CIP-010-5 - Attachment 1

Required Sections for Plans for Transient Cyber Assets and Removable Media

Responsible Entities shall include each of the sections provided below in their plan(s) for Transient Cyber Assets (TCA)and Removable Media as required under Requirement R4.

Section 1. TCA(s) Managed by the Responsible Entity.

1.1. TCA Management: Responsible Entities shall manage TCAs, individually or by group: (1) in an ongoing manner to ensure compliance with applicable requirements at all times, (2) in an on-demand manner applying the applicable requirements before connection, or (3) a combination of both (1) and (2) above.

1.2. TCA Authorization: For each individual or group of TCAs, each Responsible Entity shall authorize:

1.2.1. Users, either individually or by group or role;

1.2.2. Locations, either individually or by group; and

1.2.3. Uses, which shall be limited to what is necessary to perform business functions.

1.3. Software Vulnerability Mitigation: Use one or a combination of the following methods to achieve the objective of mitigating the risk of vulnerabilities posed by unpatched software on the TCA (per TCA capability):

- Security patching, including manual or managed updates;
- Controls that maintain the state of the operating system and software such that it is in a known state prior to execution that mitigates the risk of introduction of malicious code;
- System hardening; or
- Other method(s) to mitigate software vulnerabilities.

1.4. Introduction of Malicious Code Mitigation: Use one or a combination of the following methods to achieve the objective of mitigating the introduction of malicious code (per TCA capability):

- Antivirus software, including manual or managed updates of signatures or patterns;
- Controls that maintain the state of the operating system and software such that it is in a known state prior to execution that mitigates the risk of introduction of malicious code;
- Application whitelisting; or
- Other method(s) to mitigate the introduction of malicious code.

1.5. Unauthorized Use Mitigation: Use one or a combination of the following methods to achieve the objective of mitigating the risk of unauthorized use of TCAs:

- Restrict physical access;
- Full-disk encryption with authentication;
- Multi-factor authentication; or
- Other method(s) to mitigate the risk of unauthorized use.

Section 2. TCAs Managed by a Party Other than the Responsible Entity.

2.1. Software Vulnerabilities Mitigation: Use one or a combination of the following methods to achieve the objective of mitigating the risk of vulnerabilities posed by unpatched software on the TCA (per TCA capability):

- Review of installed security patch(es);
- Review of security patching process used by the party;
- Review of other vulnerability mitigation performed by the party; or
- Review of other method(s) to mitigate software vulnerabilities.

2.2. Introduction of malicious code mitigation: Use one or a combination of the following methods to achieve the objective of mitigating malicious code (per TCA capability):

- Review of antivirus update level;
- Review of antivirus update process used by the party;
- Review of application whitelisting used by the party;
- Review of controls that maintain the state of the operating system and software such that it is in a known state prior to execution that mitigates the risk of introduction of malicious code;
- Review of system hardening used by the party; or
- Review of other method(s) to mitigate malicious code.

2.3. For any method used to mitigate software vulnerabilities or malicious code as specified in 2.1 and 2.2, Responsible Entities shall determine whether any additional mitigation actions are necessary and implement such actions prior to connecting the TCA.

Section 3. Removable Media

3.1. Removable Media Authorization: For each individual or group of Removable Media, each Responsible Entity shall authorize:

3.1.1. Users, either individually or by group or role; and

3.1.2. Locations, either individually or by group.

3.2. Malicious Code Mitigation: To achieve the objective of mitigating the threat of introducing malicious code, each Responsible Entity shall:

3.2.1. Use method(s) to detect malicious code on Removable Media prior to connecting; and

3.2.2. Mitigate the threat of detected malicious code.

CIP-010-5 - Attachment 2

Examples of Evidence for Plans for Transient Cyber Assets and Removable Media

Section 1.1: Examples of evidence for Section 1.1 may include, but are not limited to, the method(s) of management for the TCAs. This can be included as part of the TCA plan(s), part of the documentation related to authorization of TCAs managed by the Responsible Entity or part of a security policy.

Section 1.2: Examples of evidence for Section 1.2 may include, but are not limited to, documentation from asset management systems, human resource management systems, or forms or spreadsheets that show authorization of TCAs managed by the Responsible Entity. Alternatively, this can be documented in the overarching plan document.

Section 1.3: Examples of evidence for Section 1.3 may include, but are not limited to, documentation of the method(s) used to mitigate software vulnerabilities posed by unpatched software such as security patch management implementation, controls to maintain the known good state of the OS and all software. Evidence can be from change management systems, automated patch management solutions, procedures or processes associated with using live operating systems, or procedures or processes associated with controls to maintain the known good state of the OS and all software. If a TCA does not have the capability to use method(s) that mitigate the risk from unpatched software, evidence may include documentation by the vendor or Responsible Entity that identifies that the TCA does not have the capability.

Section 1.4: Examples of evidence for Section 1.4 may include, but are not limited to, documentation of the method(s) used to mitigate the introduction of malicious code such as antivirus software and processes for managing signature or pattern updates, application whitelisting practices, controls to maintain the known good state of the OS and all software, evidence may include documentation by the vendor or Responsible Entity that identifies that the TCA does not have the capability.

Section 1.5: Examples of evidence for Section 1.5 may include, but are not limited to, documentation through policies or procedures of the method(s) to restrict physical access; method(s) of the full-disk encryption solution along with the authentication protocol; method(s) of the multi-factor authentication solution; or documentation of other method(s) to mitigate the risk of unauthorized use.

Section 2.1: Examples of evidence for Section 2.1 may include, but are not limited to, documentation from change management systems, electronic mail or procedures that document a review of installed security patch(es); memoranda, electronic mail, policies or contracts from parties other than the Responsible Entity that identify the security patching process or vulnerability mitigation performed by the party other than the Responsible Entity; evidence from change management systems, electronic mail, system documentation or contracts that identifies acceptance by the Responsible Entity that the practices of the party other than the Responsible Entity are acceptable; or documentation of other method(s) to mitigate software vulnerabilities for TCAs managed by a party other than the Responsible Entity. If a TCA does not have the capability to use method(s) that mitigate the risk from unpatched software, evidence may include documentation by the Responsible Entity or the party other than the Responsible Entity that identifies that the TCA does not have the capability.

Section 2.2: Examples of evidence for Section 2.2 may include, but are not limited to, documentation from change management systems, electronic mail or procedures that document a review of the installed antivirus update level; memoranda, electronic mail, system documentation, policies or contracts from the party other than the Responsible Entity that identify the antivirus update process, the use of application whitelisting, controls to maintain the known good state of the OS and all software by the party other than the Responsible Entity; evidence from change management systems, electronic mail or contracts that identifies the Responsible Entity's acceptance that the practices of the party other than the Responsible Entity are acceptable; or documentation of other method(s) to mitigate malicious code for TCAs managed by a party other than the Responsible Entity. If a TCA does not have the capability to use method(s) that mitigate the introduction of malicious code, evidence may include documentation by the Responsible Entity or the party other than the Responsible Entity that identifies that the TCA does not have the capability.

Section 2.3: Examples of evidence for Section 2.3 may include, but are not limited to, documentation from change management systems, electronic mail, or contracts that identifies a review to determine whether additional mitigations are necessary and that they have been implemented prior to connecting the TCA managed by a party other than the Responsible Entity.

Section 3.1: Examples of evidence for Section 3.1 may include, but are not limited to, documentation from asset management systems, human resource management systems, forms or spreadsheets that shows authorization of Removable Media. The documentation must identify Removable Media, individually or by group of Removable Media, along with the authorized users, either individually or by group or role, and the authorized locations, either individually or by group.

Section 3.2: Examples of evidence for Section 3.2 may include, but are not limited to, documented process(es) of the method(s) used to mitigate malicious code such as results of scan settings for Removable Media, or implementation of on-demand scanning. Documented process(es) for the method(s) used for mitigating the threat of detected malicious code on Removable Media, such as logs from the method(s) used to detect malicious code that show the results of scanning and that show mitigation of detected malicious code on Removable Media or documented confirmation by the entity that the Removable Media was deemed to be free of malicious code.

Version History

Version	Date	Action	Change Tracking
1	11/26/12	Adopted by the NERC Board of Trustees.	Developed to define the configuration change management and vulnerability assessment requirements in coordination with other CIP standards and to address the balance of the FERC directives in its Order 706.
1	11/22/13	FERC Order issued approving CIP-010-1. (Order becomes effective on 2/3/14.)	
2	11/13/14	Adopted by the NERC Board of Trustees.	Addressed two FERC directives from Order No. 791 related to identify, assess, and correct language and communication networks.
2	2/12/15	Adopted by the NERC Board of Trustees.	Replaces the version adopted by the Board on 11/13/2014. Revised version addresses remaining directives from Order No. 791 related to transient devices and low impact BES Cyber Systems.
2	1/21/16	FERC Order issued approving CIP-010-3. Docket No. RM15-14-000	
3	07/20/17	Modified to address certain directives in FERC Order No. 829.	Revised
3	08/10/17	Adopted by the NERC Board of Trustees.	
3	10/18/18	FERC Order approving CIP-010-3. Docket No. RM17-13-000.	

Version	Date	Action	Change Tracking
4	TBD	Modified to address directives in FERC Order No. 850.	
5	TBD	Virtualization modifications	

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

This is the ~~final~~ second draft of the proposed standard~~ for formal 10-day comment period~~.

Completed Actions	Date
Standards Committee (SC) approved Standard Authorization Request (SAR) for posting	March 9, 2016
SAR posted for comment	March 23–April 21, 2016
SAR posted for comment	June 1–June 30, 2016
SC Accepted the SAR	July 20, 2016
~~45~~60-day formal comment period with ballot	January 21–~~February~~ March 22~~8~~, 2021
45-day formal comment period with ballot	June 30 – August 13, 2021

Anticipated Actions	Date
~~45-day formal comment period with ballot~~	~~May 11–June 24, 2021~~
45-day formal comment period with ballot	August ~~3~~29–~~September 16~~October 11, 2021
Final Ballot	October 19–28, 2021
Board adoption	November 4, 2021

A. Introduction

1. Title: Cyber Security —Change Management and Vulnerability Assessments

2. Number: CIP-010-5

3. Purpose: To prevent and detect unauthorized changes to BES Cyber Systems by specifying configuration change management and vulnerability assessment requirements in support of protecting BES Cyber Systems from compromise that could lead to misoperation or instability in the Bulk Electric System (BES).

4. Applicability:

4.1. Functional Entities: For the purpose of the requirements contained herein, the following list of functional entities will be collectively referred to as "Responsible Entities." For requirements in this standard where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are specified explicitly.

4.1.1. Balancing Authority

4.1.2. Distribution Provider that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:

4.1.2.1. Each underfrequency Load shedding (UFLS) or undervoltage Load shedding (UVLS) system that:

4.1.2.1.1. is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.1.2.1.2. performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.1.2.2. Each Remedial Action Scheme (RAS) where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.1.3. Generator Operator

4.1.4. Generator Owner

4.1.5. Reliability Coordinator

4.1.6. Transmission Operator

4.1.7. Transmission Owner

4.2. Facilities: For the purpose of the requirements contained herein, the following Facilities, systems, and equipment owned by each Responsible Entity in Section 4.1 above are those to which these requirements are applicable. For requirements in this standard where a specific type of Facilities, system, or equipment or subset of Facilities, systems, and equipment are applicable, these are specified explicitly.

4.2.1. Distribution Provider: One or more of the following Facilities, systems and equipment owned by the Distribution Provider for the protection or restoration of the BES:

4.2.1.1. Each UFLS or UVLS System that:

4.2.1.1.1. is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.2.1.1.2. performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.2.1.2. Each RAS where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.2.2. Responsible Entities listed in 4.1 other than Distribution Providers: All BES Facilities.

4.2.3. Exemptions: The following are exempt from Standard CIP-010-5:

4.2.3.1. Cyber ~~s~~Systems at Facilities regulated by the Canadian Nuclear Safety Commission.

4.2.3.2. Cyber ~~s~~Systems associated with communication links ~~logically isolated from, but not providing logical isolation for, BES Cyber~~

~~Systems or SCI~~between discrete Electronic Security Perimeters (ESP).

4.2.3.3. Cyber ~~s~~Systems, associated with communication links, ~~-~~between Cyber ~~Assets, Virtual Cyber Assets, or Shared Cyber Infrastructure performing logical isolation that~~Systems providing confidentiality and integrity of an ESP that extends to one or more geographic locations.

4.2.3.4. The systems, structures, and components that are regulated by the Nuclear Regulatory Commission under a cyber security plan pursuant to 10 C.F.R. Section 73.54.

4.2.3.5. For Distribution Providers, the systems and equipment that are not included in section 4.2.1 above.

4.2.3.6. Responsible Entities that identify that they have no BES Cyber Systems categorized as high impact or medium impact according to the CIP-002 identification and categorization processes.

4.3. **“Applicable Systems” Columns in Tables:** Each table has an “Applicable Systems” column to ~~further~~ define the scope of systems to which a specific requirement ~~row~~ part applies. ~~This concept was adapted from the National Institute of Standards and Technology (“NIST”) Risk Management Framework as a way of applying requirements more appropriately based on impact and connectivity characteristics.~~

5. **Effective Date:** See “Project 2016-02 ~~Virtualization~~ Modification to CIP Standards Implementation Plan.”

B. Requirements and Measures

R1. Each Responsible Entity shall implement one or more documented change management process(es) that collectively include each of the applicable requirement parts in *CIP-010-5 Table R1 –Change Management*. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning].*

M1. Evidence must include each of the applicable documented processes that collectively include each of the applicable requirement parts in *CIP-010-5 Table R1 –Change Management* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-010-5 Table R1 – Change Management			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.1	High Impact BES Cyber Systems (BCS) and their associated: 1. EACMS; 2. PACS; and 3. PCA Medium Impact ~~BES Cyber Systems~~BCS and their associated: 1. EACMS; 2. PACS; and 3. PCA SCI identified independently supporting an Applicable System above ~~SCI hosting High or Medium Impact BCS or their associated:~~ - ~~PACS;~~ - ~~EACMS; or~~	Authorize changes to: 1.1.1. Operating system(s) (OS); or firmware where no independent OS exists; or images used to derive operating systems; or firmware; 1.1.2. Commercially available or open-source application software, including application containers ~~Self-Contained Applications~~; 1.1.3. Custom software installed, including~~- Self-Contained A~~applications containers; and 1.1.4. Any logical network accessible ~~services,~~ports (or ~~logical ports~~services if unable to determine ~~service)~~ports).~~;~~ ~~Security patches applied;~~	Examples of evidence may include, but are not limited to: - A change request record and associated electronic authorization (performed by the individual or group with the authority to authorize the change) in a change management system for each change. - Documentation of authorization for cyber security patch implementation.

Part	Applicable Systems	Requirements	Measures
3.4	High Impact BCS and their associated: 1. EACMS; 2. PACS; and 3. PCA Medium Impact BCS and their associated: 1. EACMS; 2. PACS; and 3. PCA SCI identified independently supporting an Applicable System above ~~SCI hosting High or Medium Impact BCS or their associated:~~ ~~• PACS;~~ ~~• EACMS; or~~ ~~• PCA~~ ~~Management Modules of SCI hosting High or Medium Impact BCS or their associated:~~ ~~• PACS;~~ ~~• EACMS; or~~ ~~PCA~~	Document the results of the assessments conducted according to Parts 3.1, 3.2, and 3.3 and the action plan to remediate or mitigate vulnerabilities identified in the assessments including the planned date of completing the action plan and the execution status of any remediation or mitigation action items.	An example of evidence may include, but is not limited to:~~,~~ • ~~a r~~Reports or logs from SCI mechanisms and remediation of VCAs at instantiation; or ~~of Management System actions, or a~~ • ~~d~~Documentation listing the results or the review or assessment, a list of action items, documented proposed dates of completion for the action plan, and records of the status of the action items (such as minutes of a status meeting, updates in a work order system, or a spreadsheet tracking the action items).

R4. Each Responsible Entity~~, for its high impact and medium impact BES Cyber Systems and associated SCI and Protected Cyber Assets,~~ shall implement, except under CIP Exceptional Circumstances, one or more documented plan(s) for Transient Cyber Assets (TCA) and Removable Media that include the sections in Attachment 1, ~~that~~ except for use on low impact BCS or SCI supporting only low impact BCS(s)~~include the sections in Attachment 1~~. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning and Operations Planning]*

M4. Evidence shall include each of the documented plan(s) for ~~Transient Cyber Asset~~TCAs and Removable Media that collectively include each of the applicable sections in Attachment 1 and additional evidence to demonstrate implementation of plan(s) for ~~Transient Cyber Asset~~TCAs and Removable Media. Additional examples of evidence per section are located in Attachment 2. If a Responsible Entity does not use ~~Transient Cyber Asset(~~TCAs~~)~~ or Removable Media, examples of evidence include, but are not limited to, a statement, policy, or other document that states the Responsible Entity does not use ~~Transient Cyber Asset(~~TCAs~~)~~ or Removable Media.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" (CEA) means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the CEA may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its CEA to retain specific evidence for a longer period of time as part of an investigation.

- Each applicable entity shall retain evidence of each requirement in this standard for three calendar years.
- If an applicable entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.
- The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

Version History

Version	Date	Action	Change Tracking
1	11/26/12	Adopted by the NERC Board of Trustees.	Developed to define the configuration change management and vulnerability assessment requirements in coordination with other CIP standards and to address the balance of the FERC directives in its Order 706.
1	11/22/13	FERC Order issued approving CIP-010-1. (Order becomes effective on 2/3/14.)	
2	11/13/14	Adopted by the NERC Board of Trustees.	Addressed two FERC directives from Order No. 791 related to identify, assess, and correct language and communication networks.
2	2/12/15	Adopted by the NERC Board of Trustees.	Replaces the version adopted by the Board on 11/13/2014. Revised version addresses remaining directives from Order No. 791 related to transient devices and low impact BES Cyber Systems.
2	1/21/16	FERC Order issued approving CIP-010-3. Docket No. RM15-14-000	
3	07/20/17	Modified to address certain directives in FERC Order No. 829.	Revised
3	08/10/17	Adopted by the NERC Board of Trustees.	
3	10/18/18	FERC Order approving CIP-010-3. Docket No. RM17-13-000.	
4	TBD	Modified to address directives in FERC Order No. 850.	
5	TBD	Virtualization modifications	

CIP-010-5 - Attachment 1

Required Sections for Plans for Transient Cyber Assets and Removable Media

Responsible Entities shall include each of the sections provided below in their plan(s) for Transient Cyber Assets (TCA)and Removable Media as required under Requirement R4.

Section 1. ~~Transient Cyber Asset~~TCA(s) Managed by the Responsible Entity.

1.1. ~~Transient Cyber Asset~~TCA Management: Responsible Entities shall manage ~~Transient Cyber Asset(~~TCAs~~)~~, individually or by group: (1) in an ongoing manner to ensure compliance with applicable requirements at all times, (2) in an on-demand manner applying the applicable requirements before connection,~~ to a BES Cyber System~~BCS~~,~~ or (3) a combination of both (1) and (2) above.

1.2. ~~Transient Cyber Asset~~TCA Authorization: For each individual or group of ~~Transient Cyber Asset(~~TCAs~~)~~, each Responsible Entity shall authorize:

1.2.1. Users, either individually or by group or role;

1.2.2. Locations, either individually or by group; and

1.2.3. Uses, which shall be limited to what is necessary to perform business functions.

1.3. Software Vulnerability Mitigation: Use one or a combination of the following methods to achieve the objective of mitigating the risk of vulnerabilities posed by unpatched software on the ~~Transient Cyber Asset~~TCA (per ~~Transient Cyber Asset~~TCA capability):

- Security patching, including manual or managed updates;
- Controls that maintain the state of the operating system and software such that it is in a known state prior to execution that mitigates the risk of introduction of malicious code~~Live operating system and software executable only from read-only media~~;
- System hardening; or
- Other method(s) to mitigate software vulnerabilities.

1.4. Introduction of Malicious Code Mitigation: Use one or a combination of the following methods to achieve the objective of mitigating the introduction of malicious code (per ~~Transient Cyber Asset~~TCA capability):

- Antivirus software, including manual or managed updates of signatures or patterns;
- Controls that maintain the state of the operating system and software such that it is in a known state prior to execution that mitigates the risk of introduction of malicious code;

- Application whitelisting; or
- Other method(s) to mitigate the introduction of malicious code.

1.5. Unauthorized Use Mitigation: Use one or a combination of the following methods to achieve the objective of mitigating the risk of unauthorized use of ~~Transient Cyber Asset(s)~~TCAs:

- Restrict physical access;
- Full-disk encryption with authentication;
- Multi-factor authentication; or
- Other method(s) to mitigate the risk of unauthorized use.

Section 2. ~~Transient Cyber Asset(s)~~TCAs Managed by a Party Other than the Responsible Entity.

2.1. Software Vulnerabilities Mitigation: Use one or a combination of the following methods to achieve the objective of mitigating the risk of vulnerabilities posed by unpatched software on the ~~Transient Cyber Asset~~TCA (per ~~Transient Cyber Asset~~TCA capability):

- Review of installed security patch(es);
- Review of security patching process used by the party;
- Review of other vulnerability mitigation performed by the party; or
- Review of ~~O~~other method(s) to mitigate software vulnerabilities.

2.2. Introduction of malicious code mitigation: Use one or a combination of the following methods to achieve the objective of mitigating malicious code (per ~~Transient Cyber Asset~~TCA capability):

- Review of antivirus update level;
- Review of antivirus update process used by the party;
- Review of application whitelisting used by the party;
- Review of controls that maintain the state of the operating system and software such that it is in a known state prior to execution that mitigates the risk of introduction of malicious code~~use of live operating system and software executable only from read-only media~~;
- Review of system hardening used by the party; or
- Review of ~~O~~other method(s) to mitigate malicious code.

2.3. For any method used to mitigate software vulnerabilities or malicious code as specified in 2.1 and 2.2, Responsible Entities shall determine whether any additional mitigation actions are necessary and implement such actions prior to connecting the ~~Transient Cyber Asset~~TCA.

Section 3. Removable Media

3.1. Removable Media Authorization: For each individual or group of Removable Media, each Responsible Entity shall authorize:

3.1.1. Users, either individually or by group or role; and

3.1.2. Locations, either individually or by group.

3.2. Malicious Code Mitigation: To achieve the objective of mitigating the threat of introducing malicious code ~~to high impact or medium impact BES Cyber Systems and their associated Protected Cyber Assets~~, each Responsible Entity shall:

3.2.1. Use method(s) to detect malicious code on Removable Media prior to connecting ~~to a BES Cyber System or Protected Cyber Assets~~; and

3.2.2. Mitigate the threat of detected malicious code ~~on Removable Media prior to connecting the Removable Media to a high impact or medium impact BES Cyber System or associated Protected Cyber Assets~~.

CIP-010-5 - Attachment 2

Examples of Evidence for Plans for Transient Cyber Assets and Removable Media

Section 1.1: Examples of evidence for Section 1.1 may include, but are not limited to, the method(s) of management for the ~~Transient Cyber Asset(~~TCAs~~)~~. This can be included as part of the ~~Transient Cyber Asset~~TCA plan(s), part of the documentation related to authorization of ~~Transient Cyber Asset(~~TCAs~~)~~ managed by the Responsible Entity or part of a security policy.

Section 1.2: Examples of evidence for Section 1.2 may include, but are not limited to, documentation from asset management systems, human resource management systems, or forms or spreadsheets that show authorization of ~~Transient Cyber Asset(~~TCAs~~)~~ managed by the Responsible Entity. Alternatively, this can be documented in the overarching plan document.

Section 1.3: Examples of evidence for Section 1.3 may include, but are not limited to, documentation of the method(s) used to mitigate software vulnerabilities posed by unpatched software such as security patch management implementation, controls to maintain the known good state of the OS and all software~~the use of live operating systems from read-only media, system hardening practices or other method(s) to mitigate the software vulnerability posed by unpatched software~~. Evidence can be from change management systems, automated patch management solutions, procedures or processes associated with using live operating systems, or procedures or processes associated with controls to maintain the known good state of the OS and all software~~system hardening practices~~. If a ~~Transient Cyber Asset~~TCA does not have the capability to use method(s) that mitigate the risk from unpatched software, evidence may include documentation by the vendor or Responsible Entity that identifies that the ~~Transient Cyber Asset~~TCA does not have the capability.

Section 1.4: Examples of evidence for Section 1.4 may include, but are not limited to, documentation of the method(s) used to mitigate the introduction of malicious code such as antivirus software and processes for managing signature or pattern updates, application whitelisting practices, controls to maintain the known good state of the OS and all software~~processes to restrict communication, or other method(s) to mitigate the introduction of malicious code. If a Transient Cyber Asset does not have the capability to use method(s) that mitigate the introduction of malicious code~~, evidence may include documentation by the vendor or Responsible Entity that identifies that the ~~Transient Cyber Asset~~TCA does not have the capability.

Section 1.5: Examples of evidence for Section 1.5 may include, but are not limited to, documentation through policies or procedures of the method(s) to restrict physical access; method(s) of the full-disk encryption solution along with the authentication protocol; method(s) of the multi-factor authentication solution; or documentation of other method(s) to mitigate the risk of unauthorized use.

Section 2.1: Examples of evidence for Section 2.1 may include, but are not limited to, documentation from change management systems, electronic mail or procedures that document a review of installed security patch(es); memoranda, electronic mail, policies or contracts from parties other than the Responsible Entity that identify the security patching process or vulnerability mitigation performed by the party other than the Responsible Entity; evidence from change management systems, electronic mail, system documentation or contracts that identifies acceptance by the Responsible Entity that the practices of the party other than the Responsible Entity are acceptable; or documentation of other method(s) to mitigate software vulnerabilities for ~~Transient Cyber Asset(~~TCAs~~)~~ managed by a party other than the Responsible Entity. If a ~~Transient Cyber Asset~~TCA does not have the capability to use method(s) that mitigate the risk from unpatched software, evidence may include documentation by the Responsible Entity or the party other than the Responsible Entity that identifies that the ~~Transient Cyber Asset~~TCA does not have the capability.

Section 2.2: Examples of evidence for Section 2.2 may include, but are not limited to, documentation from change management systems, electronic mail or procedures that document a review of the installed antivirus update level; memoranda, electronic mail, system documentation, policies or contracts from the party other than the Responsible Entity that identify the antivirus update process, the use of application whitelisting, controls to maintain the known good state of the OS and all software ~~use of live of operating systems or system hardening performed~~ by the party other than the Responsible Entity; evidence from change management systems, electronic mail or contracts that identifies the Responsible Entity's acceptance that the practices of the party other than the Responsible Entity are acceptable; or documentation of other method(s) to mitigate malicious code for ~~Transient Cyber Asset(~~TCAs~~)~~ managed by a party other than the Responsible Entity. If a ~~Transient Cyber Asset~~TCA does not have the capability to use method(s) that mitigate the introduction of malicious code, evidence may include documentation by the Responsible Entity or the party other than the Responsible Entity that identifies that the ~~Transient Cyber Asset~~TCA does not have the capability.

Section 2.3: Examples of evidence for Section 2.3 may include, but are not limited to, documentation from change management systems, electronic mail, or contracts that identifies a review to determine whether additional mitigations are necessary and that they have been implemented prior to connecting the ~~Transient Cyber Asset~~TCA managed by a party other than the Responsible Entity.

Section 3.1: Examples of evidence for Section 3.1 may include, but are not limited to, documentation from asset management systems, human resource management systems, forms or spreadsheets that shows authorization of Removable Media. The documentation must identify Removable Media, individually or by group of Removable Media, along with the authorized users, either individually or by group or role, and the authorized locations, either individually or by group.

Section 3.2: Examples of evidence for Section 3.2 may include, but are not limited to, documented process(es) of the method(s) used to mitigate malicious code such as results of scan settings for Removable Media, or implementation of on-demand scanning. Documented process(es) for the method(s) used for mitigating the threat of detected malicious code on Removable Media, such as logs from the method(s) used to detect malicious code that show the results of scanning and that show mitigation of detected malicious code on Removable Media or documented confirmation by the entity that the Removable Media was deemed to be free of malicious code.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

Completed Actions	Date
Standards Committee (SC) approved Standard Authorization Request (SAR) for posting	March 9, 2016
SAR posted for comment	March 23–April 21, 2016
SAR posted for comment	June 1–June 30, 2016
SC Accepted the SAR	July 20, 2016
60-day formal comment period with ballot	January 21–March 22, 2021
45-day formal comment period with ballot	June 30 – August 13, 2021

Anticipated Actions	Date
45-day formal comment period with ballot	August 29– October 11, 2021
Final Ballot	October 19–28, 2021
Board adoption	November 4, 2021

A. Introduction

1. **Title:** Cyber Security — Information Protection
2. **Number:** CIP-011-Y
3. **Purpose:** To prevent unauthorized access to BES Cyber System Information (BCSI) by specifying information protection requirements in support of protecting BES Cyber Systems against compromise that could lead to misoperation or instability in the Bulk Electric System (BES).
4. **Applicability:**

4.1. Functional Entities: For the purpose of the requirements contained herein, the following list of functional entities will be collectively referred to as "Responsible Entities." For requirements in this standard where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are specified explicitly.

4.1.1 Balancing Authority

4.1.2 Distribution Provider that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:

4.1.2.1 Each underfrequency Load shedding (UFLS) or undervoltage Load shedding (UVLS) system that:

4.1.2.1.1 is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.1.2.1.2 performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.1.2.2 Each Remedial Action Scheme (RAS) where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.3 Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.4 Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.1.3 Generator Operator

4.1.4 Generator Owner

4.1.5 Reliability Coordinator

4.1.6 Transmission Operator

4.1.7 Transmission Owner

4.2. Facilities: For the purpose of the requirements contained herein, the following Facilities, systems, and equipment owned by each Responsible Entity in 4.1 above are those to which these requirements are applicable. For requirements in this standard where a specific type of Facilities, system, or equipment or subset of Facilities, systems, and equipment are applicable, these are specified explicitly.

4.2.1 Distribution Provider: One or more of the following Facilities, systems and equipment owned by the Distribution Provider for the protection or restoration of the BES:

4.2.1.1 Each UFLS or UVLS System that:

4.2.1.1.1 is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.2.1.1.2 performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.2.1.2 Each RAS where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.3 Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.4 Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.2.2 Responsible Entities listed in 4.1 other than Distribution Providers: All BES Facilities.

4.2.3 Exemptions: The following are exempt from Standard CIP-011-Y:

4.2.3.1 Cyber Systems at Facilities regulated by the Canadian Nuclear Safety Commission.

4.2.3.2 Cyber Systems associated with communication links between discrete Electronic Security Perimeters (ESP).

4.2.3.3 Cyber Systems, associated with communication links, between the Cyber Systems providing confidentiality and integrity of an ESP that extends to one or more geographic locations.

4.2.3.4 The systems, structures, and components that are regulated by the Nuclear Regulatory Commission under a cyber security plan pursuant to 10 C.F.R. Section 73.54.

4.2.3.5 For Distribution Providers, the systems and equipment that are not included in section 4.2.1 above.

4.2.3.6 Responsible Entities that identify that they have no BES Cyber Systems categorized as high impact or medium impact according to the CIP-002 identification and categorization processes.

5. **“Applicable Systems” Columns in Tables:** Each table has an “Applicable Systems” column to define the scope of systems to which a specific requirement part applies.

6. **Effective Dates:** See Project 2016-02 “Modification to CIP Standards Implementation Plan”.

B. Requirements and Measures

R1. Each Responsible Entity shall implement one or more documented information protection program(s) for BES Cyber System Information (BCSI) pertaining to “Applicable Systems” identified in *CIP-011-Y Table R1 – Information Protection Program* that collectively includes each of the applicable requirement parts in *CIP-011-Y Table R1 – Information Protection Program*. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning].*

M1. Evidence for the information protection program must include the applicable requirement parts in *CIP-011-Y Table R1 – Information Protection Program* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-011-Y Table R1 – Information Protection Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.1	High Impact BES Cyber Systems (BCS) and their associated: 1. EACMS; and 2. PACS Medium Impact BES Cyber Systems and their associated: 1. EACMS; and 2. PACS SCI identified independently supporting an Applicable System above	Method(s) to identify BCSI.	Examples of evidence may include, but are not limited to, the following: • Documented method(s) to identify BCSI from the entity’s information protection program; or • Indications on information (e.g., labels or classification) that identify BCSI as designated in the entity’s information protection program; or • Training materials that provide personnel with sufficient knowledge to identify BCSI; or • Storage locations identified for housing BCSI in the entity’s information protection program.

CIP-011-Y Table R1 – Information Protection Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.2	High Impact BCS and their associated: 1. EACMS; and 2. PACS Medium Impact BES Cyber Systems and their associated: 1. EACMS; and 2. PACS SCI identified independently supporting an Applicable System above	Method(s) to protect and securely handle BCSI to mitigate risks of compromising confidentiality.	Examples of evidence for on-premises BCSI may include, but are not limited to, the following: • Procedures for protecting and securely handling, which include topics such as storage, security during transit, and use of BCSI; or • Records indicating that BCSI is handled in a manner consistent with the entity's documented procedure(s). Examples of evidence for off-premises BCSI may include, but are not limited to, the following: • Implementation of electronic technical method(s) to protect electronic BCSI (e.g., data masking, encryption, hashing, tokenization, cipher, electronic key management); or • Implementation of physical technical method(s) to protect physical BCSI (e.g., physical lock and key management, physical badge management, biometrics, alarm system); or

CIP-011-Y Table R1 – Information Protection Program			
Part	Applicable Systems	Requirements	Measures
			• Implementation of administrative method(s) to protect BCSI (e.g., vendor service risk assessments, business agreements).

R2. Each Responsible Entity shall implement one or more documented process(es) that collectively include the applicable requirement parts in *CIP-011-Y Table R2 –Reuse and Disposal*. *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning].*

M2. Evidence must include each of the applicable documented processes that collectively include each of the applicable requirement parts in *CIP-011-Y Table R2 –Reuse and Disposal* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-011-Y Table R2 –Reuse and Disposal			
Part	**Applicable Systems**	**Requirements**	**Measures**
2.1	High Impact BES Cyber Systems and their associated: 1. EACMS; 2. PACS; and 3. PCA Medium Impact BES Cyber Systems and their associated: 1. EACMS; 2. PACS; and 3. PCA SCI identified independently supporting an Applicable System above	Method(s) to prevent the unauthorized retrieval of BCSI from Applicable Systems containing BCSI, prior to their disposal or reuse (except for reuse within other systems identified in the "Applicable Systems" column).	Examples of evidence may include, but are not limited to, the following: • Records tracking sanitization actions taken to prevent unauthorized retrieval of BCSI such as clearing, purging, or destroying; or • Records tracking actions such as encrypting, retaining in the Physical Security Perimeter or other methods used to prevent unauthorized retrieval of BCSI.

