objective and let the Entity develop a program or plan to address that security objective and include the identification of the controls, and potentially a means to measure control effectiveness. An Entity would have to maintain an effectiveness greater than X to stay compliant. Or a third-party review like CIP-014 could be implemented. The threat remains relatively unchanged over the years; someone with malicious intent causing adverse impact to one or more BES Facilities. However, the attack vectors and protections against those attack vectors continue to change. Unless Entities can be allowed to develop their

own programs to identify the attach vectors and protections, then the requirements will always lag the existing threat landscape when new vectors are identified.

In review, NRG asserts that the modifications presented by the SDT represent a drastic shift in philosophy of the standards that are significantly more substantial than an introduction of virtualuzation defintion, akin to the shift from v3 to v5. NRG applauds the SDT in the attempt at shifting the focus to enourage security. However, an ambiguous approach could lead to a wide disparity in implementation between Registered Entities. This could `make the auditing of CIP much more subjective and also industry inderstanding much more subjective also. The shift raises concerns of reintroducing difficulties from previous versions of the standards, i.e. risk-based methodology for CIP-002 and "spaghetti" requirements.

Be consistent with the use of “such as,”, “e.g.,” and other illustrative phrases. While the changes proposed are a definite improvement to the standards, there will be a significant cost to implement these changes. These include revisions to change management systems, inventory systems, and other supporting tools used for audit evidence. As the drafting team looks at the implementation plan for these changes, consider how to allow entities to absorb these costs over time.

Comment

In the development of EEI comments, members struggled with trying to find some middle ground that acknowledges the hard work and laudable efforts made by the SDT as most members identified with the progressive, forward thinking of several proposed concepts. However, EEI members agree that many of the ideas being developed by the SDT have merit.

As noted in question 1, these comments do not represent a consensus, but we offer them for the SDT to consider. At this time, the EEI members who participated in the development of these comments do not support the level of change being proffered due to the recognition that virtualization remains limited in its adoption within the industry and is expected to continue as such for the foreseeable future. This is not to diminish the fact that in many sectors outside of the electric utility industry virtualization is making great advancements that enable many security improvements. EEI recognizes that the existing CIP reliability standards may be overly prescriptive and at times drive unnecessary costs, while limiting security benefits available through the application of modern technology. Nevertheless, fixing these problems needs to be taken a step at a time to avoid disruption to existing systems and processes used by companies. EEI encourages the SDT to focus more on how virtualization might be effectively integrated into BES Cyber Systems, under the current standards, rather than trying to solve all these issues at an early stage of industry adoption.

Given the pace of change of the CIP reliability standards to which the industry has been responsive and will continue to be responsive as it contemplates upcoming compliance effective dates, the members who participated in the development of these comments do not, at this time, support the overly broad and sweeping changes proposed by the SDT. For these members, the modifications are premature and, while there are aspects of what the SDT is considering that may have future benefit and utility, employing those changes at this time could prove to be too disruptive to existing efforts by the industry. Furthermore, the use of virtualized networks within the industry is still limited and efforts to try and tailor the current body of standards to accommodate this emerging security solution is likely to create new security concerns. Instead, we encourage the SDT to work toward addressing the more immediate needs of the industry such as clarifying how the security and management of BES Cyber Systems can be accomplished in a virtualized environment using the existing body of standards, as currently approved. Additionally, EEI further suggests that the level of change being considered by the SDT may be better addressed through a separate initiative spanning several years to allow more engagement by the industry.

EEI also notes that, while the SDT has offered up some very interesting ideas to address virtualization within BES Cyber Systems, many Responsible Entities still feel there is a lack of overall clarity necessary to address the design, control, and protection of these systems in a virtualized environment.

EEI’s last concern centers on the auditability of the proposed approach. While the security objective-based approach does provide a friendlier environment for virtualization, there is concern that, from an audit perspective, this approach may prove to be difficult for Responsible Entities and auditors to demonstrate compliance leading to interpretations and judgements that could impact the security of BES Cyber Systems, while placing into question whether the proposed solution can be effectively and consistently audited.

Payam Farahbakhsh - Hydro One Networks, Inc. - 1,3

Answer	
Document Name	

Comment

Hydro One supports the comments submitted by NPCC TFIST. In addition, the real fork maybe it is time to determine whether the CIP set of Standards are ready to be transitioned into a full risk-based set of standards (starting from CIP-002) rather than control-based set of standards. The SDT is trying to have it both ways for the sake of backwards compatibility. In the current proposed revisions, certain security controls are maintained mainly for routable protocols and objective oriented requirements are being introduced to address virtualization. backwards compatibility is a desired outcome but it maybe time for SDT to consider the following:

- Is the industry mature enough for a full risk-based approach to cyber security?
- Have the auditors figured out how to audit CIP standards in a more risk-based/objective oriented world?

Until the answer to both questions above are "yes", Hydro One recommends that the SDT develop one or more standard(s) with a set of controls applicable to virtualized components.

Chris Wagner - Santee Cooper - 1,3,5,6, Group Name Santee Cooper

Answer

Document Name

Comment

Santee Cooper appreciates the SDTs effort in drafting the complex virtualization standards.

CIP-005 1.1-1.1.1. Are you talking about a firewall or something else to logically isolate our systems? How could this be accomplished when using dial up? Will dial-up require the use of an EAMS?

CIP-005 2.1 - With the revised definition of Intermediate System and Interactive Remote Access does this mean an Intermediate System is required to connect with medium impact sites that use dial up? CIP-005 2.2 – With the removal of “with External Routable Connectivity” under applicable systems, are dial up connections going to be required to be encrypted?

CIP-005 2.3 – With the removal of “with External Routable Connectivity” under applicable systems, will multi-factor authentication be required for dial up systems?

CIP-010 – This is a situation where in the past the prescriptive model would be a better fit than the higher level objective based model. Currently this standard is specific on what the expectations are and what needs to be done to meet the requirements of the standard. In the proposed revision requirements they are too vague and leave it open to an auditor’s interpretation.

For entities not pursuing virtualization, these revisions tend to create more confusion around what is required for compliance.

1. As written, the proposed changes in the standard package may add unintended compliance risk to applicable entities. The standard proposes flexibility to allow the responsible entity to implement controls for the Secure Configuration; however, this may not comport to audit situations where the auditors are deciding whether the entity's controls meets the auditors' expectations of compliance. The SSRG suggests anticipates the Implementation Guidance document to be posted in the future may relieve some of these concerns.

2. Questions to consider: How will the retirement of the defined term for EACMS affect the Order 848 FERC directed CIP-008 changes? Will CIP-008 need revising once this current project is approved by FERC? Should changes to CIP-008 be part of this exercise?

Pamela Hunter - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - SERC, Group Name Southern Company	
Answer	
Document Name	
Comment	

Generally speaking, Southern Company is in favor of this change in methodology. These changes will facilitate the use of more current and potentially more secure technology while allowing Registered Entities the flexibility to use virtualized or physical systems to do so. We recognize the inherent risk in any change to the compliance methodology and wish to embark on such changes taking care to balance the risk associated with the change with the benefits received from the change.

That said, additional clarity and technical guidance is needed in documenting a Secure Configuration. Southern would like to see more clarity in how far the Secure Configuration boundary goes. At this time, it appears overly broad and we are concerned that it may start to include things like firewall rules, iDRACs and other more in-depth configuration items.

Comment

APPA recognizes the complex and difficult job the SDT had in drafting the virtualization standards. The SDT’s efforts are appreciated. Project 2016-02 provides best practices for security standards that strive to stay ahead of adversaries’ efforts. The Project is groundbreaking and is the first step toward the next level of the best practices in security standards. APPA acknowledges that the comments herein largely question the draft standards and request clarity. Because the questions are open ended, public power did not see a need to provide yes/no answers, believing that is best left too registered entities. Public power sees this effort to date as significant progress.

Importantly, implementing the virtualization standards will be a challenge for NERC and industry. APPA, therefore, believes that the implementation plan and its timing is now the most crucial consideration. APPA encourages the SDT to draft an implementation plan with a two- to four-year implementation phase. The implementation plan needs to be facilitated by sufficient guidance. Guidance will need to be provided during implementation based on best practices learned during the implementation period. The period of putting Project 2016-02 in place should be a phase of learning so that best security practices can be implemented by all entities big and small. Because these changes are extensive, involve complex new concepts, and may have many unintended consequences, a pilot project involving volunteer utilities and NERC should be part of the implementation effort for these changes, similar to the pilot performed for the CIP v5 transition.

To reiterate, the following are some general principles that might be applied to guide revisions to the proposed virtualization changes:

1. APPA supports the SDTs efforts on proposed changes and believe this is a great initial step.

2. Changes are more extensive than expected, probably have many unintended consequences, are complex and largely untried, and in some cases expand CIP scope to address new vulnerabilities introduced by virtualization.

3. Therefore, consider a parallel “virtualization overlay” approach, in which the existing definitions and requirements are retained, but the proposed new definitions and new requirements are also an option. An entity must identify which approach they choose, on a cyber-system by cyber-system basis.

4. The overlay approach might sunset after a time or be reassessed at a certain point based on lessons learned.

5. Expansion of CIP scope to address new vulnerabilities associated with virtualization should be restricted only to virtualized BCS. These changes should not increase scope for non-virtualized BCS. 6. Public power strongly urges that a NERC-sponsored pilot project with volunteer utilities, as happened with CIP v5 changes, be utilized with virtualization.

Virtualization Informal Posting Consideration of Comments

Project 2016-02 Modifications to CIP Standards

The standard drafting team (SDT) for Project 2016-02 Modifications to the CIP Standards, investigated the issues and unique risks associated with virtualization technologies. During the SDT's review, it was discovered that accommodating virtualization technologies in the CIP standards could affect many of the technical definitions, such as the foundational "Cyber Asset" used within CIP standards, and also the technical CIP standards (CIP-005, CIP-007, and CIP-010). Virtualization changes fundamental assumptions and some legacy standards requirements. There is no longer a need to prescribe the Electronic Security Perimeter (ESP) and Electronic Access Point (EAP) architecture with perimeter-based security or the exclusive use of routable protocol. The SDT found virtualization to be not only a driver of change, but also a pointer to a larger issue with the standards' adaptability to current and future technology innovation.

The SDT concluded that the more technical standards could benefit from removing inherent prescription of certain architectures and topologies, and moving requirements to an objective or results-oriented level that do not make assumptions about architecture. In other words, the SDT asserts that the standards should not prescribe how to secure today's newer architectures. Rather they should require that certain security objectives be met regardless of topology or architecture. In doing this, the standards will support virtualization and other future innovations that can increase reliability, resiliency, and security of our BES Cyber Systems.

The SDT posted the virtualization work that was completed to date for an informal posting November 2 to December 18, 2018. There were 76 sets of responses, including comments from approximately 199 different people from approximately 132 companies representing 10 of the Industry Segments.

The SDT thanks the industry for the time and attention given to these matters and the resulting comments. The SDT captured some of the overall themes from all the comments received to focus the SDT's efforts as we progress towards a formal posting.

Overall Themes

- Several commenters questioned the need for changes to requirements since virtualization is not prohibited and several entities have undergone successful audits on virtualized systems. An example of one of the fundamental issues would be when a Cyber Asset or an entire BES Cyber System and its associated systems (not only hosts, but storage, networks, EAPs, etc.) become logical constructs composed of software and data only. In response, the SDT will focus on communicating the case for change; why some changes are needed to allow different architectures and approaches that can significantly improve cyber security in virtualized environments but do not fit well with standards such as CIP-005. Virtualization technologies also present some unique risks that should be addressed.

- Commenters had suggestions on approaches they believe would help alleviate the amount of change to the current standards. The SDT will consider each approach as the team moves forward determining what changes can and should be made to the standards.
- Commenters pointed out some issues with the move away from the Cyber Asset level to a system level approach. They raised the concern this could cause an industry wide CIP-002 reassessment of all systems. They also pointed out that the systems concept has been used to group devices of like attributes (such as Operating Systems) for ease of reporting evidence on a per requirement basis. This type of grouping interferes with the concept of “Each BES Cyber System must be in a logical isolation zone.” The SDT is considering how to incorporate changes based on these comments.
- Several commenters spoke to the security objective statements within the requirements. While there was support that objectives do provide clarity about the goal of a requirement, commenters suggested they are written too broadly, which introduces auditability concerns. The SDT will work towards drafting objective and measurable requirements.
- Almost all commenters responded to the removal of the term “programmable” within the definitions as we were looking at a full move to a systems approach. The concern was over the potential to bring in non-cyber components of systems such as electro-mechanical devices. The SDT will work on restoring the programmable terminology.
- Commenters suggested the Logical Isolation Zone (LIZ) concept needs further refinement and explanation. The SDT is considering refining this concept or identifying other options to clarify how security requirements will be applied within the standards.
- Commenters generally agreed with splitting out the ‘monitoring only’ portion of Electronic Access Control or Monitoring Systems (EACMS) and Physical Access Control Systems (PACS) and treating that security risk at the information level. Some commenters suggested that the applicability of Electronic Access Monitoring Systems/Physical Access Monitoring Systems proposed in CIP-004 needs further review because it would continue to prevent the use of monitoring services. The SDT is continuing to consider options to allow monitoring information to be treated as BES Cyber Security Information to limit the scope of applicability.
- The proposed CIP Exceptional Circumstances (CEC) additions met with approval though several commenters suggested that all CEC phrasing should be at main requirement level. The SDT has considered this but must balance whether or not a CEC should be available for every requirement part. In those cases where the CEC does apply to every part it was moved to the main requirement.
- Many commenters suggested the Secure Configuration concept involved a fairly broad scope expansion from five discrete software items to numerous areas that would also include methods and processes. They believe that these would be difficult to inventory because they are not necessarily discrete items. Commenters suggested that several of the items in a Secure Configuration as defined are procedural, which conflicts with the change management requirement. Some pointed out that methods could differ per system, times thousands of systems. The SDT will continue to consider options to address the objective level requirement changes to limit the scope of change.

Unofficial Nomination Form

Project Number 2016-02 Modifications to CIP Standards

Do not use this form for submitting nominations. Use the electronic form to submit nominations by **8 p.m. Eastern, Friday, March 29, 2019.** This unofficial version is provided to assist nominees in compiling the information necessary to submit the electronic form.

Additional information can be found on the Project 2016-02 Modifications to the CIP Standards page. If you have questions, contact Jordan Mallory (via email), or at 404-446-2589.

By submitting a nomination form, you are indicating your willingness and agreement to actively participate in face-to-face meetings and conference calls.

Previous drafting or review team experience is beneficial, but not required. A brief description of the desired qualifications, expected commitment, and other pertinent information is included below.

Project 2016-02 Modifications to CIP Standards

This solicitation for nominations is to augment the existing Project 2016-02 Modifications to CIP Standards drafting team that is continuing to address the Standard Authorization Request. NERC is seeking individuals from the United States and Canada who possess experience in one or more of the following areas, but are not limited to:

- Virtualization;
- Cooperative representation;
- Canadian representation; and
- Guidelines and Technical Basis representation.

Standards Affected

CIP-002-6, CIP-003-7, CIP-004-6, CIP-005-5, CIP-006-6, CIP-007-6, CIP-008-5, CIP-009-6, CIP-010-2, CIP-011-2, and CIP-012-1.

The time commitment for this project is expected to be up to four face-to-face meetings per quarter (on average two full working days each meeting) with conference calls scheduled as needed to meet the agreed-upon timeline the review or drafting team sets forth. Team members may also have side projects, either individually or by subgroup, to present to the larger team for discussion and review. Lastly, an important component of the review and drafting team effort is outreach. Members of the team will be expected to conduct industry outreach during the development process to support a successful project outcome.

Standards Announcement

Project 2016-02 Modifications to CIP Standards

Nomination Period Open through March 29, 2019

Now Available

Nominations are being sought for standard drafting team members through **8 p.m. Eastern, Friday, March 29, 2019**.