B. Compliance

1. **Compliance Monitoring Process:**

   1.1. **Compliance Enforcement Authority:** "Compliance Enforcement Authority" (CEA) means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

   1.2. **Evidence Retention:** The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the CEA may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

   The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its CEA to retain specific evidence for a longer period of time as part of an investigation:

   - The applicable entity shall retain evidence of each requirement in this standard for three calendar years.
   - If an applicable entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.
   - The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

   1.3. **Compliance Monitoring and Enforcement Program:** As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

R #	Time Horizon	VRF	Violation Severity Levels (CIP-011-Y)			
			Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	**Operations Planning**	**Medium**	N/A	N/A	The Responsible Entity documented, but did not, implement one or more BCSI protection program(s). (R1) OR The Responsible Entity documented but did not implement at least one method to identify BCSI. (1.1) OR The Responsible Entity documented but did not implement at least one method to protect and securely handle BCSI. (1.2)	The Responsible Entity neither documented nor implemented one or more BCSI protection program(s). (R1)
R2	**Operations Planning**	**Lower**	N/A	The Responsible Entity implemented one or more documented	The Responsible Entity implemented one or more documented	The Responsible Entity has not documented or implemented any

Version History

Version	Date	Action	Change Tracking
1	11/26/12	Adopted by the NERC Board of Trustees.	Developed to define the information protection requirements in coordination with other CIP standards and to address the balance of the FERC directives in its Order 706.
1	11/22/13	FERC Order issued approving CIP-011-1. (Order becomes effective on 2/3/14.)	
2	11/13/14	Adopted by the NERC Board of Trustees.	Addressed two FERC directives from Order No. 791 related to identify, assess, and correct language and communication networks.
2	2/12/15	Adopted by the NERC Board of Trustees.	Replaces the version adopted by the Board on 11/13/2014. Revised version addresses remaining directives from Order No. 791 related to transient devices and low impact BES Cyber Systems.
2	1/21/16	FERC Order issued approving CIP-011-2. Docket No. RM15-14-000	
3	TBD	Adopted by the NERC Board of Trustees	Revised to enhance BES reliability for entities to manage their BCSI.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Final Ballot	October 19–28, 2021
Board adoption	November 4, 2021

A. Introduction

1. **Title:** Cyber Security — Information Protection

2. **Number:** CIP-011-~~X~~Y

3. **Purpose:** To prevent unauthorized access to BES Cyber System Information (BCSI) by specifying information protection requirements in support of protecting BES Cyber Systems against compromise that could lead to misoperation or instability in the Bulk Electric System (BES).

4. **Applicability:**

   4.1. Functional Entities: For the purpose of the requirements contained herein, the following list of functional entities will be collectively referred to as “Responsible Entities.” For requirements in this standard where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are specified explicitly.

   4.1.1 Balancing Authority

   4.1.2 Distribution Provider that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:

   4.1.2.1 Each underfrequency Load shedding (UFLS) or undervoltage Load shedding (UVLS) system that:

   4.1.2.1.1 is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

   4.1.2.1.2 performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

   4.1.2.2 Each Remedial Action Scheme (RAS) where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

   4.1.2.3 Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

   4.1.2.4 Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

   4.1.3 Generator Operator

   4.1.4 Generator Owner

   4.1.5 Reliability Coordinator

4.1.6 Transmission Operator

4.1.7 Transmission Owner

4.2. Facilities: For the purpose of the requirements contained herein, the following Facilities, systems, and equipment owned by each Responsible Entity in 4.1 above are those to which these requirements are applicable. For requirements in this standard where a specific type of Facilities, system, or equipment or subset of Facilities, systems, and equipment are applicable, these are specified explicitly.

4.2.1 Distribution Provider: One or more of the following Facilities, systems and equipment owned by the Distribution Provider for the protection or restoration of the BES:

4.2.1.1 Each UFLS or UVLS System that:

4.2.1.1.1 is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.2.1.1.2 performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.2.1.2 Each RAS where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.3 Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.4 Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.2.2 Responsible Entities listed in 4.1 other than Distribution Providers:

All BES Facilities.

4.2.3 Exemptions: The following are exempt from Standard CIP-011-~~X~~Y:

4.2.3.1 Cyber ~~Assets~~ Systems at Facilities regulated by the Canadian Nuclear Safety Commission.

4.2.3.2 Cyber ~~Assets~~ Systems associated with communication ~~networks and data communication~~ links between discrete Electronic Security Perimeters (ESP).

4.2.3.3 Cyber Systems, associated with communication links, between the Cyber Systems providing confidentiality and integrity of an ESP that extends to one or more geographic locations.

~~4.2.3.3~~4.2.3.4 The systems, structures, and components that are regulated by the Nuclear Regulatory Commission under a cyber security plan pursuant to 10 C.F.R. Section 73.54.

~~4.2.3.4~~4.2.3.5 For Distribution Providers, the systems and equipment that are not included in section 4.2.1 above.

~~4.2.3.5~~4.2.3.6 Responsible Entities that identify that they have no BES Cyber Systems categorized as high impact or medium impact according to the CIP-002~~-5.1a~~ identification and categorization processes.

5. “Applicable Systems” Columns in Tables: Each table has an “Applicable Systems” column to define the scope of systems to which a specific requirement part applies.

~~5.~~6. Effective Dates: See Project 2016-02 “Modification to CIP Standards Implementation Plan”~~ for CIP-011-X~~.

6. ~~**Background:** Standard CIP-011 exists as part of a suite of CIP Standards related to cyber security, which require the initial identification and categorization of BES Cyber Systems and require a minimum level of organizational, operational, and procedural controls to mitigate risk to BES Cyber Systems.~~

~~Most requirements open with, *“Each Responsible Entity shall implement one or more documented [processes, plan, etc.] that include the applicable items in [Table Reference].”* The referenced table requires the applicable items in the procedures for the requirement’s common subject matter.~~

~~The term *documented processes* refers to a set of required instructions specific to the Responsible Entity and to achieve a specific outcome. This term does not imply any particular naming or approval structure beyond what is stated in the requirements. An entity should include as much as it believes necessary in its documented processes, but it must address the applicable requirements in the table.~~

~~The terms *program* and *plan* are sometimes used in place of *documented processes* where it makes sense and is commonly understood. For example, documented processes describing a response are typically referred to as *plans* (i.e., incident response plans and recovery plans). Likewise, a security plan can describe an approach involving multiple procedures to address a broad subject matter.~~

~~Similarly, the term *program* may refer to the organization’s overall implementation of its policies, plans and procedures involving a subject matter. Examples in the standards include the personnel risk assessment program and the personnel training program.~~

~~The full implementation of the CIP Cyber Security Standards could also be referred to as a program. However, the terms *program* and *plan* do not imply any additional requirements beyond what is stated in the standards.~~

~~Responsible Entities can implement common controls that meet requirements for multiple high and medium impact BES Cyber Systems. For example, a single training program could meet the requirements for training personnel across multiple BES Cyber Systems.~~

~~Measures for the initial requirement are simply the documented processes themselves. Measures in the table rows provide examples of evidence to show documentation and implementation of applicable items in the documented processes. These measures serve to provide guidance to entities in acceptable records of compliance and should not be viewed as an all-inclusive list.~~

~~Throughout the standards, unless otherwise stated, bulleted items in the requirements and measures are items that are linked with an “or,” and numbered items are items that are linked with an “and.”~~

~~Many references in the Applicability section use a threshold of 300 MW for UFLS and UVLS. This particular threshold of 300 MW for UVLS and UFLS was provided in Version 1 of the CIP Cyber Security Standards. The threshold remains at 300 MW since it is specifically addressing UVLS and UFLS, which are last ditch efforts to save the BES. A review of UFLS tolerances defined within regional reliability standards for UFLS program requirements to date indicates that the historical value of 300 MW represents an adequate and reasonable threshold value for allowable UFLS operational tolerances.~~

~~“Applicable Systems” Columns in Tables:~~

~~Each table has an “Applicable Systems” column to further define the scope of systems to which a specific requirement row applies. The CSO706 SDT adapted this concept from the National Institute of Standards and Technology (“NIST”) Risk Management Framework as a way of applying requirements more appropriately based on impact and connectivity characteristics. The following conventions are used in the “Applicable Systems” column as described.~~

~~High Impact BES Cyber Systems –~~ ~~Applies to BES Cyber Systems categorized as high impact according to the CIP-002-5.1a identification and categorization processes.~~

~~Medium Impact BES Cyber Systems –~~ ~~Applies to BES Cyber Systems categorized as medium impact according to the CIP-002-5.1a identification and categorization processes.~~

~~**Electronic Access Control or Monitoring Systems (EACMS) –** Applies to each Electronic Access Control or Monitoring System associated with a referenced high impact BES Cyber System or medium impact BES Cyber System. Examples may include, but are not limited to, firewalls, authentication servers, and log monitoring and alerting systems.~~

~~**Physical Access Control Systems (PACS) –** Applies to each Physical Access Control System associated with a referenced high impact BES Cyber System or medium impact BES Cyber System with External Routable Connectivity.~~

~~**Protected Cyber Assets (PCA) –** Applies to each Protected Cyber Asset associated with a referenced high impact BES Cyber System or medium impact BES Cyber System.~~

B. Requirements and Measures

R1. Each Responsible Entity shall implement one or more documented information protection program(s) for BES Cyber System Information (BCSI) pertaining to “Applicable Systems” identified in *CIP-011-~~X~~ Y Table R1 – Information Protection Program* that collectively includes each of the applicable requirement parts in *CIP-011-~~X~~ Y Table R1 – Information Protection Program*. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning].*

M1. Evidence for the information protection program must include the applicable requirement parts in *CIP-011-~~X~~ Y Table R1 – Information Protection Program* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-011-~~X~~ Y Table R1 – Information Protection Program			
Part	**Applicable Systems**	**Requirements**	**Measures**
1.1	High Impact BES Cyber Systems (BCS) and their associated: 1. EACMS; and 2. PACS Medium Impact BES Cyber Systems and their associated: 1. EACMS; and 2. PACS SCI identified independently supporting an Applicable System above	Method(s) to identify BCSI.	Examples of ~~acceptable~~ evidence may include, but are not limited to, the following: • Documented method(s) to identify BCSI from the entity’s information protection program; or • Indications on information (e.g., labels or classification) that identify BCSI as designated in the entity’s information protection program; or • Training materials that provide personnel with sufficient knowledge to identify BCSI; or • Storage locations identified for housing BCSI in the entity’s information protection program.

Part	Applicable Systems	Requirements	Measures
1.2	High Impact ~~BES Cyber Systems~~BCS and their associated: 1. EACMS; and 2. PACS Medium Impact BES Cyber Systems and their associated: 1. EACMS; and 2. PACS SCI identified independently supporting an Applicable System above	Method(s) to protect and securely handle BCSI to mitigate risks of compromising confidentiality.	Examples of evidence for on-premises BCSI may include, but are not limited to, the following: - Procedures for protecting and securely handling, which include topics such as storage, security during transit, and use of BCSI; or - Records indicating that BCSI is handled in a manner consistent with the entity's documented procedure(s). Examples of evidence for off-premises BCSI may include, but are not limited to, the following: - Implementation of electronic technical method(s) to protect electronic BCSI (e.g., data masking, encryption, hashing, tokenization, cipher, electronic key management); or - Implementation of physical technical method(s) to protect physical BCSI (e.g., physical lock and key management, physical badge management, biometrics, alarm system); or

CIP-011-~~X~~ Y Table R1 – Information Protection Program			
Part	Applicable Systems	Requirements	Measures
			- Implementation of administrative method(s) to protect BCSI (e.g., vendor service risk assessments, business agreements).

R2. Each Responsible Entity shall implement one or more documented process(es) that collectively include the applicable requirement parts in *CIP-011-~~X~~ Y Table R2 – ~~BES Cyber Asset~~ Reuse and Disposal*. *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning].*

M2. Evidence must include each of the applicable documented processes that collectively include each of the applicable requirement parts in *CIP-011-~~X~~ Y Table R2 – ~~BES Cyber Asset~~ Reuse and Disposal* and additional evidence to demonstrate implementation as described in the Measures column of the table.

CIP-011-~~X~~ Y Table R2 – ~~BES Cyber Asset~~ Reuse and Disposal

Part	Applicable Systems	Requirements	Measures
2.1	High Impact BES Cyber Systems and their associated: 1. EACMS; 2. PACS; and 3. PCA Medium Impact BES Cyber Systems and their associated: 1. EACMS; 2. PACS; and 3. PCA SCI identified independently supporting an Applicable System above	~~Prior to the release for reuse of applicable Cyber Assets that contain BCSI (except for reuse within other systems identified in the “Applicable Systems” column), the Responsible Entity shall take action~~Method(s) to prevent the unauthorized retrieval of BCSI from ~~the Cyber Asset data storage media~~Applicable Systems containing BCSI, prior to their disposal or reuse (except for reuse within other systems identified in the “Applicable Systems” column).	Examples of ~~acceptable~~ evidence may include, but are not limited to, the following: • Records tracking sanitization actions taken to prevent unauthorized retrieval of BCSI such as clearing, purging, or destroying; or • Records tracking actions such as encrypting, retaining in the Physical Security Perimeter or other methods used to prevent unauthorized retrieval of BCSI.

CIP-011-~~X~~ Y Table R2 – ~~BES Cyber Asset~~ Reuse and Disposal			
Part	Applicable Systems	Requirements	Measures
~~2.2~~	~~High Impact BES Cyber Systems and their associated:~~ ~~1. EACMS;~~ ~~2. PACS; and~~ ~~PCA~~ ~~Medium Impact BES Cyber Systems and their associated:~~ ~~0. EACMS;~~ ~~0. PACS; and~~ ~~PCA~~	~~Prior to the disposal of applicable Cyber Assets that contain BCSI, the Responsible Entity shall take action to prevent the unauthorized retrieval of BCSI from the Cyber Asset or destroy the data storage media.~~	~~Examples of acceptable evidence may include, but are not limited to, the following:~~ ~~Records that indicate that data storage media was destroyed prior to the disposal of an applicable Cyber Asset; or~~ ~~Records of actions taken to prevent unauthorized retrieval of BCSI prior to the disposal of an applicable Cyber Asset.~~

B. Compliance

1. Compliance Monitoring Process:

1.1. Compliance Enforcement Authority: “Compliance Enforcement Authority” (CEA) means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the CEA may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its CEA to retain specific evidence for a longer period of time as part of an investigation:

- The applicable entity shall retain evidence of each requirement in this standard for three calendar years.
- If an applicable entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.
- The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, “Compliance Monitoring and Enforcement Program” refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Board adoption	November 4, 2021

A. Introduction

1. **Title:** **Cyber Security - Supply Chain Risk Management**

2. **Number:** **CIP-013-3**

3. **Purpose:** To mitigate cyber security risks to the reliable operation of the Bulk Electric System (BES) by implementing security controls for supply chain risk management of BES Cyber Systems and their associated cyber systems.

4. **Applicability:**

4.1. **Functional Entities:** For the purpose of the requirements contained herein, the following list of functional entities will be collectively referred to as “Responsible Entities.” For requirements in this standard where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are specified explicitly.

4.1.1. **Balancing Authority**

4.1.2. **Distribution Provider** that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:

4.1.2.1. Each underfrequency Load shedding (UFLS) or undervoltage Load shedding (UVLS) system that:

4.1.2.1.1. Is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.1.2.1.2. Performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.1.2.2. Each Remedial Action Scheme (RAS) where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.3. **Generator Operator**

4.1.4. **Generator Owner**

4.1.5. **Reliability Coordinator**

4.1.6. **Transmission Operator**

4.1.7. **Transmission Owner**

4.2. Facilities: For the purpose of the requirements contained herein, the following Facilities, systems, and equipment owned by each Responsible Entity in 4.1 above are those to which these requirements are applicable. For requirements in this standard where a specific type of Facilities, system, or equipment or subset of Facilities, systems, and equipment are applicable, these are specified explicitly.

4.2.1. Distribution Provider: One or more of the following Facilities, systems and equipment owned by the Distribution Provider for the protection or restoration of the BES:

4.2.1.1. Each UFLS or UVLS System that:

4.2.1.1.1. Is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.2.1.1.2. Performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.2.1.2. Each RAS where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.2.2. Responsible Entities listed in 4.1 other than Distribution Providers: All BES Facilities.

4.2.3. Exemptions: The following are exempt from Standard CIP-013-3:

4.2.3.1. Cyber Systems at Facilities regulated by the Canadian Nuclear Safety Commission.

4.2.3.2. Cyber Systems associated with communication links between discrete Electronic Security Perimeters (ESP).

4.2.3.3. Cyber Systems, associated with communication links, between Cyber Systems providing confidentiality and integrity of an ESP that extends to one or more geographic locations.

4.2.3.4. The systems, structures, and components that are regulated by the Nuclear Regulatory Commission under a cyber security plan pursuant to 10 C.F.R. Section 73.54.

4.2.3.5. For Distribution Providers, the systems and equipment that are not included in section 4.2.1 above.

4.2.3.6. Responsible Entities that identify that they have no BES Cyber Systems categorized as high impact or medium impact according to the identification and categorization process required by CIP-002 or any subsequent version of that Reliability Standard.

5. **Effective Date:** See “Project 2016-02 Modification to CIP Standards Implementation Plan.”

B. Requirements and Measures

R1. Each Responsible Entity shall develop one or more documented supply chain cyber security risk management plan(s) for high and medium impact BES Cyber Systems (BCS), their associated Electronic Access Control or Monitoring Systems (EACMS), Physical Access Control Systems (PACS), and SCI identified independently supporting these BCS or their associated EACMS and PACS. The plan(s) shall include: *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

1.1. One or more process(es) used in planning for the procurement of systems listed in R1 to identify and assess cyber security risk(s) to the Bulk Electric System (BES) from vendor products or services resulting from: (i) procuring and installing vendor equipment and software; and (ii) transitions from one vendor(s) to another vendor(s).

1.2. One or more process(es) used in procuring systems listed in R1 that address the following, as applicable:

1.2.1. Notification by the vendor of vendor-identified incidents related to the products or services provided to the Responsible Entity that pose cyber security risk to the Responsible Entity;

1.2.2. Coordination of responses to vendor-identified incidents related to the products or services provided to the Responsible Entity that pose cyber security risk to the Responsible Entity;

1.2.3. Notification by vendors when remote or onsite access should no longer be granted to vendor representatives;

1.2.4. Disclosure by vendors of known vulnerabilities related to the products or services provided to the Responsible Entity;

1.2.5. Verification of software integrity and authenticity of all software and patches provided by the vendor; and

1.2.6. Coordination of controls for vendor-initiated remote access.

M1. Evidence shall include one or more documented supply chain cyber security risk management plan(s) as specified in the Requirement.

R2. Each Responsible Entity shall implement its supply chain cyber security risk management plan(s) specified in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

Note: Implementation of the plan does not require the Responsible Entity to renegotiate or abrogate existing contracts (including amendments to master agreements and purchase orders). Additionally, the following issues are beyond the scope of Requirement R2: (1) the actual terms and conditions of a procurement contract; and (2) vendor performance and adherence to a contract.

M2. Evidence shall include documentation to demonstrate implementation of the supply chain cyber security risk management plan(s), which could include, but is not limited to, correspondence, policy documents, or working documents that demonstrate use of the supply chain cyber security risk management plan.

R3. Each Responsible Entity shall review and obtain CIP Senior Manager or delegate approval of its supply chain cyber security risk management plan(s) specified in Requirement R1 at least once every 15 calendar months. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

M3. Evidence shall include the dated supply chain cyber security risk management plan(s) approved by the CIP Senior Manager or delegate(s) and additional evidence to demonstrate review of the supply chain cyber security risk management plan(s). Evidence may include, but is not limited to, policy documents, revision history, records of review, or workflow evidence from a document management system that indicate review of supply chain risk management plan(s) at least once every 15 calendar months; and documented approval by the CIP Senior Manager or delegate.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" (CEA) means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the CEA may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Responsible Entity shall keep data or evidence to show compliance as identified below unless directed by its CEA to retain specific evidence for a longer period of time as part of an investigation.

- Each Responsible Entity shall retain evidence of each requirement in this standard for three calendar years.
- If a Responsible Entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.
- The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.	The Responsible Entity developed one or more documented supply chain cyber security risk management plan(s) which include the use of process(es) in planning for procurement of BES Cyber Systems, and their associated EACMS, PACS, and SCI, to identify and assess cyber security risk(s) to the BES as specified in Part 1.1, and include the use of process(es) for procuring BES Cyber Systems, and their associated EACMS, PACS, and SCI, as specified in Part 1.2, but the plans do not include one of the parts in Requirement R1 Part 1.2.1 through Part 1.2.6. 45-day formal comment period with ballot	August ~~3~~29–~~September 16~~October 11, 2021
Final Ballot	October 19–28, 2021
Board adoption	November 4, 2021

A. Introduction

1. **Title:** **Cyber Security - Supply Chain Risk Management**

2. **Number:** **CIP-013-3**

3. **Purpose:** To mitigate cyber security risks to the reliable operation of the Bulk Electric System (BES) by implementing security controls for supply chain risk management of BES Cyber Systems and their associated cyber systems.

4. **Applicability:**

    4.1. Functional Entities: For the purpose of the requirements contained herein, the following list of functional entities will be collectively referred to as "Responsible Entities." For requirements in this standard where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are specified explicitly.

    4.1.1. Balancing Authority

    4.1.2. Distribution Provider that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:

    4.1.2.1. Each underfrequency Load shedding (UFLS) or undervoltage Load shedding (UVLS) system that:

    4.1.2.1.1. Is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

    4.1.2.1.2. Performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

    4.1.2.2. Each Remedial Action Scheme (RAS) where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

    4.1.2.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

    4.1.3. Generator Operator

    4.1.4. Generator Owner

    4.1.5. Reliability Coordinator

    4.1.6. Transmission Operator

    4.1.7. Transmission Owner

4.2. Facilities: For the purpose of the requirements contained herein, the following Facilities, systems, and equipment owned by each Responsible Entity in 4.1 above are those to which these requirements are applicable. For requirements in this standard where a specific type of Facilities, system, or equipment or subset of Facilities, systems, and equipment are applicable, these are specified explicitly.

4.2.1. Distribution Provider: One or more of the following Facilities, systems and equipment owned by the Distribution Provider for the protection or restoration of the BES:

4.2.1.1. Each UFLS or UVLS System that:

4.2.1.1.1. Is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.2.1.1.2. Performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.2.1.2. Each RAS where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.2.2. Responsible Entities listed in 4.1 other than Distribution Providers: All BES Facilities.

4.2.3. Exemptions: The following are exempt from Standard CIP-013-3:

4.2.3.1. Cyber ~~s~~Systems at Facilities regulated by the Canadian Nuclear Safety Commission.

4.2.3.2. Cyber ~~s~~Systems associated with communication links ~~logically isolated from, but not providing logical isolation for, BES Cyber Systems (BCS) or Shared Cyber Infrastructure (SCI)~~between discrete Electronic Security Perimeters (ESP).

4.2.3.3. Cyber ~~s~~Systems, associated with communication links, between Cyber ~~Assets~~Systems~~, Virtual Cyber Assets, or SCI performing~~

~~logical isolation that~~ providing confidentiality and integrity of an ESP that extends to one or more geographic locations.

4.2.3.4. The systems, structures, and components that are regulated by the Nuclear Regulatory Commission under a cyber security plan pursuant to 10 C.F.R. Section 73.54.

4.2.3.5. For Distribution Providers, the systems and equipment that are not included in section 4.2.1 above.

4.2.3.6. Responsible Entities that identify that they have no BES Cyber Systems categorized as high impact or medium impact according to the identification and categorization process required by CIP-002 or any subsequent version of that Reliability Standard.

5. **Effective Date:** See "Project 2016-02 ~~Virtualization~~ Modification to CIP Standards Implementation Plan."

B. Requirements and Measures

R1. Each Responsible Entity shall develop one or more documented supply chain cyber security risk management plan(s) for high and medium impact BES Cyber Systems (BCS), their associated Electronic Access Control or Monitoring Systems (EACMS), Physical Access Control Systems (PACS), and ~~the~~ SCI identified independently supporting these BCS or their associated EACMS and PACS. ~~hosting high or medium impact BCS or their associated Electronic Access Controlling or Monitoring System (EACMS) or Physical Access Control System (PACS).~~ The plan(s) shall include: *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

1.1. One or more process(es) used in planning for the procurement of systems listed in R1 ~~of SCI, BCS, and their associated EACMS and PACS~~ to identify and assess cyber security risk(s) to the Bulk Electric System (BES) from vendor products or services resulting from: (i) procuring and installing vendor equipment and software; and (ii) transitions from one vendor(s) to another vendor(s).

1.2. One or more process(es) used in procuring systems listed in R1 ~~SCI, BCS, and their associated EACMS and PACS,~~ that address the following, as applicable:

1.2.1. Notification by the vendor of vendor-identified incidents related to the products or services provided to the Responsible Entity that pose cyber security risk to the Responsible Entity;

1.2.2. Coordination of responses to vendor-identified incidents related to the products or services provided to the Responsible Entity that pose cyber security risk to the Responsible Entity;

1.2.3. Notification by vendors when remote or onsite access should no longer be granted to vendor representatives;

1.2.4. Disclosure by vendors of known vulnerabilities related to the products or services provided to the Responsible Entity;

1.2.5. Verification of software integrity and authenticity of all software and patches provided by the vendor ~~for use in the SCI, BCS and their associated EACMS and PACS~~; and

1.2.6. Coordination of controls for vendor-initiated remote access.

M1. Evidence shall include one or more documented supply chain cyber security risk management plan(s) as specified in the Requirement.

R2. Each Responsible Entity shall implement its supply chain cyber security risk management plan(s) specified in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

Note: Implementation of the plan does not require the Responsible Entity to renegotiate or abrogate existing contracts (including amendments to master agreements and purchase orders). Additionally, the following issues are beyond the

scope of Requirement R2: (1) the actual terms and conditions of a procurement contract; and (2) vendor performance and adherence to a contract.

M2. Evidence shall include documentation to demonstrate implementation of the supply chain cyber security risk management plan(s), which could include, but is not limited to, correspondence, policy documents, or working documents that demonstrate use of the supply chain cyber security risk management plan.

R3. Each Responsible Entity shall review and obtain CIP Senior Manager or delegate approval of its supply chain cyber security risk management plan(s) specified in Requirement R1 at least once every 15 calendar months. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

M3. Evidence shall include the dated supply chain cyber security risk management plan(s) approved by the CIP Senior Manager or delegate(s) and additional evidence to demonstrate review of the supply chain cyber security risk management plan(s). Evidence may include, but is not limited to, policy documents, revision history, records of review, or workflow evidence from a document management system that indicate review of supply chain risk management plan(s) at least once every 15 calendar months; and documented approval by the CIP Senior Manager or delegate.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority:

“Compliance Enforcement Authority” (CEA) means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention:

The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the CEA may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Responsible Entity shall keep data or evidence to show compliance as identified below unless directed by its CEA to retain specific evidence for a longer period of time as part of an investigation.

- Each Responsible Entity shall retain evidence of each requirement in this standard for three calendar years.
- If a Responsible Entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.
- The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program

As defined in the NERC Rules of Procedure, “Compliance Monitoring and Enforcement Program” refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Applicable Standard(s)

- Reliability Standard CIP-002-7 – Cyber Security – BES Cyber System Categorization
- Reliability Standard CIP-003-9 – Cyber Security – Security Management Controls
- Reliability Standard CIP-004-7 – Cyber Security – Personnel & Training
- Reliability Standard CIP-005-8 – Cyber Security – BES Cyber System Logical Isolation
- Reliability Standard CIP-006-7 – Cyber Security – Physical Security of BES Cyber Systems
- Reliability Standard CIP-007-7 – Cyber Security – System Security Management
- Reliability Standard CIP-008-7 – Cyber Security – Incident Reporting and Response Planning
- Reliability Standard CIP-009-7 – Cyber Security – Recovery Plans for BES Cyber Systems
- Reliability Standard CIP-010-5 – Cyber Security – Change Management and Vulnerability Assessments
- Reliability Standard CIP-011-3 – Cyber Security – Information Protection
- Reliability Standard CIP-013-3 – Cyber Security – Supply Chain Risk Management
- Proposed new or modified terms listed in the “CIP Definitions Posting Document (Project 2016-02)”

These standards and Definitions of Terms used in the versions listed above of the CIP Cyber Security Standards are posted for ballot by NERC concurrently with this Implementation Plan.

These standards and new and modified terms used in the standards above will be referenced as the “Revised CIP Standards and Definitions” within the Implementation Plan.

Requested Retirement(s)

- Reliability Standard CIP-002-6 – Cyber Security – BES Cyber System Categorization
- Reliability Standard CIP-003-8 – Cyber Security – Security Management Controls
- Reliability Standard CIP-004-6 – Cyber Security – Personnel & Training
- Reliability Standard CIP-005-7 – Cyber Security – Electronic Security Perimeter(s)
- Reliability Standard CIP-006-6 – Cyber Security – Physical Security of BES Cyber Systems
- Reliability Standard CIP-007-6 – Cyber Security – System Security Management

- Reliability Standard CIP-008-6 – Cyber Security – Incident Reporting and Response Planning
- Reliability Standard CIP-009-6 – Cyber Security – Recovery Plans for BES Cyber Systems
- Reliability Standard CIP-010-4 – Cyber Security – Configuration Change Management and Vulnerability Assessments
- Reliability Standard CIP-011-2 – Cyber Security – Information Protection
- Reliability Standard CIP-013-2 – Cyber Security – Supply Chain Risk Management
- Proposed terms for retirement listed in the "Definitions of Terms used in the above listed CIP Cyber Security Standards" document

These standards and definitions used in the versions listed above will be referenced as the "Requested CIP Retired Standards and Definitions" within the Implementation Plan.

Prerequisite Standard(s) or Definitions

These standard(s) or definitions must be approved or retired before the Applicable Standard become effective:

- BES Cyber Asset (BCA)
- BES Cyber System
- BES Cyber System Information
- CIP Senior Manager
- Cyber Asset
- Cyber Security Incident
- Electronic Access Control or Monitoring Systems (EACMS)
- Electronic Access Point (EAP)
- External Routable Connectivity (ERC)
- Electronic Security Perimeter (ESP)
- Interactive Remote Access (IRA)
- Intermediate Systems (IS)
- Management Interface
- Management Module
- Management Systems
- Physical Access Control Systems
- Physical Security Perimeter (PSP)

- Protected Cyber Asset (PCA)
- Removable Media
- Reportable Cyber Security Incident
- Self-Contained Application
- Shared Cyber Infrastructure (SCI)
- Transient Cyber Asset (TCA)
- Virtual Cyber Asset (VCA)

Applicable Entities

- Balancing Authority
- Distribution Provider[1]
- Generator Operator
- Generator Owner
- Reliability Coordinator
- Transmission Operator
- Transmission Owner

General Considerations

The intent of the Initial Performance of Periodic Requirements section is for Responsible Entities to remain on the same time interval of the prior versions of the standards for their performance of the requirements under the new versions. The intent of the Compliance Dates for Early Adoption of Revised CIP Standards and Definitions section is to permit Responsible Entities the adoption to comply with the Revised CIP Standards and Definitions prior to the Effective Date.

Effective Date and Phased-in Compliance Dates

The Effective Dates for the Revised CIP Standards and Definitions are provided below. As noted in the General Considerations section above, the standard drafting team determined to clarify initial performance of periodic requirements and permit Responsible Entities to comply with the Revised CIP Standards and Definitions prior to the effective date. These provisions also are provided below.

Revised CIP Standards and Definitions

Where approval by an applicable governmental authority is required, the Revised CIP Standards and Definitions shall become effective on the first day of the first calendar quarter that is twenty-four (24) months after the effective date of the applicable governmental authority's order approving the

---

[1] See Applicability section of Revised CIP Standards and Definitions for additional information on Distribution Providers subject to the standards.

Revised CIP Standards and Definitions, or as otherwise provided for by the applicable governmental authority.

Where approval by an applicable governmental authority is not required, the Revised CIP Standards and Definitions shall become effective on the first day of the first calendar quarter that is twenty-four (24) months after the date the Revised CIP Standards and Definitions are adopted by the NERC Board of Trustees, or as otherwise provided for in that jurisdiction.

Initial Performance of Periodic Requirements

Responsible Entities shall initially comply with the periodic requirements in the Revised CIP Standards and Definitions within the periodic timeframes of their last performance under the Requested CIP Retired Standards and Definitions.

Compliance Dates for Early Adoption of Revised CIP Standards and Definitions

A Responsible Entity may elect to comply with the Revised CIP Standards and Definitions following their approval by the applicable governmental authority, but prior to the Effective Date. In such a case, the Responsible Entity shall notify the applicable Regional Entities of the date of compliance with the Revised CIP Standards and Definitions. Responsible Entities must comply with applicable Requested CIP Retired Standards and Definitions until that date.

Retirement Date

Requested CIP Retired Standards and Definitions

The Requested CIP Retired Standards and Definitions shall be retired immediately prior to the effective date of the Revised CIP Standards and Definitions in the particular jurisdiction in which the Revised CIP Standards and Definitions are becoming effective.

Unofficial Comment Form

Project 2016-02 Modifications to CIP Standards

Do not use this form for submitting comments. Use the Standards Balloting and Commenting System (SBS) to submit comments on the **Virtualization Modifications** by **8 p.m. Eastern, Friday, August 13, 2021.**

Additional information is available on the project page. If you have questions, contact Senior Standards Developer, Jordan Mallory (404-446-2589).

Background Information

Project 2016-02 (1) addresses the Federal Energy Regulatory Commission (Commission) directives contained in Order No. 822 and (2) considers the Version 5 Transition Advisory Group (V5TAG) issues identified in the CIP V5 Issues for Standard Drafting Team Consideration (V5TAG Transfer Document).

The V5TAG, which consisted of representatives from NERC, Regional Entities, and industry stakeholders, was formed to issue guidance regarding possible methods to achieve compliance with the CIP Version 5 standards and to support industry’s implementation activities. During the V5TAG’s activities, it identified certain issues with the CIP Reliability Standards that would be better addressed by a standard drafting team (SDT) for the CIP Reliability Standards. The V5TAG developed the CIP Version 5 Transition Advisory Group Issues for Consideration document to formally recommend that the SDT address these issues and consider modifications to the standard language during the standards development process. Among other issues, the V5TAG stated “The CIP Version 5 standards comments.

Summary of Changes Overview

The SDT reviewed all comments and made modifications to the Reliability Standards and Definitions accordingly. The SDT revised many standards based on industry comments to revert much of the language back to previously approved, which will be reflected as redline, but is currently the approved language. Below are questions the SDT is seeking industry input. In order to allow the SDT to sort comments received by topic, the SDT respectfully requests comments be submitted with the respective question topic. The SDT thanks industry for your time and review during this comment period.