Use the electronic form to submit a nomination. If you experience difficulties using the electronic form, contact Wendy Muller. An unofficial Word version of the nomination form is posted on the Standard Drafting Team Vacancies and the project page.

By submitting a nomination form, you are indicating your willingness and agreement to actively participate in face-to-face meetings and conference calls.

Previous drafting or review team experience is beneficial, but not required. A brief description of the desired qualifications, expected commitment, and other pertinent information is included below.

Project 2016-02 Modifications to CIP Standards

This solicitation for nominations is to augment the existing Project 2016-02 Modifications to CIP Standards drafting team that is continuing to address the Standard Authorization Request. NERC is seeking individuals from the United States and Canada who possess experience in one or more of the following areas, but are not limited to:

- Virtualization;
- Cooperative representation;
- Canadian representation; and
- Guidelines and Technical Basis representation.

Standards Affected

CIP-002-6, CIP-003-7, CIP-004-6, CIP-005-5, CIP-006-6, CIP-007-6, CIP-008-5, CIP-009-6, CIP-010-2, CIP-011-2, and CIP-012-1.

The time commitment for this project is expected to be up to four face-to-face meetings per quarter (on average two full working days each meeting) with conference calls scheduled as needed to meet the agreed-upon timeline the review or drafting team sets forth. Team members may also have side projects, either individually or by subgroup, to present to the larger team for discussion and review. Lastly, an important component of the review and drafting team effort is outreach. Members of the team will be expected to conduct industry outreach during the development process to support a successful project outcome.

Next Steps

The Standards Committee is expected to appoint members to the team in April 2019. Nominees will be notified shortly after they have been appointed**.**

For information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Standards Developer, Jordan Mallory (via email) or at (404) 446-2589.

Virtualization and Future Technologies

Project 2016-02 Standards Drafting Team: The Case for Change

April 2019

Table of Contents

Executive Summary

What the interconnected power grid does for Bulk Electric System (BES) reliability, virtualization does for the computing infrastructure supporting vital control systems. Individual utilities interconnected their power systems to form a power grid to share spare capacity for meeting demand peaks and surviving contingencies such as generating unit and transmission line outages. Virtualization connects processors, networks, and storage into ‘computing grids’ that allow our vital systems and applications to meet peak demands and survive outages of individual components.

This is accomplished by abstracting servers, networks, and storage into virtual or logical resources that can be independent of specific underlying hardware such as individual processors, circuits, and disks. A control system and its underlying operating system become a virtual machine and can move to any available hardware. This greatly increases reliability and resiliency of our control systems that support BES reliability.

Virtualization technologies also allow enhanced cyber security controls and the ability to move access controls from the edge of our networks to much deeper inside of them. This is analogous to having generation close to load centers to reduce the susceptibility to outages. These newer security controls allow us to provide tighter security by moving access controls from an outer perimeter closer to the actual code performing reliability tasks.

Virtualization and advanced technology are challenging the way we characterize the Critical Infrastructure Protection (CIP) standards’ objectives and how we develop technical requirements. Use of virtualization and advanced technology can provide benefits for implementing both operational and security enhancements to a system. The goal is to require technology-enforced controls as alternatives to the current prescriptive requirements like those requiring a physically structured architecture, without forcing the use of the new technology. The existing standards with their prescriptive language limit the ability to take full advantage of the new technologies. The Project 2016-02 Modifications to CIP Standards Standard Drafting Team (SDT) is drafting new requirements to support virtualization capabilities. This leaves Responsible Entities with the option to maintain a non-virtualized environment and use backward compatibility to preserve current CIP investments and security postures.

This white paper represents the views of the SDT and presents a sampling of virtualization concepts. It explains, in the SDT’s opinion, how the use of these concepts is inhibited by some of the CIP standards’ definitions and requirements. It also introduces the SDT’s ideas on how to address these issues while maintaining compatibility with current state. The goal is to allow for the use of these technologies and newer security controls by removing prescribed “how’s” and replacing them with clear “what’s” that would allow both current state and these enhanced features.

Introduction

Note: The Project 2016-02 SDT developed this white paper to explain the need to change the cyber security CIP Reliability Standards. This white paper has not been approved or endorsed by NERC and is solely the views of the Project 2016-02 SDT.

In the history of the CIP standards, industry has seen many versions and changes. Some have been straightforward and almost self-explanatory. Others, complex and time-consuming to implement. Still others have been foundational, like the ‘do-over’ change from Versions 1 – 3 to Version 5. Not surprisingly, the prospect of another set of fairly major changes, this time involving virtualization sparks a great deal of industry concern. It raises valid questions about the timing and the drivers of those changes, and whether or not they are truly necessary. The white paper is designed to provide detailed answers to those questions from the viewpoint of the SDT. This introductory section provides a short, high level introduction to the white paper discussion on what brought about the SDT’s focus on future revisions to the CIP standards to address virtualization.

Recognizing the continuing growth in technology innovation, many entities in the Electricity Sector have implemented virtualization as part of their CIP programs. Many of these same entities, however, have implemented this new technology without taking full advantage of virtualization’s advanced capabilities. There are a number of reasons for this from the constraints of the current CIP architecture to the ongoing ambiguity around how new virtualization technology applies to CIP compliance. Some of those who are implementing virtualization are experiencing a great deal of uncertainty and difficulty around developing implementation strategies that will support compliance and achieve greater reliability and security.

These issues began coming to light following the NERC “Virtualization Summit” in 2015. Ultimately, the Version 5 Transition Advisory Group (V5TAG) heard about the industry concerns and determined that the issues around the standards and virtualization would be best addressed by a drafting team. The Project 2016-02 SDT was assigned the task to address the technological innovation in virtualization within the CIP standards.

The SDT’s purpose of incorporating the virtualization concept into the CIP standards is not to merely augment the current standards. The SDT’s intent is to better position the CIP standards to be applicable to any future technological innovation. Leveraging the abstraction that virtualization provides will allow the industry to more readily adopt new technology and increase security posture. This paper presents the SDT’s case for change to the NERC CIP standards that is needed to allow for the innovative security techniques and new concepts brought about by virtualization.

As virtualization has progressed, many of these types of issues cannot be addressed with Implementation Guidance. Documenting a possible way to implement a requirement is of great value, but Implementation Guidance cannot, for example, change current requirements so they do not prescribe a perimeter-based model, or allow remediation VLANs. It also cannot add new requirements that are needed for issues like management plane isolation or handling shared infrastructure. These new concepts and techniques require changes to the standards to make them viable and to clarify how they should be secured.

Chapter 1: Virtualization Benefits

The most basic concepts of CIP are essentially unchanged from the Urgent Action 1200 standard in 2003. The primary focus of those standards was the "critical cyber asset"; an "electronic device" such as a server, workstation, or relay as a physical object. It had an operating system, always on and performing its function, and communicating with other components over routable protocols. It was protected by traditional firewalls at the network edge looking at source and destination protocol addresses and ports as the only mechanism by which to make network access control decisions.

Figure 1

Today, virtualization has changed this scenario. With virtualization, physical devices are no longer the primary units of organization. An entire control system infrastructure can be virtualized (such as "software defined data centers") and only exist as logical constructs. An EMS database server may never exist as a discrete physical object. With containers (operating system emulation), there may not be a concrete tie between application logic and an operating system. Virtual machines can be created and destroyed dynamically and are neither always on, nor tied to specific hardware. Workloads may mirror their information for reliability purposes across great distances without using routable protocols. With micro-segmentation, network access control lists are now much more granular than IP addresses at a perimeter. They are enhanced by policy-based control templates enforcing access at a "user to workload" level throughout the system infrastructure. Electronic access control may no longer be based solely on routable protocol addresses or found only at an ESP boundary.

Benefits of Virtualization

Virtualization technologies bring many reliability benefits to BES Cyber Systems (BCS).

- Increased uptime, very fast recovery capability and flexible architecture that can instantly adapt to changing workloads.
- Virtualization allows for racks of CPUs, memory and disks to be tied together with high speed mesh networks and viewed simply as raw computing resources.
- If the workload on a particular virtual server is nearing capacity, the infrastructure orchestration system can create and configure an additional server on the fly, bring it online to help with the peak workload, and then destroy it when it is no longer needed.

- If a physical machine runs out of resources, the workload can be moved to another physical machine dynamically based upon relative load. When a virtual server or workstation is not in use, it is similar to a physical server that is powered off.
- This flexible and dynamic architecture also allows improved security controls such as those provided by micro-segmentation.
- Users can be granted access to specific workloads that can be placed dynamically throughout the infrastructure with managed access to provided services.

More secure, more reliable, cost effective technology solutions

New and innovative security capabilities continue to evolve to address current threats, particularly in virtualized environments. These capabilities can increase the security of hosted BES Cyber Systems. For example, *distributed firewalls* based on software defined access policies can enforce access controls at a much deeper level within the infrastructure to help prevent an attacker's lateral movement through the network. *Privileged introspection* allows security service such as anti-malware, to operate in a tamper-proof way outside of the instances they protect. *Zero trust models* allow communication to be protected end to end between individual processes across cyber assets without having to trust that devices in the path (such as all firewalls and switches) are configured correctly to protect the data. We'll consider each of these and other examples in more detail to show the benefits and the case for change in the CIP standards.

Chapter 2: Virtualization challenges in the NERC CIP Standards

Virtualization brings benefits to reliability and resiliency of our BES Cyber Systems. It also brings challenges with determining how some of the newer concepts fit within the framework of the NERC CIP standards. Some of these newer techniques and concepts are:

- Identification of Virtual Cyber Assets
- Distributed Firewalls vs. Perimeter models
- Zero Trust models
- Virtualized Firewall Interfaces
- Virtual Storage challenges
- Management Plane Isolation
- Privileged Introspection
- Remediation VLANs

Each of these topics will be covered in detail in the following sections.

Identification of Virtual Cyber Assets

One of the issues requiring change within the CIP standards is the need to clarify the treatment of virtual machines (VMs) under today's definitions. The foundational term Cyber Asset is defined as "Programmable electronic devices, including the hardware, software, and data in those devices." This definition, since it includes the hardware, does not fit with virtualized environments. A literal use of this foundational definition would mean a server hardware platform may be a BES Cyber System, the hypervisor software could be the "operating system", and all the virtual machines running on the hardware are applications or simply data. The CIP-007 requirements, most of which are aimed at an operating system instance, would not be applied to these virtual machines since they aren't hardware. This is referred to in the Figure 2 as the "Physical System w/Software Model."

To require that VM operating systems be classified correctly, the tie between a virtual machine and the hardware needs to be clarified. The standards and their associated definitions need to clearly support the "VM as a CA Model" (Virtual Machine as a Cyber Asset) as pictured in Figure 2. Here it is clear that the physical server hardware and the hypervisor are in scope and each VM is subject to requirements such as CIP-007.

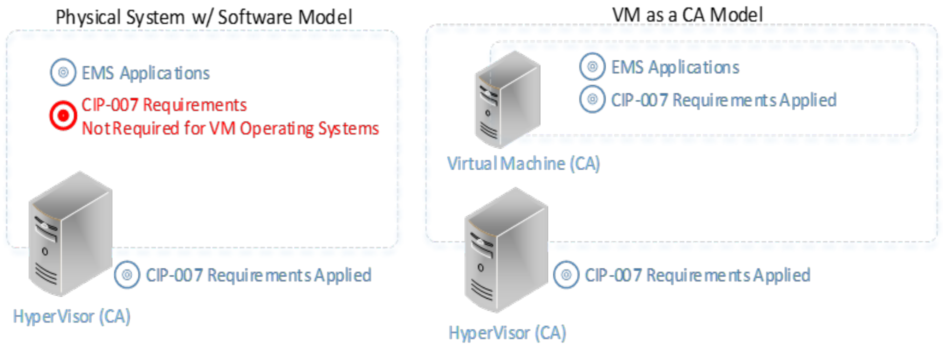

Figure 2

The Cyber Asset definition assumes a 1:1 relationship between a BES Cyber Asset and its hardware. Virtualization, however, breaks that concept because in some cases hundreds of virtual BES Cyber Assets can share a pool of hardware resources (compute, network, and storage). The outdated concepts need to be changed to recognize the one-to-many relationships that are now possible between a BES Cyber Asset, an instance of an operating system supporting applications, and the underlying hardware so it is clear how each is to be treated. There are three different types of asset classes involved in today's BES Cyber Systems:

- Self-contained devices that are composed of dedicated hardware, some form of operating system or firmware, and the application code. This is the traditional definition of a Cyber Asset and applies to things such as digital relays, RTUs, physical operator workstations and dedicated physical servers.
- Virtual "cyber assets" composed of an operating system and applications or containers minus any dedicated hardware. These types of assets are logical or virtual constructs by nature and exist only in memory or files. They can, however, appear from a network perspective the same as any other host.
- Shared Infrastructure consists of the hardware resource pools (compute, network, storage) and is shared by virtual cyber assets and can host numerous virtual cyber assets, networks, or storage locations.

The current CIP standards only recognize the first class and changes are needed to properly address the other two. This will allow BES Cyber Systems, which can be composed of all three asset classes, to be properly identified and classified and the proper requirements applied to each one.

Distributed Firewalls vs. Perimeter Models

Distributed firewalls based on software defined access policies can enforce access controls deeply within the infrastructure to help prevent an attacker's lateral movement through the network. The CIP standards (CIP-005) today require a perimeter-based model as shown in the left side of Figure 3. It has an Electronic Security Perimeter (ESP) as a logical border around a group of cyber assets, and defined interfaces (on a firewall for example) as an Electronic Access Point (EAP). This perimeter model is a prescriptive topology, and for many scenarios is still a valid way to perform network security. What may be prescribed, however, for a small network of similar cyber assets may not be ideal for a large network of virtualized BES Cyber Assets.

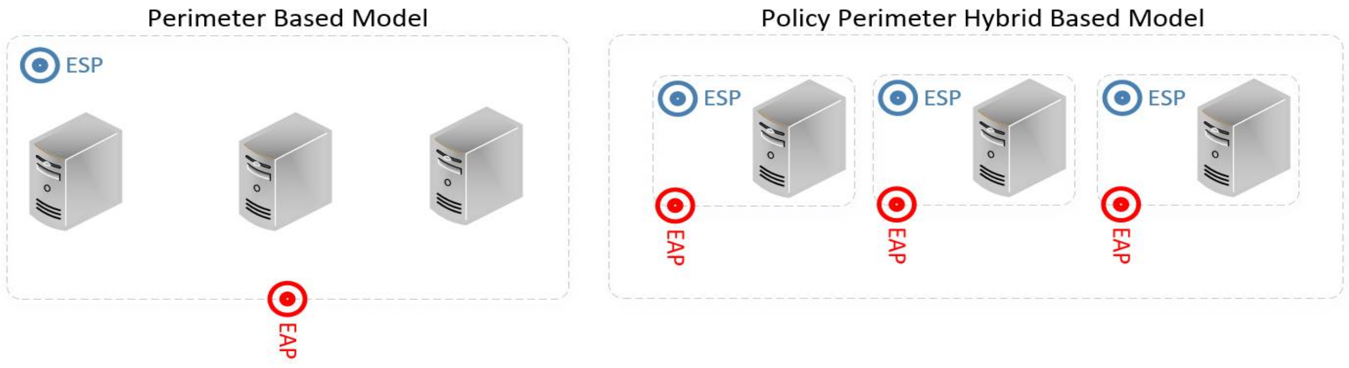

Figure 3

The issue is that network access is permitted or denied at the outer EAP "gate." Even if access is only needed to a single cyber asset inside the perimeter and a strict rule is instituted at the EAP "gate" to allow someone access to that single cyber asset, that control is implemented only at the gate. Once inside the perimeter, there are no network level access controls that would prevent hopping ("pivoting") from that cyber asset to all other cyber assets inside the perimeter. Attackers today depend upon this; if they can get a foothold on a single cyber asset inside a perimeter they can work over time to move laterally within the environment from there.