Questions

1. Are the two options for identification of SCI within CIP-002 clear and is it understood that when SCI is included in the CIP Systems that it is treated like the CIP System, it is a part of for CIP Requirement Applicability?

   ☐ Yes
   ☐ No

   Comments:

2. The Applicable Systems column may include “SCI identified independently…” Is this clear or is additional clarification (such as “SCI identified as supporting, but not part of…”) needed?

   ☐ Yes
   ☐ No

   Comments:

3. The SDT modified the ERC definition to reference “outside the asset containing”. This is to allow scoping based on connectivity of the logging systems as required by CIP-007 Requirement R4 as well as the scoping of requirement parts in CIP-004 and CIP-006 based on risk. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

   ☐ Yes
   ☐ No

   Comments:

4. The SDT proposes that the modified ESP definition can be used for both traditional firewall based networks, as well as future networks such as zero trust. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

   ☐ Yes
   ☐ No

   Comments:

5. The SDT modified the IRA definition based on industry comments. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

   ☐ Yes
   ☐ No

   Comments:

6. The SDT modified the Management Interface definition based on industry comments. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

   ☐ Yes
   ☐ No

   Comments:

7. As discussed in the CIP Definitions and Exemptions Technical Rationale (TR), the SDT believes that the use of configurations or policy in the modified ESP definition can reduce the burden of documenting ESPs in a zero trust environment. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

   ☐ Yes
   ☐ No

   Comments:

8. The SDT added new and revised several defined terms to incorporate virtualization and future technologies within the CIP Standards. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

☐ Yes
☐ No

Comments:

9. The SDT revised CIP-002 based on industry comments. Do you agree with the proposed changes to the CIP-002 Reliability Standard? If not, please provide the basis for your disagreement and an alternate proposal.

☐ Yes
☐ No

Comments:

10. The SDT revised CIP-005 based on industry comments. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

☐ Yes
☐ No

Comments:

11. The SDT revised CIP-007 based on industry comments. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

☐ Yes
☐ No

Comments:

12. The SDT revised CIP-010 based on industry comments. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

☐ Yes
☐ No

Comments:

13. The SDT revised CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013 (conforming changes) based on industry comments. Do you agree with the proposed changes to these Reliability Standards? If not, please provide the basis for your disagreement and an alternate proposal.

    ☐ Yes
    ☐ No

    Comments:

14. Please provide any additional comments for the SAR drafting team to consider, if desired.

CIP Definitions

Project 2016-02 Modifications to CIP Standards

The standard drafting team (SDT) is seeking comment on the following new, modified, or retired terms used in the proposed standards. The first column (*NERC Glossary Term*) provides the NERC Glossary term being modified or proposed as a new. The SDT is proposing acronyms to some currently approved and new glossary terms as shown in redline. The second column (*Currently Approved Definition*) provides the currently approved definition and the third column (*CIP SDT Proposed New or Revised)* reflects the proposed modifications to the current definitions in redline and also reflects newly proposed definitions in clean view.

Table 1: Retired, Modified, or Newly Proposed Definitions

NERC Glossary Term	Currently Approved Definition	CIP SDT Proposed New or Revised
BES Cyber Asset (BCA)	A Cyber Asset that if rendered unavailable, degraded, or misused would, within 15 minutes of its required operation, misoperation, or non-operation, adversely impact one or more Facilities, systems, or equipment, which, if destroyed, degraded, or otherwise rendered unavailable when needed, would affect the reliable operation of the Bulk Electric System. Redundancy of affected Facilities, systems, and equipment shall not be considered when determining adverse impact. Each BES Cyber Asset is included in one or more BES Cyber Systems.	A Cyber Asset or Virtual Cyber Asset, that if rendered unavailable, degraded, or misused would, within 15 minutes of its required operation, misoperation, or non-operation, adversely impact one or more Facilities, systems, or equipment, which, if destroyed, degraded, or otherwise rendered unavailable when needed, would affect the reliable operation of the Bulk Electric System. Redundancy of affected Facilities, systems, and equipment shall not be considered when determining adverse impact. Each BES Cyber Asset is included in one or more BES Cyber Systems.
BES Cyber System (BCS)	One or more BES Cyber Assets logically grouped by a responsible entity to perform one or more reliability tasks for a functional entity.	One or more BES Cyber Assets logically grouped by a R~~r~~esponsible E~~e~~ntity to perform one or more reliability tasks for a functional entity, including Shared Cyber Infrastructure grouped, by the Responsible Entity, in the BES Cyber System it supports.

		Virtual machines hosted on a physical TCA can be treated as software on that physical TCA. Examples of Transient Cyber Assets include, but are not limited to, Cyber Assets or Virtual Cyber Assets used for data transfer, vulnerability assessment, maintenance, or troubleshooting purposes.
Virtual Cyber Asset (VCA) ***New Definition***		A logical instance of an operating system or firmware hosted on Shared Cyber Infrastructure or a PCA.

NERC
NORTH AMERICAN ELECTRIC
RELIABILITY CORPORATION

Technical Rationale

New and Modified Terms, and Exemption Language Used in NERC Reliability Standards | Project 2016-02 Modification to CIP Standards

Proposed Modified Terms:

BES Cyber Asset (BCA)

A Cyber Asset or Virtual Cyber Asset, that if rendered unavailable, degraded, or misused would, within 15 minutes of its required operation, misoperation, or non-operation, adversely impact one or more Facilities, systems, or equipment, which, if destroyed, degraded, or otherwise rendered unavailable when needed, would affect the reliable operation of the Bulk Electric System. Redundancy of affected Facilities, systems, and equipment shall not be considered when determining adverse impact. Each BES Cyber Asset is included in one or more BES Cyber Systems.

Rationale

The BCA definition is changing to allow for BCA to be either Cyber Assets (hardware included) or Virtual Cyber Assets (VCA) (software only virtual machines without the underlying hardware). The definition of BCA excludes the underlying hardware for virtualized environments, now defined as Shared Cyber Infrastructure (SCI). The standards drafting team (SDT) recognizes that SCI indeed has the same impact as a virtual BCA and even more so if hosting numerous BCA, and those risks will be addressed in requirements specifically for the SCI. See the VCA and SCI definition below.

BES Cyber System (BCS)

One or more BES Cyber Assets logically grouped by a Responsible Entity to perform one or more reliability tasks for a functional entity, including Shared Cyber Infrastructure grouped, by the Responsible Entity, in the BES Cyber System it supports.

Rationale

The SDT is adding the option (known as the “all-in” scenario) for entities to group their SCI within a BCS it supports. See the CIP-002 Technical Rationale document for a description of the options for identifying SCI and reasons an entity may choose between the options. In addition, to shorten several applicability statements within the body of CIP standards, the SDT proposes that “BCS” be added as the defined acronym for “BES Cyber System” to the NERC glossary.

BES Cyber System Information (BCSI)

Information about the BES Cyber System or Shared Cyber Infrastructure that could be used to gain unauthorized access or pose a security threat to the BES Cyber System. BES Cyber System Information does not include individual pieces of information that by themselves do not pose a threat or could not be used to allow unauthorized access to BES Cyber Systems, such as, but not limited to, device names, individual IP addresses without context, ESP names, or policy statements. Examples of BES Cyber System Information may include, but are not limited to, security procedures or security information about BES Cyber Systems, Shared Cyber Infrastructure, Physical Access Control Systems, and Electronic Access Control or Monitoring

Systems that is not publicly available and could be used to allow unauthorized access or unauthorized distribution; collections of network addresses; and network topology of the BES Cyber System

Rationale

Conforming changes such that BCSI includes information about SCI.

CIP Senior Manager

A single senior management official with overall authority and responsibility for leading and managing implementation of and continuing adherence to the requirements within the NERC Critical Infrastructure Protection Standards.

Rationale

Remove explicit reference to the CIP standards as only “CIP-002 through CIP-011” as the body of CIP standards has grown beyond CIP-011. As an example, the CIP Senior Manager also has requirements within CIP-013.

Cyber Assets

Programmable electronic devices, including the hardware, software, and data in those devices; excluding Shared Cyber Infrastructure.

Rationale

Modified to explicitly exclude SCI from the definition of CA such that SCI and CA are two hardware ‘forms’ on which the other types of cyber systems reside. SCI is another form of ‘programmable electronic devices’ that do NOT include the software and data in the hardware devices. SCI is defined separately such that it can be the object of additional requirements based on its unique risks.

Cyber Security Incident

A malicious act or suspicious event that:

- For a high or medium impact BES Cyber System, compromises or attempts to compromise (1) an Electronic Security Perimeter, (2) a Physical Security Perimeter, (3) an Electronic Access Control or Monitoring System, or (4) Shared Cyber Infrastructure; or
- Disrupts or attempts to disrupt the operation of a BES Cyber System.

Rationale

Modified to add SCI to the scope of compromised or attempted compromise systems.

Electronic Access Control or Monitoring Systems (EACMS)

Cyber Assets, Virtual Cyber Assets, or Shared Cyber Infrastructure that perform electronic access control or electronic access monitoring of the Electronic Security Perimeter(s) or BES Cyber Systems or Shared Cyber Infrastructure. This includes Intermediate Systems and SCI grouped, by the Responsible Entity, in the EACMS it supports.

Rationale

Modified to add VCA and SCI as two other forms that an EACMS can take and add SCI as an object of the access control or monitoring. EACMS also includes the SCI grouped by the Responsible Entity with a virtualized EACMS it supports.

Electronic Access Point (EAP)

A policy enforcement point, or a Cyber Asset interface that allows routable communication to and from the BES Cyber System within an ESP.

Rationale

As network security moves deeper into the infrastructure, its no longer necessary to prescribe that network security be performed on a 'Cyber Asset interface on an ESP'; at one point on a network edge. Zero Trust, for example, highly distributes the network security model and is not perimeter-based. With the added flexibility in CIP-005 to adopt these models in addition to the traditional ESP model, the term EAP is being modified to allow for policy enforcement points and no longer prescribes an architecture.

External Routable Connectivity (ERC)

The ability to communicate to a CIP System using a bi-directional routable protocol from outside the asset containing the CIP System.

Rationale

The ERC definition is undergoing a clarification from an ability to "access" to an ability to "communicate" so it is a more connectivity-based term and distinguished from user access-based terms such as IRA. The ERC term is used throughout the CIP Standards within the Applicable Systems column as a scoping mechanism based on the inherent risk associated with external routable connectivity as well as to limit the scope of requirements that would require ERC to function. The SDT is maintaining this use of ERC, but also clarifying the relationship between ERC and IRA in that a non-routable, serial only CIP System may have ERC and have IRA through the ERC through a subsequent IP/serial conversion (see changes to IRA definition). The definition was also modified to use the newly proposed 'CIP System' glossary term as shorthand for the various types of Cyber Systems that are in CIP scope. The intent is a CIP System within a BES asset has ERC if it is reachable by a bi-directional routable protocol from outside of the asset containing it. Cyber Assets on an isolated, standalone routable protocol network within a BES asset that cannot be reached from outside the asset (e.g., a PLC, HMI, and switch network as a standalone system with no firewall or router connections to any other network) would not have ERC.

ERC is no longer based on 'external' being defined in terms of the ESP as ESPs are changing in light of Zero Trust models. Zero Trust will shrink ESP's over time to the smallest, most granular object possible including a single device or possibly to process or resource level on a device. In this model, many dynamic, short-lived session level 'perimeters' may exist. In these implementations as the ESP shrinks, if ERC continues to be based on ESP then the 'external' in ERC begins to lose meaning, thus the move away from ESP for the determination of what is external. Therefore, the SDT is modifying the object of the "outside of " statement to be external to the asset containing the CIP System being accessed, because that ts the logical object where both the risk elevates, and the connectivity capability must exist so that the ERC definition can fulfill both of the current scoping goals in place within the CIP Standards.

Electronic Security Perimeter (ESP)

A set of configurations or policies enforced by an EACMS that controls communications to or from any part of a BES Cyber System. These configurations or policies group CIP Systems of the same impact rating and their associated PCAs.

Rationale

The traditional network-edge Electronic Security Perimeter remains a valid network security model, however it is no longer the only prescribed model as CIP-005 allows other access control models that are not based on network perimeters such as Zero Trust architectures. The proposed ESP definition is more objective-oriented and is no longer network-location centric as security models such as Zero Trust move away from implicit trust within network perimeters and using network location as a primary factor in access control decisions. In these models, the perimeter shrinks to increasingly more granular levels, potentially down to a process or resource level on a BCS and nothing on the network is trusted for unrestricted communications. The proposed definition allows for an ESP to be (a) static point(s) on a network boundary such as a traditional FW that is enforcing access policies or configurations (e.g., FW rulesets), (b) many dynamic, short-lived, session-level 'perimeters' established at time of access that are network independent (e.g., users to resources, for example), or (c) hybrid implementations combining elements of both.

Interactive Remote Access (IRA)

User-initiated real-time access by a person from outside of the Responsible Entity's Electronic Security Perimeters (ESP) using a routable protocol:

- to a Cyber System within an ESP;
- through a Cyber Asset or Virtual Cyber Asset that is converting communications from a routable protocol to a non-routable protocol to a Cyber System not within an Electronic Security Perimeter;
- To Management Interfaces of a Shared Cyber Infrastructure; or
- To Management Interfaces of an Electronic Access Control or Monitoring Systems that enforces an ESP.

.

Rationale

The proposed IRA definition changes in two fundamental ways: (1) to incorporate as IRA situations where a BCS has ERC and through it users outside of any of the Responsible Entity's ESPs have access to non-routable (serial) CIP Systems within the asset through a subsequent IP/serial conversion, and (b) to include the Management Interfaces of SCI or EACMS that enforce an ESP as targets of IRA, such that IRA includes not only objects within an ESP, but the objects that enforce the ESP as well. The references to ownership of the remote client have been removed.

Intermediate Systems

One or more Electronic Access Control or Monitoring Systems that are used to restrict Interactive Remote Access to only authorized users .

Rationale

The IS definition is changing to remove requirement language (i.e., where an Intermediate System must reside) embedded within the definition. Such language has been moved to CIP-005 R2 within a mandatory requirement. The definition was also updated from a Cyber Asset focus to an EACMS focus to include more forms (i.e., VCA) the Intermediate System can take.

Physical Access Control Systems (PACS)

Cyber Assets, Virtual Cyber Assets, or Shared Cyber Infrastructure (SCI) (including SCI grouped, by the Responsible Entity, in the Physical Access Control Systems it supports) that control, alert, or log access to the Physical Security Perimeter(s), exclusive of locally mounted hardware or devices at the Physical Security Perimeter such as motion sensors, electronic lock control mechanisms, and badge readers.

Rationale

Modified to add VCA and SCI as two other forms that a PACS can take. PACS also include the SCI grouped by the Responsible Entity with a virtualized PACS it supports.

Physical Security Perimeter (PSP)

The physical border surrounding locations in which BES Cyber Assets, BES Cyber Systems, Shared Cyber Infrastructure, or Electronic Access Control or Monitoring Systems reside, and for which access is controlled.

Rationale

The PSP definition is changing to add SCI as type of device which must be within a PSP.

Protected Cyber Asset (PCA)

One or more Cyber Assets or Virtual Cyber Assets that:

- Is within an Electronic Security Perimeter, but is not part of the highest impact BES Cyber System within the same Electronic Security Perimeter; or
- Share CPU or memory with any part of a BES Cyber System, excluding Virtual Cyber Assets that are being actively remediated prior to introduction to the ESP.

Rationale

The PCA definition is being updated to include “share CPU or memory with any part of a BES Cyber System” to mitigate the risks of hardware-based vulnerabilities (Spectre, Meltdown, Rowhammer, etc.) on Shared Cyber Infrastructure for any virtual machines allowed to run on the same hardware as BES Cyber Systems. Since virtualization can allow systems of differing trust levels to simultaneously execute on the same hypervisor servers in the hardware underlay and thus share the same CPU and memory, this addition to the PCA definition requires that those VCAs that do share CPU and memory with a BCS become associated PCA’s of the BCS. This provides the high water marking of VCAs sharing a single hypervisor’s CPU or memory. Affinity rules can be used within the virtualization configuration to prevent this situation and keep other VCAs from becoming associated PCAs. Finally, the definition is being modified to account for “remediation VLAN” automation of security controls where a VCA may instantiate in a logical network reserved for vulnerability assessment and updates (OS patches, AV updates, etc.).

The intent is the VCA does not become a PCA while temporarily in this state as its being updated prior to being connected to its production network.

Removable Media

Storage media that (i) are not Cyber Assets or Shared Cyber Infrastructure, (ii) are capable of transferring executable code, (iii) can be used to store, copy, move, or access data, and (iv) are directly connected for 30 consecutive calendar days or less to a BES Cyber Asset, Shared Cyber Infrastructure, a network within an ESP, or a Protected Cyber Asset.

Rationale

The Removable Media definition is being updated to add SCI as a target of the Removable Media connection.

Reportable Cyber Security Incident

A Cyber Security Incident that compromised or disrupted:
- A BES Cyber System that performs one or more reliability tasks of a functional entity;
- An Electronic Security Perimeter of a high or medium impact BES Cyber System;
- An Electronic Access Control or Monitoring System of a high or medium impact BES Cyber System; or
- Shared Cyber Infrastructure supporting a BES Cyber System.

Rationale

This definition is being modified to add compromised or disrupted SCI supporting a BCS as a target.

Transient Cyber Asset (TCA)

A Cyber Asset or Virtual Cyber Asset that is:

1. capable of transmitting or transferring executable code,
2. not included in a BES Cyber System,
3. not a Protected Cyber Asset (PCA) associated with high or medium impact BES Cyber Systems, and
4. connected for 30 consecutive calendar days or less:
    - to a network within an Electronic Security Perimeter containing high or medium impact BES Cyber Systems, or
    - directly (e.g., using Ethernet, serial, Universal Serial Bus, or wireless including near field or Bluetooth communication) to a:
        - BES Cyber Asset,
        - Shared Cyber Infrastructure, or
        - Protected Cyber Asset associated with high or medium impact BES Cyber Systems.

Virtual machines hosted on a physical TCA can be treated as software on that physical TCA.
Examples of Transient Cyber Assets include, but are not limited to, Cyber Assets or Virtual Cyber Assets used for data transfer, vulnerability assessment, maintenance, or troubleshooting purposes.

Rationale

The TCA definition is being updated to add VCA as a form a TCA can take. The intent is to handle VCAs that are created for typical TCA uses but are normally dormant (e.g. a VCA with Wireshark for troubleshooting network issues within a virtualized infrastructure). Additionally, SCI was added as a target to which TCA's can be directly connected. The statement "Virtual machines hosted on a physical TCA can be treated as software on that physical TCA" is to clarify that on a physical TCA (laptop) with hypervisor software and one or more VCA images, the hypervisor and VCAs are treated as software on the one physical TCA. This is to clarify that the one physical TCA does not have to be tracked simultaneously as multiple distinct virtual TCAs. Corresponding clarifications have been made to the methods in CIP-003 and CIP-010 used to mitigate the risks of TCA software.

Proposed New Terms:

CIP System

A Cyber System identified by the Responsible Entity as a BES Cyber System, Electronic Access Control or Monitoring System, Physical Access Control System, Shared Cyber Infrastructure, Protected Cyber Asset, or Transient Cyber Asset.

Rationale

This term was created to simplify applicability when referring in the standards or other definitions to objects in scope of the NERC CIP standards in any form they may take (CA, VCA, SCI). It also simplifies applicability when a referral to a "non-CIP System" is needed. If other object types are needed in the future, their addition to this one definition can reduce needed edits throughout the standards.

Cyber System

A group of one or more Cyber Assets, Virtual Cyber Assets, or Shared Cyber Infrastructure.

Rationale

This proposed new term is used to simplify applicability when referring in the standards or other definitions to all the forms an object may take (CA, VCA, or SCI). If other forms are needed in the future, their addition to this one definition can reduce needed edits throughout the standards.

Management Interface

A user interface, logical interface, or dedicated physical port that is used to:

- Control the processes of initializing, deploying, and configuring SCI; or
- Provide lights-out management capabilities; or
- Configure an ESP;

excluding physical user interfaces (e.g., power switch, touch panel, etc)..

Rationale

This term is being defined so that requirements can be addressed to SCI and EACMS Management Interfaces to target the unique risks for virtualized environments presented by the management ‘consoles’ for such environments. With ‘infrastructure as a service’ (IaaS) environments, the management consoles can not only be used to create, but also to destroy or reconfigure virtual servers, networks, switches, firewalls, etc. The term also includes interfaces commonly known as ILO (Integrated Lights Out), that can be used to remotely manage hardware (usually including power on/off, access to the physical console, etc.). It also includes interfaces used to configure an ESP (such as on firewalls or a network switch that is enforcing an ESP between different logical networks (e.g., VLANs).

Shared Cyber Infrastructure (SCI)

One or more programmable electronic devices, including the software and Management Interfaces, that share:

- CPU and memory resources with one or more Virtual Cyber Assets identified as a BCA, EACMS, or PACS; or
- storage resources with any part of a BES Cyber System or their associated EACMS or PACS

Each SCI is either:

- included in one or more BES Cyber Systems, EACMS, or PACS; or
- identified independently.

SCI does not include the supported VCA or CA with which it shares its resources. .

Rationale

The SCI definition is being created to separate the underlying hardware from the VCAs that it hosts. This allows security requirements to be targeted to SCI to address the unique risks of virtualization and shared hardware. There are many requirements that now include the newly defined term SCI in the “Applicable Systems” column to maintain security level parity with traditional Cyber Assets.

Beyond security level parity with protecting a typical hardware based Cyber Asset, the SCI can have a more significant impact in a virtualized environment since it can host, and therefore impact, multiple virtualized systems. Because of this capability, some additional controls only apply to SCI, such as the management plane isolation required by the proposed CIP-005. Addressing these unique risks requires separation of the hardware underlay into a separate definition.

The second set of bullets in the definition outlines two options for identifying SCI. Please see the CIP-002-7 Technical Rationale document for a discussion of these options.

The phrase “SCI does not include the supported VCA or CA with which it shares its resources” is included to clarify that, for example, electronic access to a hosted VCA by a user is not electronic access to the SCI on which it executes.

Of note is that shared network devices are not in the scope of this definition. Since network switches and firewalls share their resources by nature, this exclusion avoids pulling all network hardware into scope as SCI. However, network switches and other hardware that does enforce an ESP (such as a network switch configured to logical isolate different VLANs) comes into scope as an EACMS.

Virtual Cyber Asset (VCA)
A logical instance of an operating system or firmware hosted on Shared Cyber Infrastructure or a Cyber Asset.

Rationale

The NERC Glossary definition of Cyber Asset has a direct tie to the hardware on which it relied. This affected the definitions of the “Applicable Systems” terms such as BES Cyber Systems (BCS), EACMS, PACS, and Protected Cyber Assets (PCAs). Because the Reliability Standard is applicable to the aforementioned systems, the control for the Cyber Assets also applies to the hardware. This one-to-one relationship between a Cyber Asset and its underlying hardware is what virtualization intentionally breaks to increase reliability and resiliency by allowing Virtual Cyber Assets to be abstracted from the hardware and therefore able move to any available hardware out of a pool of resources.

The proposed NERC Glossary definition of Virtual Cyber Asset (VCA) allows the tie between a specific piece of hardware and the related applicable systems to no longer be singularly defined. The definition of VCA is not inclusive of hardware, and other related definitions (EACMS, PACS, PCA, TCA, etc.) have been updated to allow for VCA versions. With the addition of SCI and revisions to the “Applicable Systems”, there can be one or more virtualized instances (each a VCA) of a BCA, EACMS, PACS or PCA that reside on SCI.
Examples of Virtual Cyber Assets may include, but are not limited to, logical instances of the following:

- Operating Systems (Virtual Machines (VM));
- Networking devices such as switches, routers, and load balancers;
- Security appliances such as firewalls and VPN concentrators; and
- Helper appliances with logical connectivity (such as malware detection, plugins, etc.).

Proposed Retired Terms:

None

Technical Rationale for Exemptions Section:

Rationale for Exemption 4.2.3.1

The term ‘Cyber Assets’ was changed to ‘Cyber systems’. Rather than changing this language to a list of all possible forms (Cyber Assets, Virtual Cyber Assets, or Shared Cyber Infrastructure) as the object of the exemption, the SDT chose to instead use the existing language in the 4.2.3.4 and 4.2.3.5 exemptions such that all five exemptions use ‘systems’ as their object.

Rationale for Exemption 4.2.3.2 and 4.2.3.3

In 4.2.3.2, the term ‘Cyber Assets’ was changed to ‘Cyber Systems’ which is a new proposed glossary addition. Rather than changing these two exemptions to list all possible forms (Cyber Assets, Virtual Cyber Assets, or Shared Cyber Infrastructure), the SDT chose to define a new term that incorporates all forms and use it within the multiple exemptions and at other points within the standards.

For 4.2.3.3, the ability to move workloads or VM's seamlessly across different sites for increased resiliency can require different sites to be connected as a flat network without layer 3 ESP's at each discrete site (e.g., a layer 2 adjacency across the sites). A "Super ESP" as its been historically known is created across the sites and thus an exemption based on having a discrete layer 3 ESP at each site no longer works to exclude, for example, the network transport equipment belonging to carriers.   The SDT is including the 4.2.3.3 exemption to further clarify this scenario. Responsible Entities should notice the exemption uses the word "between" – when extending an ESP between geographic locations, CIP-005 requires the confidentiality and integrity protection of the data (typically through encryption) between the relevant PSPs. This exemption then covers the related Cyber Systems "between" those encryption points but does not exclude the endpoints performing the encryption.

Technical Rationale for Reliability Standard CIP-002-7

Introduction

This document explains the technical rationale and justification for the proposed Reliability Standard CIP-002-7. It provides stakeholders and the ERO Enterprise with an understanding of the technology and technical requirements in the Reliability Standard. This Technical Rationale and Justifications for CIP-002-7 is not a Reliability Standard and should not be considered mandatory and enforceable.

Updates to this document now include the Project 2016-02 – Modifications to CIP Standards Drafting Team's (SDT's) intent in drafting changes to the requirements.

Background

The Version 5 Transition advisory Group (V5TAG), which consists of representatives from NERC, Regional Entities, and industry stakeholders, was formed to issue guidance regarding possible methods to achieve compliance with the CIP V5 standards and to support industry's implementation activities. During the course of the V5TAG's activities, the V5TAG identified certain issues with the CIP Reliability Standards that were more appropriately addressed by a SDT. The V5TAG developed the V5TAG Transfer Document to explain the issues and recommend that they be considered in future development activity. As Project 2016-02 was formed to address the directives in FERC Order 822 issued on January 21, 2016, that team also received the V5TAG issues as part of its Standard Authorization Request (SAR).

One of the areas of issue was virtualization. The V5TAG Transfer document said, "The CIP Version 5 standards do not specifically address virtualization. However, because of the increasing use of virtualization in industrial control system environments, questions around treatment of virtualization within the CIP Standards are due for consideration. The SDT should consider revisions to CIP-005 and the definitions of Cyber Asset and Electronic Access Point that make clear the permitted architecture and address the security risks of network, server and storage virtualization technologies."

New and Modified Terms and Applicability

This standard uses new or modified terms and contains new or modified exemptions in Section 4 Applicability. The rationale for this global content can be found in "CIP Definitions and Exemptions Technical Rationale" document for reference when reading the technical rationale that follows.

Requirement R1 Part 1.1-1.3

Change Rationale:

The SDT has modified these requirement parts such that identification of Shared Cyber Infrastructure (SCI) that hosts high impact BES Cyber Systems (BCS) (Part 1.1) and medium impact BCS (Part 1.2) is included in the existing Requirement Parts. SCI can host not just a single but multiple BCS, Electronic Access Control or Monitoring Systems (EACMS), Physical Access Control Systems (PACS), Protected Cyber Assets (PCA), etc. of varying impact levels or association to a BCS. As such, they may present a higher level of risk than a single BCS and are to be identified for the application of requirements in the remainder of the CIP standards.

The SDT modified the requirement parts to allow Responsible Entities options in how they identify and group virtualized systems. The two bullet points (this example will use Requirement R1 Part 1.1 for high impact) are designed to allow:

- A high impact BCS including any supporting SCI identified as part of the BCS; or
    - This option is known as the "All-in Option". In this option, if any part of the BCS is virtualized the underlying SCI is identified and included in the composition of the entity's BCS.

- A high impact BES Cyber System and independent SCI supporting any part of the high impact BES Cyber System or its associated EACMS, PACS, or PCAs.
    - This option is known as the "Identified SCI option". In this option, if any part of the BCS is virtualized it allows the entity to identify its high impact BCS (including any Cyber Assets and Virtual Cyber Assets (VCA)), however the underlying SCI is identified separately as a distinct object that is not a part of a hosted BCS.

See discussion below for the rationale behind the two options for identifying virtualized system's SCI and considerations for choosing one over the other.

Options For Identifying Virtualized System's SCI

The SDT has modified CIP-002 to allow Responsible Entities a choice between two options for identifying the SCI supporting virtualized systems. These two options represent two different ways entities may treat SCI within their programs. One allows for a simpler identification exercise but then limits the flexibility of the impact classification of the VCAs hosted on the SCI, while the other allows for more flexibility in the impact classification of the VCA's hosted on the SCI, but requires a slightly more complex identification process. These two options have come to be known as the "All-in" or the "Identified SCI" options. In either option, the security requirements within the standards are equivalent for the SCI itself; the difference in the options is the level of flexibility in categorizing VCAs hosted on the SCI.

All-in Option

This option would typically be chosen by entities that have SCI dedicated to a BCS environment of a single impact category. The entity identifies their BCS and its Cyber Assets, VCA, and any associated SCI all as part of one or more BCS of the same impact category. However, since the SCI is part of the BCS, every VCA hosted on the SCI is either a BCA of the same impact as the BCS or an associated PCA of the highest impact BCS hosted on the SCI. Thus the name "All-in"; the SCI and all VCAs hosted on it are all high watermarked as the SCI is identified as a component of the BCS.

Identified SCI Option

This option would typically be chosen by entities that use their SCI to support a broader range of VCAs than just BCS of a single impact category. They may desire to use the tools and security controls available within their SCI to logically segment/isolate these varying systems of differing impact levels without having to consider everything hosted on an SCI as an associated PCA and thus high watermarking the SCI and everything it hosts. In this option, the entity would identify their SCI independently and **not** as a a part of any BCS. The SCI in this option is a separate object that may host high, medium, low, or no impact cyber systems with the proper security controls and logical isolation in place between these impact categories to meet the CIP requirements.

Requirement R1 Part 1.3

Change Rationale:

The SDT modified Requirement R1 Part 1.3 to include the identification of "asset that contains" to include low impact BCS as well as SCI that supports any portion of a low impact BCS. This modification was made because SCI, which can host multiple BCS, may pose a greater risk to the BES than a single BCS. Additionally, the term Cyber Asset was modified to exclude SCI so that SCI could could be addressed separately from any hosted VCAs. Responsible Entities should note that the definition of SCI contains its associated Management Interface, thus an "asset that contains" could be a location of the Management Interface used to manage a distributed SCI.

For example, hypervisors within one SCI may be distributed across numerous assets such as substations, generating sites, or control centers and the Management Interface for the SCI could be located at yet another location. With this change, the rationale is the "asset" containing the Management Interface becomes important as it relates to potential impact to the low impact BCS and would be another identified entry on the Responsible Entity's evidence for

Requirement R1 Part1.3 that is later subject to controls in CIP-003 Requirement R2 that parallell those for the asset containing the low impact BCS.

Attachment 1 – Impact Rating Criteria

Change Rationale:

In the medium impact rating criterion 2.1 referencing shared BCS for commissioned generation, the SDT has proposed a change to incorporate an earlier approved Request For Interpretation (RFI). The RFI was submitted seeking clarification of Criterion 2.1 of Attachment 1 regarding the use of the phrase “shared BES Cyber Systems.” The resulting approved interpretation was introduced as Appendix 1 in CIP-002-5.1a.

The SDT incorporated the interpretation into CIP-002-7 Attachement 1 criterion 2.1 by modifying it to reference “each discrete shared BCS” and removed the RFI appendix from the standard.

Former Background Section from Reliability Standard CIP-002-5.1a

The **Background** section has been retired and removed from the Standard, and preserved by cutting and pasting as-is below.

Background

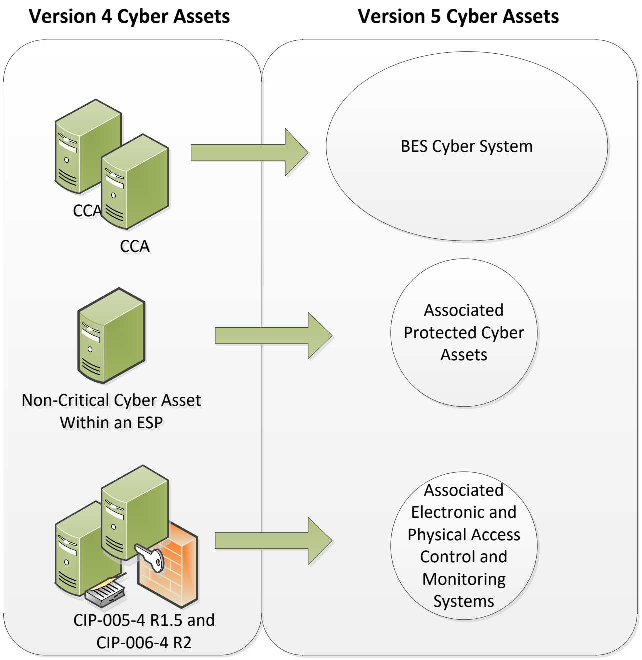
This standard provides “bright-line” criteria for applicable Responsible Entities to categorize their BES Cyber Systems based on the impact of their associated Facilities, systems, and equipment, which, if destroyed, degraded, misused, or otherwise rendered unavailable, would affect the reliable operation of the Bulk Electric System. Several concepts provide the basis for the approach to the standard.

Throughout the standards, unless otherwise stated, bulleted items in the requirements are items that are linked with an “or,” and numbered items are items that are linked with an “and.”

Many references in the Applicability section and the criteria in Attachment 1 of CIP-002 use a threshold of 300 MW for UFLS and UVLS. This particular threshold of 300 MW for UVLS and UFLS was provided in Version 1 of the CIP Cyber Security Standards. The threshold remains at 300 MW since it is specifically addressing UVLS and UFLS, which are last ditch efforts to save the Bulk Electric System. A review of UFLS tolerances defined within regional reliability standards for UFLS program requirements to date indicates that the historical value of 300 MW represents an adequate and reasonable threshold value for allowable UFLS operational tolerances.