Virtualized environments, especially those of cloud providers that support tenants from various customers, had to be designed to implement new, more granular security techniques to not only mitigate this threat but to also keep customer's workloads totally isolated from one another. These new techniques are philosophically simple – every cyber asset is inside its own "perimeter" and the EAP "gates" are specific to each virtual cyber asset. This is shown on the right side of Figure 3 in the "Policy Perimeter Hybrid Based Model." In this model, network access is controlled at an individual cyber asset level and access to a single cyber asset gives you no additional access to any other cyber asset. An attacker's ability to move laterally or pivot in this environment is greatly reduced. These techniques are also configured at a *network access policy* level and the infrastructure dynamically implements it at various levels throughout the entire infrastructure. Even as these cyber assets move dynamically within the infrastructure, these access controls move with them. All of this, however, precludes the ability of administrators to provide a "list" of potentially hundreds or thousands of ESPs, EAPs, or the discrete rules per EAP. This is because it is all dynamically generated by the infrastructure to control access in accordance with a higher-level access policy.

These same techniques can be used to mitigate the same risks within virtualized CIP environments. The problem is that CIP requires the perimeter model with EAP "gates" as the only prescribed way to implement network level security. The SDT is planning to change the CIP standards and definitions in a way that does not *preclude* the perimeter based model, but also does not t *prescribe* that model as the only way. For example, the language in CIP-005 R1.2 "All External Routable Connectivity must be through an identified Electronic Access Point (EAP)." This creates an issue since historically this is a physical interface on a physical device. More current, virtualized architectures distribute the policy enforcement tasks to multiple devices and each of them validates that the network communications passing through it are permitted. The current standards do not align with these architectures because there is no single interface identified that is responsible for policy enforcement.

Identifying non-routable EAPs and the OSI Model

Related to the ESP issue, today's CIP Standards are limited to prescriptive topologies even as potentially more secure, reliable and cost-effective solutions are available. ESP's are defined today by the access provided at the network layer (OSI Layer 3) and are therefore limited to making access decisions based on routable protocol addresses. This method does not support security evaluation or compliance via security solutions at any of the other layers of the OSI model. This presents two issues:

- There may be network access into and out of the perimeter at different layers other than by a purely routable protocol that allow for things like high speed replication of data. This will be discussed further in the "Multi-Site Data Center Extensions (Super ESP)" section below.
- Virtualized environments have much more context and can enforce network access control at more granular levels in much better ways. These include by user, process, or certificate and are not limited to only a source/destination IP address of a routable protocol.

In many environments today, the perimeter model is sufficient and routable protocol addresses are all an entity has to make access control decisions. However, the standards should not prescribe this as the only way and should allow entities to use these more granular controls that may operate at other layers.

Zero Trust Models

The zero trust network model is a new and different way of thinking about network security. In most cases it can be implemented within the security model that an entity currently has deployed.

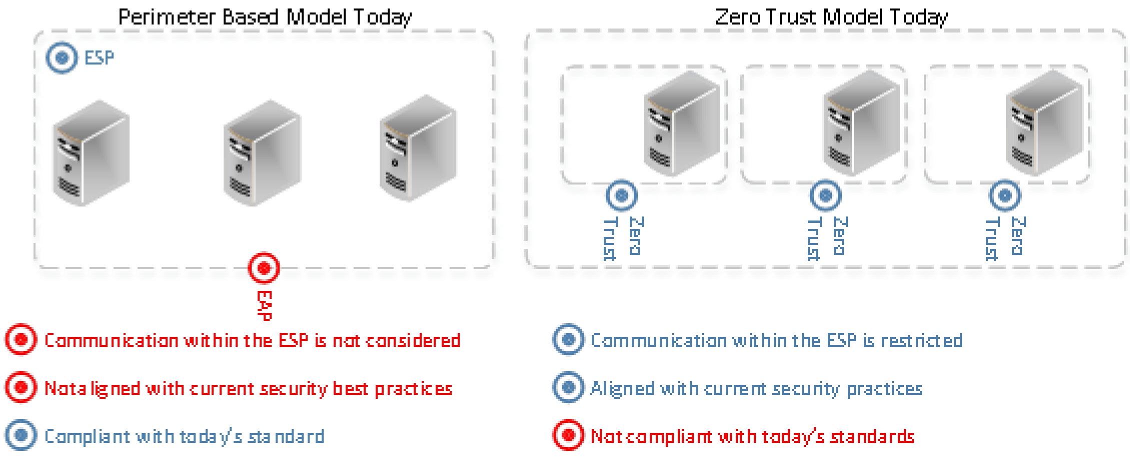

Figure 4

Most entities have a perimeter model deployed, which is what the current ESP model requires as in Figure 4. Traditionally, this consists of a firewall (or firewalls), with a single path into the network (EAP). This model protects the BES Cyber System indirectly, by protecting the network topology. This access point is protected by rules and policies that tell the firewall what kind of traffic to pass and what kind of traffic to stop. This model can be loosely compared to a gated community, where the fence is the firewall, and the gate and security guard are the access control.

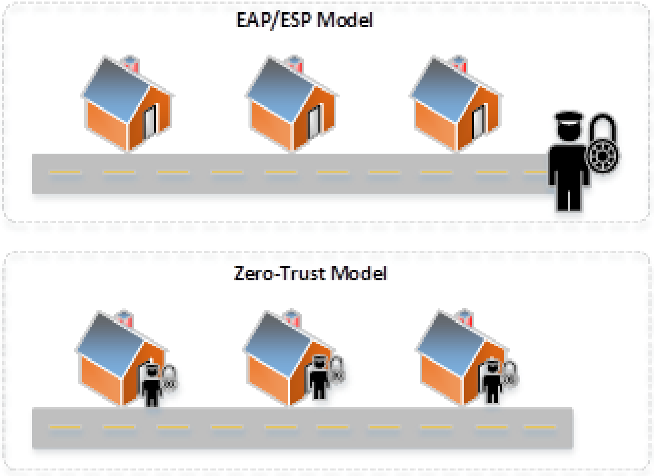

Figure 5

The overarching problem with this model is that if attackers should get past the firewalls and through the gate, they would have free rein throughout the network and could pose a serious threat to other BES Cyber Systems within the ESP.

A zero trust model brings the protection directly to the cyber asset or even to the process level. Using network policies, whitelisting, certificates, and other technologies, the ability of an intruder to move around is severely restricted. A zero trust model usually starts with simple items like restricting network traffic to the device except that which is necessary for it to perform its job function. It also restricts what logins can access the device. Finally, it introduces more complex ideas such as digitally signed executables, restrictions on what time a process can be started, and end to end encrypted traffic, even within the local network. This model protects the BES Cyber System directly by protecting the workloads, the devices and the topology. Unfortunately, this model is very difficult to describe using the current language constructs of the CIP requirements.

Referring to the gated community analogy in Figure 5, this would put a fence in every yard, a lock on every door and an alarm system in every house. This effectively isolates the intruder to the public areas of the neighborhood.

Virtualized Firewall Interfaces (‘Firewall on a Stick’)

As the use of network segmentation grows and firewalls are used to control traffic flows between the network segments, firewalls need higher densities of interfaces. To obtain these higher densities, products today rely on fewer physical ports and instead use virtualized network interfaces to emulate many physical interfaces. Some modern firewalls are service modules (a “firewall on a stick”) installed in a switch or router where virtual interfaces are the only option to route traffic to and from the firewall as shown in Figure 6.

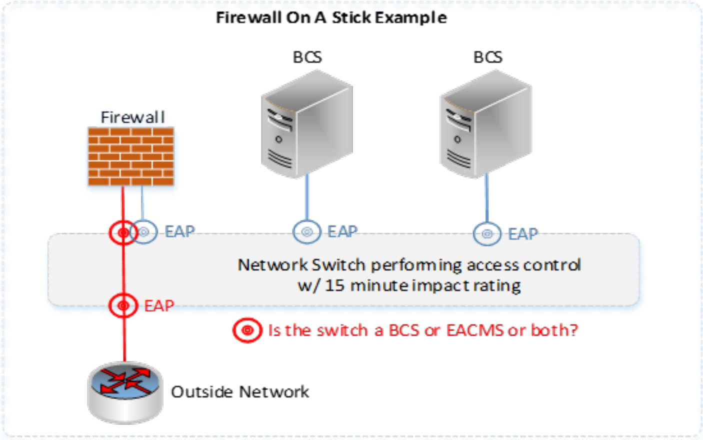

Figure 6

The CIP standards are ambiguous on how to properly identify these assets. If this were simply a network switch allowing two BES Cyber Systems to communicate with each other with a 15 minute impact if the switch is unavailable, then the switch itself is part of a BES Cyber System. In this example, the entity wanted to increase security of the communications between these two systems. To accomplish this, it put each BCS on its own network segment so it can filter all traffic between these two systems through a firewall. A “firewall on a stick” is installed in the switch and the ports on the switch are divided into virtual networks so the traffic between different segments is directed to the firewall and controlled. Since the firewall either has no physical interface or may use its few physical interfaces for redundancy, the outside network must connect to the same switch and that port is configured to the “outside” interface of the firewall. All communications to and from the outside network and between the two BCS are all controlled via the firewall. The entity has increased the security of these systems, but it is now undecided on how to identify the cyber assets in this scenario. As one example, are all the network switch ports now EAPs on an EACMS, or is this switch still just a part of the BCS? As access control is pushed deeper into networks as in this example, the current paradigms are ambiguous. The answer may lie in identifying new asset classes and developing new objective requirements that do not include prescriptive network topology assumptions. Trunks and sub-interfaces are common network technologies to aggregate data streams and better utilize limited physical interfaces[1].

---

[1] Trunking is the use of a single link to aggregate multiple data streams. This technology is widely used in networking and telecommunications. Sub-interfaces allow for multiple LAN segments to share a common physical interface.

Virtual Storage Challenges

As we move to virtual storage, there are issues with some of today's CIP concepts. For example, the CIP-011-2, requirement R2 restricts unauthorized access to BES Cyber System Information on systems meant for reuse outside of the CIP environment or systems meant for disposal. This causes a challenge for virtualized infrastructure. Today, when disposing of a physical medium or high impact BES Cyber Asset, access to BCSI can be restricted by sanitizing or destroying the media associated with the physical asset. If storage media is provided from a Storage Area Network (SAN) or Network Attached Storage (NAS) array, there may be no easy way to identify the specific drives where the data might have been stored. Additionally, there is no significant benefit to pulling drives from an array to sanitize or destroy them if there is another way to manage this media.

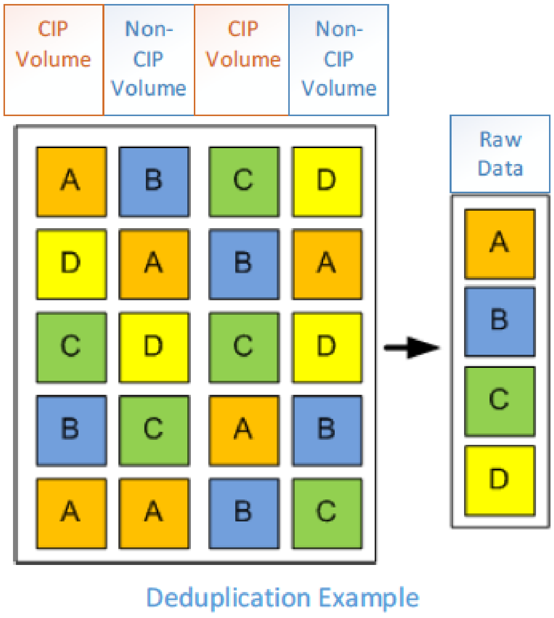

Figure 7

To extend this challenge further, many SAN and NAS environments can de-duplicate and move data to various storage tiers within the array to optimize access times and reduce latency. This process analyzes the data in small enough chunks to create single instances of data that are used within multiple volumes that may be assigned to any number of devices. The chunks with the highest access rates are then placed on fast storage media because the data is constantly referenced. This effectively causes data re-use if storage media is shared between CIP and Non-CIP assets even when the information contained within these de-duplicated chunks is not readily retrievable individually.

That was one example. The CIP standards were built on a paradigm of disk storage being physical disks dedicated to a Cyber Asset. Updates to the standards are needed to reflect the realities of virtual storage technologies that are in use today.

Management Plane Isolation

Because virtualized servers, networks, switches, firewalls, and storage are logical constructs, controlling access and communications to the management plane of these systems is imperative. Access to the management plane (interface/console/etc.) allows a user to create, modify, or delete these objects or entire infrastructures from one place, or move objects from one zone or network to another. Administrative level or "management plane" access to the hypervisors is therefore absolutely critical to the security and reliability of the hosted systems. These types of access must be brought into the scope of CIP standards if hosting BES Cyber Systems and will require changes to the CIP standards.

Another challenge of the perimeter model is it can drive less secure topologies in order to provide clear adherence to the perimeter model. In Figure 8 below on the right is the desired separation between the management plane of a virtualized environment and the production or "data plane". The management port of the BCA is connected to a switch on the management network. The production network switch is connected to the network interface on the BCA. This creates two different network paths to the BCA: one for normal production traffic and a separate network path with separate access controls for administrative or management plane access. It is unclear, however, if the BCA has now created two ESP's with two EAPs, and whether or not it is now an EACMS. It is not functioning as an EACMS, but from the topology it appears as one. The prescriptive CIP model may create a temptation to place the management interface into the production ESP as in the picture on the left. This is very clear from a CIP standard adherence perspective but is the less secure choice.

Figure 8

Privileged Introspection

Privileged introspection allows security services, such as malware detection, to be performed outside of the operating system and applications it is protecting in a tamper-proof way. Previously, malware that could gain elevated privileges on a cyber asset could then disable security services such as anti-virus solutions running on the same OS. Virtualized environments, however, can allow privileged introspection where anti-virus or application whitelisting services run as part of the hypervisor; outside of the operating system they are protecting so malware with elevated privileges inside the OS cannot reach them. Another benefit of privileged introspection is it allows integration with distributed firewalls because it can inspect network traffic entering or leaving virtual machines and make decisions with vastly more context. For example, these firewalls can control access not simply at a network address level (IP source/destination) but down to the level of a process with a particular certificate.

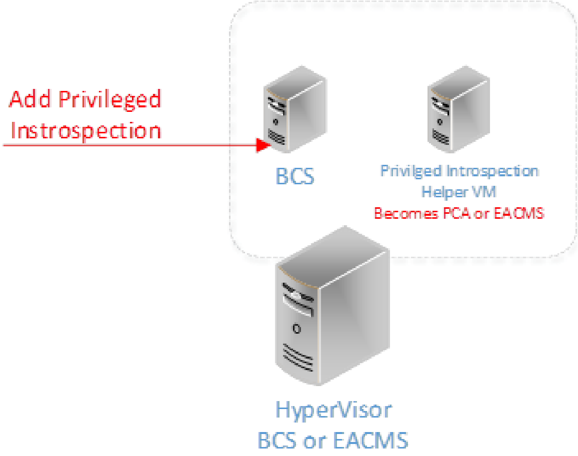

Figure 9

Even though the current CIP-007 R3 is already written at a security objective level and can work with privileged introspection, there can still be CIP standards issues brought into play. If this functionality uses "helper VMs", it is not clear how to identify and classify these under the current CIP standards. Since the status of malware detection is now outside the VM's, it requires grouping the VM's protected by privileged introspection into a particular BES Cyber System.

Remediation VLANs

As another example of the need for change in the CIP standards brought about by new virtualization technologies, CIP-010 R3.3 states, "Prior to adding a new applicable Cyber Asset to a production environment, perform an active vulnerability assessment of the new Cyber Asset..." This is a valid requirement that cyber assets be in a CIP compliant state before being added to a production CIP environment. The issue is that this is written with the idea that an entity's new cyber asset is a separate physical asset it can configure in a compliant state prior to it being placed in a "production environment" and connected to a production network.

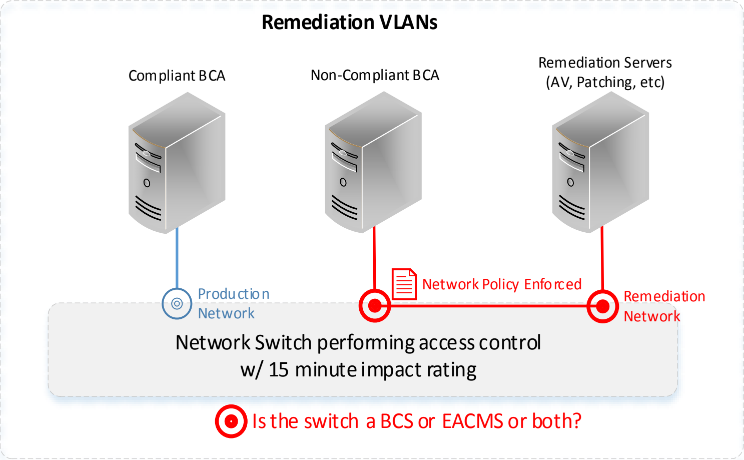

Figure 10

Virtualized environments, however, allow for a concept known as remediation VLANs. When a new cyber asset, such as a server or operator workstation is instantiated from an image, it is already "in" a production environment. However, it is brought up in a remediation VLAN where its network visibility is restricted to those services (patching, anti-virus updates, etc.) that it needs to assess vulnerabilities, update itself, and become compliant. Only after it is fully compliant with policy, can it be moved to a production VLAN where it has the full network visibility. Should this virtual machine become non-compliant with the network policy, it is moved back to the remediation VLAN to be made compliant again. This is an advanced security control, beyond what CIP-010 envisions, where real time checks are performed to ensure a cyber asset is compliant with security policy. The way the CIP standards are currently written, however, could preclude such advanced controls since this Remediation VLAN must be either part of an ESP or a separate ESP in order to host BCAs per CIP-005-5 R1. Requirements such as those in CIP-005 and CIP-010 need to be modified to allow for these more advanced features and controls.

Multi-Site Data Center Extensions (Super ESP)

There are technology solutions now that support very high levels of resiliency, so much so that virtual machines can be seamlessly moved from physical infrastructure at one data center across great distances to physical infrastructure at another data center. For example, control center functions could move easily and seamlessly from a primary control center to a backup control center across town or across the state. For this to work, an entity would use tunneling protocols that make the two data center networks appear as one local network ("layer 2 adjacency"). You've "stretched" a LAN across a WAN. The issue with CIP is that it assumes a LAN at each site with a defined ESP and access control at a point on that ESP at each site, with all the WAN communications equipment in between these ESPs exempted from scope. In

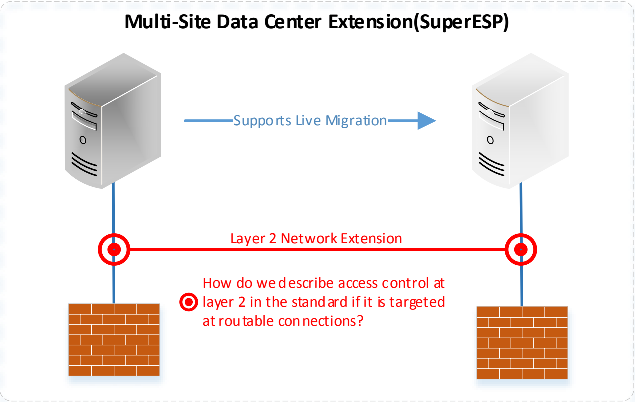

Figure 11

this situation, however, we have a single “local network” stretched between different sites creating at one level a “Super ESP”. Complicating the issue is that underneath this logical network extension, the data may actually ride in encrypted tunnels created at a routable protocol layer. At that layer, firewalls on an ESP can’t really provide any security, but that is prescriptively where the CIP standards say it must be done.

Chapter 3: Future Concept Example

Previously the proposed solution to address these issues with virtualization was a full embrace of the cyber system concept (retiring device level terms like Cyber Asset and BES Cyber Asset) and writing the technical requirements (e.g. CIP-005, CIP-007, CIP-010) at a more objective level. However, through industry feedback several important issues came to light:

- Eliminating the BES Cyber Asset definition and moving to the BES Cyber System as the sole foundational object with no further granularity would cause a complete overhaul and “do-over” of entities’ CIP-002 processes with insufficient benefit for the effort required.
- Requiring grouping systems by function exclusively conflicts with a number of different ways the industry has used the systems grouping flexibility; for example to group all Cyber Assets of a like operating system for patching purposes.
- Stating security objectives in requirements must be at a level where they are clearly measurable.

With these issues in mind, the future concept is to leave the foundational definitions largely unmodified. A “Cyber Asset” would remain as-is and be inclusive of the hardware as it is today. However, including the hardware for virtual cyber assets does not work, even though it needs to be protected the same as a discrete physical cyber asset. To resolve this the SDT will create a separate definition to capture virtual cyber assets so that they can be added to the applicability of the appropriate requirements. The hardware that provides compute, network, and storage resources would become its own new term to capture shared infrastructure and allow requirements to be written for risks unique to that environment. BES Cyber Systems would remain as-is and allow for all the various ways entities have used that concept to date.

The direction remains to establish objective level requirements but these need to be written at the appropriate level. For example, if CIP-005 R1 were written as “Mitigate the risk of unauthorized network access”, it is certainly an objective but is too high level to be measurable. No one would be able to state when, or to what degree this objective had been accomplished. If CIP-005 R1 were written as “Only allow known valid layer 3 IP addresses into or out of the network and implement this only at a Cyber Asset interface located only at the network edge”, it would be a prescribed topology and a prescriptive “how.” This should be avoided as it precludes much of the newer technologies presented in this paper. The latter is essentially the CIP-005 R1 of today and is one of the primary requirements that needs to change to remove this prescriptive topology and “how’s”.

An example of an alternative objective requirement that clearly describes a measurable “what” but avoids prescriptive “how’s” for CIP-005 R1 could conceptually be:

> *Deny all access to and from the networks on which high and medium impact BES Cyber Systems and their associated PCAs are connected and only allow network communication that has documented access permissions including the reason for granting access.*

This is a much clearer objective to accomplish but it avoids telling the entity how or where they must implement it or how their network must be architected. As for backward compatibility, an entity could still define an ESP with designated EAPs and provide firewall configurations as they do today. However, an entity using the advanced virtualization techniques from earlier in this paper, or future techniques to control network access that have not yet been contemplated can still show they meet this same objective.

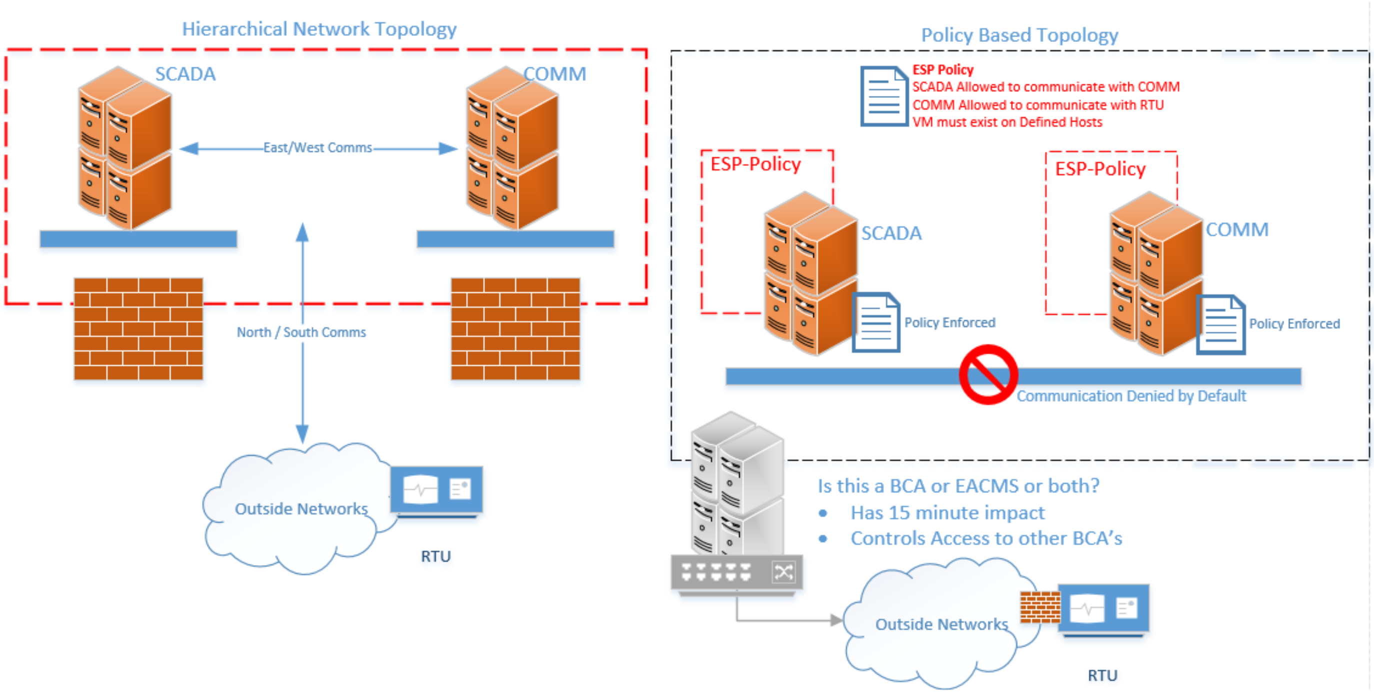

Figure 12

As shown in Figure 12, the current state ESP/EAP model on the left continues to be a valid architecture and topology with which to meet the objective. It is prescribed under the current requirements, but is not the ONLY way to accomplish the objective. On the right is a policy-based model in a fully virtualized system which can also accomplish the same objective once it is no longer prohibited by the requirement language. It has no distinct EAP; no distinct 'point' or 'interface' where the access controls are implemented. This is because the access policy is implemented throughout the infrastructure and the controls move with the virtual workloads. Access control is applied at a deeper level, closer to the functions that require protection and the policy allows no communication to occur that isn't explicitly allowed. The objective stated in the requirement can be met in either scenario.

For the asset classification, nothing changes for the architecture on the left. For the virtualized architecture on the right, the concept is to clarify that the systems in orange are virtual cyber assets, but without including the hardware. They exist as a virtual entity and need much of the same protection as a physical cyber asset. The systems depicted in grey are the Shared Infrastructure, a new asset class that hosts virtual cyber assets. Having these additional asset classes would allow the CIP standards to require protection appropriate to each class, whether a discrete physical system, a virtual cyber asset, or shared infrastructure hosting many virtual BES Cyber Systems.

]

Chapter 4: Conclusion

This paper has stepped through the benefits of virtualization in terms of increased reliability and resiliency for BES Cyber Systems. It also discusses how virtualization provides newer techniques for securing access to those systems, such as distributed firewalls and zero trust models. It has highlighted some of the issues created by several of these concepts and the required topologies contained within today's CIP requirements. Many of these issues revolve around the proper classification of cyber assets in virtualized environments and having asset classes whereby requirements can be properly scoped. Several other issues revolve around the prescriptive "how" of today's CIP-005 ESP/EAP model, the CIP-010 data requirements in a virtual storage world, or how CIP-011's requirements need minor changes to allow for technologies such as remediation VLAN's.

The CIP standards require some changes to:

- Address risks unique to virtualized environments such as the sharing of hardware resources and management plane access.
- Provide clarity around how to identify and categorize the various types of cyber assets in a virtualized infrastructure and scope requirements appropriately.
- Allow entities to fully implement newer security techniques in these environments that can provide higher levels of access control that are easier to manage, and don't require purchasing extra hardware to show compliance with prescribed topologies.

Many of these issues can be addressed as shown in the CIP-005 R1 example concept, where the prescriptive 'how' has been removed and replaced with a clearly stated security objective – one that fully allows for current state but also allows these newer techniques. Developing technology-agnostic security objectives can not only solve the issues presented by today's virtualization technologies, but also help address future issues brought about by technologies that aren't even contemplated today.

Project 2016-02 Modifications to CIP Standards
Virtualization and Future Technologies: Case for Change White Paper

Do not use this form for submitting comments. Use the Standards Balloting and Commenting System (SBS) to submit comments on the **Virtualization and Future Technologies – Case for Change White Paper**. Comments must be submitted by **8 p.m. Eastern, Friday, June 28, 2019**.

Additional information is available on the project page. If you have questions, contact Standards Developer, Jordan Mallory (via email) or at (404) 446-2589.

Background Information

Many entities in the Electricity Sector have implemented virtualization as part of their CIP programs. Many of these same entities, however, have implemented this new technology without taking full advantage of virtualization's advanced capabilities. There are a number of reasons for this, from the constraints of the current NERC CIP standards architecture to the ongoing ambiguity around how new virtualization technology applies to CIP compliance. Some of those who are implementing virtualization are experiencing a great deal of uncertainty and difficulty around developing implementation strategies that will support compliance and achieve greater reliability and security. The Project 2016-02 Standard Drafting Team (SDT) was assigned the task to address the technological innovation in virtualization within the CIP standards.

This paper presents the SDT's case for change to the NERC CIP standards. It discusses what is needed to allow for the innovative security techniques and new concepts brought about by virtualization. It outlines several technical areas where either prescriptive network topology in the standards or ambiguity around how to handle new security capabilities create issues. The paper then describes a high level way forward using new definitions for the virtualized environment. It also changes some requirements to technical security objectives, stating what security objective to achieve, but allowing the entity to choose the technology to accomplish it.

The SDT is interested in any comments you may have on the white paper.

Questions

1. Do you agree with the case for change based on the virtualization issues discussed in the white paper? Please provide comments.

   ☐ Yes
   ☐ No

   Comments:

2. Do you agree with the proposed path forward as discussed in the white paper? Please provide comments.

   ☐ Yes
   ☐ No

Virtualization and Future Technologies: Case for Change Webinar Q & A

Project 2016-02 Modifications to CIP Standards

The Project 2016-02 Modifications to CIP Standards Drafting Team (SDT) held a Virtualization: Case for Change Webinar on April 24, 2019. The following items are questions and answers from the webinar. The SDT encourages industry to review this document prior to responding to the Case for Change Informal Comment period.

Q1. The White Paper states "Here it is clear the physical server hardware and the hypervisor are in scope and each VM is subject to requirements such as CIP-007" (page 3). Is it the SDT's position that this is true for hypervisors ONLY containing EACMS?

A1. No, the Cyber Asset definition is used for all asset classes including EACMS, BCA, PCA, etc. and it is inclusive of hardware. What the SDT is pointing out is that:

- If the Cyber Asset definition is inclusive of hardware and;
- If the entity classifies their VM as a Cyber Asset; then the hardware is included in that definition.

Q2. With the Zero Trust Model, now it looks like it would allow the co-located systems without a separate EAP (gated) around the ESP, and allow VM's to be an EAP/ESP individually and would not be requiring physical segmentation from NON-Compliance systems.

A2. Zero trust is a methodology for implementing access control and integrity. In principle the services on top in this model would not even trust their own underlying architecture. We will talk later in the presentation about the SDT's strategy for handling mixed-mode or mixed trust systems through the use of new requirements targeted at new definitions.

Q3. Since a Cyber System can be one CA, doesn't the model on the right just provide defense in depth, like physical security?