BES Cyber Systems

One of the fundamental differences between Versions 4 and 5 of the CIP Cyber Security Standards is the shift from identifying Critical Cyber Assets to identifying BES Cyber Systems. This change results from the drafting team’s review of the NIST Risk Management Framework and the use of an analogous term “information system” as the target for categorizing and applying security controls.



In transitioning from Version 4 to Version 5, a BES Cyber System can be viewed simply as a grouping of Critical Cyber Assets (as that term is used in Version 4). The CIP Cyber Security Standards use the “BES Cyber System” term primarily

to provide a higher level for referencing the object of a requirement. For example, it becomes possible to apply requirements dealing with recovery and malware protection to a grouping rather than individual Cyber Assets, and it becomes clearer in the requirement that malware protection applies to the system as a whole and may not be necessary for every individual device to comply.

Another reason for using the term “BES Cyber System” is to provide a convenient level at which a Responsible Entity can organize their documented implementation of the requirements and compliance evidence. Responsible Entities can use the well-developed concept of a *security plan* for each BES Cyber System to document the programs, processes, and plans in place to comply with security requirements.

It is left up to the Responsible Entity to determine the level of granularity at which to identify a BES Cyber System within the qualifications in the definition of BES Cyber System. For example, the Responsible Entity might choose to view an entire plant control system as a single BES Cyber System, or it might choose to view certain components of the plant control system as distinct BES Cyber Systems. The Responsible Entity should take into consideration the operational environment and scope of management when defining the BES Cyber System boundary in order to maximize efficiency in secure operations. Defining the boundary too tightly may result in redundant paperwork and authorizations, while defining the boundary too broadly could make the secure operation of the BES Cyber System difficult to monitor and assess.

Reliable Operation of the BES

The scope of the CIP Cyber Security Standards is restricted to BES Cyber Systems that would impact the reliable operation of the BES. In order to identify BES Cyber Systems, Responsible Entities determine whether the BES Cyber Systems perform or support any BES reliability function according to those reliability tasks identified for their reliability function and the corresponding functional entity’s responsibilities as defined in its relationships with other functional entities in the NERC Functional Model. This ensures that the *initial* scope for consideration includes only those BES Cyber Systems and their associated BES Cyber Assets that perform or support the reliable operation of the BES. The definition of BES Cyber Asset provides the basis for this scoping.

Real-time Operations

One characteristic of the BES Cyber Asset is a real-time scoping characteristic. The time horizon that is significant for BES Cyber Systems and BES Cyber Assets subject to the application of these Version 5 CIP Cyber Security Standards is defined as that which is material to real-time operations for the reliable operation of the BES. To provide a better defined time horizon than “Real-time,” BES Cyber Assets are those Cyber Assets that, if rendered unavailable, degraded, or misused, would adversely impact the reliable operation of the BES within 15 minutes of the activation or exercise of the compromise. This time window must not include in its consideration the activation of redundant BES Cyber Assets or BES Cyber Systems: from the cyber security standpoint, redundancy does not mitigate cyber security vulnerabilities.

Categorization Criteria

The criteria defined in Attachment 1 are used to categorize BES Cyber Systems into impact categories. Requirement 1 only requires the discrete identification of BES Cyber Systems for those in the high impact and medium impact categories. All BES Cyber Systems for Facilities not included in Attachment 1 – Impact Rating Criteria, Criteria 1.1 to 1.4 and Criteria 2.1 to 2.11 default to be low impact.

This general process of categorization of BES Cyber Systems based on impact on the reliable operation of the BES is consistent with risk management approaches for the purpose of application of cyber security requirements in the remainder of the Version 5 CIP Cyber Security Standards.

Electronic Access Control or Monitoring Systems, Physical Access Control Systems, and Protected Cyber Assets that are associated with BES Cyber Systems

BES Cyber Systems have associated Cyber Assets, which, if compromised, pose a threat to the BES Cyber System by virtue of: (a) their location within the Electronic Security Perimeter (Protected Cyber Assets), or (b) the security control function they perform (Electronic Access Control or Monitoring Systems and Physical Access Control Systems). These Cyber Assets include:

Electronic Access Control or Monitoring Systems ("EACMS")

Examples include: Electronic Access Points, Intermediate Systems, authentication servers (e.g., RADIUS servers, Active Directory servers, Certificate Authorities), security event monitoring systems, and intrusion detection systems.

Physical Access Control Systems ("PACS")

Examples include: authentication servers, card systems, and badge control systems.

Protected Cyber Assets ("PCA")

Examples may include, to the extent they are within the ESP: file servers, ftp servers, time servers, LAN switches, networked printers, digital fault recorders, and emission monitoring systems.

Technical Rationale for Reliability Standard CIP-002-5.1a

This section contains a "cut and paste" of the former Guidelines and Technical Basis (GTB) as-is of from the CIP-002-5.1a standard to preserve any historical references. No modifications have been made.

Guidelines and Technical Basis

Section 4 – Scope of Applicability of the CIP Cyber Security Standards

Section "4. Applicability" of the standards provides important information for Responsible Entities to determine the scope of the applicability of the CIP Cyber Security Requirements.

Section "4.1. Functional Entities" is a list of NERC functional entities to which the standard applies. If the entity is registered as one or more of the functional entities listed in section 4.1, then the NERC CIP Cyber Security Standards apply. Note that there is a qualification in section 4.1 that restricts the applicability in the case of Distribution Providers to only those that own certain types of systems and equipment listed in 4.2.

Section "4.2. Facilities" defines the scope of the Facilities, systems, and equipment owned by the Responsible Entity, as qualified in section 4.1, that is subject to the requirements of the standard. In addition to the set of BES Facilities, Control Centers, and other systems and equipment, the list includes the qualified set of systems and equipment owned by Distribution Providers. While the NERC Glossary term "Facilities" already includes the BES characteristic, the additional use of the term BES here is meant to reinforce the scope of applicability of these Facilities where it is used, especially in this applicability scoping section. This in effect sets the scope of Facilities, systems, and equipment that is subject to the standards. This section is especially significant in CIP-002-5.1a and represents the total scope of Facilities, systems, and equipment to which the criteria in Attachment 1 apply. This is important because it determines the balance of these Facilities, systems, and equipment that are Low Impact once those that qualify under the High and Medium Impact categories are filtered out.

For the purpose of identifying groups of Facilities, systems, and equipment, whether by location or otherwise, the Responsible Entity identifies assets as described in Requirement R1 of CIP-002-5.1a. This is a process familiar to Responsible Entities that have to comply with versions 1, 2, 3, and 4 of the CIP standards for Critical Assets. As in versions 1, 2, 3, and 4, Responsible Entities may use substations, generation plants, and Control Centers at single site locations as identifiers of these groups of Facilities, systems, and equipment.

CIP-002-5.1a

CIP-002-5.1a requires that applicable Responsible Entities categorize their BES Cyber Systems and associated BES Cyber Assets according to the criteria in Attachment 1. A BES Cyber Asset includes in its definition, "…that if rendered unavailable, degraded, or misused would, within 15 minutes adversely impact the reliable operation of the BES."

The following provides guidance that a Responsible Entity may use to identify the BES Cyber Systems that would be in scope. The concept of BES reliability operating service is useful in providing Responsible Entities with the option of a defined process for scoping those BES Cyber Systems that would be subject to CIP-002-5.1a. The concept includes a number of named BES reliability operating services. These named services include:

- Dynamic Response to BES conditions
- Balancing Load and Generation
- Controlling Frequency (Real Power)
- Controlling Voltage (Reactive Power)
- Managing Constraints

- Monitoring & Control
- Restoration of BES
- Situational Awareness
- Inter-Entity Real-Time Coordination and Communication

Responsibility for the reliable operation of the BES is spread across all Entity Registrations. Each entity registration has its own special contribution to reliable operations and the following discussion helps identify which entity registration, in the context of those functional entities to which these CIP standards apply, performs which reliability operating service, as a process to identify BES Cyber Systems that would be in scope. The following provides guidance for Responsible Entities to determine applicable reliability operations services according to their Function Registration type.

Entity Registration	RC	BA	TOP	TO	DP	GOP	GO
Dynamic Response		X	X	X	X	X	X
Balancing Load & Generation	X	X	X	X	X	X	X
Controlling Frequency		X				X	X
Controlling Voltage			X	X	X		X
Managing Constraints	X		X			X	
Monitoring and Control			X			X	
Restoration			X			X	
Situation Awareness	X	X	X			X	
Inter-Entity coordination	X	X	X	X		X	X

Dynamic Response

The Dynamic Response Operating Service includes those actions performed by BES Elements or subsystems which are automatically triggered to initiate a response to a BES condition. These actions are triggered by a single element or control device or a combination of these elements or devices in concert to perform an action or cause a condition in reaction to the triggering action or condition. The types of dynamic responses that may be considered as potentially having an impact on the BES are:

- Spinning reserves (contingency reserves)
  - Providing actual reserve generation when called upon (GO,GOP)
  - Monitoring that reserves are sufficient (BA)
- Governor Response
  - Control system used to actuate governor response (GO)
    - Protection Systems (transmission & generation)
  - Lines, buses, transformers, generators (DP, TO, TOP, GO, GOP)
  - Zone protection for breaker failure (DP, TO, TOP)
  - Breaker protection (DP, TO, TOP)
  - Current, frequency, speed, phase (TO,TOP, GO,GOP)

        - Special Protection Systems or Remedial Action Schemes
    - Sensors, relays, and breakers, possibly software (DP, TO, TOP)
        - Under and Over Frequency relay protection (includes automatic load shedding)
    - Sensors, relays & breakers (DP)
        - Under and Over Voltage relay protection (includes automatic load shedding)
    - Sensors, relays & breakers (DP)
        - Power System Stabilizers (GO)

Balancing Load and Generation

The Balancing Load and Generation Operations Service includes activities, actions and conditions necessary for monitoring and controlling generation and load in the operations planning horizon and in real-time. Aspects of the Balancing Load and Generation function include, but are not limited to:

- Calculation of Area Control Error (ACE)
    - Field data sources (real time tie flows, frequency sources, time error, etc) (TO, TOP)
    - Software used to perform calculation (BA)
- Demand Response
    - Ability to identify load change need (BA)
    - Ability to implement load changes (TOP,DP)
- Manually Initiated Load shedding
    - Ability to identify load change need (BA)
    - Ability to implement load changes (TOP, DP)
- Non-spinning reserve (contingency reserve)
    - Know generation status, capability, ramp rate, start time (GO, BA)
    - Start units and provide energy (GOP)

Controlling Frequency (Real Power)

The Controlling Frequency Operations Service includes activities, actions and conditions which ensure, in real time, that frequency remains within bounds acceptable for the reliability or operability of the BES. Aspects of the Controlling Frequency function include, but are limited to:

- Generation Control (such as AGC)
    - ACE, current generator output, ramp rate, unit characteristics (BA, GOP, GO)
    - Software to calculate unit adjustments (BA)
    - Transmit adjustments to individual units (GOP)
    - Unit controls implementing adjustments (GOP)
- Regulation (regulating reserves)
    - Frequency source, schedule (BA)
    - Governor control system (GO)

Controlling Voltage (Reactive Power)

The Controlling Voltage Operations Service includes activities, actions and conditions which ensure, in real time, that voltage remains within bounds acceptable for the reliability or operability of the BES. Aspects of the Controlling Voltage function include, but are not limited to:

- Automatic Voltage Regulation (AVR)
  - Sensors, stator control system, feedback (GO)
- Capacitive resources
  - Status, control (manual or auto), feedback (TOP, TO,DP)
- Inductive resources (transformer tap changer, or inductors)
  - Status, control (manual or auto), feedback (TOP,TO,DP)
- Static VAR Compensators (SVC)
  - Status, computations, control (manual or auto), feedback (TOP, TO,DP)

Managing Constraints

Managing Constraints includes activities, actions and conditions that are necessary to ensure that elements of the BES operate within design limits and constraints established for the reliability and operability of the BES. Aspects of the Managing Constraints include, but are not limited to:

- Available Transfer Capability (ATC) (TOP)
- Interchange schedules (TOP, RC)
- Generation re-dispatch and unit commit (GOP)
- Identify and monitor SOL's & IROL's (TOP, RC)
- Identify and monitor Flow gates (TOP, RC)

Monitoring and Control

Monitoring and Control includes those activities, actions and conditions that provide monitoring and control of BES Elements. An example aspect of the Control and Operation function is:

- All methods of operating breakers and switches
  - SCADA (TOP, GOP)
  - Substation automation (TOP)

Restoration of BES

The Restoration of BES Operations Service includes activities, actions and conditions necessary to go from a shutdown condition to an operating condition delivering electric power without external assistance. Aspects of the Restoration of BES function include, but are not limited to:

- Restoration including planned cranking path
  - Through black start units (TOP, GOP)
  - Through tie lines (TOP, GOP)
- Off-site power for nuclear facilities. (TOP, TO, BA, RC, DP, GO, GOP)
- Coordination (TOP, TO, BA, RC, DP, GO, GOP)

Situational Awareness

The Situational Awareness function includes activities, actions and conditions established by policy, directive or standard operating procedure necessary to assess the current condition of the BES and anticipate effects of planned and unplanned changes to conditions. Aspects of the Situation Awareness function include:

- Monitoring and alerting (such as EMS alarms) (TOP, GOP, RC,BA)
- Change management (TOP,GOP,RC,BA)
- Current Day and Next Day planning (TOP)
- Contingency Analysis (RC)
- Frequency monitoring (BA, RC)

Inter-Entity Coordination

The Inter-Entity coordination and communication function includes activities, actions, and conditions established by policy, directive, or standard operating procedure necessary for the coordination and communication between Responsible Entities to ensure the reliability and operability of the BES. Aspects of the Inter-Entity Coordination and Communication function include:

- Scheduled interchange (BA,TOP,GOP,RC)
- Facility operational data and status (TO, TOP, GO, GOP, RC, BA)
- Operational directives (TOP, RC, BA)

Applicability to Distribution Providers

It is expected that only Distribution Providers that own or operate facilities that qualify in the Applicability section will be subject to these Version 5 Cyber Security Standards. Distribution Providers that do not own or operate any facility that qualifies are not subject to these standards. The qualifications are based on the requirements for registration as a Distribution Provider and on the requirements applicable to Distribution Providers in NERC Standard EOP-005.

Requirement R1:

Requirement R1 implements the methodology for the categorization of BES Cyber Systems according to their impact on the BES. Using the traditional risk assessment equation, it reduces the measure of the risk to an impact (consequence) assessment, assuming the vulnerability index of 1 (the Systems are assumed to be vulnerable) and a probability of threat of 1 (100 percent). The criteria in Attachment 1 provide a measure of the impact of the BES assets supported by these BES Cyber Systems.

Responsible Entities are required to identify and categorize those BES Cyber Systems that have high and medium impact. BES Cyber Systems for BES assets not specified in Attachment 1, Criteria 1.1 – 1.4 and Criteria 2.1 – 2.11 default to low impact.

Attachment 1

Overall Application

In the application of the criteria in Attachment 1, Responsible Entities should note that the approach used is based on the impact of the BES Cyber System as measured by the bright-line criteria defined in Attachment 1.

- When the drafting team uses the term “Facilities”, there is some latitude to Responsible Entities to determine included Facilities. The term Facility is defined in the NERC Glossary of Terms as “A set of electrical equipment that operates as a single Bulk Electric System Element (e.g., a line, a generator, a shunt compensator, transformer, etc.).” In most cases, the criteria refer to a group of Facilities in a given location that supports

the reliable operation of the BES. For example, for Transmission assets, the substation may be designated as the group of Facilities. However, in a substation that includes equipment that supports BES operations along with equipment that only supports Distribution operations, the Responsible Entity may be better served to consider only the group of Facilities that supports BES operation. In that case, the Responsible Entity may designate the group of Facilities by location, with qualifications on the group of Facilities that supports reliable operation of the BES, as the Facilities that are subject to the criteria for categorization of BES Cyber Systems. Generation Facilities are separately discussed in the Generation section below. In CIP-002-5.1a, these groups of Facilities, systems, and equipment are sometimes designated as BES assets. For example, an identified BES asset may be a named substation, generating plant, or Control Center. Responsible Entities have flexibility in how they group Facilities, systems, and equipment at a location.

- In certain cases, a BES Cyber System may be categorized by meeting multiple criteria. In such cases, the Responsible Entity may choose to document all criteria that result in the categorization. This will avoid inadvertent miscategorization when it no longer meets one of the criteria, but still meets another.
- It is recommended that each BES Cyber System should be listed by only one Responsible Entity. Where there is joint ownership, it is advisable that the owning Responsible Entities should formally agree on the designated Responsible Entity responsible for compliance with the standards.

High Impact Rating (H)

This category includes those BES Cyber Systems, used by and at Control Centers (and the associated data centers included in the definition of Control Centers), that perform the functional obligations of the Reliability Coordinator (RC), Balancing Authority (BA), Transmission Operator (TOP), or Generator Operator (GOP), as defined under the Tasks heading of the applicable Function and the Relationship with Other Entities heading of the functional entity in the NERC Functional Model, and as scoped by the qualification in Attachment 1, Criteria 1.1, 1.2, 1.3 and 1.4. While those entities that have been registered as the above-named functional entities are specifically referenced, it must be noted that there may be agreements where some of the functional obligations of a Transmission Operator may be delegated to a Transmission Owner (TO). In these cases, BES Cyber Systems at these TO Control Centers that perform these functional obligations would be subject to categorization as high impact. The criteria notably specifically emphasize functional obligations, not necessarily the RC, BA, TOP, or GOP facilities. One must note that the definition of Control Center specifically refers to reliability tasks for RCs, Bas, TOPs, and GOPs. A TO BES Cyber System in a TO facility that does not perform or does not have an agreement with a TOP to perform any of these functional tasks does not meet the definition of a Control Center. However, if that BES Cyber System operates any of the facilities that meet criteria in the Medium Impact category, that BES Cyber System would be categorized as a Medium Impact BES Cyber System.

The 3000 MW threshold defined in criterion 1.2 for BA Control Centers provides a sufficient differentiation of the threshold defined for Medium Impact BA Control Centers. An analysis of BA footprints shows that the majority of Bas with significant impact are covered under this criterion.

Additional thresholds as specified in the criteria apply for this category.

Medium Impact Rating (M)

Generation

The criteria in Attachment 1's medium impact category that generally apply to Generation Owner and Operator (GO/GOP) Registered Entities are criteria 2.1, 2.3, 2.6, 2.9, and 2.11. Criterion 2.13 for BA Control Centers is also included here.

- Criterion 2.1 designates as medium impact those BES Cyber Systems that impact generation with a net Real Power capability exceeding 1500 MW. The 1500 MW criterion is sourced partly from the Contingency Reserve requirements in NERC standard BAL-002, whose purpose is "to ensure the Balancing Authority is able to utilize its Contingency Reserve to balance resources and demand and return Interconnection frequency within defined limits following a Reportable Disturbance." In particular, it requires that "as a minimum, the Balancing Authority or Reserve Sharing Group shall carry at least enough Contingency Reserve to cover the most severe single contingency." The drafting team used 1500 MW as a number derived from the most significant Contingency Reserves operated in various Bas in all regions.

In the use of net Real Power capability, the drafting team sought to use a value that could be verified through existing requirements as proposed by NERC standard MOD-024 and current development efforts in that area.

By using 1500 MW as a bright-line, the intent of the drafting team was to ensure that BES Cyber Systems with common mode vulnerabilities that could result in the loss of 1500 MW or more of generation at a single plant for a unit or group of units are adequately protected.

The drafting team also used additional time and value parameters to ensure the bright-lines and the values used to measure against them were relatively stable over the review period. Hence, where multiple values of net Real Power capability could be used for the Facilities' qualification against these bright-lines, the highest value was used.

- In Criterion 2.3, the drafting team sought to ensure that BES Cyber Systems for those generation Facilities that have been designated by the Planning Coordinator or Transmission Planner as necessary to avoid BES Adverse Reliability Impacts in the planning horizon of one year or more are categorized as medium impact. In specifying a planning horizon of one year or more, the intent is to ensure that those are units that are identified as a result of a "long term" reliability planning, i.e that the plans are spanning an operating period of at least 12 months: it does not mean that the operating day for the unit is necessarily beyond one year, but that the period that is being planned for is more than 1 year: it is specifically intended to avoid designating generation that is required to be run to remediate short term emergency reliability issues. These Facilities may be designated as "Reliability Must Run," and this designation is distinct from those generation Facilities designated as "must run" for market stabilization purposes. Because the use of the term "must run" creates some confusion in many areas, the drafting team chose to avoid using this term and instead drafted the requirement in more generic reliability language. In particular, the focus on preventing an Adverse Reliability Impact dictates that these units are designated as must run for reliability purposes beyond the local area. Those units designated as must run for voltage support in the local area would not generally be given this designation. In cases where there is no designated Planning Coordinator, the Transmission Planner is included as the Registered Entity that performs this designation.

  If it is determined through System studies that a unit must run in order to preserve the reliability of the BES, such as due to a Category C3 contingency as defined in TPL-003, then BES Cyber Systems for that unit are categorized as medium impact.

  The TPL standards require that, where the studies and plans indicate additional actions, that these studies and plans be communicated by the Planning Coordinator or Transmission Planner in writing to the Regional Entity/RRO. Actions necessary for the implementation of these plans by affected parties (generation owners/operators and Reliability Coordinators or other necessary party) are usually formalized in the form of an agreement and/or contract.

- Criterion 2.6 includes BES Cyber Systems for those Generation Facilities that have been identified as critical to the derivation of IROLs and their associated contingencies, as specified by FAC-014-2, **Establish and Communicate System Operating Limits**, R5.1.1 and R5.1.3.

  IROLs may be based on dynamic System phenomena such as instability or voltage collapse. Derivation of these IROLs and their associated contingencies often considers the effect of generation inertia and AVR response.

- Criterion 2.9 categorizes BES Cyber Systems for Special Protection Systems and Remedial Action Schemes as medium impact. Special Protection Systems and Remedial Action Schemes may be implemented to prevent disturbances that would result in exceeding IROLs if they do not provide the function required at the time it is required or if it operates outside of the parameters it was designed for. Generation Owners and Generator Operators which own BES Cyber Systems for such Systems and schemes designate them as medium impact.
- Criterion 2.11 categorizes as medium impact BES Cyber Systems used by and at Control Centers that perform the functional obligations of the Generator Operator for an aggregate generation of 1500 MW or higher in a single interconnection, and that have not already been included in Part 1.
- Criterion 2.13 categorizes as medium impact those BA Control Centers that “control” 1500 MW of generation or more in a single interconnection and that have not already been included in Part 1. The 1500 MW threshold is consistent with the impact level and rationale specified for Criterion 2.1.

Transmission

The SDT uses the phrases “Transmission Facilities at a single station or substation” and “Transmission stations or substations” to recognize the existence of both stations and substations. Many entities in industry consider a substation to be a location with physical borders (i.e. fence, wall, etc.) that contains at least an autotransformer. Locations also exist that do not contain autotransformers, and many entities in industry refer to those locations as stations (or switchyards). Therefore, the SDT chose to use both “station” and “substation” to refer to the locations where groups of Transmission Facilities exist.

- Criteria 2.2, 2.4 through 2.10, and 2.12 in Attachment 1 are the criteria that are applicable to Transmission Owners and Operators. In many of the criteria, the impact threshold is defined as the capability of the failure or compromise of a System to result in exceeding one or more Interconnection Reliability Operating Limits (IROLs). Criterion 2.2 includes BES Cyber Systems for those Facilities in Transmission Systems that provide reactive resources to enhance and preserve the reliability of the BES. The nameplate value is used here because there is no NERC requirement to verify actual capability of these Facilities. The value of 1000 MVARs used in this criterion is a value deemed reasonable for the purpose of determining criticality.
- Criterion 2.4 includes BES Cyber Systems for any Transmission Facility at a substation operated at 500 kV or higher. While the drafting team felt that Facilities operated at 500 kV or higher did not require any further qualification for their role as components of the backbone on the Interconnected BES, Facilities in the lower EHV range should have additional qualifying criteria for inclusion in the medium impact category.

  It must be noted that if the collector bus for a generation plant (i.e. the plant is smaller in aggregate than the threshold set for generation in Criterion 2.1) is operated at 500kV, the collector bus should be considered a Generation Interconnection Facility, and not a Transmission Facility, according to the “Final Report from the Ad Hoc Group for Generation Requirements at the Transmission Interface.” This collector bus would not be a facility for a medium impact BES Cyber System because it does not significantly affect the 500kV Transmission grid; it only affects a plant which is below the generation threshold.
- Criterion 2.5 includes BES Cyber Systems for facilities at the lower end of BES Transmission with qualifications for inclusion if they are deemed highly likely to have significant impact on the BES. While the criterion has been specified as part of the rationale for requiring protection for significant impact on the BES, the drafting team included, in this criterion, additional qualifications that would ensure the required level of impact to the BES. The drafting team:
  - Excluded radial facilities that would only provide support for single generation facilities.
  - Specified interconnection to at least three transmission stations or substations to ensure that the level of impact would be appropriate.

The total aggregated weighted value of 3,000 was derived from weighted values related to three connected 345 kV lines and five connected 230 kV lines at a transmission station or substation. The total aggregated weighted value is used to account for the true impact to the BES, irrespective of line kV rating and mix of multiple kV rated lines.

Additionally, in NERC's document "Integrated Risk Assessment Approach – Refinement to Severity Risk Index", Attachment 1, the report used an average MVA line loading based on kV rating:

- 230 kV –> 700 MVA
- 345 kV –> 1,300 MVA
- 500 kV –> 2,000 MVA
- 765 kV –> 3,000 MVA

In the terms of applicable lines and connecting "other Transmission stations or substations" determinations, the following should be considered:

- For autotransformers in a station, Responsible Entities have flexibility in determining whether the groups of Facilities are considered a single substation or station location or multiple substations or stations. In most cases, Responsible Entities would probably consider them as Facilities at a single substation or station unless geographically dispersed. In these cases of these transformers being within the "fence" of the substation or station, autotransformers may not count as separate connections to other stations. The use of common BES Cyber Systems may negate any rationale for any consideration otherwise. In the case of autotransformers that are geographically dispersed from a station location, the calculation would take into account the connections in and out of each station or substation location.
- Multiple-point (or multiple-tap) lines are considered to contribute a single weight value per line and affect the number of connections to other stations. Therefore, a single 230 kV multiple-point line between three Transmission stations or substations would contribute an aggregated weighted value of 700 and connect Transmission Facilities at a single station or substation to two other Transmission stations or substations.
- Multiple lines between two Transmission stations or substations are considered to contribute multiple weight values per line, but these multiple lines between the two stations only connect one station to one other station. Therefore, two 345 kV lines between two Transmission stations or substations would contribute an aggregated weighted value of 2600 and connect Transmission Facilities at a single station or substation to one other Transmission station or substation.

Criterion 2.5's qualification for Transmission Facilities at a Transmission station or substation is based on 2 distinct conditions.

1. The first condition is that Transmission Facilities at a single station or substation where that station or substation connect, at voltage levels of 200 kV or higher to three (3) other stations or substations, to three other stations or substations. This qualification is meant to ensure that connections that operate at voltages of 500 kV or higher are included in the count of connections to other stations or substations as well.
2. The second qualification is that the aggregate value of all lines entering or leaving the station or substation must exceed 3000. This qualification does not include the consideration of lines operating at lower than 200 kV, or 500 kV or higher, the latter already qualifying as medium impact under criterion 2.4. : there is no value to be assigned to lines at voltages of less than 200 kV or 500 kV or higher in the table of values for the contribution to the aggregate value of 3000.

The Transmission Facilities at the station or substation must meet both qualifications to be considered as qualified under criterion 2.5.

- Criterion 2.6 include BES Cyber Systems for those Transmission Facilities that have been identified as critical to the derivation of IROLs and their associated contingencies, as specified by FAC-014-2, **Establish and Communicate System Operating Limits**, R5.1.1 and R5.1.3.
- Criterion 2.7 is sourced from the NUC-001 NERC standard, Requirement R9.2.2, for the support of Nuclear Facilities. NUC-001 ensures that reliability of NPIR's are ensured through adequate coordination between the Nuclear Generator Owner/Operator and its Transmission provider "for the purpose of ensuring nuclear plant safe operation and shutdown." In particular, there are specific requirements to coordinate physical and cyber security protection of these interfaces.
- Criterion 2.8 designates as medium impact those BES Cyber Systems that impact Transmission Facilities necessary to directly support generation that meet the criteria in Criteria 2.1 (generation Facilities with output greater than 1500 MW) and 2.3 (generation Facilities generally designated as "must run" for wide area reliability in the planning horizon). The Responsible Entity can request a formal statement from the Generation owner as to the qualification of generation Facilities connected to their Transmission systems.
- Criterion 2.9 designates as medium impact those BES Cyber Systems for those Special Protection Systems (SPS), Remedial Action Schemes (RAS), or automated switching Systems installed to ensure BES operation within IROLs. The degradation, compromise or unavailability of these BES Cyber Systems would result in exceeding IROLs if they fail to operate as designed. By the definition of IROL, the loss or compromise of any of these have Wide Area impacts.
- Criterion 2.10 designates as medium impact those BES Cyber Systems for Systems or Elements that perform automatic Load shedding, without human operator initiation, of 300 MW or more. The SDT spent considerable time discussing the wording of Criterion 2.10, and chose the term "Each" to represent that the criterion applied to a discrete System or Facility. In the drafting of this criterion, the drafting team sought to include only those Systems that did not require human operator initiation, and targeted in particular those underfrequency load shedding (UFLS) Facilities and systems and undervoltage load shedding (UVLS) systems and Elements that would be subject to a regional Load shedding requirement to prevent Adverse Reliability Impact. These include automated UFLS systems or UVLS systems that are capable of Load shedding 300 MW or more. It should be noted that those qualifying systems which require a human operator to arm the system, but once armed, trigger automatically, are still to be considered as not requiring human operator initiation and should be designated as medium impact. The 300 MW threshold has been defined as the aggregate of the highest MW Load value, as defined by the applicable regional Load Shedding standards, for the preceding 12 months to account for seasonal fluctuations.

  This particular threshold (300 MW) was provided in CIP, Version 1. The SDT believes that the threshold should be lower than the 1500MW generation requirement since it is specifically addressing UVLS and UFLS, which are last ditch efforts to save the Bulk Electric System and hence requires a lower threshold. A review of UFLS tolerances defined within regional reliability standards for UFLS program requirements to date indicates that the historical value of 300 MW represents an adequate and reasonable threshold value for allowable UFLS operational tolerances.

  In ERCOT, the Load acting as a Resource ("LaaR") Demand Response Program is not part of the regional load shedding program, but an ancillary services market. In general, similar demand response programs that are not part of the NERC or regional reliability Load shedding programs, but are offered as components of an ancillary services market do not qualify under this criterion.

The language used in section 4 for UVLS and UFLS and in criterion 2.10 of Attachment 1 is designed to be consistent with requirements set in the PRC standards for UFLS and UVLS.

- Criterion 2.12 categorizes as medium impact those BES Cyber Systems used by and at Control Centers and associated data centers performing the functional obligations of a Transmission Operator and that have not already been categorized as high impact.
- Criterion 2.13 categorizes as Medium Impact those BA Control Centers that “control” 1500 MW of generation or more in a single Interconnection. The 1500 MW threshold is consistent with the impact level and rationale specified for Criterion 2.1.

Low Impact Rating (L)

BES Cyber Systems not categorized in high impact or medium impact default to low impact. Note that low impact BES Cyber Systems do not require discrete identification.

Restoration Facilities

- Several discussions on the CIP Version 5 standards suggest entities owning Blackstart Resources and Cranking Paths might elect to remove those services to avoid higher compliance costs. For example, one Reliability Coordinator reported a 25% reduction of Blackstart Resources as a result of the Version 1 language, and there could be more entities that make this choice under Version 5.

  In response, the CIP Version 5 drafting team sought informal input from NERC’s Operating and Planning Committees. The committees indicate there has already been a reduction in Blackstart Resources because of increased CIP compliance costs, environmental rules, and other risks; continued inclusion within Version 5 at a category that would very significantly increase compliance costs can result in further reduction of a vulnerable pool.

  The drafting team moved from the categorization of restoration assets such as Blackstart Resources and Cranking Paths as medium impact (as was the case in earlier drafts) to categorization of these assets as low impact as a result of these considerations. This will not relieve asset owners of all responsibilities, as would have been the case in CIP-002, Versions 1-4 (since only Cyber Assets with routable connectivity which are essential to restoration assets are included in those versions). Under the low impact categorization, those assets will be protected in the areas of cyber security awareness, physical access control, and electronic access control, and they will have obligations regarding incident response. This represents a net gain to bulk power system reliability, however, since many of those assets do not meet criteria for inclusion under Versions 1-4.

  Weighing the risks to overall BES reliability, the drafting team determined that this re-categorization represents the option that would be the least detrimental to restoration function and, thus, overall BES reliability. Removing Blackstart Resources and Cranking Paths from medium impact promotes overall reliability, as the likely alternative is fewer Blackstart Resources supporting timely restoration when needed.

  BES Cyber Systems for generation resources that have been designated as Blackstart Resources in the Transmission Operator’s restoration plan default to low impact. NERC Standard EOP-005-2 requires the Transmission Operator to have a Restoration Plan and to list its Blackstart Resources in its plan, as well as requirements to test these Resources. This criterion designates only those generation Blackstart Resources that have been designated as such in the Transmission Operator’s restoration plan. The glossary term Blackstart Capability Plan has been retired.