A3. An ESP within an ESP? The SDT does not believe the standard should prescribe a particular technology solution to these issues. In addition, within the standard the entity's network access control is only measured at the network edge. We believe the entity does not get credit for the defense in depth strategy, so it does not encourage them to use it.

Q4. As you discussed the BCSI issues, how will this team work with the separate SDT working on BCSI?

A4. Both CIP SDTs will keep open collaboration regarding BCSI through the development of each project.

Q5. The Case for change paper speaks to Distributed Firewalls as a more secure option in a virtualized involvement. Why can't this approach be effectively used in today's environment either behind an identified EAP or have the large ESP broken down into multiple ESPs?

A5. The SDT does not believe the standard should prescribe a particular technology solution to these issues. Within the standard the entity is only measured at the edge and we believe the entity does not get credit for the defense in depth strategy so it does not encourage them to use it.

Q6. To clarify: if a hypervisor hosts EACMS and non-EACMS, is the hypervisor an EACMS? Are the other non-EACMS VMs high watermarked? We've been told EACMS do not high watermark like BCAs.

A6. The SDT believes that how to handle the described scenario is unclear. This is the primary reason that it was presented in the challenges section of this presentation. EACMS relies on the CA definition and the CA definition includes hardware.

Q7. In regards to VLANs on a switch and port security. If I am using a trunk port connecting to a firewall, would this make the switch an EACMS? When any type of port security is used, i.e. mac security or 802.1x ... would this also make the switch an EACMS?

A7. The SDT believes that this is also an area that needs clarity. Through our analysis the switch itself performing the access control could fall into the EACMS category. However, if it has a 15 minute impact it may also fall into the classification of a BCA.

Q8. Why is the SDT working on still addressing hardware instead of addressing the Virtual environment risk (using the highest risk application principle)? SDT is not the first to draft virtual security, PCI council and NIST already have a risk based approach.

A8. The SDT believes that it is not simply addressing the hardware but that the existing definitions are limiting our ability to describe virtual environments. We have been looking to other frameworks as guides to effectively describe these new technologies while maximizing our ability to be backward compatible with existing programs.

Q9. BCSI explanation was very confusing. If SAN is part of the environment, why should not the storage area be the focus?

A9. The SDT is addressing the storage architecture as a core area of virtualization as you will see on many of our drawings. While changes may be needed, we are not directly addressing the handling of BCSI at this time because there is a separate team evaluating the topic.

Q10. For Entities that are moving toward virtualized environments, will the SDT provide some guidance for those moving to it prior to the finalization of the revised standard? Alternatively, will there be a pilot implementation group similar to the V5 TAG pilot?

A10. The SDT plans to provide as much clarification as possible through guidance, outreach, and white papers. Many entities are already using virtualization in their environments and we will try to work with NERC to help provide a smooth transition.

Q11. What is SCI?

A11. Shared Cyber Infrastructure. It is a new definition to target requirements at the shared infrastructure on which virtual objects (machines, networks, and storage) execute (As depicted in grey in the drawings).

Q12. Does the proposed approach for the “shared infrastructure” categorization create a dual standard for compliance between data center (compliance at SCI) and substation environments (compliance at BCA level with ports and services and passwords, etc.)?

A12. The SDT plans to use the new term for Shared Cyber Infrastructure to target applicability within the standards.

Q13. From slide 27, how does the approach to 'deny all access to and from networks, with "networks" being the operative term, permit the use of a zero trust model. Doesn't this still prescribe the gated community model and preclude 'house'-level protections?

A13. The language on the screen was draft and we realize that it may not be the correct target for this requirement. We did want to share this approach with you for your consideration as we continue to draft better requirements.

Q14. How do you address the problem of VLAN hopping/crossover? Do you make a distinction between port based and logic based VLANs?

A14. To date, the SDT has been using the concept of logical isolation that can be created by various means including those you mentioned. The entity would be responsible to prove that their logical isolation is sufficient to meet the requirements.

Q15. Can you clarify the segregation requirements of shared storage? I understand the need for separate hosts for CIP and non-CIP assets - does that mean we need separate storage arrays or will logical access controls that segregate LUNs to hosts suffice?

A15. As we have been describing it so far, we would need to draft a new requirement targeted at the shared infrastructure to create logical separation. Those requirements are not yet complete.

Q16. Are there any lessons learned that will be delivered soon about those challenges?

A16. The SDT has been working on a model we call Pinecone Power, a fictitious entity that will be the foundation for guidance and future lessons learned whitepapers.

Standards Announcement

2016-02 Modifications to CIP Standards
Virtualization and Future Technologies: Case for Change White Paper

Informal Comment Period Open through June 28, 2019

Now Available

A 30-day informal comment period for the **Virtualization and Future Technologies: Case for Change White Paper** is open through **8 p.m. Eastern, Friday, June 28, 2019.**

Commenting

Use the Standards Balloting and Commenting System (SBS) to submit comments. If you experience issues using the SBS, contact Wendy Muller. An unofficial Word version of the comment form is posted on the project page.

- *If you are having difficulty accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out, contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern).*
- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*
- *Please be mindful of ballot and comment period closing dates. We ask to **allow at least 48 hours** for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts **prior to the last day.***

Next Steps

The drafting team will review all responses received during the informal comment period and determine the next steps of the project.

For information on the Standards Development Process, refer to the Standard Processes Manual**.**

For more information or assistance, contact Standards Developer, Jordan Mallory (via email) or at (404) 446-2589.

Comment Report

Project Name:	2016-02 Modifications to CIP Standards | Virtualization and Future Technologies: Case for Change White Paper
Comment Period Start Date:	5/30/2019
Comment Period End Date:	6/28/2019
Associated Ballots:	

There were 30 sets of responses, including comments from approximately 84 different people from approximately 61 companies representing 10 of the Industry Segments as shown in the table on the following pages.

Questions

1. Do you agree with the case for change based on the virtualization issues discussed in the white paper? Please provide comments.

2. Do you agree with the proposed path forward as discussed in the white paper? Please provide comments.

1. Do you agree with the case for change based on the virtualization issues discussed in the white paper? Please provide comments.

Shirley Mayadewi - Manitoba Hydro - 1,3,5,6 - MRO

Answer	No
Document Name	

Comment

We disagree with the case for change based on the virtualization issues.

In our view, except the Cyber Asset definition doesn't clearly include virtual machine, all the cases that are listed in the white paper can be addressed by the current Version CIP standards without significate changes.

The following are our assessments and suggestions for each case in the white paper:

1. Identification of Virtual Cyber Assets

We agree the current Cyber Asset definition doesn't include virtual machines explicitly. Given that any requirements apply to virtual cyber assets should as well as apply to physical cyber assets for the logical consistency, we suggest to modify the Cyber Asset definition to include virtual cyber asset rather than creating a new term "Virtual Cyber Asset", otherwise, the applicable system will become more complicated such as Virtual BCA, Physical BCA , Virtual EACMS and Physical EACMS, etc. We suggest modifying Cyber Asset definition as follows:

"A programmable electronic or virtual devices, including the hardware or virtual hardware, software, and data in those devices. Each virtual machine and host is a distinct device."

In addition, we suggest the hypervisor host should be identified as follows:

- the hypervisor host that contains one or more BCAs must be identified as a highest impact level BCA since it meets BCA criteria (deleting a BCA causes 15 minutes adverse impact).
- the hypervisor host that contains one or more EACMS must be identified as an highest impact level EACMS
- the hypervisor host that contains one or more PACS must be identified as an highest impact level PACS
- the hypervisor host that contains one or more BCAs, PCAs and EACMS must be identified as an highest impact level BCAs (high water-marking)

2. Distributed Firewalls vs. Perimeter Models

We haven't seen any challenges for applying current CIP requirements to this case. After VM falls within modified Cyber Asset definition, the Perimeter Model would apply to VM. If SDT thinks the ESP is not enough for the defense in depth and wants to add another layer network access control at an individual asset level (zero trust Model), it would become an expansion of CIP-005 requirements, which has nothing to do with virtualization. If it is allowable for individual VM to have high-level policy based network access control (zero trust Model) without designating perimeter level ESPs, the individual physical cyber asset should be allowable to do so as well (e.g., using local host firewall). In this case, CIP-005 R1.1 will be still applicable and CIP-005 R1.2 needs to be modified as follows for allowing device level network access control as an alternative measure:

“All External Routable Connectivity must be through an identified Electronic Access Point (EAP) or have network access control on each individual applicable Cyber Asset.”

Even though virtualization environments can force network access control at more granular levels including by user, process, or certificate and are not limited to only a source/destination IP address of a routable protocol, entities cannot get around the routable connectivity for the virtual networking. Regardless of virtual or physical network environments, routable protocols will be involved since only routable protocols allow devices to communicate between two different networks by forwarding packets between the two networks. Non-routable protocols only use a “device” address, and do not allow messages to be sent from one network to another, thus allowing communications to take place only on a single network. Note that Layer 3 protocols such as IP are often encapsulated in Layer 2 protocols such as Frame Relay, ATM (“Asynchronous Transfer Mode”), and MPLS (“Multiprotocol Label Switching”) for delivery of packets to distant networks. When such mechanisms are employed in Layer 2, the IP routable protocol is still in use. Therefore, the routable connectivity and ESP that have been used in current CIP standards are still correct and effective for addressing network access controls in a physical or virtual networking environment. Defining a new term ESZ is unnecessary since it cause more confusing and more unnecessary topology changes unless the project goal is for the defense in depth.

3. Virtualized Firewall Interfaces (‘Firewall on a Stick’)

We haven’t seen any challenges for applying current CIP requirements to this case. This switch with a firewall module can be addressed as follows using the current CIP requirements:

- For the layer 2 switch, If the switch is identified as a BCA, all (virtual and physical) devices are connected to the switch must be within an ESP
- For the layer 3 switch, the virtual firewall or the physical firewall module can be identified as a separate ECAMS containing EAP.
    - If the switch meets BCA criteria, it should be identified as a BCA, otherwise as an EACMS, where all non-BCA devices that are connected to the switch can be segregated by the above firewall.

  Given that the switch with a firewall module is not prohibited by the current CIP requirements, we don’t think the new asset classifications such as ESZ and SCI are needed.

    - 4. Virtual Storage Challenges

We haven’t seen any challenges for applying current CIP requirements to SAN. Also we disagree the SAN is only related to the CIP-011 information protection since SAN is normally used by a CIP Cyber Asset for the real time operations. Given that virtual or physical SAN like a local hard drive is used for the real time operations of a (virtual or physical) Cyber Asset; it must be treated as part of the Cyber Asset. For instance, if the Cyber Asset is a BCA, the SAN device must be identified as BCA and all BCA requirements would apply. If entities don’t want high-water marking the whole SAN as a BCA when the SAN is used in a mixed-trust environment, they should separate the non-BCA SAN for BCA SAN.

5. Management Plane Isolation

We haven’t seen any challenges for applying current CIP requirements to management plane. We disagree a shared cyber infrastructure classification is needed. The management plane device should be identified as part of CIP Cyber Asset it manages as follows:

- If the management plane device is used for creating, modifying, or deleting a virtual BCA, it meets BCA criteria (misuse causes 15 minutes adverse impact) and must be identified as a BCA.
- If the management plane device is used for creating, modifying, or deleting a virtual EACMS or PACS, it should be identified as an EACMS or PACS device. For clarifying this identification, we suggest modifying EACMS and PACS definitions to include the management devices as follows:

Modified EACMS: “Cyber Assets that perform electronic access control or electronic access monitoring of the Electronic Security Perimeter(s) or BES Cyber Systems. This includes the Cyber Assets that can create, modify or delete the said Cyber Assets and Intermediate Systems”

Modified PACS: “Cyber Assets that control, alert, or log access to the Physical Security Perimeter(s), exclusive of locally mounted hardware or devices at the Physical Security Perimeter such as motion sensors, electronic lock control mechanisms, and badge readers. This includes the Cyber Assets that can create, modify or delete the said Cyber Assets.”

The concept of Figure 8 examples is wrong since BCA cannot be identified as an EACMS from the identification methodology perspective. In addition, if the management plane doesn’t meet BCA criteria, it would be a remote client and has to pass through an Intermedia System or identify the management plane itself as an Intermedia System.

6. Privileged Introspection

We haven’t seen any challenges for applying current CIP requirements to privileged introspection. After resolving the identification of Cyber Asset and management plane (see above), the current CIP-007 R3 already written at a security objective level and can work with privileged introspection seamlessly.

7. Remediation VLANs

We haven’t seen any challenges for dealing with remediation VLAN using current CIP requirements. As we described in Section 3), if the virtual firewall or the physical firewall module is identified as a separate ECAMS containing EAP, regardless of whether the switch is identified as a BCA or not, the remediation VLAN that is connected to the switch can be segregated from ESP since the remediation VLAN is not required to be within ESP by the current requirements if the remediation VLAN doesn’t contain any BCAs.

8. Multi-Site Data Center Extensions (Super ESP)

We haven’t seen any challenges for applying current CIP requirements to a super ESP. For the current CIP requirements, if a super ESP is designated across multiple geographic locations, all Cyber Assets within the ESP must be identified as BCAs or PCAs. If a primary control center to a backup control center across town or across the state, the Cyber Assets between two locations within a super ESP may be impossible to be managed as PCAs since some switches and routers may be owned by third parties. In this case, super ESP is not allowed by the current requirements and it is reasonable. Given that Protocol tunneling can explicitly bypass security restrictions and poses a serious challenge to network security, SDT shouldn’t modify the current CIP-005 requirements to allow use tunneling protocols between Control Centers within a super ESP without identifying in-between switches and routers as PCAs for protection.

Comment

Note - please see attached word version as well as it has pitures which do not show up in this rich text box.

While the whitepaper provides some insightful thoughts on why change may be required, it is trying to create a solution for a problem that does not exist. This paper seems more of a proposal for allowing mixed-mode or mixed-trust environments as opposed to a need for change to accommodate virtualization. The term “shared infrastructure,” in the last paragraph in the Introduction section on page iv seems to hint towards a case for mixed-mode or mixed-trust environments. The term “shared infrastructure,” is not further documented or mentioned throughout the paper nor are it’s benefits communicated in the “Chapter 1: Virtualization Benefits” section. In addition to the concept of shared infrastructure, Figure 1 seems to leave out some critical layers of the conversion including the Hypervisor and network layers which is what logically and sometimes physically manages and connects the layers together as described in my proposed updated figure shown below.

Additionally, all of the benefits specifically listed in the “Chapter 1: Benefits of Virtualization,” section can already be used in the current CIP Standards just not used in a mixed-mode or mixed-trust environments. If all systems are high watermarked within the “shared infrastructure,” along with the proposed techniques and concepts being brought into scope, there would be minimal to no need for change.

Most entities audited to date in the RF footprint understand how a Guest VM should be categorized, with no changes to the current Standards or Requirements. As stated in the Guidelines and Technical Basis for CIP-005 – Electronic Security Perimeters (ESP) are required as a primary defense layer for those BES Cyber Systems (BCS) that may not have inherent cyber security functionality (such as relays, RTUs, or other physical Cyber Assets that would remain unprotected in some of the scenarios presented). In addition, the ESP provides clarity to determine what systems or Cyber Assets are in scope and what requirements they must meet. This does not preclude the use of a Zero Trust Model, but places the burden of compliance (and explanation at audit) on the Responsible Entity wanting to implement said model. Not only is there a burden of compliance, but also an additional burden of implementation and compliance with zero trust model technology on network, server, and security engineers and administrators.

For well over 10 years, most Microsoft, Linux, and Unix based operating systems have the ability to enforce zero trust models through built-in firewalls and application layer firewalls such as but not limited to:

- Microsoft Windows Firewall
- Ipchains
- ipfirewall
- iptables
- Netfiler
- nftables
- Anti-Virus/Anti-Malware vendor tools.