  Regarding concerns of communication to BES Asset Owners and Operators of their role in the Restoration Plan, Transmission Operators are required in NERC Standard EOP-005-2 to “provide the entities identified in

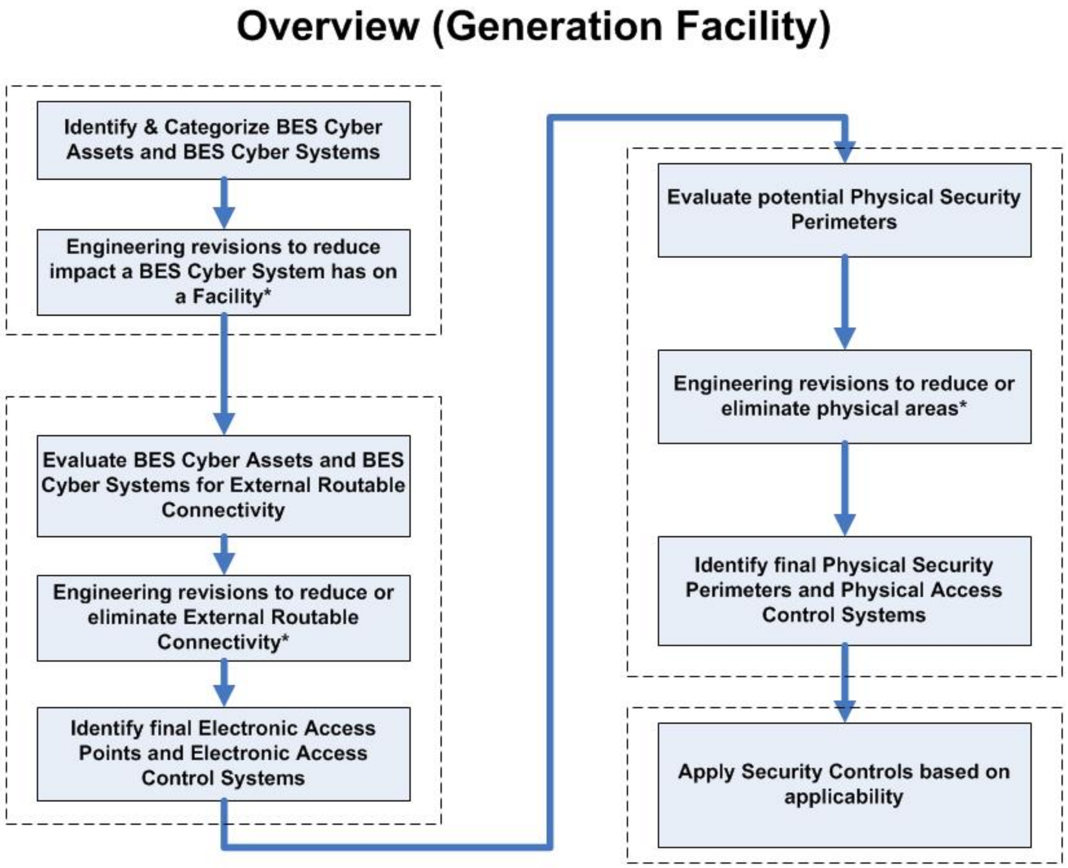
its approved restoration plan with a description of any changes to their roles and specific tasks prior to the implementation date of the plan."

- BES Cyber Systems for Facilities and Elements comprising the Cranking Paths and meeting the initial switching requirements from the Blackstart Resource to the first Interconnection point of the generation unit(s) to be started, as identified in the Transmission Operator's restoration plan, default to the category of low impact: however, these systems are explicitly called out to ensure consideration for inclusion in the scope of the version 5 CIP standards. This requirement for inclusion in the scope is sourced from requirements in NERC standard EOP-005-2, which requires the Transmission Operator to include in its Restoration Plan the Cranking Paths and initial switching requirements from the Blackstart Resource and the unit(s) to be started.

  Distribution Providers may note that they may have BES Cyber Systems that must be scoped in if they have Elements listed in the Transmission Operator's Restoration Plan that are components of the Cranking Path.

Use Case: CIP Process Flow

The following CIP use case process flow for a generator Operator/Owner was provided by a participant in the development of the Version 5 standards and is provided here as an example of a process used to identify and categorize BES Cyber Systems and BES Cyber Assets; review, develop, and implement strategies to mitigate overall risks; and apply applicable security controls.



* - Engineering revisions will need to be reviewed for cost justification, operational\safety requirements, support requirements, and technical limitations.

Rationale

During development of this standard, text boxes were embedded within the standard to explain the rationale for various parts of the standard. Upon BOT approval, the text from the rationale text boxes was moved to this section.

Rationale for R1:

BES Cyber Systems at each site location have varying impact on the reliable operation of the Bulk Electric System. Attachment 1 provides a set of "bright-line" criteria that the Responsible Entity must use to identify these BES Cyber Systems in accordance with the impact on the BES. BES Cyber Systems must be identified and categorized according to their impact so that the appropriate measures can be applied, commensurate with their impact. These impact categories will be the basis for the application of appropriate requirements in CIP-003-CIP-011.

Rationale for R2:

The lists required by Requirement R1 are reviewed on a periodic basis to ensure that all BES Cyber Systems required to be categorized have been properly identified and categorized. The miscategorization or non-categorization of a BES Cyber System can lead to the application of inadequate or non-existent cyber security controls that can lead to compromise or misuse that can affect the real-time operation of the BES. The CIP Senior Manager's approval ensures proper oversight of the process by the appropriate Responsible Entity personnel.

Appendix 1

Requirement Number and Text of Requirement

CIP-002-5.1, Requirement R1

R1. Each Responsible Entity shall implement a process that considers each of the following assets for purposes of parts 1.1 through 1.3:

- i. Control Centers and backup Control Centers;
- ii. Transmission stations and substations;
- iii. Generation resources;
- iv. Systems and facilities critical to system restoration, including Blackstart Resources and Cranking Paths and initial switching requirements;
- v. Special Protection Systems that support the reliable operation of the Bulk Electric System; and
- vi. For Distribution Providers, Protection Systems specified in Applicability section 4.2.1 above.

1.1. Identify each of the high impact BES Cyber Systems according to Attachment 1, Section 1, if any, at each asset;

1.2. Identify each of the medium impact BES Cyber Systems according to Attachment 1, Section 2, if any, at each asset; and

1.3. Identify each asset that contains a low impact BES Cyber System according to Attachment 1, Section 3, if any (a discrete list of low impact BES Cyber Systems is not required).

Attachment 1, Criterion 2.1

2. Medium Impact Rating (M)

Each BES Cyber System, not included in Section 1 above, associated with any of the following:

2.1 Commissioned generation, by each group of generating units at a single plant location, with an aggregate highest rated net Real Power capability of the preceding 12 calendar months equal to or exceeding 1500 MW in a single Interconnection. For each group of generating units, the only BES Cyber Systems that meet this criterion are those shared BES Cyber Systems that could, within 15 minutes, adversely impact the reliable operation of any combination of units that in aggregate equal or exceed 1500 MW in a single Interconnection.

Questions

Energy Sector Security Consortium, Inc. (EnergySec) submitted a Request for Interpretation (RFI) seeking clarification of Criterion 2.1 of Attachment 1 in Reliability Standard CIP-002-5.1 regarding the use of the phrase "shared BES Cyber Systems."

The Interpretation Drafting Team identified the following questions in the RFI:

1. Whether the phrase "shared BES Cyber Systems" means that the evaluation for Criterion 2.1 shall be performed individually for each discrete BES Cyber System at a single plant location, or collectively for groups of BES Cyber Systems?
2. Whether the phrase "shared BES Cyber Systems" refers to discrete BES Cyber Systems that are shared by multiple units, or groups of BES Cyber Systems that could collectively impact multiple units?
3. If the phrase applies collectively to groups of BES Cyber Systems, what criteria should be used to determine which BES Cyber Systems should be grouped for collective evaluation?

Responses

Question 1: Whether the phrase "shared BES Cyber Systems," means that the evaluation for Criterion 2.1 shall be performed individually for each discrete BES Cyber System at a single plant location, or collectively for groups of BES Cyber Systems?

The evaluation as to whether a BES Cyber System is shared should be performed individually for each discrete BES Cyber System. In the standard language of CIP-002-5.1, there is no reference to or obligation to group BES Cyber Systems. Requirement R1, part 1.2 states "Identify *each* of the medium impact BES Cyber Systems according to Attachment 1, Section 2…" Further, the preamble of Section 2 of CIP-002-5.1 Attachment 1 states "*Each BES Cyber System*…associated with any of the following [criteria]." (emphasis added)

Additionally, the Background section of CIP-002-5.1 states that "[i]t is left up to the Responsible Entity to determine the level of granularity at which to identify a BES Cyber System within the qualifications in the definition of BES Cyber System." The Background section also provides:

> The Responsible Entity should take into consideration the operational environment and scope of management when defining the BES Cyber System boundary in order to maximize efficiency in secure operations. Defining the boundary too tightly may result in redundant paperwork and authorizations, while defining the boundary too broadly could make the secure operation of the BES Cyber System difficult to monitor and assess.

Question 2: Whether the phrase "shared BES Cyber Systems" refers to discrete BES Cyber Systems that are shared by multiple units, or groups of BES Cyber Systems that could collectively impact multiple units?

The phrase “shared BES Cyber Systems” refers to discrete BES Cyber Systems that are shared by multiple generation units.

The use of the term “shared” is also clarified in the NERC Frequently Asked Questions (FAQ) document issued by NERC Compliance to support implementation of the CIP Reliability Standards. FAQ #49 provides:

> Shared BES Cyber Systems are those that are associated with any combination of units in a single Interconnection, as referenced in CIP-002-5.1, Attachment 1, impact rating criteria 2.1 and 2.2. For criterion 2.1 “BES Cyber Systems that could, within 15 minutes, adversely impact the reliable operation of any combination of units that in aggregate equal or exceed 1500 MW in a single Interconnection.” For criterion 2.2: “BES Cyber Systems that could, within 15 minutes, adversely impact the reliable operation of any combination of resources that in aggregate equal or exceed 1000 MVAR. Also refer to the Lesson Learned for CIP-002-5.1 Requirement R1: **Impact Rating of Generation Resource Shared BES Cyber Systems** for further information and examples.

Question 3: If the phrase applies collectively to groups of BES Cyber Systems, what criteria should be used to determine which BES Cyber Systems should be grouped for collective evaluation?

The phrase applies to each discrete BES Cyber System.

Technical Rationale for Reliability Standard CIP-003-Y

Introduction

This document explains the technical rationale and justification for the proposed Reliability Standard CIP-003-9. It provides stakeholders and the ERO Enterprise with an understanding of the technology and technical requirements in the Reliability Standard. This Technical Rationale and Justifications for CIP-003-Y is not a Reliability Standard and should not be considered mandatory and enforceable.

Updates to this document now include the Project 2016-02 – Modifications to CIP Standards Drafting Team's (SDT's) intent in drafting changes to the requirements.

Background

The Version 5 Transition advisory Group (V5TAG), which consists of representatives from NERC, Regional Entities, and industry stakeholders, was formed to issue guidance regarding possible methods to achieve compliance with the CIP V5 standards and to support industry's implementation activities. During the course of the V5TAG's activities, the V5TAG identified certain issues with the CIP Reliability Standards that were more appropriately addressed by a standard drafting team (SDT). The V5TAG developed the V5TAG Transfer Document to explain the issues and recommend that they be considered in future development activity. As Project 2016-02 was formed to address the directives in FERC Order 822 issued on January 21, 2016, that team also received the V5TAG issues as part of its Standard Authorization Request (SAR).

One of the areas of issue was virtualization. The V5TAG Transfer document stated, "The CIP Version 5 standards do not specifically address virtualization. However, because of the increasing use of virtualization in industrial control system environments, questions around treatment of virtualization within the CIP Standards are due for consideration. The SDT should consider revisions to CIP-005 and the definitions of Cyber Asset and Electronic Access Point that make clear the permitted architecture and address the security risks of network, server and storage virtualization technologies."

New and Modified Terms and Applicability

This standard uses new or modified terms and contains new or modified exemptions in Section 4 Applicability. The rationale for this global content can be found in "CIP Definitions and Exemptions Technical Rationale." document for reference when reading the technical rationale that follows.

Requirement R1

Rationale

The Project 2016-02 SDT made conforming changes to Reliability Standard CIP-003-Y to shorten applicability statements within the body of CIP standards with “BCS” as the defined acronym for “BES Cyber System”. The SDT added the option (known as the “all-in” scenario) for entities to group SCI within a BCS it supports; Therefore, no other changes were necessary in Requirement R1 (See the CIP-002 Technical Rationale document for a description of the options for identifying SCI and reasons an entity may choose between the options).

Requirement R2

Rationale

The Project 2016-02 SDT made conforming changes to Reliability Standard CIP-003-Y to align security management control requirements with the virtualization changes.

To ensure SCI supporting low impact BCS is afforded equal physical security controls as the BCS, the SDT changed “their associated SCI” to “SCI that supports any part of a low impact BCS”, and included the same exclusions regarding discrete lists for low impact BCS as well as the supporting SCI as identified in CIP-002.

Attachment 1 Section 2

Rationale

To ensure SCI that supports any part of a low impact BCS is afforded equal physical security controls as the BCS, the SDT added “the asset or the locations of the SCI hosting low impact BES Cyber Assets within the asset.”

Additionally, to ensure virtual infrastructure providing electronic access controls for the low impact BCS is afforded equal physical security controls as the physical Cyber Assets that provide electronic access controls for the low impact BCS, the SDT modified this section to include the Virtual Cyber Asset (VCA) where only Cyber Assets had previously been listed.

Attachment 1 Section 3

Rationale

To ensure an asset containing a low impact BCS or an SCI supporting a low impact BCS is afforded equal electronic access controls as the low impact BCS, the SDT added “SCI that supports any part of a low impact BCS” as identified in CIP-002.

Attachment 1 Section 3 Part 3.1

Rationale

Part 3.1(i) To stay in keeping with the systems concept and the exclusion for a discrete list of Cyber Assets, while enabling the use of Virtual Cyber Assets (VCAs), the SDT adjusted the language to refer to communications that are between a low impact BCS and a system(s) outside the asset containing low impact BCS, instead of discrete Cyber Assets outside the assets containing low impact BCS. The use of the term system(s) no longer restricts this section to physical Cyber Assets, thereby permitting VCAs as part of the BCS grouping under the modified definition.

Part 3.1(ii) To ensure only necessary inbound and outbound electronic access is permitted for SCI hosting a low impact BCS just as is required for access control to the low impact BCS, the SDT adjusted the language to include communications that are between SCI that supports any part of a low impact BCS and a system(s) outside the asset(s) containing the SCI that supports any part of a low impact BCS.

Part 3.1 (iii) To ensure SCI supporting low impact BCS is afforded equal electronic access controls for routable communications entering or leaving the asset containing the low impact BCS, the SDT added “the asset containing the SCI that supports any part of a low impact BCS" to the low impact BCS. Also, in the interest of brevity and consistency, examples were removed from the requirement language in favor of deference to Implementation Guidance where such examples exist.

Attachment 1 Section 3 Part 3.2

Rationale

To ensure SCI supporting low impact BCS are afforded equal electronic access controls for Dial-up Connectivity, the SDT added "the asset containing the SCI that supports any part of a low impact BCS" to the low impact BCS. Per VCA capability was included in addition to per Cyber Asset capability to accommodate for incapability of both physical and virtual aspects of the low impact BCS or its associated SCI.

Attachment 1 Section 5

Rationale

To ensure SCI supporting a low impact BCS are afforded equal mitigations from the introduction of malicious code as the low impact BCS, the SDT added "SCI that supports any part of a low impact BCS" to the low impact BCS.

Attachment 1 Section 5 Part 5.1

Rationale

To enable for virtualization technologies and capabilities the SDT added, "Controls that maintain the state of the operating system and software such that it is in a known state prior to execution that mitigates the risk of introduction of malicious code" as an option in Attachment 1 Section 5 Part 5.1.

Attachment 1 Section 5 Part 5.2

Rationale

To ensure SCI supporting a low impact BCS are afforded equal protections when a TCA managed by a party other than the Responsible Entity is used, the SDT added "SCI that supports any part of a low impact BCS" to the low impact BCS in Attachment 1 Section 5 Part 5.2.1.

To enable for virtualization technologies and capabilities the SDT added, "Controls that maintain the state of the operating system and software such that it is in a known state prior to execution that mitigates the risk of introduction of malicious code" as an option in Attachment 1 Section 5 Part 5.2.1.

The final bullet of Attachment 1 Section 5 Part 5.2.1 was preceded with the language "Review of" to make the requirement for other methods parallel to the five options listed above it.

Attachment 1 Section 5 Part 5.3

Rationale

To ensure SCI supporting a low impact BCS are afforded equal protections from malicious code when using Removable Media, the SDT added "SCI that supports any part of a low impact BCS" to the low impact BCS in Attachment 1 Section 5 Parts 5.3.1 & 5.3.2.

Former Background Section from Reliability Standard CIP-003-8

The section **6. Background** has been retired and removed from the Standard, and preserved by cutting and pasting as-is below.

Background

Standard CIP-003 exists as part of a suite of CIP Standards related to cyber security, which require the initial identification and categorization of BES Cyber Systems and require organizational, operational, and procedural controls to mitigate risk to BES Cyber Systems.

The term policy refers to one or a collection of written documents that are used to communicate the Responsible Entities' management goals, objectives and expectations for how the Responsible Entity will protect its BES Cyber Systems. The use of policies also establishes an overall governance foundation for creating a culture of security and compliance with laws, regulations, and standards.

The term documented processes refers to a set of required instructions specific to the Responsible Entity and to achieve a specific outcome. This term does not imply any naming or approval structure beyond what is stated in the requirements. An entity should include as much as it believes necessary in its documented processes, but it must address the applicable requirements.

The terms program and plan are sometimes used in place of documented processes where it makes sense and is commonly understood. For example, documented processes describing a response are typically referred to as plans (i.e., incident response plans and recovery plans). Likewise, a security plan can describe an approach involving multiple procedures to address a broad subject matter.

Similarly, the term program may refer to the organization's overall implementation of its policies, plans, and procedures involving a subject matter. Examples in the standards include the personnel risk assessment program and the personnel training program. The full implementation of the CIP Cyber Security Reliability Standards could also be referred to as a program. However, the terms program and plan do not imply any additional requirements beyond what is stated in the standards.

Responsible Entities can implement common controls that meet requirements for multiple high, medium, and low impact BES Cyber Systems. For example, a single cyber security awareness program could meet the requirements across multiple BES Cyber Systems.

Measures provide examples of evidence to show documentation and implementation of the requirement. These measures serve to provide guidance to entities in acceptable records of compliance and should not be viewed as an all-inclusive list.

Throughout the standards, unless otherwise stated, bulleted items in the requirements and measures are items that are linked with an "or," and numbered items are items that are linked with an "and."

Many references in the Applicability section use a threshold of 300 MW for UFLS and UVLS. This particular threshold of 300 MW for UVLS and UFLS was provided in Version 1 of the CIP Cyber Security Standards. The threshold remains at 300 MW since it is specifically addressing UVLS and UFLS, which are last ditch efforts to save the BES. A review of UFLS tolerances defined within Regional Reliability Standards for UFLS program requirements to date indicates that the historical value of 300 MW represents an adequate and reasonable threshold value for allowable UFLS operational tolerances.

Technical Rational for Reliability Standard CIP-003-8

This section contains a “cut and paste” of the former Guidelines and Technical Basis (GTB) as-is of from CIP-003-8 standard to preserve any historical references. No modifications have been made.

Guidelines and Technical Basis

Section 4 – Scope of Applicability of the CIP Cyber Security Standards

Section “4. Applicability” of the standards provides important information for Responsible Entities to determine the scope of the applicability of the CIP Cyber Security Requirements.

Section “4.1. Functional Entities” is a list of NERC functional entities to which the standard applies. If the entity is registered as one or more of the functional entities listed in Section 4.1, then the NERC CIP Cyber Security Standards apply. Note that there is a qualification in Section 4.1 that restricts the applicability in the case of Distribution Providers to only those that own certain types of systems and equipment listed in 4.2.

Section “4.2. Facilities” defines the scope of the Facilities, systems, and equipment owned by the Responsible Entity, as qualified in Section 4.1, that is subject to the requirements of the standard. In addition to the set of BES Facilities, Control Centers, and other systems and equipment, the list includes the set of systems and equipment owned by Distribution Providers. While the NERC Glossary term “Facilities” already includes the BES characteristic, the additional use of the term BES here is meant to reinforce the scope of applicability of these Facilities where it is used, especially in this applicability scoping section. This in effect sets the scope of Facilities, systems, and equipment that is subject to the standards.

Requirement R1:

In developing policies in compliance with Requirement R1, the number of policies and their content should be guided by a Responsible Entity's management structure and operating conditions. Policies might be included as part of a general information security program for the entire organization, or as components of specific programs. The Responsible Entity has the flexibility to develop a single comprehensive cyber security policy covering the required topics, or it may choose to develop a single high-level umbrella policy and provide additional policy detail in lower level documents in its documentation hierarchy. In the case of a high-level umbrella policy, the Responsible Entity would be expected to provide the high-level policy as well as the additional documentation in order to demonstrate compliance with CIP-003-8, Requirement R1.

If a Responsible Entity has any high or medium impact BES Cyber Systems, the one or more cyber security policies must cover the nine subject matter areas required by CIP-003-8, Requirement R1, Part 1.1. If a Responsible Entity has identified from CIP-002 any assets containing low impact BES Cyber Systems, the one or more cyber security policies must cover the six subject matter areas required by Requirement R1, Part 1.2.

Responsible Entities that have multiple-impact rated BES Cyber Systems are not required to create separate cyber security policies for high, medium, or low impact BES Cyber Systems. The Responsible Entities have the flexibility to develop policies that cover all three impact ratings.

Implementation of the cyber security policy is not specifically included in CIP-003-8, Requirement R1 as it is envisioned that the implementation of this policy is evidenced through successful implementation of CIP-003 through CIP-011. However, Responsible Entities are encouraged not to limit the scope of their cyber security policies to only those requirements in NERC cyber security Reliability Standards, but to develop a holistic cyber security policy appropriate for its organization. Elements of a policy that extend beyond the scope of NERC’s cyber security Reliability Standards will not be considered candidates for potential violations although they will help demonstrate the organization’s internal culture of compliance and posture towards cyber security.

For Part 1.1, the Responsible Entity may consider the following for each of the required topics in its one or more cyber security policies for medium and high impact BES Cyber Systems, if any:

1.1.1 Personnel and training (CIP-004)

- Organization position on acceptable background investigations
- Identification of possible disciplinary action for violating this policy
- Account management

1.1.2 Electronic Security Perimeters (CIP-005) including Interactive Remote Access

- Organization stance on use of wireless networks
- Identification of acceptable authentication methods
- Identification of trusted and untrusted resources
- Monitoring and logging of ingress and egress at Electronic Access Points
- Maintaining up-to-date anti-malware software before initiating Interactive Remote Access
- Maintaining up-to-date patch levels for operating systems and applications used to initiate Interactive Remote Access
- Disabling VPN “split-tunneling” or “dual-homed” workstations before initiating Interactive Remote Access

For vendors, contractors, or consultants: include language in contracts that requires adherence to the Responsible Entity’s Interactive Remote Access controls

1.1.3 Physical security of BES Cyber Systems (CIP-006)

- Strategy for protecting Cyber Assets from unauthorized physical access
- Acceptable physical access control methods
- Monitoring and logging of physical ingress

1.1.4 System security management (CIP-007)

- Strategies for system hardening
- Acceptable methods of authentication and access control
- Password policies including length, complexity, enforcement, prevention of brute force attempts
- Monitoring and logging of BES Cyber Systems

1.1.5 Incident reporting and response planning (CIP-008)

- Recognition of Cyber Security Incidents
- Appropriate notifications upon discovery of an incident
- Obligations to report Cyber Security Incidents

1.1.6 Recovery plans for BES Cyber Systems (CIP-009)

- Availability of spare components
- Availability of system backups

1.1.7 Configuration change management and vulnerability assessments (CIP-010)

- Initiation of change requests
- Approval of changes
- Break-fix processes

1.1.8 Information protection (CIP-011)

- Information access control methods
- Notification of unauthorized information disclosure
- Information access on a need-to-know basis

1.1.9 Declaring and responding to CIP Exceptional Circumstances

- Processes to invoke special procedures in the event of a CIP Exceptional Circumstance
- Processes to allow for exceptions to policy that do not violate CIP requirements

For Part 1.2, the Responsible Entity may consider the following for each of the required topics in its one or more cyber security policies for assets containing low impact BES Cyber Systems, if any:

1.2.1 Cyber security awareness

- Method(s) for delivery of security awareness
- Identification of groups to receive cyber security awareness

1.2.2 Physical security controls

- Acceptable approach(es) for selection of physical security control(s)

1.2.3 Electronic access controls

- Acceptable approach(es) for selection of electronic access control(s)

1.2.4 Cyber Security Incident response

- Recognition of Cyber Security Incidents
- Appropriate notifications upon discovery of an incident
- Obligations to report Cyber Security Incidents

1.2.5 Transient Cyber Assets and Removable Media Malicious Code Risk Mitigation

- Acceptable use of Transient Cyber Asset(s) and Removable Media
- Method(s) to mitigate the risk of the introduction of malicious code to low impact BES Cyber Systems from Transient Cyber Assets and Removable Media
- Method(s) to request Transient Cyber Asset and Removable Media

1.2.6 Declaring and responding to CIP Exceptional Circumstances

- Process(es) to declare a CIP Exceptional Circumstance
- Process(es) to respond to a declared CIP Exceptional Circumstance

Requirements relating to exceptions to a Responsible Entity’s security policies were removed because it is a general management issue that is not within the scope of a reliability requirement. It is an internal policy requirement and not a reliability requirement. However, Responsible Entities are encouraged to continue this practice as a component of their cyber security policies.

In this and all subsequent required approvals in the NERC CIP Reliability Standards, the Responsible Entity may elect to use hardcopy or electronic approvals to the extent that there is sufficient evidence to ensure the authenticity of the approving party.

Requirement R2:

The intent of Requirement R2 is for each Responsible Entity to create, document, and implement one or more cyber security plan(s) that address the security objective for the protection of low impact BES Cyber Systems. The required protections are designed to be part of a program that covers the low impact BES Cyber Systems collectively at an asset level (based on the list of assets containing low impact BES Cyber Systems identified in CIP-002), but not at an individual device or system level.

Requirement R2, Attachment 1

As noted, Attachment 1 contains the sections that must be included in the cyber security plan(s). The intent is to allow entities that have a combination of high, medium, and low impact BES Cyber Systems the flexibility to choose, if desired, to cover their low impact BES Cyber Systems (or any subset) under their programs used for the high or medium impact BES Cyber Systems rather than maintain two separate programs. The purpose of the cyber security plan(s) in Requirement R2 is for Responsible Entities to use the cyber security plan(s) as a means of documenting their approaches to meeting the subject matter areas. The cyber security plan(s) can be used to reference other policies and procedures that demonstrate "how" the Responsible Entity is meeting each of the subject matter areas, or Responsible Entities can develop comprehensive cyber security plan(s) that contain all of the detailed implementation content solely within the cyber security plan itself. To meet the obligation for the cyber security plan, the expectation is that the cyber security plan contains or references sufficient details to address the implementation of each of the required subject matters areas.

Guidance for each of the subject matter areas of Attachment 1 is provided below.

Requirement R2, Attachment 1, Section 1 – Cyber Security Awareness

The intent of the cyber security awareness program is for entities to reinforce good cyber security practices with their personnel at least once every 15 calendar months. The entity has the discretion to determine the topics to be addressed and the manner in which it will communicate these topics. As evidence of compliance, the Responsible Entity should be able to produce the awareness material that was delivered according to the delivery method(s) (e.g., posters, emails, or topics at staff meetings, etc.). The standard drafting team does not intend for Responsible Entities to be required to maintain lists of recipients and track the reception of the awareness material by personnel.

Although the focus of the awareness is cyber security, it does not mean that only technology-related topics can be included in the program. Appropriate physical security topics (e.g., tailgating awareness and protection of badges for physical security, or "If you see something, say something" campaigns, etc.) are valid for cyber security awareness. The intent is to cover topics concerning any aspect of the protection of BES Cyber Systems.

Requirement R2, Attachment 1, Section 2 – Physical Security Controls

The Responsible Entity must document and implement methods to control physical access to (1) the asset or the locations of low impact BES Cyber Systems within the asset, and (2) Cyber Assets that implement the electronic access control(s) specified by the Responsible Entity in Attachment 1, Section 3.1, if any. If these Cyber Assets implementing the electronic access controls are located within the same asset as the low impact BES Cyber Asset(s) and inherit the same physical access controls and the same need as outlined in Section 2, this may be noted by the Responsible Entity in either its policies or cyber security plan(s) to avoid duplicate documentation of the same controls.

The Responsible Entity has the flexibility to select the methods used to meet the objective of controlling physical access to (1) the asset(s) containing low impact BES Cyber System(s) or the low impact BES Cyber Systems themselves and (2) the electronic access control Cyber Assets specified by the Responsible Entity, if any. The Responsible Entity may use one or a combination of physical access controls, monitoring controls, or other operational, procedural, or technical physical security controls. Entities may use perimeter controls (e.g., fences with locked gates, guards, or site access policies, etc.) or more granular areas of physical access control in areas where low impact BES Cyber Systems are located, such as control rooms or control houses.

The security objective is to control the physical access based on need as determined by the Responsible Entity. The need for physical access can be documented at the policy level. The standard drafting team did not intend to obligate an entity to specify a need for each physical access or authorization of an individual for physical access.

Monitoring as a physical security control can be used as a complement or an alternative to physical access control. Examples of monitoring controls include, but are not limited to: (1) alarm systems to detect motion or entry into a controlled area, or (2) human observation of a controlled area. Monitoring does not necessarily require logging and maintaining logs but could include monitoring that physical access has occurred or been attempted (e.g., door alarm, or human observation, etc.). The standard drafting team's intent is that the monitoring does not need to be per low impact BES Cyber System but should be at the appropriate level to meet the security objective of controlling physical access.

User authorization programs and lists of authorized users for physical access are not required although they are an option to meet the security objective.

Requirement R2, Attachment 1, Section 3 – Electronic Access Controls

Section 3 requires the establishment of electronic access controls for assets containing low impact BES Cyber Systems when there is routable protocol communication or Dial-up Connectivity between Cyber Asset(s) outside of the asset containing the low impact BES Cyber System(s) and the low impact BES Cyber System(s) within such asset. The establishment of electronic access controls is intended to reduce the risks associated with uncontrolled communication using routable protocols or Dial-up Connectivity.

When implementing Attachment 1, Section 3.1, Responsible Entities should note that electronic access controls to permit only necessary inbound and outbound electronic access are required for communications when those communications meet all three of the criteria identified in Attachment 1, Section 3.1. The Responsible Entity should evaluate the communications and when all three criteria are met, the Responsible Entity must document and implement electronic access control(s).

When identifying electronic access controls, Responsible Entities are provided flexibility in the selection of the electronic access controls that meet their operational needs while meeting the security objective of allowing only necessary inbound and outbound electronic access to low impact BES Cyber Systems that use routable protocols between a low impact BES Cyber System(s) and Cyber Asset(s) outside the asset.

In essence, the intent is for Responsible Entities to determine whether there is communication between a low impact BES Cyber System(s) and a Cyber Asset(s) outside the asset containing low impact BES Cyber System(s) that uses a routable protocol when entering or leaving the asset or Dial-up Connectivity to the low impact BES Cyber System(s). Where such communication is present, Responsible Entities should document and implement electronic access control(s). Where routable protocol communication for time-sensitive protection or control functions between intelligent electronic devices that meets the exclusion language is present, Responsible Entities should document that communication, but are not required to establish any specific electronic access controls.

The inputs to this requirement are the assets identified in CIP-002 as containing low impact BES Cyber System(s); therefore, the determination of routable protocol communications or Dial-up Connectivity is an attribute of the asset. However, it is not intended for communication that provides no access to or from the low impact BES Cyber System(s), but happens to be located at the asset with the low impact BES Cyber System(s), to be evaluated for electronic access controls.

Electronic Access Control Exclusion

In order to avoid future technology issues, the obligations for electronic access controls exclude communications between intelligent electronic devices that use routable communication protocols for time-sensitive protection or control functions, such as IEC TR-61850-90-5 R-GOOSE messaging. Time-sensitive in this context generally means functions that would be negatively impacted by the latency introduced in the communications by the required electronic access controls. This time-sensitivity exclusion does not apply to SCADA communications which typically operate on scan rates of 2 seconds or greater. While technically time-sensitive, SCADA communications over routable protocols can withstand the delay introduced by electronic access controls. Examples of excluded time-sensitive communications are those communications which may necessitate the tripping of a breaker within a few cycles. A Responsible Entity using this technology is not expected to implement the electronic access controls noted herein. This exception was included so as not to inhibit the functionality of the time-sensitive characteristics related to this technology and not to preclude the use of such time-sensitive reliability enhancing functions if they use a routable protocol in the future.

Considerations for Determining Routable Protocol Communications

To determine whether electronic access controls need to be implemented, the Responsible Entity has to determine whether there is communication between a low impact BES Cyber System(s) and a Cyber Asset(s) outside the asset containing the low impact BES Cyber System(s) that uses a routable protocol when entering or leaving the asset.

When determining whether a routable protocol is entering or leaving the asset containing the low impact BES Cyber System(s), Responsible Entities have flexibility in identifying an approach. One approach is for Responsible Entities to identify an “electronic boundary” associated with the asset containing low impact BES Cyber System(s). This is not an Electronic Security Perimeter *per se*, but a demarcation that demonstrates the routable protocol communication entering or leaving the asset between a low impact BES Cyber System and Cyber Asset(s) outside the asset to then have electronic access controls implemented. This electronic boundary may vary by asset type (Control Center, substation, generation resource) and the specific configuration of the asset. If this approach is used, the intent is for the Responsible Entity to define the electronic boundary such that the low impact BES Cyber System(s) located at the asset are contained within the “electronic boundary.” This is strictly for determining which routable protocol communications and networks are internal or inside or local to the asset and which are external to or outside the asset.

Alternatively, the Responsible Entity may find the concepts of what is inside and outside to be intuitively obvious for a Cyber Asset(s) outside the asset containing low impact BES Cyber System(s) communicating to a low impact BES Cyber System(s) inside the asset. This may be the case when a low impact BES Cyber System(s) is communicating with a Cyber Asset many miles away and a clear and unambiguous demarcation exists. In this case, a Responsible Entity may decide not to identify an “electronic boundary,” but rather to simply leverage the unambiguous asset demarcation to ensure that the electronic access controls are placed between the low impact BES Cyber System(s) and the Cyber Asset(s) outside the asset.

Determining Electronic Access Controls

Once a Responsible Entity has determined that there is routable communication between a low impact BES Cyber System(s) and a Cyber Asset(s) outside the asset containing the low impact BES Cyber System(s) that uses a routable protocol when entering or leaving the asset containing the low impact BES Cyber System(s), the intent is for the Responsible Entity to document and implement its chosen electronic access control(s). The control(s) are intended to allow only “necessary” inbound and outbound electronic access as determined by the Responsible Entity. However the Responsible Entity chooses to document the inbound and outbound access permissions and the need, the intent is that the Responsible Entity is able to explain the reasons for the electronic access permitted. The reasoning for "necessary" inbound and outbound electronic access controls may be documented within the Responsible Entity's cyber security plan(s), within a comment on an access control list, a database, spreadsheet or other policies or procedures associated with the electronic access controls.

Concept Diagrams

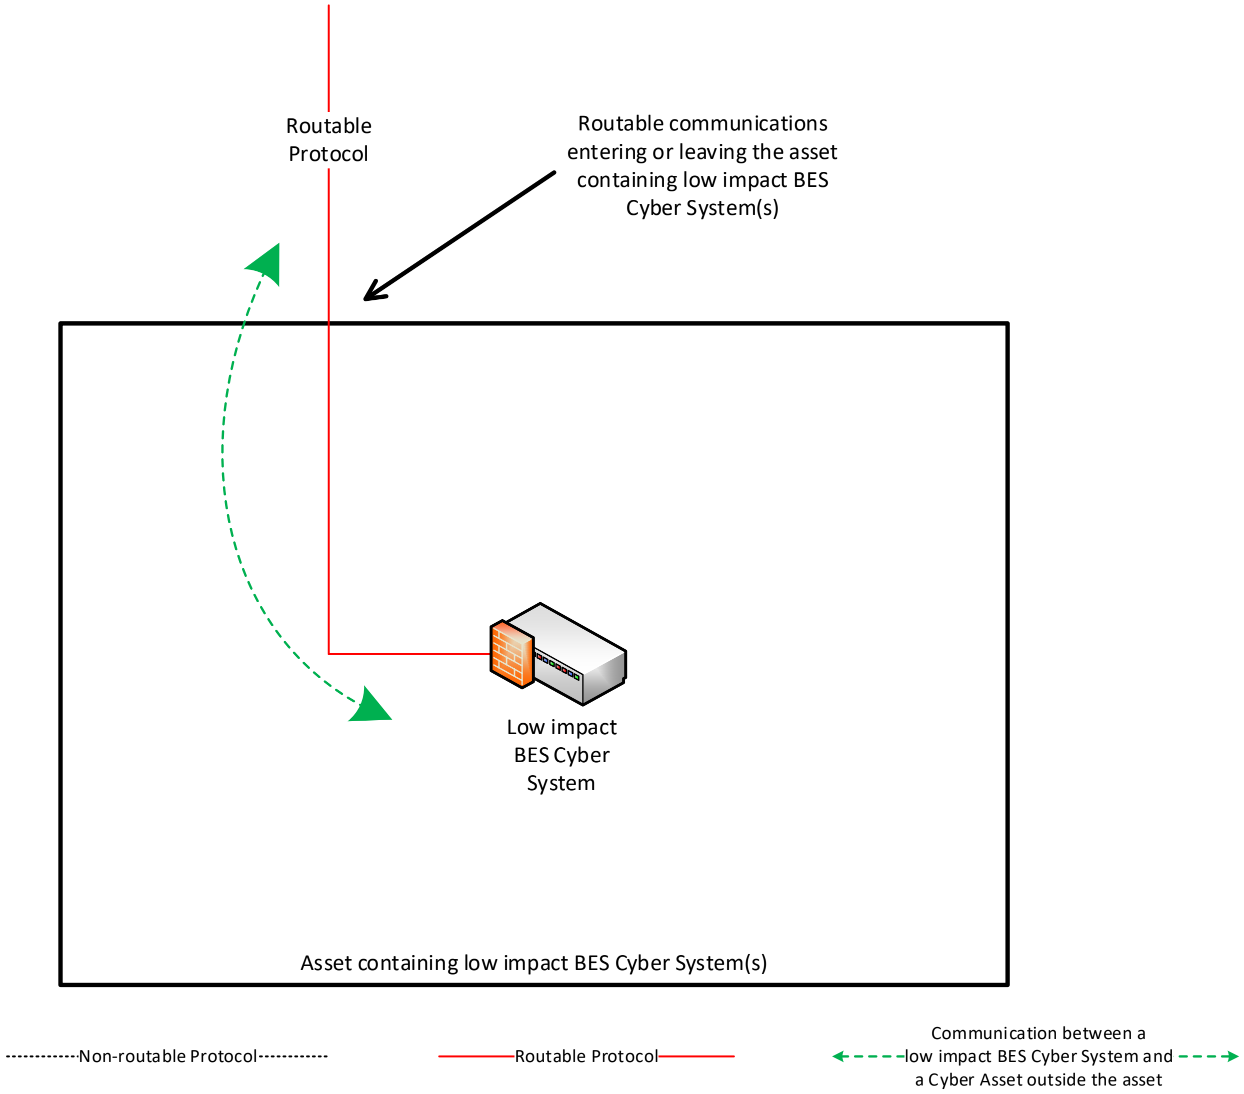
The diagrams on the following pages are provided as examples to illustrate various electronic access controls at a conceptual level. Regardless of the concepts or configurations chosen by the Responsible Entity, the intent is to achieve the security objective of permitting only necessary inbound and outbound electronic access for communication between low impact BES Cyber Systems and Cyber Asset(s) outside the asset containing the low impact BES Cyber System(s) using a routable protocol when entering or leaving the asset.

NOTE:

- This is not an exhaustive list of applicable concepts.
- The same legend is used in each diagram; however, the diagram may not contain all of the articles represented in the legend.

Reference Model 1 – Host-based Inbound & Outbound Access Permissions

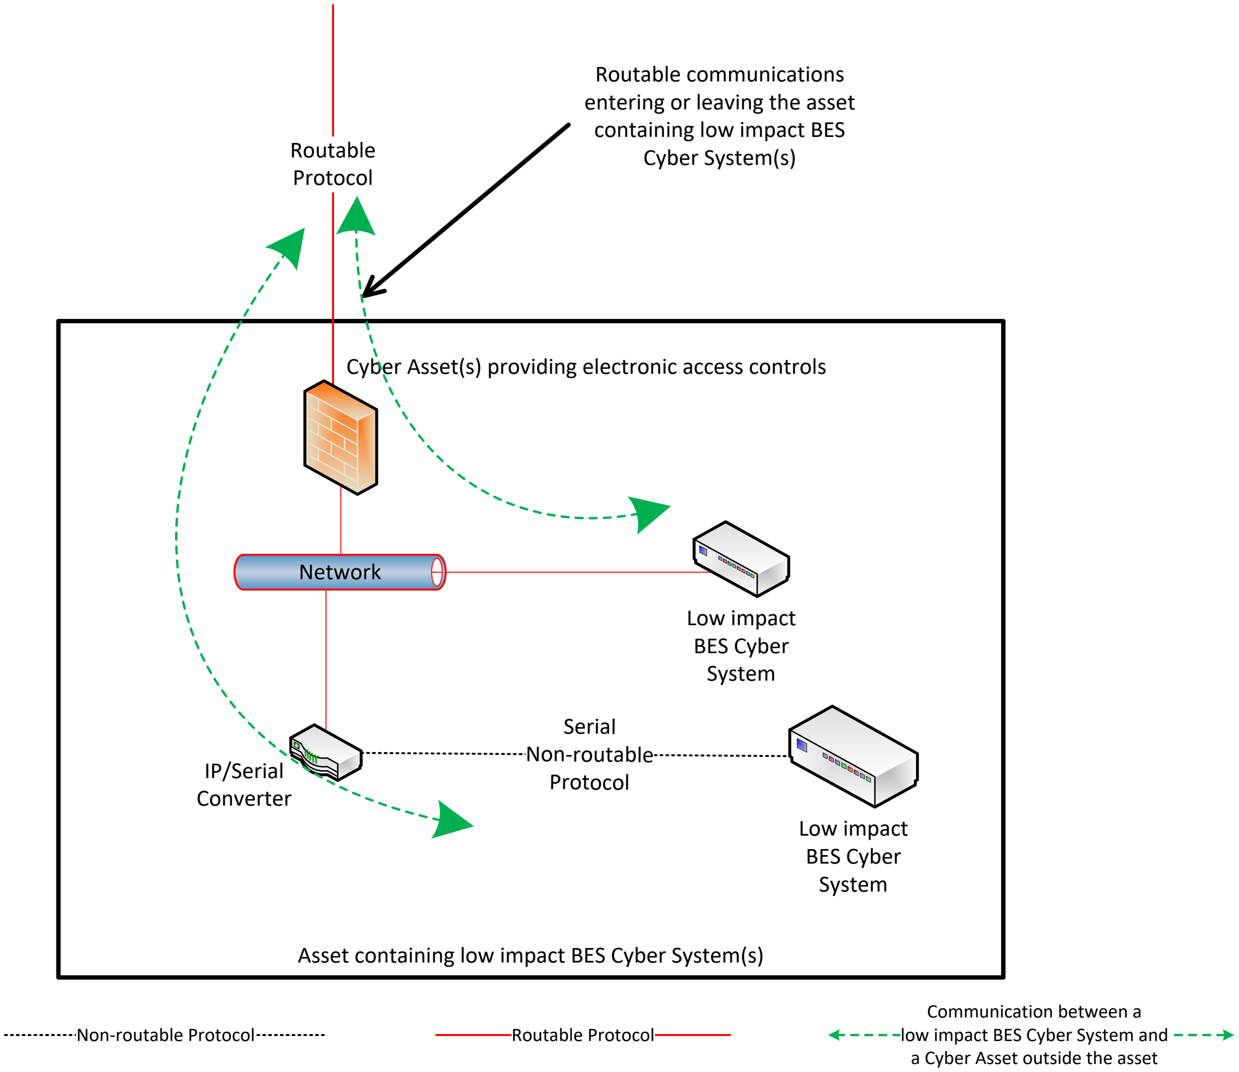
The Responsible Entity may choose to utilize a host-based firewall technology on the low impact BES Cyber System(s) itself that manages the inbound and outbound electronic access permissions so that only necessary inbound and outbound electronic access is allowed between the low impact BES Cyber System(s) and the Cyber Asset(s) outside the asset containing the low impact BES Cyber System(s). When permitting the inbound and outbound electronic access permissions using access control lists, the Responsible Entity could restrict communication(s) using source and destination addresses or ranges of addresses. Responsible Entities could also restrict communication(s) using ports or services based on the capability of the electronic access control, the low impact BES Cyber System(s), or the application(s).



Reference Model 1

Reference Model 2 – Network-based Inbound & Outbound Access Permissions

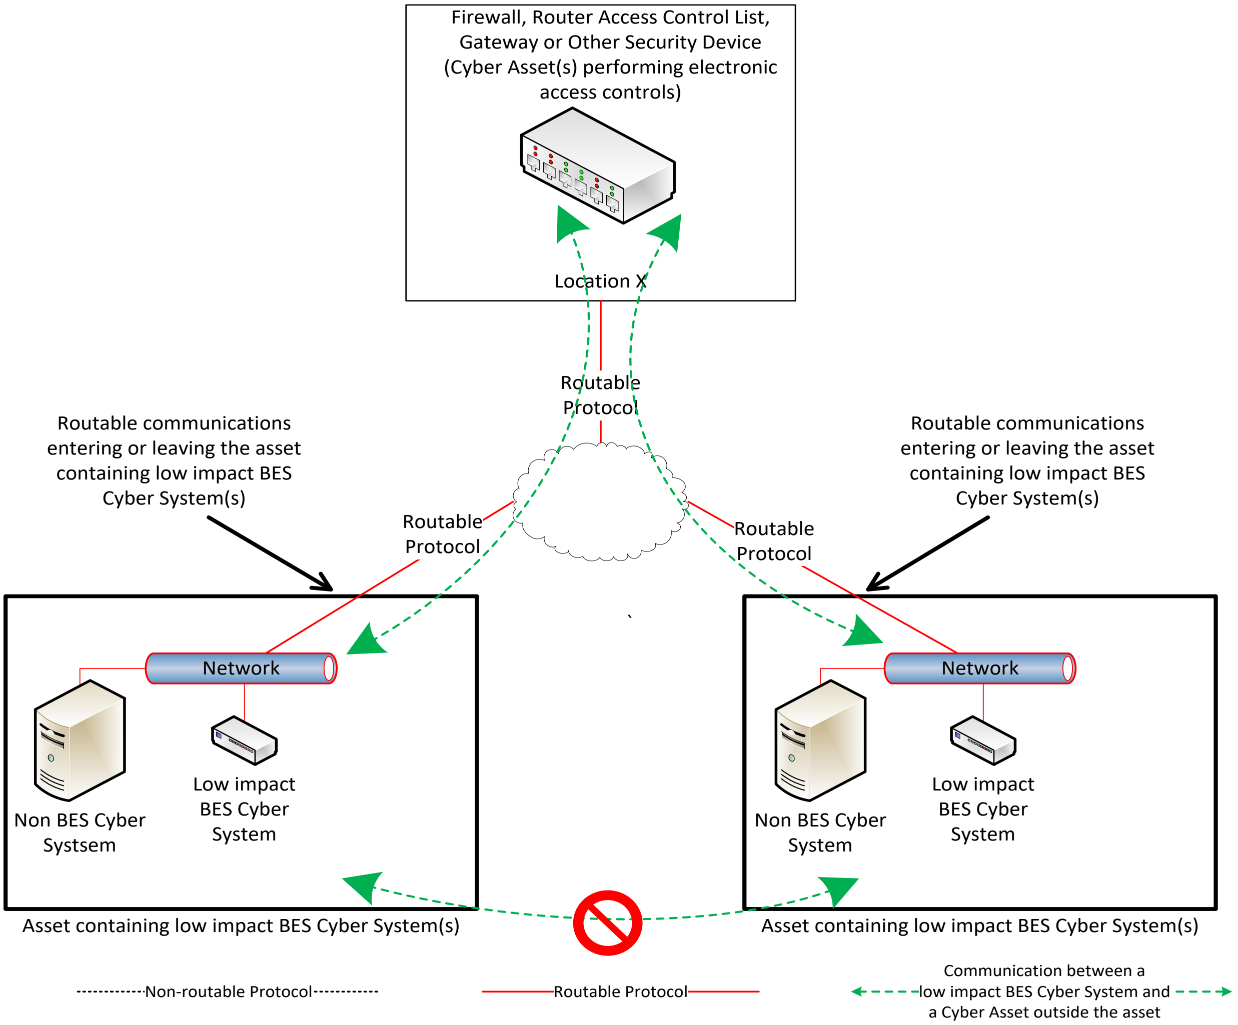
The Responsible Entity may choose to use a security device that permits only necessary inbound and outbound electronic access to the low impact BES Cyber System(s) within the asset containing the low impact BES Cyber System(s). In this example, two low impact BES Cyber Systems are accessed using the routable protocol that is entering or leaving the asset containing the low impact BES Cyber System(s). The IP/Serial converter is continuing the same communications session from the Cyber Asset(s) that are outside the asset to the low impact BES Cyber System(s). The security device provides the electronic access controls to permit only necessary inbound and outbound routable protocol access to the low impact BES Cyber System(s). When permitting the inbound and outbound electronic access permissions using access control lists, the Responsible Entity could restrict communication(s) using source and destination addresses or ranges of addresses. Responsible Entities could also restrict communication(s) using ports or services based on the capability of the electronic access control, the low impact BES Cyber System(s), or the application(s).



Reference Model 2

Reference Model 3 – Centralized Network-based Inbound & Outbound Access Permissions

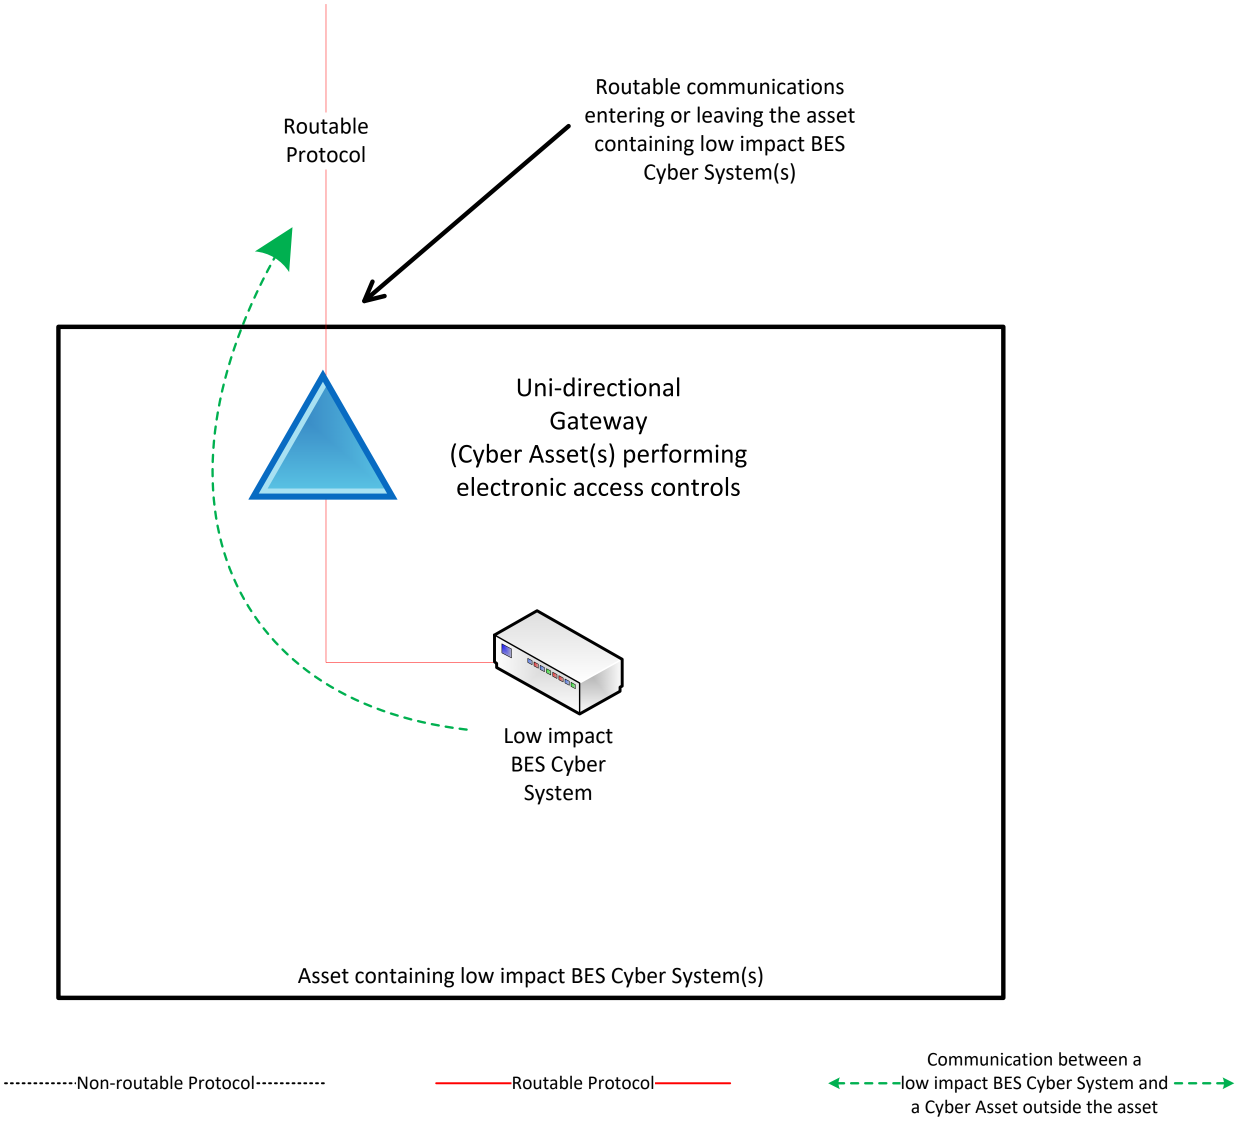
The Responsible Entity may choose to utilize a security device at a centralized location that may or may not be at another asset containing low impact BES Cyber System(s). The electronic access control(s) do not necessarily have to reside inside the asset containing the low impact BES Cyber System(s). A security device is in place at "Location X" to act as the electronic access control and permit only necessary inbound and outbound routable protocol access between the low impact BES Cyber System(s) and the Cyber Asset(s) outside each asset containing low impact BES Cyber System(s). Care should be taken that electronic access to or between each asset is through the Cyber Asset(s) determined by the Responsible Entity to be performing electronic access controls at the centralized location. When permitting the inbound and outbound electronic access permissions using access control lists, the Responsible Entity could restrict communication(s) using source and destination addresses or ranges of addresses. Responsible Entities could also restrict communication(s) using ports or services based on the capability of the electronic access control, the low impact BES Cyber System(s), or the application(s).



Reference Model 3

Reference Model 4 – Uni-directional Gateway

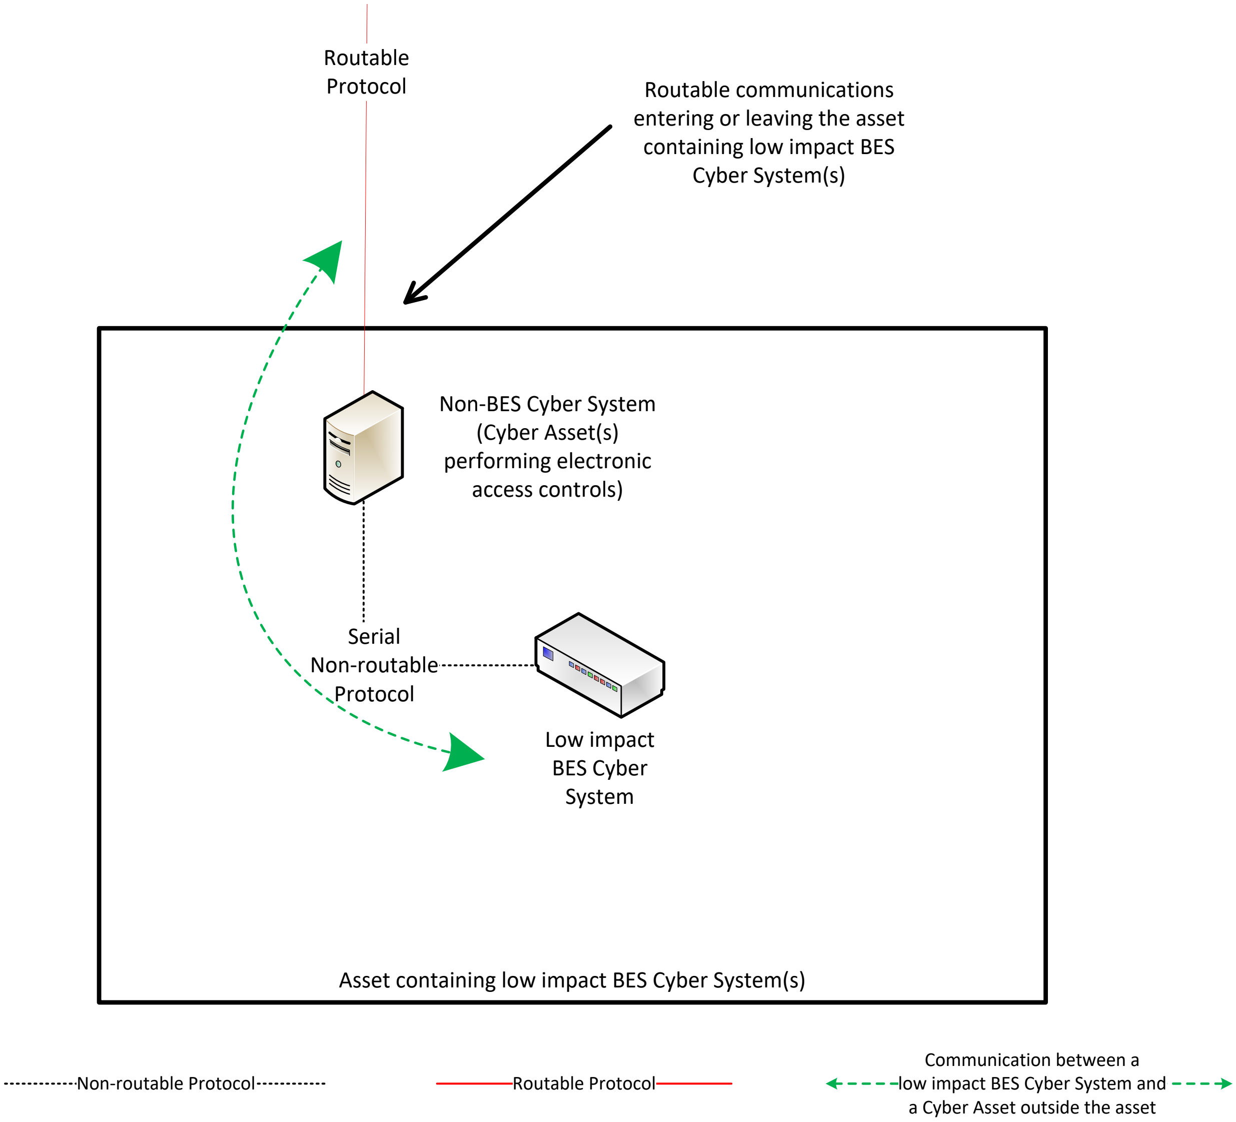
The Responsible Entity may choose to utilize a uni-directional gateway as the electronic access control. The low impact BES Cyber System(s) is not accessible (data cannot flow into the low impact BES Cyber System) using the routable protocol entering the asset due to the implementation of a “one-way” (uni-directional) path for data to flow. The uni-directional gateway is configured to permit only the necessary outbound communications using the routable protocol communication leaving the asset.



Reference Model 4

Reference Model 5 – User Authentication

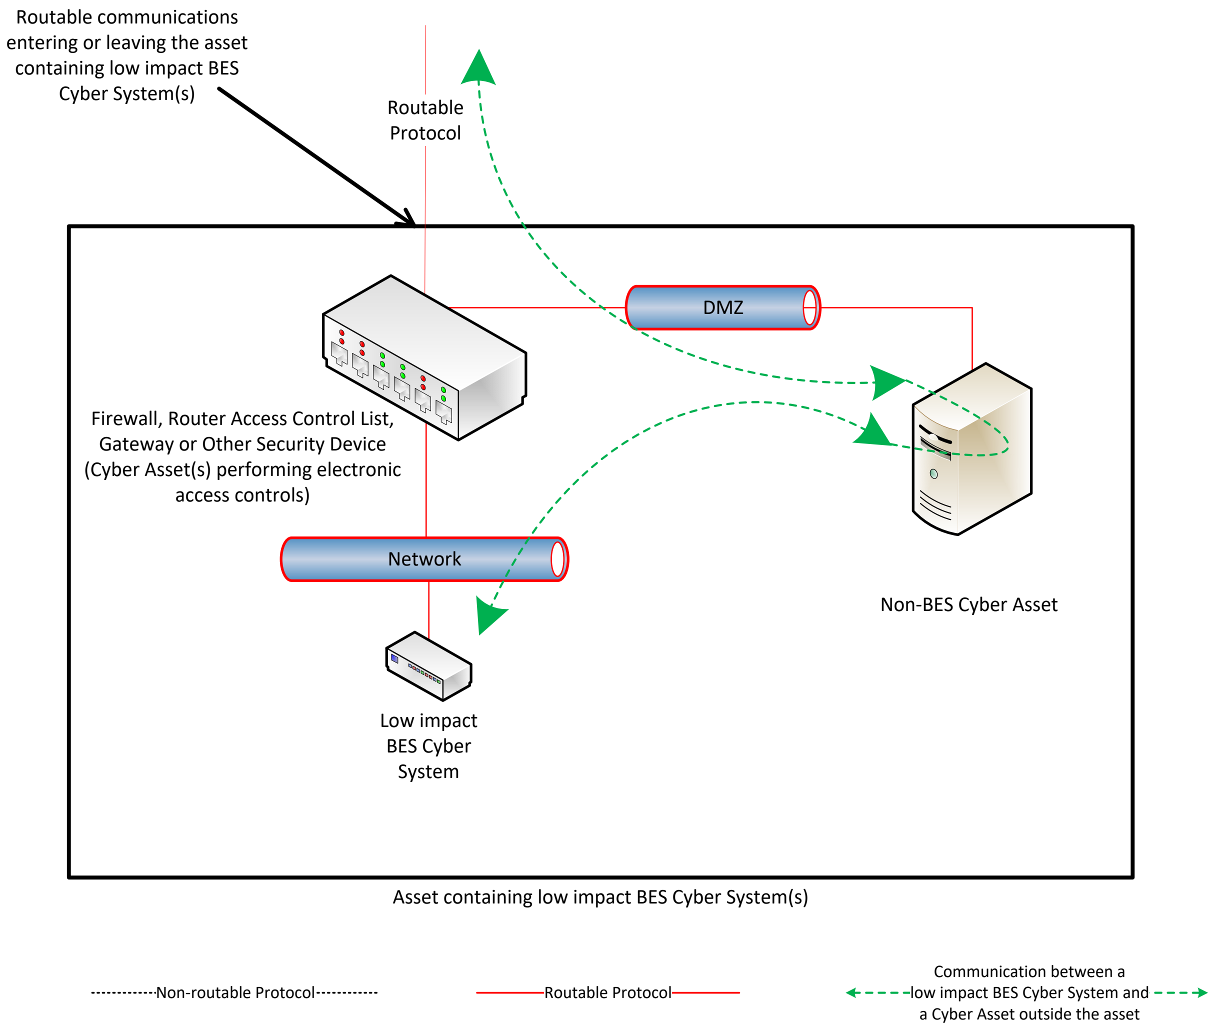
This reference model demonstrates that Responsible Entities have flexibility in choosing electronic access controls so long as the security objective of the requirement is met. The Responsible Entity may choose to utilize a non-BES Cyber Asset located at the asset containing the low impact BES Cyber System that requires authentication for communication from the Cyber Asset(s) outside the asset. This non-BES Cyber System performing the authentication permits only authenticated communication to connect to the low impact BES Cyber System(s), meeting the first half of the security objective to permit only necessary inbound electronic access. Additionally, the non-BES Cyber System performing authentication is configured such that it permits only necessary outbound communication meeting the second half of the security objective. Often, the outbound communications would be controlled in this network architecture by permitting no communication to be initiated from the low impact BES Cyber System. This configuration may be beneficial when the only communication to a device is for user-initiated interactive access.



Reference Model 5

Reference Model 6 – Indirect Access

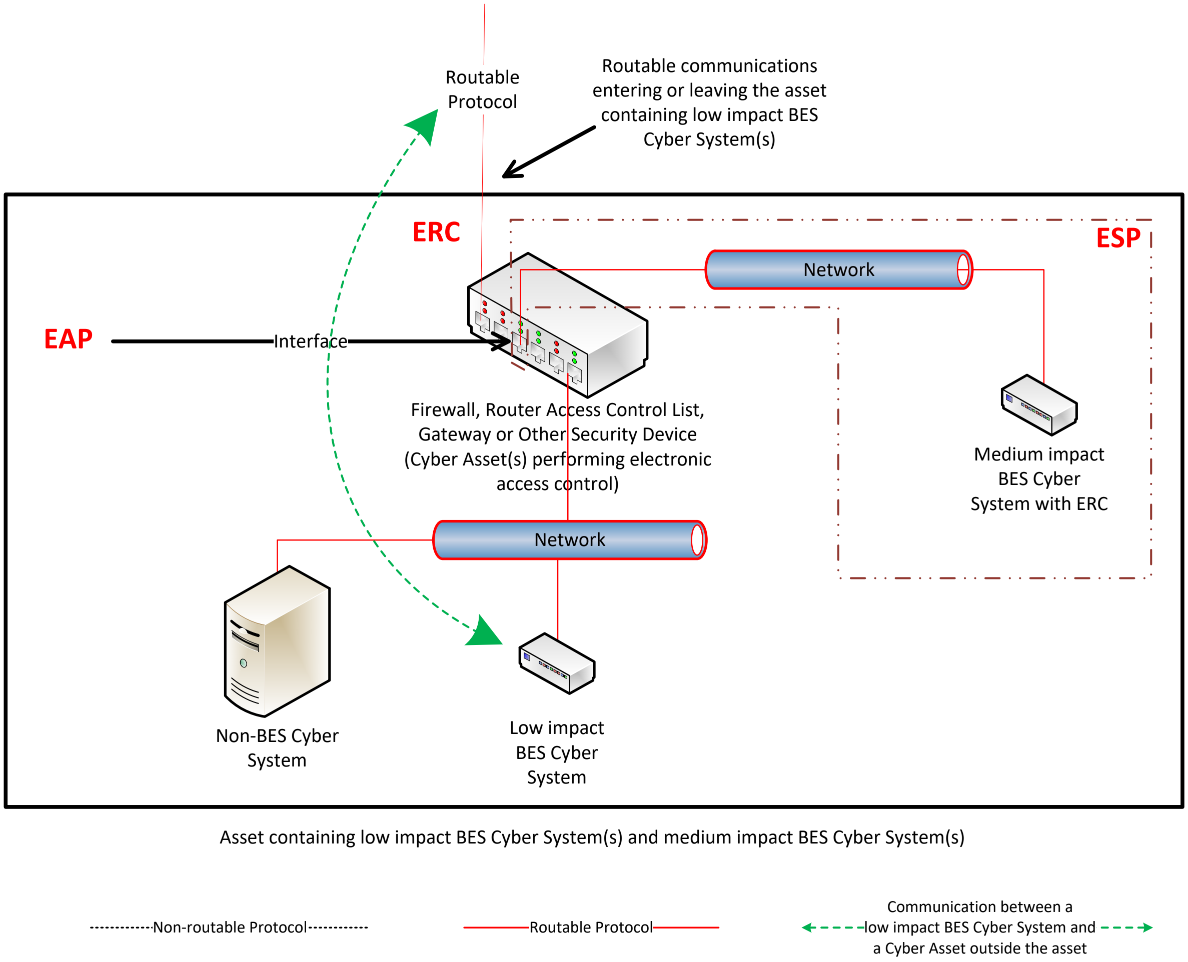
In implementing its electronic access controls, the Responsible Entity may identify that it has indirect access between the low impact BES Cyber System and a Cyber Asset outside the asset containing the low impact BES Cyber System through a non-BES Cyber Asset located within the asset. This indirect access meets the criteria of having communication between the low impact BES Cyber System and a Cyber Asset outside the asset containing the low impact BES Cyber System. In this reference model, it is intended that the Responsible Entity implement electronic access controls that permit only necessary inbound and outbound electronic access to the low impact BES Cyber System. Consistent with the other reference models provided, the electronic access in this reference model is controlled using the security device that is restricting the communication that is entering or leaving the asset.



Reference Model 6

Reference Model 7 – Electronic Access Controls at assets containing low impact BES Cyber Systems and ERC

In this reference model, there is both a routable protocol entering and leaving the asset containing the low impact BES Cyber System(s) that is used by Cyber Asset(s) outside the asset and External Routable Connectivity because there is at least one medium impact BES Cyber System and one low impact BES Cyber System within the asset using the routable protocol communications. The Responsible Entity may choose to leverage an interface on the medium impact Electronic Access Control or Monitoring Systems (EACMS) to provide electronic access controls for purposes of CIP-003. The EACMS is therefore performing multiple functions – as a medium impact EACMS and as implementing electronic access controls for an asset containing low impact BES Cyber Systems.