In many instances, these firewall services are disabled due to the complexity of:

- Troubleshooting network or application issues
- Changes in application network behavior from upgrades or patches
- Maintaining the additional amount of host based rulesets individually or through centralized management that would need to be assess per BES Cyber Systems and Cyber Asset.

-
- Whether zero-trust model tools as the ones described above, introspective versions done through a middle-ware layer in virtualization hypervisors, or 3rd generation switches/firewalls are used, these tools will not be a set-and-forget implementation. They will require regular tuning and maintenance, monitored closely through change management and require more documented elements to track and show for baselines and change management. Zero-trust models regardless of virtualization will greatly improve security and would be highly encouraged to do so, but it will require a high degree of monitoring, review, and constant tuning.
-
- Whether a zero-trust model and introspection tools are enforced or not, the underlying hardware supporting both the hypervisor and Guest VM are required for the operation of the Guest VMs, therefore it must be high water marked to the level of highest Applicable System impacted by the loss of associated physical hardware. This argument is the same for the hypervisor – without which the Guest VM cannot function or operate. Ultimately, minor changes to definitions to assist Responsible Entities in identifying and categorizing virtual devices would be beneficial, but not to the degree called for in the white paper and further cautions against mixed-mode and mixed-trust environments.

Many of the techniques and concepts described in the whitepaper are already allowable even though they are not specifically called out in the current standards or guidance. Many of the techniques and concepts could be used as above and beyond compensating controls for Technical Feasibility Exceptions (TFE)s and for Patch Mitigations. Noting these techniques and concepts as requirements for virtualization could preclude them from the use as TFEs and Patch Mitigations.

While virtualization is not specifically defined in the Standards, there is sufficient understanding between the Responsible Entities and CIP Auditors to set expectations and employ professional judgement to support the security of the BES at this time. Admittedly, virtualization will require minor changes in the current definitions to assist Responsible Entities with identifying Cyber Assets and their associated hypervisors and physical hardware, but not to the level outlined in the white paper.

Finally, RF noted that the white paper authors seemed to find extreme examples to include without noting more common layouts and examples that many Responsible Entities have already implemented. A suggestion would be to modify the current white paper to balance the examples presented with examples that Responsible Entities already have in place for further review and discussion.

Response

Trevor Tidwell - PNM Resources - 1,3 - WECC,Texas RE	
Answer	No
Document Name	
Comment	

As the question is overly broad, we will be providing comments broken down for the individual issues.

Identification of Virtual Cyber Asset – YES

PNM Resources agrees that there is a need to allow the Cyber Asset model to apply to virtual machines. There is also a need to identify the shared infrastructure the virtual machines need to function. Furthermore, the standards need to address when a machine has multiple CIP roles. For example, BES Cyber Asset that has only local accounts could also be considered an EACMS. If it has only local accounts is it not also preforming electronic access control? Or does the device high watermark to BCA? The current implementation guidance is not clear on this.

In addition to virtual machines the SDT needs to consider that technology is changing. Virtual machines are a decades old concept, but the standards are far behind at addressing. Today virtual applications or process virtual machines are also a reality. Depending on the implementation the virtual machine hosting the virtual application may be created from a template when the user calls on the application. The virtual machine is then destroyed when the application is closed. This mayfly virtual machine would have a hard time with the current CIP requirements. Yet this is a concept that virtualization allows and yet the white paper doesn’t address it.

Distributed Firewalls vs Perimeter Models – NO to the current reason

It is unclear as to why virtualization is driving this change. The white paper states, “This perimeter model is a prescriptive topology, and for many scenarios is still a valid way to perform network security. What may be prescribed, however, for a small network of similar cyber assets may not be ideal for a large network of virtualized BES Cyber Assets.” It doesn’t consider that it may not be ideal for even a large network of cyber assets. Virtualization may have a use case where the standard needs to allow for the distributed model, but the actual impetus for this is the current standard is overly prescriptive. It doesn’t allow for a defense in depth approach. Ideally entities would be using both the perimeter model and each host also protected with its own firewall. The white paper should make it clear that the current standard is preventing a more robust security approach that could apply to non-virtual systems. This is not a virtualization challenge in the NERC CIP Standards, but a challenge of overly prescriptive standards.

Zero Trust Models – NO to the current reason

The white paper does not make much of a case for change when it comes to the Zero Trust Model. Yes, the problem is that if a person gets past the community gate (EAP) and fence (ESP), then they could get into the house (Cyber Asset). This is not a problem with just virtual cyber assets, but physical cyber assets. It is unclear if a Zero Trust Model is required for only virtual cyber assets when physical cyber assets have the same problem.   Gated communities exist to provide a second layer of protection. The white paper doesn’t make it clear if this is an either-or proposition or if both will be allowed.

Virtualized Firewall Interfaces (‘Firewall on a Stick’) – NO to the current reason

Most of the problems such as the EAP conundrum in the Virtual Firewall Interfaces section are already covered in the Distributed Firewall vs Perimeter Models and Zero Trust Models and addressed by our comments in those sections. The more unique issue brought up in this section is regarding the question if the Network Switch is a BCS, EACMS or both. This concept is one that we have already discussed in our comments regarding Identification of Virtual Cyber Assets. This scenario highlights again that the standards are not clear regarding multi-role devices. Multi-role issues are not unique to virtualization. This is not a virtualization challenge in the NERC CIP Standards, but a potential gap in the current standards that impacts non-virtualized systems as well.

Virtual Storage Challenges – NO to the current reason

The white paper discusses challenges to virtual storage. The example of a Storage Area Network (SAN) or Network Attached Storage (NAS) array could very easily apply to a Redundant Array of Independent Disks (RAID). All entities should be utilizing a RAID on their BES Cyber Assets, so it is unclear why this challenge only comes up with virtual systems. It is unclear what this statement from the whitepaper means, “Additionally, there is no significant benefit to pulling drives from an array to sanitize or destroy them if there is another way to manage this media.” Is this saying that there is problem with CIP-011 when it comes to any disk array like a RAID. If so, does this mean that CIP-011 with regard to disposal or reuse should not apply to individual drives in an array? This is not a virtualization challenge in the NERC CIP Standards, but a challenge of overly prescriptive standards that impacts non-virtualized systems as well.

This topic also discusses de-duplication. This is not just an issue of virtualization. Many backup systems also employ de-duplication since many systems have similar information as described in the white paper. What happens to de-duplicated backups if all the BCAs are retired in a system upgrade, but some systems that share the de-duplicated data remain? Is the backup storage media still containing BCI or not? De-duplication is not just an issue of virtualization. This is not a virtualization challenge in the NERC CIP Standards, but a challenge of overly prescriptive standards that impacts non-virtualized systems as well.

Management Plane Isolation – NO to the current reason

The white paper discusses controlling access to the management plan of virtualized systems because they are logical constructs. However, this is not exclusively a virtualization issue. Many modern Cyber Assets that are servers or appliances have a baseboard management controller. This is the management plane of a physical server. If management plan isolation is an issue, then it an issue under the current standards for existing physical cyber assets. This is not a virtualization challenge in the NERC CIP Standards, but a potential gap in the current standards that impacts non-virtualized systems as well.

Privileged Introspection - NO to the current reason

While privileged introspection is a concept that does not have a physical corollary like some of the other concepts mention in Chapter 2, the paper fails to clearly identify the problem. The problem with “helper VMs” is that they have access to the entire kernel memory of the VMs they are monitoring. This kernel memory is “information about the BES Cyber System that could be used to gain unauthorized access or pose a security threat to the BES Cyber System." So, the "helper VM" contains BCSI. CIP-011 already requires procedures to protecting and securing handling BCSI including its storage, transit, and use. The "helper VM" is thus a designated storage location of BES Cyber System Information per CIP-004-5 R4.1.3., R4.4, and R5.3. This concept of a storage location isn't even in CIP-011-2, so the objective could be clarified in CIP-011-2 that storage locations of BES Cyber System Information needs to be identified. This is not a virtualization challenge in the NERC CIP Standards, but a potential gap in the current standards that impacts non-virtualized systems as well.

Remediation VLANs – NO to the current reason

The problem brought up in the white paper regarding adding a Cyber Asset under CIP-010 R3.3 is not unique to virtual systems. Virtual images can be physically moved from a non-production environment to the production environment using Removal Media just as a physical device is moved from non-production environment to the production environment. The concept of a remediation VLAN is misconstrued in the white paper. A limited VLAN with restricted network visibility can be setup for physical Cyber Assets so they can be assessed for vulnerabilities, update itself, and apply security controls to become compliant. The issue of the VLAN being inside the ESP or a separate ESP is the same. The remediation part only comes in when a machine becomes non-compliant and it is moved to the remediation VLAN. Any network switch utilizing Network Access Control can accomplish this.   This is not only possible with virtualization. This is not a virtualization challenge in the NERC CIP Standards, but a challenge of overly prescriptive standards that impacts non-virtualized systems as well.

Multi-Site Data Center Extensions (Super ESP) - YES

While the problem of Super ESP is introduced with a virtualization use case the reality is that the problem is anytime an entity stretches the layer 2 LAN across a WAN. At least the white paper in the last sentence of the section recognizes that the problem is not with virtualization, but prescriptive CIP standards that do not allow security measure that could achieve the security objective to be located somewhere.

Summary

PNM Resources does not see the challenges as being issues brought about by virtualization. Instead the problem is prescriptive standards that do not allow for other means to accomplish security objectives. Virtualization just happens to be the current technology that has revealed the prescriptive approach to cyber security is broken. It is to slow to change and the actual case for change is prescriptive standards don't allow for future methods to be easily applied and remain compliant. The standards drafting process is too slow to keep adjusting every time best practices for cyber security change. The white paper is "Virtualization and Future Technologies" yet future technologies is only referred to once in the document. The issue isn't even virtualization. The problem is the standards have prescribed best practices as a particular point in time. However, technology of how tasks are done is changing and with it is the technology of how to secure it. What isn't changing as much are the objectives of security which is discussed more in response to question #2.

Response

Leanna Lamatrice - AEP - 3,5

Answer	Yes

Document Name	
Comment	
AEP supports the efforts of the SDT to change or add definitions and requirements related to the application of virtualization technology to an objective level; making the language describe “what” is required not “how” it is to be implemented. The danger is that the requirement language may be too broad thereby adding to the compliance burden and making compliance assessment more difficult or; too specific such that it excludes viable security solutions. AEP requests the SDT take the time necessary to find that “just right” language that creates the desirable outcomes and avoids unintended consequences.

Comment	
Reclamation supports modifications to the CIP standards to future-proof the standards and allow for changing technologies. The proposed approach will benefit industry by allowing entities to achieve compliance while protecting their BES Cyber Systems regardless of the composition of the BCS. Reclamation supports a less prescriptive and more objective-based security framework that allows entities to define their systems at the level that makes sense for a situation. Reclamation recommends the SDT clarify the usage of “(compute, network, storage)” on page 3 of the white paper. Reclamation also recommends a more thorough quality review of the white paper to correct typographical errors throughout the document.

N&ST considers it reasonable to calll attention to virtualization's potential benefits, but only up to a point, and we consider the WP's negative comments about many current CIP implementations (e.g., Fig. 4 "Perimeter Based Model" is characterized as "Not aligned with current security best practices") to be needlessly pejorative. Moreover the WP:

- makes several assertions that N&ST considers inaccurate, such as the suggestion that multi-site ESPs and the current Standards are incompatible,

- pays fairly little attention to the issue of how compliance with current or modified CIP Standards could be demonstrated, and

- does not directly address the question N&ST believes entities have found most nettlesome, which is whether it is allowable for CIP and non-CIP VMs, managed by a single hypervisor, to coexist on a shared hardware platform and, if so, what conditions would have to be satisfied.

These concerns notwithstanding, N&ST agrees with the WP's main premise, which is that the Standards, along with several current definitions such as "Cyber Asset," should be updated to accommodate entity implementations that are partially or even entirely based on virtual systems. N&ST also strongly supports the goal that any and all revisions should be developed in a manner that fully supports "backward compatibility" and does not compel entities with no major technology updates on their planning calendars to revise their existing set of CIP policies, plans, and procedures.

EEI member companies generally agree that the SDT has provided a clear and concise case for change based on the virtualization issues identified within their white paper. We recognize that steps need to be taken to provide a path forward for those entities that see reliability and security benefits in virtualization technologies while not disrupting the compliance programs of others. EEI appreciates the direction described in the white paper and support the SDT's current, more moderate approach, which we believe will better ensure broader industry acceptance of the changes being proposed. However, more work is needed to identify the security risks associated with virtualization and address methods to mitigate those risks to ensure continued BES reliability and security. We also note that while cloud computing is not directly addressed in the white paper, the document should be clear that the SDT's approach is not seeking to enable the use of off-premise third party cloud platforms for BES system operations (e.g., Supervisory Control and Data Acquisition (SCADA)).

EEI member companies would also like to take this opportunity to commend NERC and the SDT on the proposed direct described in the white paper while also encouraging NERC's long term objective of transforming the NERC CIP Reliability Standards into a body of standards that more closely conform to the results-based standards concept that currently drives all other NERC Reliability Standards. Still, EEI believes that the drafting team has selected the right path for this current effort.

In the white paper, and Q9 in the Q&A document, it’s unclear whether the SDT is treating a Storage Area Nework (SAN) as a separate BES Cyber Asset (BCA) or only as a BES Cyber System Information (BCSI) storage location. NRECA requests that the SDT clarify this going forward. NRECA recommends that the SDT be congnizant of the layering that can occur through virtualization, especially if the CIP requirements are already applying to the hardware. In this situation, any new requirements applying to virtual devices on that hardware should be limited or non-existent. The current CIP standards are unclear as to whether a programmable electronic device definition can exclude a virtual machine. NRECA recommends that the SDT take this into consideration while drafting new or revised requirements.

Comment

Seattle City Light finds the white paper to be an excellent summary of the technological evolution in virtualized systems and the challenges the standards drafting body faces in updating the standards to accommodate that evolution. We were very impressed by how well the technical concepts of virtualization were described for a non-technical audience and how they were cross-referenced to the existing physical asset-centric approach of the current standards.

The Q&A document illustrated that, as good as the white paper was, there is still work to be done to help the industry not lose sight of the forest for the trees.

ERCOT requests that the SDT make clear whether the implementations referenced are for on-premises solutions only. If the intent is to include cloud provisions, that should be articulated specifically. There is a lot of dispute about cloud solutions for BES Cyber Systems and other asset types subject to NERC CIP Standards that may not make this the right venue to address and achieve a timely solution as noted in the paper. More concrete work is needed by NERC related to cloud services before it is appropriate to include those issues.

Many of the concepts documented in the paper also apply to physical systems. The paper points out some significant vulnerabilities with current implementation. ERCOT requests that the SDT look at these issues as well as the virtualization issues to ensure that gaps are addressed with legacy systems.

Systems and technologies supporting Control Centers, where IT-based solutions are prevalent, are rapidly evolving beyond concepts that are foundational to the current NERC CIP Reliability Standards. Multiple vendors have indicated intentions to fully virtualize their offerings in the next few years, and hardware suppliers are hinting that the traditional rack-mount physical server will no longer be an option in the future. The SDT's case for change focuses on virtualization, but the concepts discussed apply to future-proofed network technologies that provide higher resiliency and flexibility for critical communication flows and to server hardware as it becomes hyper-converged with multiple individually-programmable components inside. The NERC CIP Reliability Standards must evolve to support these technology advances. Although some lag behind bleeding edge tech is expected regulatory standards should not preclude the use of resources that are generally available and meet security objectives, such that entities are forced to turn to grey-market sourcing in an effort to obtain compliant resources.

Texas RE appreciates the standard drafting team's (SDT) effort to align the NERC Reliability Standards within the current technology. Texas RE agrees with the following concepts described in the white paper:	

- Identification of Virtual Cyber Assets: Texas RE believes providing clarity on how to identify and categorize Virtual Cyber Assets to ensure consistency across all regions would be beneficial for the industry.
- Virtual Storage Challenges: Texas RE agrees that with the proposed changes to CIP-011-2 R2 there may be difficulties proving compliance in a virtualized storage environment.
- Remediation VLANs: While it is technically possible to comply with CIP-010-2 R3.3 in a virtualized environment Texas RE recognizes that additional clarity on how to deploy this technology in a secure and compliant manner would benefit the industry.

The white paper appears to argue that certain components of virtualization are not possible due to the way the standards are written. While Texas RE agrees there could be additional clarity and specific mention of virtual machines, nothing prevents entities from implementing the following:

- Distributed firewalls: Perimeter controls would also need to be deployed to meet CIP compliance, however this existence of perimeter controls does not prevent entities from deploying additional controls.
- Zero Trust Models: Perimeter controls would also need to be deployed to meet CIP compliance, however this existence of perimeter controls does not prevent entities from deploying additional controls.
- Management Plane Isolation: Entities are capable of deploying secure management plane communications today.
- Privileged Introspection: CIP-007-6 R3.1 states “Deploy method(s) to deter, detect, or prevent malicious code.” An entity using privileged introspection would only need to document that this is their method of deterring, detecting, or preventing malicious code. The SDT also stated that this technology would require grouping VM’s protected by privileged introspection into a particular BES Cyber System. Texas RE is unsure why the SDT believes this to be the necessary.

Texas RE suggests that the discussion surrounding Multi-Site Data Center Extensions (Super ESP) is applicable to all Super ESPs, and is not a change specifically necessary for the standards to be able to successfully address virtualization.

Additionally, Texas RE is concerned with a mixed-trust environment. Due to the parent child relationship between host and virtual machine, you can never fully eliminate impacts a VM could have on other VM’s and the host.

2. Do you agree with the proposed path forward as discussed in the white paper? Please provide comments.

Trevor Tidwell - PNM Resources - 1,3 - WECC,Texas RE

Answer	No
Document Name	

Comment

The path forward should be more requirements focused on an objective and meeting that objective. Allow the entity to define how it is meeting the objective, so that it can be changed as security technologies change, but the objectives generally do not change as much over time. New threat vectors may arise and necessitate a change to the standards to add a new objective, but that is easier to achieve than rewrite the prescription on how to stay compliant.

The reason for the no vote is for two reasons. The first is that the proposed path forward isn't entirely clear. While the whitepaper appears to be suggesting that the path forward is more objective than prescriptive, it is short on detail. It gives only one example and would be better off with a couple of more if the intent is to truly move to objective level rather than prescribing the method of meeting the objective. In a world of Advanced Persistent Threats, we need to move to an objective model. While the threats are persistent, they are not static. Industry best practices typically are our defense playbook. These threats adapt to the playbook and find new ways defeat it. As a result, technology and practices used by industry change in response. Yet the security objectives remain the same, but the means of doing so have changed. Writing the NERC CIP Standards to mimic today's best practices do not allow industry to have the ability to adapt when those practices change. As a result, Entities are potentially more exposed to a threat because a new security method doesn't fit the prescription imposed on it. Technology is always changing and writing a prescription for security methods today and attempting to look to the future is a fool's errand. We cannot image today what technology will be like in 5 to 10 years. However, we can foresee what the security objectives are. It is much like war where the objectives are the same, but over the centuries the tools of warfare have greatly changed how you achieve those objectives.

The second reason for the no vote is that the current path forward does not address defense in depth. For example, if an entity implemented both a perimeter and distributed firewalls and had a failure of a perimeter control, but all the devices in the ESP had some compensating control that mitigated the risk of the failure then that should not be a violation of the standards. While one method of achieving the security, objective failed another remained in place. This would help encourage defense in depth if entities could have multiple controls that met the security objective if they could also mitigate risk of non-compliance. To be clear this would be multiple independent controls capable of meeting the security objective where failure of one doesn't result in failure of the other. It is not saying that an entity could have many controls with interdependency of meeting the security objective where a failure of one control results in a failure to meet the objective.

In summary, PNM Resources would encourage the drafting team to think of what the objectives are then rewrite the standards with those in mind. Do not try to keep the current framework as it is broken when trying to adapt to new technology. While this effort discusses virtualization, the reality cloud computing has resulted in a new effort on CIP-011. Thus, the current prescriptive paradigm needs to move to an objective paradigm where an SDT isn't formed with every new emerging technology. We would encourage the SDT to develop this new framework then map the old requirements to the new objective-based framework. Not everyone may appreciate another major paradigm shift with CIP. However, if the SDT can put out a good draft product of revised standards and framing it as more objective standards and less prescriptive standards are the right way to go, then the rest of the industry will hopefully agree. The SDT needs to stop framing this as a virtualization problem since many are already virtualized under v5. The problem is overly prescriptive standards preventing Entities from being able to change the methods of accomplishing the security objective in a compliant manner.

While there may be some credence to modifying the definitions of what a BES Cyber Asset is to better accommodate virtual environments (see discussion above), for the most part, the Responsible Entities that RF audits correctly identify and protect Guest VMs, hypervisors, and supporting physical hardware. The Responsible Entities do not identify Guest VMs as “software” but as BES Cyber Assets, Protected Cyber Assets (PCA), or BES Cyber Systems (BCS). RF does not agree that Guest VMs are specifically excluded from the current CIP-007 Requirements as stated in Figure 2 on page 3.

Admittedly, there is a 1:1 relationship assumed between BES Cyber Assets and their underlying hardware, however, minor changes to current definitions will support one-to-many relationships afforded in VM environments without creating new asset classes.

The argument put forth under “Distributed Firewalls vs. Perimeter Models” on page 4 is already possible as mentioned above. Entities can choose to identify and protect each BCA in their own separate ESP, with their own separate EAP, under the current CIP Standards. While virtualization may reduce the amount of time and effort to implement such an environment, maintaining it with a high degree of confidence that it is performing as designed, and then explaining this environment to an outside auditor could prove challenging.

Further, current “Next Generation” firewalls are fully capable of limiting network access into and out of the ESP across most layers of the OSI model through security zones. Figure 4 compares Perimeter-based and Zero-Trust models, and as most Cyber Assets use the same LDAP or Active Directory (AD) access, the Zero-Trust model is not as secure as portrayed – unless there is the same granularity implemented within the AD or LDAP environment for Groups or ACL Sets and incorporated in the Guest VMs security group.

Remediation VLANs, as shown in Figure 10 on page 10, would be considered “above and beyond” the CIP Standards and would earn a Responsible Entity a Positive Observation, showing strong internal controls for patch management and malware detection.

RF already identifies Super-ESPs (mentioned on page10) and has multiple entities that have currently implemented and support these extended ESPs. There are no additional requirements or changes required for this to be implemented.

Best practices support rings of security in a “defense-in-depth” model that creates tighter security controls the closer you get to key systems. Access control applied at deeper levels as described within the white paper on page 13 does not require virtualization, but at the discretion of the Responsible Entity can be done through a combination of firewall rulesets or security zones, intelligent switches with ACLs or zones, host firewalls, Group Membership (AD), ACL Sets (LDAP), and individual Cyber Asset malware detection.

Regardless of what the paper calls “Shared Infrastructure,” there does not need to be new asset classes, as any new asset classes would still require identification at the high water mark to the level of highest Applicable System the Cyber Assets are controlling access within a distinct ESP. CIP definition changes to include “per device capability” would allow leeway for the auditors to have a conversation and draw conclusions based on professional judgment based on the story the Responsible Entity tells.

Conclusion

RF as a region supports virtualization; however, all supporting hypervisors and underlying physical hardware must be included and categorized correctly. Much in the same way that a network switch within the ESP cannot operate in mixed-mode, neither can Guest VMs that are categorized as PCA, BCA or part of a BCS operate in a mixed-mode environment with non-CIP Guest VMs. Only those Applicable Systems outside of the identified ESP – PACS and EACMS – may operate in a mixed-mode environment; and the underlying hypervisor and physical Cyber Assets must be protected as either a PACS, EACMS, or both – if both are running as Guest VMs.

Using virtualization completely within the ESP – or outside of the ESP for EACMS and PACS – leverages virtualization and captures many of the benefits while limiting the changes required to meet current or future CIP Standards and Requirements.

We disagree with the proposed path forward as discussed in the white paper. In our view, current CIP requirements can apply to virtualization environment smoothly without significant changes. Given that the CIP compliance program today works fairly smoothly by implementing the existing requirements, any changes of requirements and definitions beyond virtualization shouldn’t be targeted. SDT should focus on how to resolve CIP compliance in the virtualization environment without prohibiting the new technology rather than try to change the requirements for the defense in depth since it is not the driver for this project. Resulting from our comments in the above question 1, as long as the Cyber Asset definition are modified to include VM, most of existing CIP V5 requirements would apply to virtualization environment seamlessly.

The path forward is needed. However, two items are of concern from this statement:

A literal use of this foundational definition would mean a server hardware platform may be a BES Cyber System, the hypervisor software could be the "operating system", and all the virtual machines running on the hardware are applications or simply data.

1. It should be clear of the differences between an operating system and an application. NIST provides the following definitions.

Operating system: A computer program, implemented in either software or firmware, which acts as an intermediary between users of a computer and the computer hardware. The purpose of an operating system is to provide an environment in which a user can execute applications.

Application: A system for collecting, saving, processing, and presenting data by means of a computer. The term application is generally used when referring to a component of software that can be executed. The terms application and software application are often used synonymously.

The OS can prevent or allow the application to run, but not necessarily vice versa. A clear hierarchy is created. The hypervisor is then above both the OS and application for each VM instance and holds primary control. Therefore, it is recommended that changes to the CIP Standards have three clear tiers when addressing virtual environments to include 1) hypervisor, 2) VMs and OSs, and 3) applications. VMs/OSs and applications should not be grouped together.

2. With all the current discussions on BES Cyber Information and controls used to protect it in cloud environments, the SDT should use caution when using the word "data". Data is not useable until it is information. The SDT may have the opportunity to also address this issue as encryption, where information is turned to data, may be used in virtual environments.

The path forward is reasonable given that current popular uses of virtualization technologies do not provide substantial direct benefits to many of the field systems that must comply with the NERC CIP Reliability Standards. Nonetheless Reliability Standards drafters, Registered Entities, Compliance

Auditors, and other stakeholders must have clarity and regulatory certainty regarding how newly proposed defined terms function in relation to current NERC Glossary of Terms Used in Reliability Standards definitions. The questions noted in the White Paper with respect to the Shared Infrastructure's possible 15-minute impact are indicative of the questions that will arise if the standards do not clearly address how to classify a given "asset" when multiple definitions align with that asset's function. Of particular concern is Shared Infrastructure supporting exclusively EACMS and PACS devices. There is no 15-minute impact question in this scenario, but if the Shared Infrastructure definition assumes a need for BCA-level protections, entities will be forced to add protections not otherwise anticipated for those environments. Similarly, the NERC Reliability Standards must provide Compliance Auditors and Registered Entities clear parameters for assessing regulatory compliance where Shared Infrastructure supports Virtual Cyber Assets that would be classified differently under current rules. For example, would a virtual BCA and virtual PACS be allowed to reside on the same Shared Infrastructure with different network protections deployed (one requiring an "ESP" and one not)? We support the SDT's efforts to develop the new NERC Glossary of Terms Used in Reliability Standards definitions, and look forward to working through these complex issues to arrive at a sustainable approach compatible with evolving technologies.

Virtualized Firewall Interfaces: ERCOT questions whether the use of the term "firewall" is too specific. More generic terms should be used to allow for other device types that provide this security capability. If the concept of an EAP is maintained, this could result in a one-to-one definition of EAP to Cyber Asset. ERCOT requests consideration of how to define the access points without too much of an administrative burden.

Management Plane Isolation: ERCOT requests that "per asset capability" be included and added to requirements related to management plane isolation.

Multi-Site Data Center Extensions (Super ESP): ERCOT requests that any future requirements related to this subject be aligned to complement and not conflict with or extend the requirements of CIP-012.

Comment

Seattle City Light generally agrees with the proposed path forward. In particular, we like the direction headed with the new “no trust” model.

We remain concerned about maintaining backward compatibility with existing CIP standard language and terminology, and encourage that, at least in certain cases (if not throughout all CIP requirement), the SDT consider use of “overlay” requirement language that accommodates virtualization approaches while also maintaining existing language and terms (i.e., give an entity the option to choose between the existing requirement—perhaps revised to focus on risk and result rather than prescriptive approach—and a new, alternative requirement for a virtualized system. This option would exist on a system-by-system basis).

We also are concerned that the virtualized shared storage (SAN) concepts require a closer look, in terms of treatment under CIP requirements. This area might be ideal for use of the virtualization “overlay” approach discussed above.

Comment

Our concern is that although the example (figure 12) follows the model given it does not represent the complexity under which the industry has implemented CIPv5

We request the SDT post updates to CIP-007 and CIP-010 sooner. Those Requirements are the biggest hurdles. The industry and SDT will quickly see if the new Requirements will be acceptable

We support the proposed creation of new “shared infrastructure” and “virtual machine” cyber asset types and new “objective-based” type requirements specifically for those virtual cyber assets (as per Chapter 3) which would allow entities to adopt virtualization incrementally and at their discretion without changing existing CIP programs for entities that choose not to adopt virtualization.

We request the SDT to describe how they plan to address mixed-use environments (hardware resources shared between CIP and non-CIP virtual machines)

Comment

While we are in favor of the proposed path forward, we feel like there is not enough evidence zero trust, software defined networking, and or other similar technologies are more reliable, less expensive, easier to manage, and provide better security in real-time controls networks ie: SCADA, DCS, ICS. These cybersecurity tools have been developed for rapidly changing IT envrionments and for highly exposed, high risk Cyber Assets. BES Cyber Systems are neither of those.

We feel the SDT should focus on the changes to virtualization in the two first bullet points in the whitepaper’s conclusion and let the “Virtualized Network” security product industry mature before changing the standard. We realize the standard is prescriptive in it’s nature around electronic border security, but does not preclude an entity from using other technologies to protect Cyber Assets discussed in the paper such as Management Plane Isolation, Privileged Introspection, etc.

Border firewalls are still considered a best practice and the cost of having a border firewall should not be considered “purchasing extra hardware to show compliance with prescribed technologies”. Firewalls are still a corner stone of protecting networks against attacks and modern firewalls are no longer confined to layer 3 of the OSI model. The standards require and EAP, but that does not preclude an entity from employing more protective and restrictive controls than the standard requires such as Next Generation Firewalls which operate up to Layer 7 of the OSI model and integrate with Identity and Access Management controls. If FERC and or NERC feel the modern threat landscape requires more granular controls then new requirements are warranted.

We do like the initial path that you have discussed and would like to see more information on:

a. direction and clarification on the Shared Storage and Shared Networks

b. examples of “access control at a deeper level”

Also, the webinars that were put together have been very helpful. We encourage you to continue to use them as an informative tool to illustrate your plan.

Finally, we feel it is important to reiterate that if an entity does not elect to leverage virtualized technologies, then they should not need to alter their programs at all to maintain compliance to any of the CIP requirements.

EEI supports the path forward as described in the Virtualization white paper, which aligns well with EEI comments provided in December 2018 to the SDT. As stated in those comments, EEI urged the SDT “to focus more on how virtualization might be effectively integrated into BES Cyber Systems, under the current standards, rather than trying to solve all these issues at an early stage of industry adoption.” As a result, we are encouraged by the proposed concept as described but also recognize that much work remains, conceding that many of the concepts will need to be developed in greater detail and vetted by the industry. However, we believe that the SDT has proposed a concept that EEI member companies can support and look forward to reviewing and providing comments that align with the direction described in the white paper.