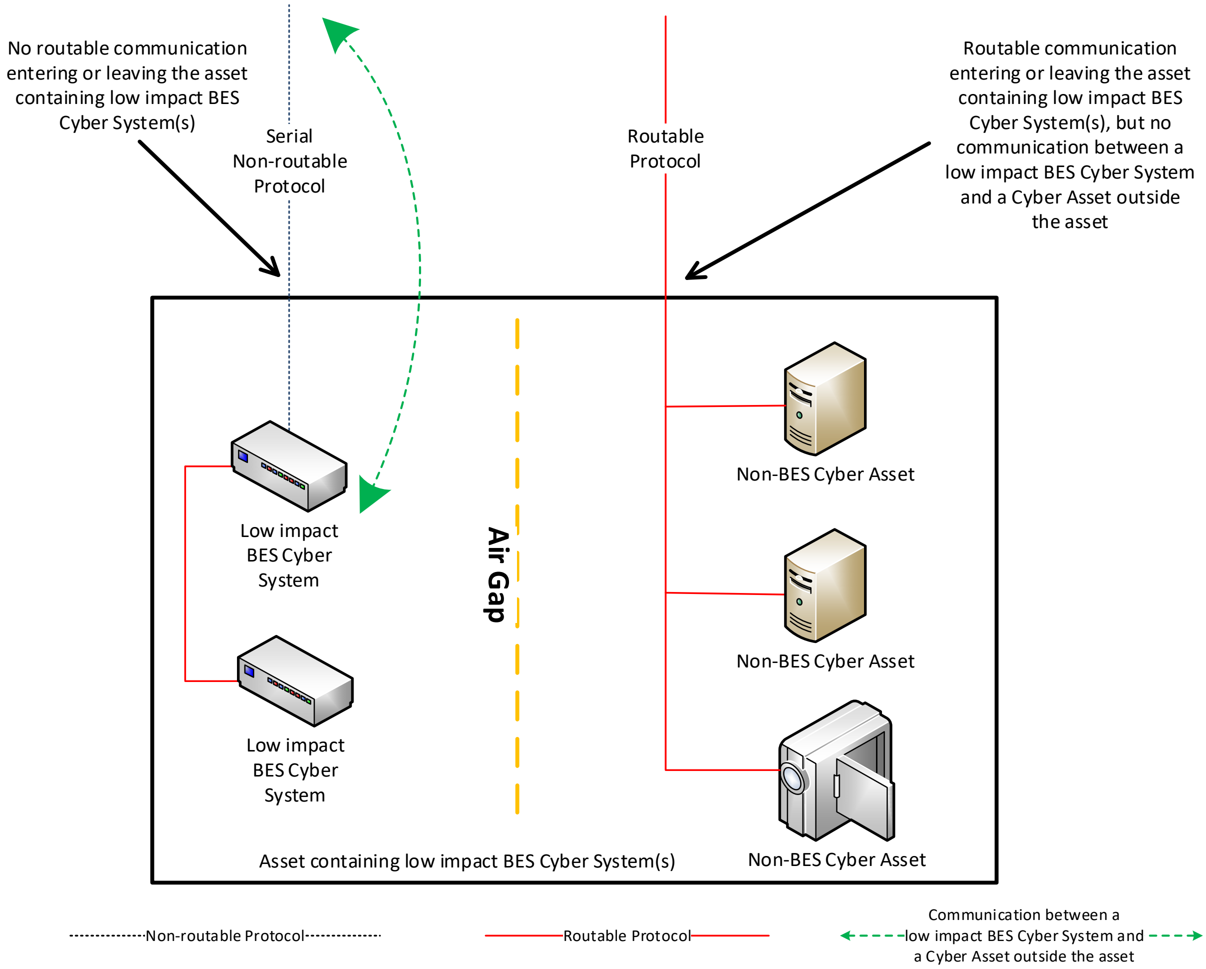
Reference Model 7

Reference Model 8 – Physical Isolation and Serial Non-routable Communications – No Electronic Access Controls Required

In this reference model, the criteria from Attachment 1, Section 3.1 requiring the implementation of electronic access controls are not met. This reference model demonstrates three concepts:

1. The physical isolation of the low impact BES Cyber System(s) from the routable protocol communication entering or leaving the asset containing the low impact BES Cyber System(s), commonly referred to as an 'air gap', mitigates the need to implement the required electronic access controls;
2. The communication to the low impact BES Cyber System from a Cyber Asset outside the asset containing the low impact BES Cyber System(s) using only a serial non-routable protocol where such communication is entering or leaving the asset mitigates the need to implement the required electronic access controls.
3. The routable protocol communication between the low impact BES Cyber System(s) and other Cyber Asset(s), such as the second low impact BES Cyber System depicted, may exist without needing to implement the required electronic access controls so long as the routable protocol communications never leaves the asset containing the low impact BES Cyber System(s).

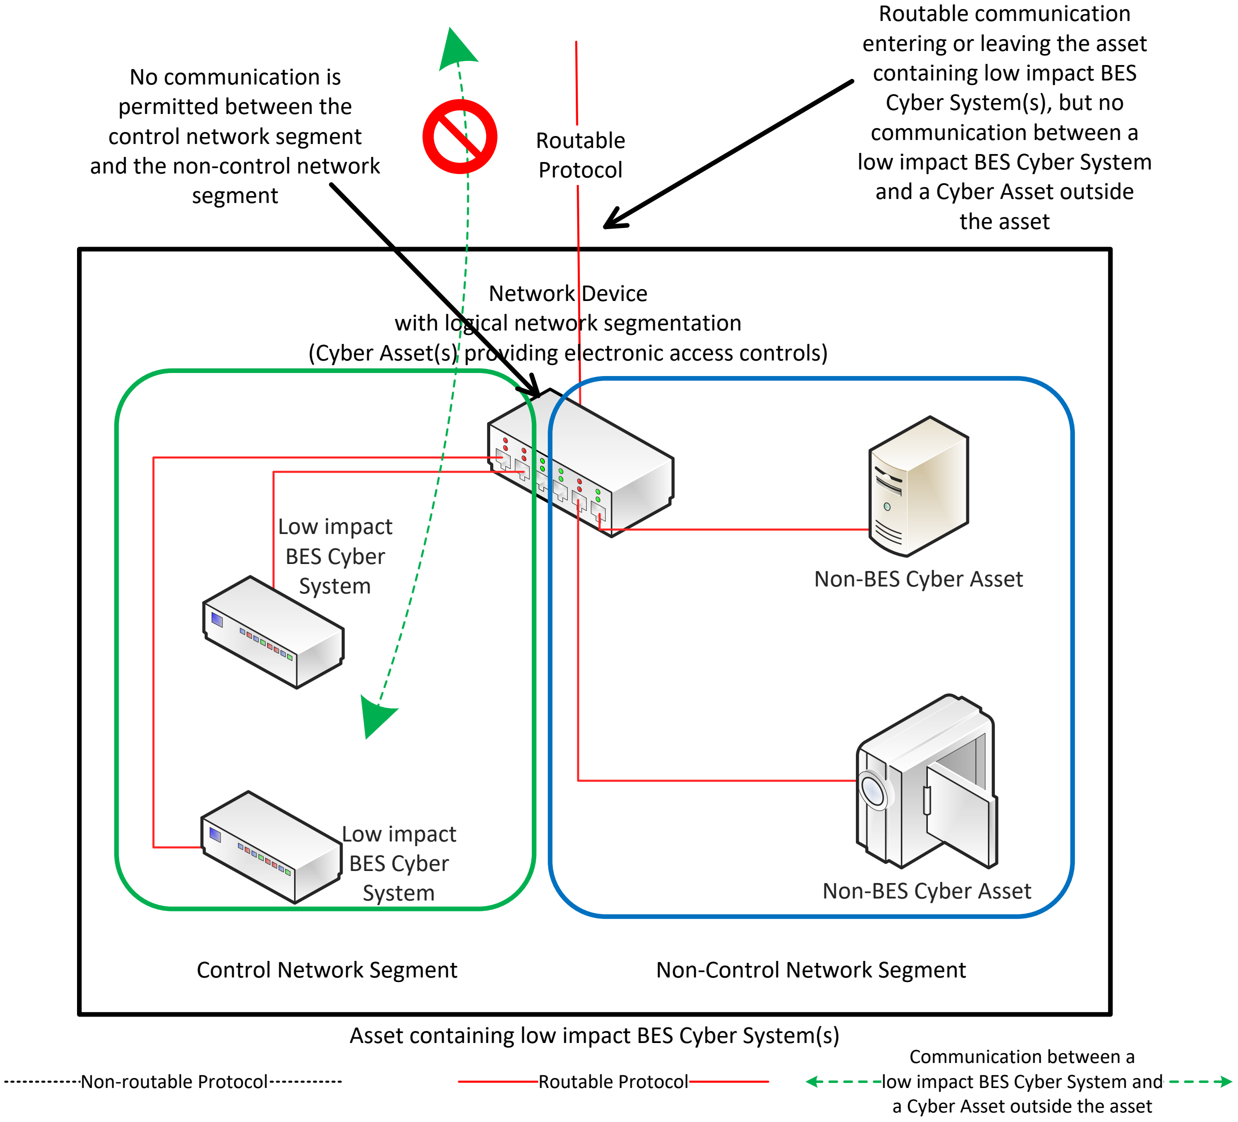
Section 1.



Reference Model 8

Reference Model 9 – Logical Isolation - No Electronic Access Controls Required

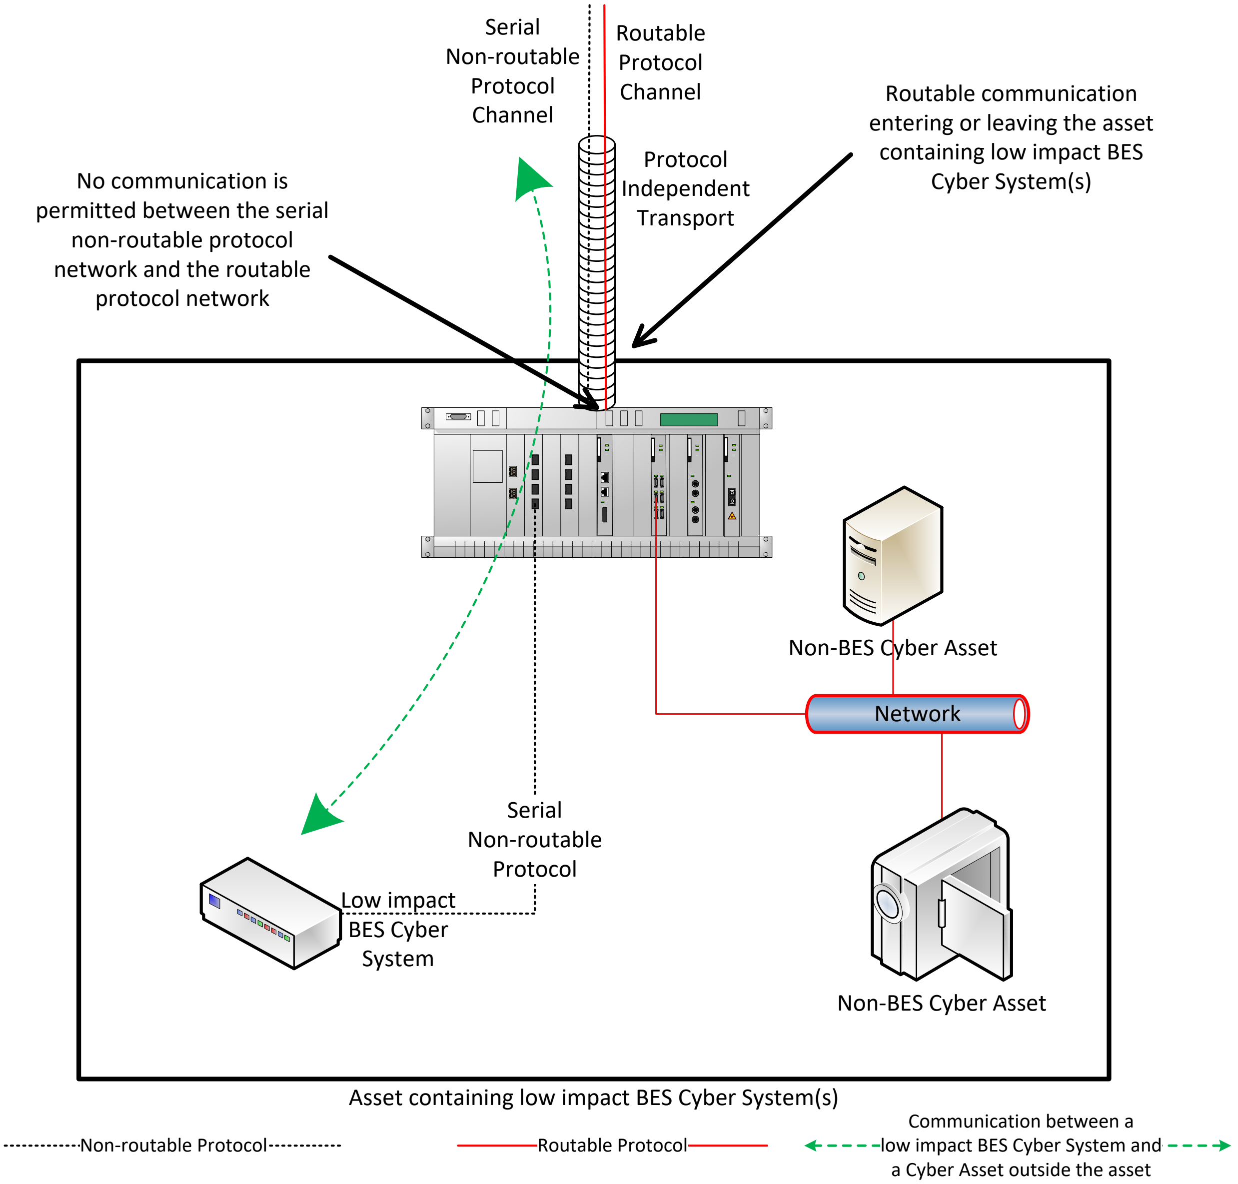
In this reference model, the criteria from Attachment 1, Section 3.1 requiring the implementation of electronic access controls are not met. The Responsible Entity has logically isolated the low impact BES Cyber System(s) from the routable protocol communication entering or leaving the asset containing low impact BES Cyber System(s). The logical network segmentation in this reference model permits no communication between a low impact BES Cyber System and a Cyber Asset outside the asset. Additionally, no indirect access exists because those non-BES Cyber Assets that are able to communicate outside the asset are strictly prohibited from communicating to the low impact BES Cyber System(s). The low impact BES Cyber System(s) is on an isolated network segment with logical controls preventing routable protocol communication into or out of the network containing the low impact BES Cyber System(s) and these communications never leave the asset using a routable protocol.



Reference Model 9

Reference Model 10 - Serial Non-routable Communications Traversing an Isolated Channel on a Non-routable Transport Network – No Electronic Access Controls Required

In this reference model, the criteria from Attachment 1, Section 3.1 requiring the implementation of electronic access controls are not met. This reference model depicts communication between a low impact BES Cyber System and a Cyber Asset outside the asset containing the low impact BES Cyber System over a serial non-routable protocol which is transported across a wide-area network using a protocol independent transport that may carry routable and non-routable communication such as a Time-Division Multiplexing (TDM) network, a Synchronous Optical Network (SONET), or a Multiprotocol Label Switching (MPLS) network. While there is routable protocol communication entering or leaving the asset containing low impact BES Cyber Systems(s) and there is communication between a low impact BES Cyber System and a Cyber Asset outside the asset, the communication between the low impact BES Cyber System and the Cyber Asset outside the asset is not using the routable protocol communication. This model is related to Reference Model 9 in that it relies on logical isolation to prohibit the communication between a low impact BES Cyber System and a Cyber Asset outside the asset from using a routable protocol.



Reference Model 10

Dial-up Connectivity

Dial-up Connectivity to a low impact BES Cyber System is set to dial out only (no auto-answer) to a preprogrammed number to deliver data. Incoming Dial-up Connectivity is to a dialback modem, a modem that must be remotely controlled by the control center or control room, has some form of access control, or the low impact BES Cyber System has access control.

Insufficient Access Controls

Some examples of situations that would lack sufficient access controls to meet the intent of this requirement include:

- An asset has Dial-up Connectivity and a low impact BES Cyber System is reachable via an auto-answer modem that connects any caller to the Cyber Asset that has a default password. There is no practical access control in this instance.
- A low impact BES Cyber System has a wireless card on a public carrier that allows the BES Cyber System to be reachable via a public IP address. In essence, low impact BES Cyber Systems should not be accessible from the Internet and search engines such as Shodan.
- Dual-homing or multiple-network interface cards without disabling IP forwarding in the non-BES Cyber Asset within the DMZ to provide separation between the low impact BES Cyber System(s) and the external network would not meet the intent of “controlling” inbound and outbound electronic access assuming there was no other host-based firewall or other security devices on the non-BES Cyber Asset.

Requirement R2, Attachment 1, Section 4 – Cyber Security Incident Response

The entity should have one or more documented Cyber Security Incident response plan(s) that include each of the topics listed in Section 4. If, in the normal course of business, suspicious activities are noted at an asset containing low impact BES Cyber System(s), the intent is for the entity to implement a Cyber Security Incident response plan that will guide the entity in responding to the incident and reporting the incident if it rises to the level of a Reportable Cyber Security Incident.

Entities are provided the flexibility to develop their Attachment 1, Section 4 Cyber Security Incident response plan(s) by asset or group of assets. The plans do not need to be on a per asset site or per low impact BES Cyber System basis. Entities can choose to use a single enterprise-wide plan to fulfill the obligations for low impact BES Cyber Systems.

The plan(s) must be tested once every 36 months. This is not an exercise per low impact BES Cyber Asset or per type of BES Cyber Asset but rather is an exercise of each incident response plan the entity created to meet this requirement. An actual Reportable Cyber Security Incident counts as an exercise as do other forms of tabletop exercises or drills. NERC-led exercises such as GridEx participation would also count as an exercise provided the entity’s response plan is followed. The intent of the requirement is for entities to keep the Cyber Security Incident response plan(s) current, which includes updating the plan(s), if needed, within 180 days following a test or an actual incident.

For low impact BES Cyber Systems, the only portion of the definition of Cyber Security Incident that would apply is, “A malicious act or suspicious event that disrupts, or was an attempt to disrupt, the operation of a BES Cyber System.” The other portion of that definition is not to be used to require ESPs and PSPs for low impact BES Cyber Systems.

Requirement R2, Attachment 1, Section 5 – Transient Cyber Assets and Removable Media Malicious Code Risk Mitigation

Most BES Cyber Assets and BES Cyber Systems are isolated from external public or untrusted networks, and therefore Transient Cyber Assets and Removable Media are needed to transport files to and from secure areas to maintain, monitor, or troubleshoot critical systems. Transient Cyber Assets and Removable Media are a potential means for cyber-attack. To protect the BES Cyber Assets and BES Cyber Systems, CIP-003 Requirement R2, Attachment 1, Section 5 requires Responsible Entities to document and implement a plan for how they will mitigate the risk of malicious code introduction to low impact BES Cyber Systems from Transient Cyber Assets and Removable Media. The approach of defining a plan allows the Responsible Entity to document processes that are supportable within its organization and in alignment with its change management processes.

Transient Cyber Assets can be one of many types of devices from a specially-designed device for maintaining equipment in support of the BES to a platform such as a laptop, desktop, or tablet that may interface with or run applications that support BES Cyber Systems and is capable of transmitting executable code to the BES Cyber Asset(s) or BES Cyber System(s). Note: Cyber Assets connected to a BES Cyber System for less than 30 days due to an unplanned removal, such as premature failure, are not intended to be identified as Transient Cyber Assets. Removable Media subject to this requirement include, among others, floppy disks, compact disks, USB flash drives, external hard drives, and other flash memory cards/drives that contain nonvolatile memory.

Examples of these temporarily connected devices include, but are not limited to:

- Diagnostic test equipment;
- Equipment used for BES Cyber System maintenance; or
- Equipment used for BES Cyber System configuration.

To meet the objective of mitigating risks associated with the introduction of malicious code at low impact BES Cyber Systems, Section 5 specifies the capabilities and possible security methods available to Responsible Entities based upon asset type and ownership.

With the list of options provided in Attachment 1, the entity has the discretion to use the option(s) that is most appropriate. This includes documenting its approach for how and when the entity reviews the Transient Cyber Asset under its control or under the control of parties other than the Responsible Entity. The entity should avoid implementing a security function that jeopardizes reliability by taking actions that would negatively impact the performance or support of the Transient Cyber Asset or BES Cyber Asset.

Malicious Code Risk Mitigation

The terms “mitigate”, “mitigating”, and “mitigation” are used in Section 5 in Attachment 1 to address the risks posed by malicious code when connecting Transient Cyber Assets and Removable Media to BES Cyber Systems. Mitigation is intended to mean that entities reduce security risks presented by connecting the Transient Cyber Asset or Removable Media. When determining the method(s) to mitigate the introduction of malicious code, it is not intended for entities to perform and document a formal risk assessment associated with the introduction of malicious code.

Per Transient Cyber Asset Capability

As with other CIP standards, the requirements are intended for an entity to use the method(s) that the system is capable of performing. The use of “per Transient Cyber Asset capability” is to eliminate the need for a Technical Feasibility Exception when it is understood that the device cannot use a method(s). For example, for malicious code, many types of appliances are not capable of implementing antivirus software; therefore, because it is not a capability of those types of devices, implementation of the antivirus software would not be required for those devices.

Requirement R2, Attachment 1, Section 5.1 - Transient Cyber Asset(s) Managed by the Responsible Entity

For Transient Cyber Assets and Removable Media that are connected to both low impact and medium/high impact BES Cyber Systems, entities must be aware of the differing levels of requirements and manage these assets under the program that matches the highest impact level to which they will connect.

Section 5.1: Entities are to document and implement their plan(s) to mitigate malicious code through the use of one or more of the protective measures listed, based on the capability of the Transient Cyber Asset.

The Responsible Entity has the flexibility to apply the selected method(s) to meet the objective of mitigating the introductions of malicious code either in an on-going or in an on-demand manner. An example of managing a device in an on-going manner is having the antivirus solution for the device managed as part of an end-point security solution with current signature or pattern updates, regularly scheduled systems scans, etc. In contrast, for devices that are used infrequently and the signatures or patterns are not kept current, the entity may manage those devices in an on-demand manner by requiring an update to the signatures or patterns and a scan of the device before the device is connected to ensure that it is free of malicious code.

Selecting management in an on-going or on-demand manner is not intended to imply that the control has to be verified at every single connection. For example, if the device is managed in an on-demand manner, but will be used to perform maintenance on several BES Cyber Asset(s), the Responsible Entity may choose to document that the Transient Cyber Asset has been updated before being connected as a Transient Cyber Asset for the first use of that maintenance work. The intent is not to require a log documenting each connection of a Transient Cyber Asset to a BES Cyber Asset.

The following is additional discussion of the methods to mitigate the introduction of malicious code.

- Antivirus software, including manual or managed updates of signatures or patterns, provides flexibility to manage Transient Cyber Asset(s) by deploying antivirus or endpoint security tools that maintain a scheduled update of the signatures or patterns. Also, for devices that do not regularly connect to receive scheduled updates, entities may choose to update the signatures or patterns and scan the Transient Cyber Asset prior to connection to ensure no malicious software is present.
- Application whitelisting is a method of authorizing only the applications and processes that are necessary on the Transient Cyber Asset. This reduces the risk that malicious software could execute on the Transient Cyber Asset and impact the BES Cyber Asset or BES Cyber System.
- When using methods other than those listed, entities need to document how the other method(s) meet the objective of mitigating the risk of the introduction of malicious code.

If malicious code is discovered on the Transient Cyber Asset, it must be mitigated prior to connection to a BES Cyber System to prevent the malicious code from being introduced into the BES Cyber System. An entity may choose to not connect the Transient Cyber Asset to a BES Cyber System to prevent the malicious code from being introduced into the BES Cyber System. Entities should also consider whether the detected malicious code is a Cyber Security Incident.

Requirement R2, Attachment 1, Section 5.2 - Transient Cyber Asset(s) Managed by a Party Other than the Responsible Entity

Section 5 also recognizes the lack of direct control over Transient Cyber Assets that are managed by parties other than the Responsible Entity. This lack of control, however, does not obviate the Responsible Entity’s responsibility to ensure that methods have been deployed to mitigate the introduction of malicious code to low impact BES Cyber System(s) from Transient Cyber Assets it does not manage. Section 5 requires entities to review the other party’s security practices with respect to Transient Cyber Assets to help meet the objective of the requirement. The use of “prior to connecting the Transient Cyber Assets” is intended to ensure that the Responsible Entity conducts the review before the first connection of the Transient Cyber Asset to help meet the objective to mitigate the introduction of malicious code. The SDT does not intend for the Responsible Entity to conduct a review for every single connection of that Transient Cyber Asset once the Responsible Entity has established the Transient Cyber Asset is meeting the security objective. The intent is to not require a log documenting each connection of a Transient Cyber Asset to a BES Cyber Asset.

To facilitate these controls, Responsible Entities may execute agreements with other parties to provide support services to BES Cyber Systems and BES Cyber Assets that may involve the use of Transient Cyber Assets. Entities may consider using the Department of Energy Cybersecurity Procurement Language for Energy Delivery dated April 2014.[1] Procurement language may unify the other party and entity actions supporting the BES Cyber Systems and BES Cyber Assets. CIP program attributes may be considered including roles and responsibilities, access controls, monitoring, logging, vulnerability, and patch management along with incident response and back up recovery may be part of the other party's support. Entities may consider the "General Cybersecurity Procurement Language" and "The Supplier's Life Cycle Security Program" when drafting Master Service Agreements, Contracts, and the CIP program processes and controls.

Section 5.2.1: Entities are to document and implement their process(es) to mitigate the introduction of malicious code through the use of one or more of the protective measures listed.

- Review the use of antivirus software and signature or pattern levels to ensure that the level is adequate to the Responsible Entity to mitigate the risk of malicious software being introduced to an applicable system.
- Review the antivirus or endpoint security processes of the other party to ensure that their processes are adequate to the Responsible Entity to mitigate the risk of introducing malicious software to an applicable system.
- Review the use of application whitelisting used by the other party to mitigate the risk of introducing malicious software to an applicable system.
- Review the use of live operating systems or software executable only from read-only media to ensure that the media is free from malicious software itself. Entities should review the processes to build the read-only media as well as the media itself.
- Review system hardening practices used by the other party to ensure that unnecessary ports, services, applications, etc. have been disabled or removed. This method intends to reduce the attack surface on the Transient Cyber Asset and reduce the avenues by which malicious software could be introduced.

Section 5.2.2: The intent of this section is to ensure that after conducting the selected review from Section 5.2.1, if there are deficiencies identified, actions mitigating the risk of the introduction of malicious code to low impact BES Cyber Systems must be completed prior to connecting the device(s) to an applicable system.

Requirement R2, Attachment 1, Section 5.3 - Removable Media

Entities have a high level of control for Removable Media that are going to be connected to their BES Cyber Assets.

Section 5.3: Entities are to document and implement their process(es) to mitigate the introduction of malicious code through the use of one or more method(s) to detect malicious code on the Removable Media before it is connected to a BES Cyber Asset. When using the method(s) to detect malicious code, it is expected to occur from a system that is not part of the BES Cyber System to reduce the risk of propagating malicious code into the BES Cyber System network or onto one of the BES Cyber Assets. If malicious code is discovered, it must be removed or mitigated to prevent it from being introduced into the BES Cyber Asset or BES Cyber System. Entities should also consider whether the detected malicious code is a Cyber Security Incident. Frequency and timing of the methods used to detect malicious code were intentionally excluded from the requirement because there are multiple timing scenarios that can be incorporated into a plan to mitigate the risk of malicious code. The SDT does not intend to obligate a Responsible Entity to conduct a review for every single connection of Removable Media, but rather to implement its plan(s) in a manner that protects all BES Cyber Systems where Removable Media may be used. The intent is to not require a log documenting each connection of Removable Media to a BES Cyber Asset.

---

[1] http://www.energy.gov/oe/downloads/cybersecurity-procurement-language-energy-delivery-april-2014

As a method to detect malicious code, entities may choose to use Removable Media with on-board malicious code detection tools. For these tools, the Removable Media are still used in conjunction with a Cyber Asset to perform the detection. For Section 5.3.1, the Cyber Asset used to perform the malicious code detection must be outside of the BES Cyber System.

Requirement R3:

The intent of CIP-003-8, Requirement R3 is effectively unchanged since prior versions of the standard. The specific description of the CIP Senior Manager has now been included as a defined term rather than clarified in the Reliability Standard itself to prevent any unnecessary cross-reference to this standard. It is expected that the CIP Senior Manager will play a key role in ensuring proper strategic planning, executive/board-level awareness, and overall program governance.

Requirement R4:

As indicated in the rationale for CIP-003-8, Requirement R4, this requirement is intended to demonstrate a clear line of authority and ownership for security matters. The intent of the SDT was not to impose any particular organizational structure, but, rather, the intent is to afford the Responsible Entity significant flexibility to adapt this requirement to its existing organizational structure. A Responsible Entity may satisfy this requirement through a single delegation document or through multiple delegation documents. The Responsible Entity can make use of the delegation of the delegation authority itself to increase the flexibility in how this applies to its organization. In such a case, delegations may exist in numerous documentation records as long as the collection of these documentation records shows a clear line of authority back to the CIP Senior Manager. In addition, the CIP Senior Manager could also choose not to delegate any authority and meet this requirement without such delegation documentation.

The Responsible Entity must keep its documentation of the CIP Senior Manager and any delegations up-to-date. This is to ensure that individuals do not assume any undocumented authority. However, delegations do not have to be re-instated if the individual who delegated the task changes roles or the individual is replaced. For instance, assume that John Doe is named the CIP Senior Manager and he delegates a specific task to the Substation Maintenance Manager. If John Doe is replaced as the CIP Senior Manager, the CIP Senior Manager documentation must be updated within the specified timeframe, but the existing delegation to the Substation Maintenance Manager remains in effect as approved by the previous CIP Senior Manager, John Doe.

Rationale:

During development of this standard, text boxes were embedded within the standard to explain the rationale for various parts of the standard. Upon BOT approval, the text from the rationale text boxes was moved to this section.

Rationale for Requirement R1:

One or more security policies enable effective implementation of the requirements of the cyber security Reliability Standards. The purpose of policies is to provide a management and governance foundation for all requirements that apply to a Responsible Entity's BES Cyber Systems. The Responsible Entity can demonstrate through its policies that its management supports the accountability and responsibility necessary for effective implementation of the requirements.

Annual review and approval of the cyber security policies ensures that the policies are kept-up-to-date and periodically reaffirms management's commitment to the protection of its BES Cyber Systems.

Rationale for Requirement R2:

In response to FERC Order No. 791, Requirement R2 requires entities to develop and implement cyber security plans to meet specific security control objectives for assets containing low impact BES Cyber System(s). The cyber security plan(s) covers five subject matter areas: (1) cyber security awareness; (2) physical security controls; (3) electronic access controls; (4) Cyber Security Incident response; and (5) Transient Cyber Asset and Removable Media Malicious

Code Risk Mitigation. This plan(s), along with the cyber security policies required under Requirement R1, Part 1.2, provides a framework for operational, procedural, and technical safeguards for low impact BES Cyber Systems.

Considering the varied types of low impact BES Cyber Systems across the BES, Attachment 1 provides Responsible Entities flexibility on how to apply the security controls to meet the security objectives. Additionally, because many Responsible Entities have multiple-impact rated BES Cyber Systems, nothing in the requirement prohibits entities from using their high and medium impact BES Cyber System policies, procedures, and processes to implement security controls required for low impact BES Cyber Systems, as detailed in Requirement R2, Attachment 1.

Responsible Entities will use their identified assets containing low impact BES Cyber System(s) (developed pursuant to CIP-002) to substantiate the sites or locations associated with low impact BES Cyber System(s). However, there is no requirement or compliance expectation for Responsible Entities to maintain a list(s) of individual low impact BES Cyber System(s) and their associated cyber assets or to maintain a list of authorized users.

Rationale for Modifications to Sections 2 and 3 of Attachment 1 (Requirement R2):
Requirement R2 mandates that entities develop and implement one or more cyber security plan(s) to meet specific security objectives for assets containing low impact BES Cyber System(s). In Paragraph 73 of FERC Order No. 822, the Commission directed NERC to modify "…the Low Impact External Routable Connectivity definition to reflect the commentary in the Guidelines and Technical Basis section of CIP-003-6…to provide needed clarity to the definition and eliminate ambiguity surrounding the term 'direct' as it is used in the proposed definition…within one year of the effective date of this Final Rule."

The revisions to Section 3 incorporate select language from the LERC definition into Attachment 1 and focus the requirement on implementing electronic access controls for asset(s) containing low impact BES Cyber System(s). This change requires the Responsible Entity to permit only necessary inbound and outbound electronic access when using a routable protocol entering or leaving the asset between low impact BES Cyber System(s) and a Cyber Asset(s) outside the asset containing low impact BES Cyber system(s). When this communication is present, Responsible Entities are required to implement electronic access controls unless that communication meets the following exclusion language (previously in the definition of LERC) contained in romanette (iii): "not used for time-sensitive protection or control functions between intelligent electronic devices (e.g. communications using protocol IEC TR-61850-90-5 R-GOOSE)".

The revisions to Section 2 of Attachment 1 complement the revisions to Section 3; consequently, the requirement now mandates the Responsible Entity control physical access to "the Cyber Asset(s), as specified by the Responsible Entity, that provide electronic access control(s) implemented for Section 3.1, if any." The focus on electronic access controls rather than on the Low Impact BES Cyber System Electronic Access Points (LEAPs) eliminates the need for LEAPs.

Given these revisions to Sections 2 and 3, the NERC Glossary terms: Low Impact External Routable Connectivity (LERC) and Low Impact BES Cyber System Electronic Access Point (LEAP) will be retired.

Rationale for Section 5 of Attachment 1 (Requirement R2):
Requirement R2 mandates that entities develop and implement one or more cyber security plan(s) to meet specific security objectives for assets containing low impact BES Cyber System(s). In Paragraph 32 of FERC Order No. 822, the Commission directed NERC to "…provide mandatory protection for transient devices used at Low Impact BES Cyber Systems based on the risk posed to bulk electric system reliability." Transient devices are potential vehicles for introducing malicious code into low impact BES Cyber Systems. Section 5 of Attachment 1 is intended to mitigate the risk of malware propagation to the BES through low impact BES Cyber Systems by requiring entities to develop and implement one or more plan(s) to address the risk. The cyber security plan(s) along with the cyber security policies

required under Requirement R1, Part 1.2, provide a framework for operational, procedural, and technical safeguards for low impact BES Cyber Systems.

Rationale for Requirement R3:

The identification and documentation of the single CIP Senior Manager ensures that there is clear authority and ownership for the CIP program within an organization, as called for in Blackout Report Recommendation 43. The language that identifies CIP Senior Manager responsibilities is included in the Glossary of Terms used in NERC Reliability Standards so that it may be used across the body of CIP standards without an explicit cross-reference.