Idaho Power believes the proposed path forward appears to be an appealing approach. However, due to the amount of significant changes that will occur as a result of this approach, it appears that the proposed path forward could result in significant increases to a Responsible Entity's overhead costs and associated resources. In addition, when any newly approved CIP standard becomes effective, Responsible Entities require long lead times to plan, interpret, document, and implement changes into their compliance programs and processes in order to have a suitable and sustainable compliance program associated with the new CIP standard. At minimum, a 24-month implementation plan should be considered.

CHPD supports the proposed concept to include new language that specifically scopes virtual environments as an extention to the existing standards, while maintaining compatibility with the compliance approach used now for existing non-virtual systems. CHPD requests that the SDT consider developing language that is more specific and reduces the potential for scoping confusion. For example, the proposed Management Plane Isolation change could be written to ensure that only applicable virtual hosts (e.g., those hosting BCAs, EACMS, etc…) and their associated hypervisors are considered under new requirement language. This approach would prevent other CIP asset types like BCAs or PCAs from being unintentionally included.

Comment	

1. In reviewing the comments on the Q&A, it’s unclear as to whether the drafting team is treating a SAN as a separate BCA or only as a BCSI storage location. Could the SDT please clarify?

2. Seminole recommends the SDT to be cognizant of the layering that can occur through virtualization in that if CIP Requirements are already applying to the hardware that Seminole would prefer that the additional Requirements applying to the virtual devices on that hardware would be limited or non-existent.

3. The Standards are unclear as to whether a programmable electronic device definition can exclude a virtual machine. The SDT should take this into consideration while drafting revised Requirements.

Wendy Center - U.S. Bureau of Reclamation - 1,5

Answer	Yes
Document Name	

Comment

Reclamation supports the SDT’s intent to create security objective-based requirements; however, the Case for Change White Paper seems to be addressing virtualization at too granular of a level. Many of the challenges and scenarios discussed are hypothetical, extremely detailed, and appear to require extremely detailed and complicated CIP requirements. Reclamation is concerned that the path forward as described will result in requirements with a compliance/documentation burden that is not commensurate with the level of risk reduction provided.

Reclamation recommends the SDT incorporate virtualization into the CIP standards by clearly identifying and defining the scope of what must be protected while retaining the language in the current versions of CIP standards. For example, a requirement might state that entities are required to protect against unauthorized access to BES Cyber Systems. To address this existing requirement for both virtualized and non-virtualized environments, Reclamation also recommends the SDT revise the definitions in the NERC Glossary of Terms to include virtualized systems and leverage the existing

requirement to protect against unauthorized access. Reclamation does not support creating a virtual counterpart definition for all existing physical definitions. Definitions should include physical and virtual aspects of the defined terms.

Leanna Lamatrice - AEP - 3,5	
Answer	Yes
Document Name	
Comment	

AEP requests the SDT include sufficient flexibility to allow entities to transition from their current compliance strategy to a newly available strategy and remain compliant throughout the process. Further, AEP requests the SDT make any new or revised requirement language backward compatible to the current obligation for systems not affected by virtualization. AEP believes there should not be a cost to entities that results from changes made to requirements and definition to accommodate virtualization technology.

Texas RE noticed that the SDT seems to have gone outside the scope of the 2016 Standard Authorization Request (SAR). Texas RE inquires as to whether a new SAR should be submitted.

The 2016 SAR states “Virtualization – The CIP V5 standards do not specifically address virtualization. Because of the increasing use of virtualization in industrial control system environments, V5TAG asked that the SDT consider CIP-005 and the definitions of Cyber Asset and Electronic Access Point regarding permitted architecture and the security risks of network, server and storage virtualization technologies.” Modifying the CIP standards to embrace new security techniques is not an issue that was included in the V5TAG Transfer Document nor was the SDT instructed to address issues with the standards’ adaptability to current and future technology innovation.

While Texas RE agrees that some changes should be made to the CIP standards, not all of the changes are necessary at this time, nor are all of the changes specific for virtualization.

Texas RE recommends the following path forward:

- Modify the Cyber Asset definition to include virtual machines, hosts, etc.
- Create a separate standard for virtualized environments or modifying CIP-005-6 to include security objectives for virtualized environments.
- Not making any changes to the ESP and EAP terms as they are defined broadly enough to give entities the flexibility in how they apply those terms within many types of network architectures.

Virtualization and Future Technologies: Case for Change White Paper Consideration of Comments

Project 2016-02 Modifications to CIP Standards

The Project 2016-02 SDT (SDT) developed the "Virtualization and Future Technologies Case for Change" White paper to explain the need to change the cyber security CIP Reliability Standards. This white paper has not been approved or endorsed by NERC and solely includes the views of the SDT.

Recognizing the continuing growth in technology innovation, many entities in the Electricity Sector have implemented virtualization as part of their CIP programs. Many of these same entities, however, have implemented this new technology without taking full advantage of virtualization's advanced capabilities. There are several reasons for this from the constraints of the current CIP architecture to the ongoing ambiguity around how new virtualization technology applies to CIP compliance. Some of those who are implementing virtualization are experiencing a great deal of uncertainty and difficulty around developing implementation strategies that will support compliance and achieve greater reliability and security. The SDT was assigned the task to address the technological innovation in virtualization within the CIP standards.

The SDT's purpose of incorporating the virtualization concept into the CIP standards is not to merely augment the current standards. The SDT's intent is to better position the CIP standards to be applicable to any future technological innovation. Leveraging the abstraction that virtualization provides will allow the industry to more readily adopt new technology and increase security posture. This paper presents the SDT's case for change to the NERC CIP standards that is needed to allow for the innovative security techniques and new concepts brought about by virtualization.

The SDT thanks the industry for its time and attention to these matters and the resulting comments. The more popular, overall themes from the comments received have been captured and considered in this report, in order to progress towards a formal posting.

Overall Themes

- **Commenters were unclear as to how the SAN would be classified and treated.** The Standards Drafting Team thanks you for your comment. The SDT contends that due to nature of the overall configuration of traditional SANs (i.e. non-IP transport protocols, data de-duplication, volume spanning across multiple drives, etc.), that this is better addressed as part of a future change to CIP-011. The SDT is considering how to address CIP-005 issues with non-IP based protocols typically used in SANs. Please refer to the forthcoming CIP-005-7 Technical Rationale for Requirement R1.5.

- **Commenters were concerned regarding double jeopardy if both the virtual machine and the host are cyber assets.** The Standards Drafting Team thanks you for your comment. The SDT contends that the physical equipment that is hosting Virtual Cyber Assets should fall within the proposed new Shared Common Infrastructure (SCI) definition. The SDT will consider this situation while drafting the next version of the standard.
- **Commenters questioned if programmable electronic devices exclude a virtual machine.** The SDT thanks you for your comment. The NERC Glossary definition of Cyber Asset has a direct tie to the hardware on which it relied. This affected the definitions of the "Applicable Systems" terms such as BES Cyber Systems (BCS), EACS, PACS, and Protected Cyber Assets (PCAs). Because the Reliability Standard is applicable to the systems, the control for the Cyber Assets also applies to the hardware. This tie to hardware implies a singular one BCA, EACS, PACS or PCA per individual hardware system. This singularity is what virtualization intentionally breaks to increase reliability, and resiliency.

  The proposed NERC Glossary definition of Virtual Cyber Asset (VCA) and ESZ allow the tie between a specific piece of hardware and the related applicable systems to no longer be singularly defined. The VCA definition references a newly defined term, Shared Cyber Infrastructure (SCI) that does not include hardware. The definition of VCA is not inclusive of hardware, and the EACS, PACS and PCA definitions have been updated to allow for VCA versions. With the addition of SCI and revisions to the "Applicable Systems", there can be one or more virtualized instances of a BCA, EACS, PACS or PCA that reside on a single SCI.
- **Commenters were concerned with cloud services.** The SDT thanks you for your comment. At this time, the changes that the SDT have proposed are intended to better futureproof the standards for the use of the same virtualization technologies that cloud providers use, but for in-house (on-premise) system. While this sets the stage for facilitating future considerations such as the use of cloud providers, the SDT is not addressing the hosting of BES Cyber Systems with off-premise cloud providers at this time.

  The SDT notes that at some later date, it will be making conforming changes in the CIP Standards in collaboration with the NERC Project 2019-02 BES Cyber System Information Access Management SDT.
- **Commenters were concerned about the technological advances that are occurring and the desire for standards to evolve to accommodate these developments.** The SDT thanks you for your comment. At this time, the changes that the SDT have proposed are intended to better futureproof the standard to reduce the number of changes required as technology evolves. The SDT contends that while futureproofing the standards for future technological changes is desirable, this must be balanced against the need for backward compatibility to exist where possible.
- **Commenters expressed that regulatory standards should not preclude the use of resources that are generally available and meet security objectives.** The SDT thanks you for your comment. Project 2016-02 SDT was assigned the task to address the technological innovation in virtualization within the CIP standards. The SDT's purpose of incorporating the virtualization concept into the CIP standards is not to merely augment the current standards. The SDT's intent is to better position the CIP standards to be applicable to any future technological innovation. The SDT agrees that the standards should be

flexible to meet security objectives with currently available resources and not prescribe technologies or architectures.

- **Commenters expressed that changes should apply to both physical and virtual devices.** The SDT thanks you for your comment. At this time, the changes that the SDT have proposed are intended to better futureproof the standard to reduce the number of changes required as technology evolves. The SDT contends that while futureproofing the standards for technological evolution is desirable, this must be balanced against the need for backward compatibility to exist where possible. This need for backwards compatibility may limit the number proposed changes possible to physical devices.
- **Commenters were concerned with problems related to multi-role devices not specific to virtual devices.** The SDT thanks you for your comment. The SDT intends to address of the possibility that Cyber Assets may fall within multiple classifications (i.e. simultaneously be both SCI and PCA) and as well as how this should be addressed within the forthcoming Technical Rationale document. Please refer to the forthcoming CIP-005-7 Technical Rationale.
- **Commenters expressed concern with the overlap of CIP-012 and the "Super ESP."** The SDT thanks you for your comment. This potential overlap was resolved with the exclusion language proposed within CIP-005-7 R1.3.
- **Commenters expressed that "per system capability" should be added to the management plane isolation requirement.** The SDT thanks you for your comment. The SDT intends to address the "per system capability" scoping mechanism vs. requiring Technical Feasibility Exceptions where this is appropriate.
- **Commenters were concerned with the potential of continuing the EAP concept within the CIP standards and the potential of a one-to-one definition of EAP to Cyber Asset.** The SDT thanks you for your comment. The SDT has proposed retiring the EAP definition. With the move to an objective based requirement in CIP-005 and the need to not prescribe a cyber asset interface, an electronic access point, on a network boundary as the only model for addressing network access control, the term EAP is no longer used within the standard and is proposed to be retired. Entities are free to continue to use the term in their internal documentation to maintain backwards compatibility.
- **Commenters expressed that SCI needs to be better defined to highlight the differences between it and regular assets.** The SDT thanks you for your comment. The SDT has proposed the following definition for SCI: "Programmable electronic devices whose compute, storage (including network transport), or network resources are shared with one or more Virtual Cyber Assets or that perform logical isolation for an ESZ or ESP. This includes its management systems." The SDT's intent with this definition was to distinguish SCI from regular assets.
- **Commenters requested to address mixed use environments.** The SDT thanks you for your comments. The SDT intends to address the use of "mixed trust" through two methods. Please refer to the forthcoming Technical Rationale.

  The use of "affinity" within the Shared Common Infrastructure (SCI) will ensure that only Virtual Cyber Assets of the same "trust" level will be allowed to share CPU and system memory. This is to prevent the possibility that vulnerability within a Virtual Cyber Asset of lower trust level could be exploited to gain control of another Virtual Cyber Asset of higher trust level running on the same hypervisor within the SCI.

The high water marking of security requirements (i.e. “equalizing” or “high water marking” the R’s) results in some Virtual Cyber Assets now sharing equal trust levels. This allows these Virtual Cyber Assets to share the same CPU and system memory with the supporting SCI.

- **Commenters were concerned about the future consistent auditing approach of these modifications.** The SDT thanks you for your comment. The SDT has previously worked with NERC and the Regional Entity auditors on our approach and plan to continue working with the Monitoring and Enforcement teams as development of the standards progress.
- **Commenters expressed confusion over the options and the hypervisor isolation.** The SDT appreciates the support on the concepts of Virtual Cyber Assets, Virtual Storage and Remediation VLANs. In the Case for Change white paper, the SDT did not intend to imply that distributed firewalls, zero trust models and management plane isolation were not possible with the current standards. The intent was to show that because of how the current standards are written, using these technologies is not encouraged, and in fact could be discouraging these methods, with the amount of administrative overhead they could entail.

  The SDT has considered the comments on Management Plane Isolation and agrees. This is reflected in our proposed R1 for CIP-005.
- **Commenters expressed the desire to create two sets of standards (physical and virtual).** The SDT thanks you for your comment. The SDT asserts that the virtual vs physical assets perform the same function and it is difficult to ascertain which standard to apply to each asset as most entities use a hybrid configuration. The SDT is incorporating new definitions and objectives based requirements to address the differences between the two types. Requiring security objectives to be met should decrease the need to be prescriptive on the difference between physical and virtual systems.
- **Commenters expressed that the CIP standards already allow for virtualization.** The SDT thanks you for your comments. The SDT recognizes that some entities have already made use of Virtualization under the existing CIP Standards or contend that the existing CIP standards do not require any changes to accommodate Virtualization.

  The SDT contends that by moving the CIP standards forward from their existing “technical requirement” basis to a more “security objective” basis will result in better futureproofing as technology evolves.

  While many of the technical concepts utilized by virtualization currently exists and could be retrofitted within the existing CIP Standards, the move towards “policy based” security controls will better fit within the “security objective” based framework of CIP standards.
- **Commenters expressed a desire to include more compliance examples and clarity to better evaluate proposed changes.** The SDT intends to produce more detailed documentation in both the forthcoming Technical Rational and Implementation Guidance to assist entities to evaluate the proposed changes.

- **Commenters expressed the need to allow for backward compatibility.** The SDT thanks you for your comments. The SDT recognizes the substantial investment that entities have made in their programs to meet the existing CIP requirements. As such, the SDT has prioritized ensuring that backwards compatibility exists for current physical infrastructure installations.

  In some cases, full backwards is not possible as the SDT is also tasked with providing clarity in situations which were not envisioned in earlier versions of the CIP Standards. The forthcoming Technical Rationale document is intended to highlight where such situations exist.

- **Commenters expressed the need for clarity on “Super ESPs.”** The SDT thanks you for your comments. The SDT recognizes that entities need clarity on how situations involving how “Super ESPs” should be handled. Please refer to the forthcoming Technical Rationale document in the section entitled, “Requirement R1 Part 1.3”. The SDT contends that the new “Super ESP/ESZ” construct allows for cases where either routing cannot be used (such as layer 2 high speed database/ file replication) or where time sensitive data would be required to cross existing ESP boundaries (IEC-61850 GOOSE).

A. Introduction

1. **Title:** Cyber Security — BES Cyber System Logical Isolation

2. **Number:** CIP-005-7

Purpose: To protect BES Cyber Systems against compromise by allowing only known and controlled communication to and from the system and logically isolating all other communication.

3. **Applicability:**

3.1. Functional Entities: For the purpose of the requirements in this standard, the following list of functional entities will be collectively referred to as "Responsible Entities." For requirements in this standard where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are specified explicitly.

4.1.1. Balancing Authority

4.1.2. **Distribution Provider** that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:

4.1.2.1. Each underfrequency Load shedding (UFLS) or undervoltage Load shedding (UVLS) system that:

4.1.2.1.1. is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.1.2.1.2. performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.1.2.2. Each Remedial Action Scheme (RAS) where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.1.3. **Generator Operator**

4.1.4. **Generator Owner**

4.1.5. Reliability Coordinator

4.1.6. Transmission Operator

4.1.7. Transmission Owner