FERC Order No. 706, Paragraph 296, requests consideration of whether the single senior manager should be a corporate officer or equivalent. As implicated through the defined term, the senior manager has “the overall authority and responsibility for leading and managing implementation of the requirements within this set of standards” which ensures that the senior manager is of sufficient position in the Responsible Entity to ensure that cyber security receives the prominence that is necessary. In addition, given the range of business models for responsible entities, from municipal, cooperative, federal agencies, investor owned utilities, privately owned utilities, and everything in between, the SDT believes that requiring the CIP Senior Manager to be a “corporate officer or equivalent” would be extremely difficult to interpret and enforce on a consistent basis.

Rationale for Requirement R4:

The intent of the requirement is to ensure clear accountability within an organization for certain security matters. It also ensures that delegations are kept up-to-date and that individuals do not assume undocumented authority.

In FERC Order No. 706, Paragraphs 379 and 381, the Commission notes that Recommendation 43 of the 2003 Blackout Report calls for “clear lines of authority and ownership for security matters.” With this in mind, the Standard Drafting Team has sought to provide clarity in the requirement for delegations so that this line of authority is clear and apparent from the documented delegations.

Technical Rationale for Reliability Standard CIP-004-Y

Introduction

This document explains the technical rationale and justification for the proposed Reliability Standard CIP-004-Y. It provides stakeholders and the ERO Enterprise with an understanding of the technology and technical requirements in the Reliability Standard. This Technical Rationale and Justifications for CIP-004-Y is not a Reliability Standard and should not be considered mandatory and enforceable.

Updates to this document now include the Project 2016-02 – Modifications to CIP Standards Drafting Team's (SDT's) intent in drafting changes to the requirements.

Background

The Version 5 Transition advisory Group (V5TAG), which consists of representatives from NERC, Regional Entities, and industry stakeholders, was formed to issue guidance regarding possible methods to achieve compliance with the CIP V5 standards and to support industry's implementation activities. During the course of the V5TAG's activities, the V5TAG identified certain issues with the CIP Reliability Standards that were more appropriately addressed by a standard drafting team (SDT). The V5TAG developed the V5TAG Transfer Document to explain the issues and recommend that they be considered in future development activity. As Project 2016-02 was formed to address the directives in FERC Order 822 issued on January 21, 2016, that team also received the V5TAG issues as part of its Standard Authorization Request (SAR).

One of the issues identified by the V5TAG was virtualization. The V5TAG Transfer document states, "The CIP Version 5 standards do not specifically address virtualization. However, because of the increasing use of virtualization in industrial control system environments, questions around treatment of virtualization within the CIP Standards are due for consideration. The SDT should consider revisions to CIP-005 and the definitions of Cyber Asset and Electronic Access Point that make clear the permitted architecture and address the security risks of network, server and storage virtualization technologies."

New and Modified Terms and Applicability

This standard uses new or modified terms and contains new or modified exemptions in Section 4 Applicability. The rationale for this global content can be found in "CIP Definitions and Exemptions Technical Rationale." Document for reference when reading the technical rationale that follows.

Requirement R1-R6

General Considerations

The Project 2016-02 SDT made conforming changes to Reliability Standard CIP-004-Y to align personnel and training requirements with the virtualization changes.

The SDT added the option (known as the "all-in" scenario) for entities to group SCI within a BCS it supports; Therefore, to enable CIP-004-Y for virtualization, the SDT added "SCI identified independently supporting an Applicable System above" each of the Parts in Applicable Systems for Requirement R1 – Requirement R6 to account for the alternative option (See the CIP-002 Technical Rationale document for a description of the options for identifying SCI and reasons an entity may choose between the options.)

Additionally, where the term BES Cyber System (BCS) was used in the requirement language, it is replaced with "Applicable Systems" to align the requirement language of each Requirement Part with the updated applicability for each Requirement Part.

Requirement R3 Part 3.5

Summary of Changes:

A CIP Exceptional Circumstance was added as an exception to processes to ensure that individuals with authorized electronic or authorized unescorted physical access have had a personnel risk assessment completed prior to granting authorized electronic access and authorized unescorted physical access.

Change Rationale:

The SDT determined Responsible Entities cannot require personnel risk assessments for first responders prior to granting them authorized unescorted physical access during certain conditions that qualify as CIP Exceptional Circumstances.

Former Background Section from Reliability Standard CIP-004-6

The section **6. Background** has been retired and removed from the Standard, and preserved by cutting and pasting as-is below.

Background

Standard CIP-004 exists as part of a suite of CIP Standards related to cyber security, which require the initial identification and categorization of BES Cyber Systems and require a minimum level of organizational, operational, and procedural controls to mitigate risk to BES Cyber Systems.

Most requirements open with, "Each Responsible Entity shall implement one or more documented [processes, plan, etc.] that include the applicable items in [Table Reference]." The referenced table requires the applicable items in the procedures for the common subject matter of the requirements.

The term documented processes refers to a set of required instructions specific to the Responsible Entity and to achieve a specific outcome. This term does not imply any particular naming or approval structure beyond what is stated in the requirements. An entity should include as much as it believes necessary in its documented processes, but it must address the applicable requirements in the table.

The terms program and plan are sometimes used in place of documented processes where it makes sense and is commonly understood. For example, documented processes describing a response are typically referred to as plans (i.e., incident response plans and recovery plans). Likewise, a security plan can describe an approach involving multiple procedures to address a broad subject matter.

Similarly, the term program may refer to the organization's overall implementation of its policies, plans and procedures involving a subject matter. Examples in the standards include the personnel risk assessment program and the personnel training program. The full implementation of the CIP Cyber Security Standards could also be referred to as a program.

However, the terms program and plan do not imply any additional requirements beyond what is stated in the standards.

Responsible Entities can implement common controls that meet requirements for multiple high and medium impact BES Cyber Systems. For example, a single training program could meet the requirements for training personnel across multiple BES Cyber Systems.

Measures for the initial requirement are simply the documented processes themselves. Measures in the table rows provide examples of evidence to show documentation and implementation of applicable items in the documented processes. These measures serve to provide guidance to entities in acceptable records of compliance and should not be viewed as an all-inclusive list.

Throughout the standards, unless otherwise stated, bulleted items in the requirements and measures are items that are linked with an "or," and numbered items are items that are linked with an "and."

Many references in the Applicability section use a threshold of 300 MW for UFLS and UVLS. This particular threshold of 300 MW for UVLS and UFLS was provided in Version 1 of the CIP Cyber Security Standards. The threshold remains at 300 MW since it is specifically addressing UVLS and UFLS, which are last ditch efforts to save the BES. A review of UFLS tolerances defined within regional reliability standards for UFLS program requirements to date indicates that the historical value of 300 MW represents an adequate and reasonable threshold value for allowable UFLS operational tolerances.

“Applicable Systems” Columns in Tables:

Each table has an “Applicable Systems” column to further define the scope of systems to which a specific requirement row applies. The CSO706 SDT adapted this concept from the National Institute of Standards and Technology (“NIST”) Risk Management Framework as a way of applying requirements more appropriately based on impact and connectivity characteristics.

The following conventions are used in the “Applicable Systems” column as described. High Impact BES Cyber Systems – Applies to BES Cyber Systems categorized as high impact according to the CIP-002-5.1 identification and categorization processes.

- **Medium Impact BES Cyber Systems** – Applies to BES Cyber Systems categorized as medium impact according to the CIP-002-5.1 identification and categorization processes.
- **Medium Impact BES Cyber Systems with External Routable Connectivity** – Only applies to medium impact BES Cyber Systems with External Routable Connectivity. This also excludes Cyber Assets in the BES Cyber System that cannot be directly accessed through External Routable Connectivity.
- **Electronic Access Control or Monitoring Systems (EACMS)** – Applies to each Electronic Access Control or Monitoring System associated with a referenced high impact BES Cyber System or medium impact BES Cyber System. Examples may include, but are not limited to, firewalls, authentication servers, and log monitoring and alerting systems.
- **Physical Access Control Systems (PACS)** – Applies to each Physical Access Control System associated with a referenced high impact BES Cyber System or medium impact BES Cyber System with External Routable Connectivity.

Technical Rationale for Reliability Standard CIP-004-6

This section contains a “cut and paste” of the former Guidelines and Technical Basis (GTB) as-is of from CIP-004-6 standard to preserve any historical references. No modifications have been made.

Guidelines and Technical Basis

Section 4 – Scope of Applicability of the CIP Cyber Security Standards

Section “4. Applicability” of the standards provides important information for Responsible Entities to determine the scope of the applicability of the CIP Cyber Security Requirements.

Section “4.1. Functional Entities” is a list of NERC functional entities to which the standard applies. If the entity is registered as one or more of the functional entities listed in Section 4.1, then the NERC CIP Cyber Security Standards apply. Note that there is a qualification in Section 4.1 that restricts the applicability in the case of Distribution Providers to only those that own certain types of systems and equipment listed in 4.2.

Section “4.2. Facilities” defines the scope of the Facilities, systems, and equipment owned by the Responsible Entity, as qualified in Section 4.1, that is subject to the requirements of the standard. As specified in the exemption section 4.2.3.5, this standard does not apply to Responsible Entities that do not have High Impact or Medium Impact BES Cyber Systems under CIP-002-5.1’s categorization. In addition to the set of BES Facilities, Control Centers, and other systems and equipment, the list includes the set of systems and equipment owned by Distribution Providers. While the NERC Glossary term “Facilities” already includes the BES characteristic, the additional use of the term BES here is meant to reinforce the scope of applicability of these Facilities where it is used, especially in this applicability scoping section. This in effect sets the scope of Facilities, systems, and equipment that is subject to the standards.

Requirement R1:

The security awareness program is intended to be an informational program, not a formal training program. It should reinforce security practices to ensure that personnel maintain awareness of best practices for both physical and electronic security to protect its BES Cyber Systems. The Responsible Entity is not required to provide records that show that each individual received or understood the information, but they must maintain documentation of the program materials utilized in the form of posters, memos, and/or presentations.

Examples of possible mechanisms and evidence, when dated, which can be used are:

- Direct communications (e.g., emails, memos, computer based training, etc.);
- Indirect communications (e.g., posters, intranet, brochures, etc.);
- Management support and reinforcement (e.g., presentations, meetings, etc.).

Requirement R2:

Training shall cover the policies, access controls, and procedures as developed for the BES Cyber Systems and include, at a minimum, the required items appropriate to personnel roles and responsibilities from Table R2. The Responsible Entity has the flexibility to define the training program and it may consist of multiple modules and multiple delivery mechanisms, but a single training program for all individuals needing to be trained is acceptable. The training can focus on functions, roles or responsibilities at the discretion of the Responsible Entity.

One new element in the training content is intended to encompass networking hardware and software and other issues of electronic interconnectivity supporting the operation and control of BES Cyber Systems as per FERC Order No. 706, Paragraph 434. Additionally, training should address the risk posed when connecting and using Transient Cyber Assets and Removable Media with BES Cyber Systems or within an Electronic Security Perimeter. As noted in FERC Order No. 791, Paragraph 135, Transient Cyber Assets and Removable Media have been the source of incidents where malware was introduced into electric generation industrial control systems in real-world situations. Training on their use is a key element in protecting BES Cyber Systems. This is not intended to provide technical training to individuals supporting networking hardware and software, but educating system users of the cyber security risks associated with the interconnectedness of these systems. The users, based on their function, role, or responsibility, should have a basic understanding of which systems can be accessed from other systems and how the actions they take can affect cyber security.

Each Responsible Entity shall ensure all personnel who are granted authorized electronic access and/or authorized unescorted physical access to its BES Cyber Systems, including contractors and service vendors, complete cyber security training prior to their being granted authorized access, except for CIP Exceptional Circumstances. To retain the authorized accesses, individuals must complete the training at least one every 15 months.

Requirement R3:

Each Responsible Entity shall ensure a personnel risk assessment is performed for all personnel who are granted authorized electronic access and/or authorized unescorted physical access to its BES Cyber Systems, including contractors and service vendors, prior to their being granted authorized access, except for program specified exceptional circumstances that are approved by the single senior management official or their delegate and impact the reliability of the BES or emergency response. Identity should be confirmed in accordance with federal, state, provincial, and local laws, and subject to existing collective bargaining unit agreements. Identity only needs to be confirmed prior to initially granting access and only requires periodic confirmation according to the entity’s process during the tenure of employment, which may or may not be the same as the initial verification action.

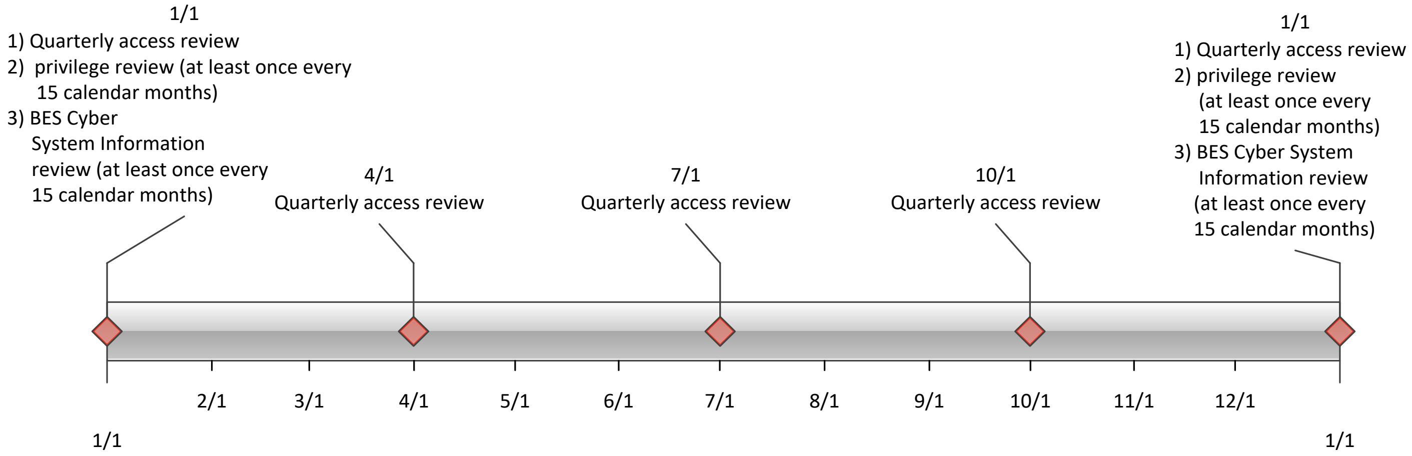
A seven year criminal history check should be performed for those locations where the individual has resided for at least six consecutive months. This check should also be performed in accordance with federal, state, provincial, and local laws, and subject to existing collective bargaining unit agreements. When it is not possible to perform a full seven year criminal history check, documentation must be made of what criminal history check was performed, and the reasons a full seven-year check could not be performed. Examples of this could include individuals under the age of 25 where a juvenile criminal history may be protected by law, individuals who may have resided in locations from where it is not possible to obtain a criminal history records check, violates the law or is not allowed under the existing collective bargaining agreement. The Responsible Entity should consider the absence of information for the full seven years when assessing the risk of granting access during the process to evaluate the criminal history check. There needs to be a personnel risk assessment that has been completed within the last seven years for each individual with access. A new criminal history records check must be performed as part of the new PRA. Individuals who have been granted access under a previous version of these standards need a new PRA within seven years of the date of their last PRA. The clarifications around the seven year criminal history check in this version do not require a new PRA be performed by the implementation date.

Requirement R4:

Authorization for electronic and unescorted physical access and access to BES Cyber System Information must be on the basis of necessity in the individual performing a work function. Documentation showing the authorization should have some justification of the business need included. To ensure proper segregation of duties, access authorization and provisioning should not be performed by the same person where possible.

This requirement specifies both quarterly reviews and reviews at least once every 15 calendar months. Quarterly reviews are to perform a validation that only authorized users have been granted access to BES Cyber Systems. This is achieved by comparing individuals actually provisioned to a BES Cyber System against records of individuals authorized to the BES Cyber System. The focus of this requirement is on the integrity of provisioning access rather than individual accounts on all BES Cyber Assets. The list of provisioned individuals can be an automatically generated account listing. However, in a BES Cyber System with several account databases, the list of provisioned individuals may come from other records such as provisioning workflow or a user account database where provisioning typically initiates.

The privilege review at least once every 15 calendar months is more detailed to ensure an individual's associated privileges are the minimum necessary to perform their work function (i.e., least privilege). Entities can more efficiently perform this review by implementing role-based access. This involves determining the specific roles on the system (e.g., system operator, technician, report viewer, administrator, etc.) then grouping access privileges to the role and assigning users to the role. Role-based access does not assume any specific software and can be implemented by defining specific provisioning processes for each role where access group assignments cannot be performed. Role-based access permissions eliminate the need to perform the privilege review on individual accounts. An example timeline of all the reviews in Requirement R4 is included below.



Separation of duties should be considered when performing the reviews in Requirement R4. The person reviewing should be different than the person provisioning access.

If the results of quarterly or at least once every 15 calendar months account reviews indicate an administrative or clerical error in which access was not actually provisioned, then the SDT intends that this error should not be considered a violation of this requirement.

For BES Cyber Systems that do not have user accounts defined, the controls listed in Requirement R4 are not applicable. However, the Responsible Entity should document such configurations.

Requirement R5:

The requirement to revoke access at the time of the termination action includes procedures showing revocation of access concurrent with the termination action. This requirement recognizes that the timing of the termination action may vary depending on the circumstance. Some common scenarios and possible processes on when the termination action occurs are provided in the following table. These scenarios are not an exhaustive list of all scenarios, but are representative of several routine business practices.

Scenario	Possible Process
Immediate involuntary termination	Human resources or corporate security escorts the individual off site and the supervisor or human resources personnel notify the appropriate personnel to begin the revocation process.
Scheduled involuntary termination	Human resources personnel are notified of the termination and work with appropriate personnel to schedule the revocation of access at the time of termination.
Voluntary termination	Human resources personnel are notified of the termination and work with appropriate personnel to schedule the revocation of access at the time of termination.
Retirement where the last working day is several weeks prior to the termination date	Human resources personnel coordinate with manager to determine the final date access is no longer needed and schedule the revocation of access on the determined day.
Death	Human resources personnel are notified of the death and work with appropriate personnel to begin the revocation process.

Revocation of electronic access should be understood to mean a process with the end result that electronic access to BES Cyber Systems is no longer possible using credentials assigned to or known by the individual(s) whose access privileges are being revoked. Steps taken to accomplish this outcome may include deletion or deactivation of accounts used by the individual(s), but no specific actions are prescribed. Entities should consider the ramifications of deleting an account may include incomplete event log entries due to an unrecognized account or system services using the account to log on.

The initial revocation required in Requirement R5.1 includes unescorted physical access and Interactive Remote Access. These two actions should prevent any further access by the individual after termination. If an individual still has local access accounts (i.e., accounts on the Cyber Asset itself) on BES Cyber Assets, then the Responsible Entity has 30 days to complete the revocation process for those accounts. However, nothing prevents a Responsible Entity from performing all of the access revocation at the time of termination.

For transferred or reassigned individuals, a review of access privileges should be performed. This review could entail a simple listing of all authorizations for an individual and working with the respective managers to determine which access will still be needed in the new position. For instances in which the individual still needs to retain access as part of a transitory period, the entity should schedule a time to review these access privileges or include the privileges in the quarterly account review or annual privilege review.

Revocation of access to shared accounts is called out separately to prevent the situation where passwords on substation and generation devices are constantly changed due to staff turnover.

Requirement 5.5 specified that passwords for shared account are to the changed within 30 calendar days of the termination action or when the Responsible Entity determines an individual no longer requires access to the account as a result of a reassignment or transfer. The 30 days applies under normal operating conditions. However, circumstances may occur where this is not possible. Some systems may require an outage or reboot of the system in order to complete the password change. In periods of extreme heat or cold, many Responsible Entities may prohibit system outages and reboots in order to maintain reliability of the BES. When these circumstances occur, the Responsible Entity must document these circumstances and prepare to change the password within 10 calendar days following the end of the operating circumstances. Records of activities must be retained to show that the Responsible Entity followed the plan they created.

Rationale:

During development of this standard, text boxes were embedded within the standard to explain the rationale for various parts of the standard. Upon BOT approval, the text from the rationale text boxes was moved to this section.

Rationale for Requirement R1:

Ensures that Responsible Entities with personnel who have authorized electronic or authorized unescorted physical access to BES Cyber Assets take action so that those personnel with such authorized electronic or authorized unescorted physical access maintain awareness of the Responsible Entity's security practices.

Rationale for Requirement R2:

To ensure that the Responsible Entity's training program for personnel who need authorized electronic access and/or authorized unescorted physical access to BES Cyber Systems covers the proper policies, access controls, and procedures to protect BES Cyber Systems and are trained before access is authorized.

Rationale for Requirement R3:

To ensure that individuals who need authorized electronic or authorized unescorted physical access to BES Cyber Systems have been assessed for risk. Whether initial access or maintaining access, those with access must have had a personnel risk assessment completed within the last 7 years.

Rationale for Requirement R4:

To ensure that individuals with access to BES Cyber Systems and the physical and electronic locations where BES Cyber System Information is stored by the Responsible Entity have been properly authorized for such access. “Authorization” should be considered to be a grant of permission by a person or persons empowered by the Responsible Entity to perform such grants and included in the delegations referenced in CIP-003-6. “Provisioning” should be considered the actions to provide access to an individual.

Access is physical, logical, and remote permissions granted to Cyber Assets composing the BES Cyber System or allowing access to the BES Cyber System. When granting, reviewing, or revoking access, the Responsible Entity must address the Cyber Asset specifically as well as the systems used to enable such access (i.e., physical access control system, remote access system, directory services).

CIP Exceptional Circumstances are defined in a Responsible Entity’s policy from CIP-003-6 and allow an exception to the requirement for authorization to BES Cyber Systems and BES Cyber System Information.

Quarterly reviews in Part 4.5 are to perform a validation that only authorized users have been granted access to BES Cyber Systems. This is achieved by comparing individuals actually provisioned to a BES Cyber System against records of individuals authorized to access the BES Cyber System. The focus of this requirement is on the integrity of provisioning access rather than individual accounts on all BES Cyber Assets. The list of provisioned individuals can be an automatically generated account listing. However, in a BES Cyber System with several account databases, the list of provisioned individuals may come from other records such as provisioning workflow or a user account database where provisioning typically initiates.

If the results of quarterly or annual account reviews indicate an administrative or clerical error in which access was not actually provisioned, then the SDT intends that the error should not be considered a violation of this requirement.

For BES Cyber Systems that do not have user accounts defined, the controls listed in Requirement R4 are not applicable. However, the Responsible Entity should document such configurations.

Rationale for Requirement R5:

The timely revocation of electronic access to BES Cyber Systems is an essential element of an access management regime. When an individual no longer requires access to a BES Cyber System to perform his or her assigned functions, that access should be revoked. This is of particular importance in situations where a change of assignment or employment is involuntary, as there is a risk the individual(s) involved will react in a hostile or destructive manner.

In considering how to address directives in FERC Order No. 706 directing “immediate” revocation of access for involuntary separation, the SDT chose not to specify hourly time parameters in the requirement (e.g., revoking access within 1 hour). The point in time at which an organization terminates a person cannot generally be determined down to the hour. However, most organizations have formal termination processes, and the timeliest revocation of access occurs in concurrence with the initial processes of termination.

Access is physical, logical, and remote permissions granted to Cyber Assets composing the BES Cyber System or allowing access to the BES Cyber System. When granting, reviewing, or revoking access, the

Responsible Entity must address the Cyber Asset specifically as well as the systems used to enable such access (e.g., physical access control system, remote access system, directory services).

Technical Rationale for Reliability Standard CIP-005-8

Introduction

This document is the technical rationale and justification for Reliability Standard CIP-005. It includes the rationale for changes in the current proposed version (CIP-005-8) as well as previous versions of the standard. The intent of this document is to provide stakeholders and the ERO Enterprise with an understanding of the revisions and the technical concepts of the Reliability Standard as well as the rationale for such revisions, both the currently proposed and historical revisions from previous versions and SDTs.

This document explains the technical rationale and justification for the proposed Reliability Standard CIP-005-8. It provides stakeholders and the ERO Enterprise with an understanding of the technology and technical requirements in the Reliability Standard. This Technical Rationale and Justifications for CIP-005-8 is not a Reliability Standard and should not be considered mandatory and enforceable.

Updates to this document now include the Project 2016-02 – Modifications to CIP Standards Drafting Team’s (SDT’s) intent in drafting changes to the requirements.

Background

The Version 5 Transition Advisory Group (V5TAG), which consisted of representatives from NERC, Regional Entities, and industry stakeholders, was formed to issue guidance regarding possible methods to achieve compliance with the CIP V5 standards and to support industry’s implementation activities. During the course of the V5TAG’s activities, the V5TAG identified certain issues with the CIP Reliability Standards that were more appropriately addressed by a standard drafting team (SDT). The V5TAG developed the V5TAG Transfer Document to explain the issues and recommend that they be considered in future development activity. As Project 2016-02 was formed to address the directives in FERC Order 822 issued on January 21, 2016, that team also received the V5TAG issues as part of its Standard Authorization Request (SAR).

One of the areas of issue was virtualization. The V5TAG Transfer document said, “The CIP Version 5 standards do not specifically address virtualization. However, because of the increasing use of virtualization in industrial control system environments, questions around treatment of virtualization within the CIP Standards are due for consideration. The SDT should consider revisions to CIP-005-8 and the definitions of Cyber Asset and Electronic Access Point (EAP) that make clear the permitted architecture and address the security risks of network, server and storage virtualization technologies.”

Summary

The Project 2016-02 Standard Drafting Team (SDT) proposal accommodates for increasing use of virtualization and other technology innovation. The SDT’s purpose of incorporating the virtualization concept into the CIP standards is not to merely augment the current standards, but also to better position the CIP standards to be applicable to additional future technological innovation while, to the extent possible, maintaining backwards compatibility.

CIP-005-8 remains a standard concerned with controlling communications to and from BES Cyber Systems by establishing an Electronic Security Perimeter (ESP) with increased security controls for Interactive Remote Access and vendor remote access. However, virtualization is enabling models for network security, such as “Zero Trust”, that are not network perimeter based. Therefore, in CIP-005-8 the ESP is focusing on being a security perimeter rather than a network perimeter. Securing the communications to and from BES Cyber Systems is the security objective, but the standard no longer prescribes “where”, as in where on a network, the controls must be implemented. Innovations such as Zero Trust models are moving access control from network borders to a session level orientation and eliminating the implicit trust within a local network. Network perimeter-based ESP and EAP implementations remain a valid option and are one method for allowing only necessary and controlled communications to the Cyber Systems within the ESP but are no longer the only prescribed option. In combination with an updated, broader ESP definition, CIP-005-8 now focuses on the objective of having policies or configuration in an EACMS that permits only needed communications and denies all other communications.

Another concept introduced within CIP-005-8 is shared infrastructure (defined as Shared Cyber Infrastructure (SCI)). With the introduction of hardware (servers, storage, networks) as a generic infrastructure fabric on top of which virtual cyber systems, networks, and storage locations are built, the need to isolate Cyber Systems from others of different trust levels must move beyond a network only separation. In these virtualized environments where SCI is used, a risk of side channel attacks exists where, for example, a low impact BCS that is isolated from a high impact BCS from a network communication perspective but still shares CPU or memory with the high impact BCS, could be used to attack the high impact BCS through hardware-level vulnerabilities (e.g., Spectre, Meltdown, Rowhammer). CIP-005-8 mitigates this risk by either:

- Using affinity controls within the virtualization environment to configure the hypervisor(s) to disallow Virtual Cyber Assets (VCA) in these differing trust levels from simultaneously executing on the same CPU and memory in the hardware underlay (SCI), or
- Treating all VCA that can simultaneously share the same CPU or memory as associated Protected Cyber Assets (PCA) of the highest impact system (high watermarking) to raise them to the same trust level.

Additionally, the SDT is proposing a new requirement (CIP-005-8 Requirement R1 Part 1.3) to separate the management plane of the Shared Cyber Infrastructure (SCI) from the data plane. This is needed to ensure the reliability and security of the SCI and the VCA's it hosts as the management plane is where network and hardware isolation is configured as well as where the VCAs themselves are created, managed, or deleted.

CIP-005-8 also introduces exemptions and requirements for extending ESPs across different Physical Security Perimeters (PSP) (often known as "Super ESPs"). This is often used to extend a flat network between two virtualization infrastructures (SCI) in two different locations to allow VCAs to seamlessly transfer between SCI at the locations to improve resilience and reliability.

New and Modified Terms and Applicability

This standard uses new or modified terms and contains new or modified exemptions in Section 4 Applicability. The rationale for this global content can be found in "CIP Definitions and Exemptions Technical Rationale" document for reference when reading the technical rationale that follows.

Requirement R1 General Considerations

ESP Redefinition

Network border-based ESPs and EAPs remain a valid option for controlling the communications to and from BES Cyber Systems. However, virtualization technologies and models such as Zero Trust present equally effective methods that are not based on network border-based solutions dealing only with layer 3 routable protocols. Virtualization and its accompanying SCI have other characteristics such as shared hypervisors, shared storage, shared virtual networks and switches, all of which pose different security concerns but also have their own security controls. To adapt to these changes, CIP-005-8 focuses on an objective-based requirement (in Requirement R1 Part 1.1) for controlling communications. Required ESPs are now more truly security perimeters rather than purely network perimeters and the standard doesn't prescribe a single place the necessary controls must be implemented (a Cyber Asset interface on an EAP on a network border). Models such as Zero Trust can implement more granular controls throughout a network and without regard to network location on a per-access or per-session level.

Shared infrastructure and "Mixed Trust" Risks

For virtualized environments where SCI is used, a risk of side channel attacks exists. Virtualization allows disparate workloads of what could be differing impact or trust levels to execute on the same CPUs and share the same memory (i.e. RAM) within the infrastructure. There are vulnerabilities that are directly related to sharing hardware such as Spectre, Meltdown, and Rowhammer. Rowhammer, for example concerns processes sharing certain forms of hardware memory. Repeated writing of bits in one process could flip bits in a process in adjacent physical memory. This type of vulnerability is one of the unique risks of SCI.

As this class of vulnerability is specifically about processes executing side by side on the same CPU or memory chips of SCI, the risk of these vulnerabilities is being mitigated in CIP-005-8 by either:

- Declaring the VCAs that share CPU or memory or are within the same ESP with a BCS as associated PCAs which will require they meet the security requirements (high water marking) that include 'associated PCAs'; or
- Configuring the virtualization infrastructure to place VCAs of differing impact or trust levels into differing ESPs and configuring affinity controls to these zones such that hypervisors do not allow workloads in these differing zones to simultaneously exist or execute on the same hypervisor.

Assets with Multiple Classifications (PCA, EACMS, Intermediate System, SCI, etc.)

The definitions created in support of the CIP Standards have historically included overlap. In this current version of CIP-005-8, the definition of PCA is updated with conforming changes that include VCAs that share CPU or memory with a BCS. Additional definitions such as SCI and VCA will add to the possibility of additional instances of assets or systems meeting multiple definitions, such as SCI that are also EACMS.

These definitions are used in both the Applicable Systems column as well as within the requirement language. The fact that one asset or system may have multiple classifications does not pose a significant challenge as long as the Responsible Entity ensures that all requirements that pertain to ANY of the classifications are applied. In other words, if an asset or system meets both the SCI and the EACMS definition, requirements that apply to either definition are applicable.

Requirement R1

Rationale

Requirement R1 requires implementation of an ESP between systems of different impact levels such that only necessary communication is allowed between them. However, there are other network security models available now (such as zero trust) that can accomplish this security objective that are not network perimeter-based and control these communications end-to-end at a session level. However, the network border-based ESP model continues unchanged as CIP-005-8 Requirement R1 moves to an objective-based requirement that the network border-based model continues to meet while allowing for other models.

Requirement R1 Part 1.1:

Rationale

This requirement part is a combination of the first three requirement parts (1.1-1.3) in the former CIP-005-7 into one security objective. Virtualization technologies introduce multiple additional methods to isolate systems and communications beyond the network perimeter-based model. This requirement part is now objective-based and does not prescribe one method of controlling communications to Applicable Systems.

By moving to an objective-based requirement, network border-based models still meet the objective but it allows for other models such as zero trust architectures. Such models are not based on network perimeter-based security that controls communications at a network boundary. Communications are authorized by policy enforcement points throughout the infrastructure. In this model, network security is less topology-based and more policy-based and is used to protect communication at a very granular level (an individual system or even process or resource level).

While zero-trust architectures are an emerging model, the objective-based requirement also allows for hybrid models that are various combinations of network border-based and zero trust architectures. As technology changes, this requirement is flexible as to how the objective is met. The ESP definition has been broadened as well to accommodate models that create a security perimeter, but not necessarily by implementing a network border-based perimeter.

The requirement part maintains the core security objective of permitting only needed communications and denying all others; it simply no longer prescribes that this must be implemented at a Cyber Asset interface on the network border (an EAP). However, by not prescribing the location it could allow for a firewall built into the host BCS itself as the location where this access control is implemented. Examples are a server running a Windows OS with the in-built Windows firewall, or a Linux server with an IPTABLES firewall, that are providing the only control of the communications to and from a system connected to a public network. In these instances, the management plane of the host is also the management plane of the network security control. The SDT's intent is a host-based firewall (see RFC 7288[1] for a discussion of host-based firewalls) does not have a sufficient level of isolation from the system it is protecting to meet this requirement. A compromise of the OS is a compromise of the network communications security control as well. Therefore, the SDT has addressed this with the statement in the requirement "*Host-based firewalls (that only protect the host on which they reside) are not a sufficient control to meet this requirement*." This does not prescribe a physically separate control. A virtual firewall running as a separate VCA on the same SCI would be sufficient, as would technology such as privileged introspection within the hypervisor; these controls are isolated from the host being protected. The intent of this Requirement Part is to control the 'reachability' of the Applicable Systems; filtering network communications *before* they reach the Applicable Systems and their OS, not as part of it. This is not to discourage the use of integrated host-based firewalls to further filter network traffic to a host, it just cannot be the ESP for the purposes of this requirement. For example, host based firewalls can be used for further system hardening as part of CIP-007 R1, but not as the ESP for CIP-005 R1.

---

[1] https://datatracker.ietf.org/doc/html/rfc7288

The Requirement Part brings to medium and high impact BCS the exclusion of communications between intelligent electronic devices (i.e., digital relays) that use routable communication protocols for time-sensitive protection or control functions. Time-sensitive in this context generally means functions that would be negatively impacted by the latency introduced in the communications by inserting an ESP and its controls. This time-sensitivity exclusion does not apply to SCADA communications which typically operate on scan rates of 2 seconds or greater. While technically time-sensitive, SCADA communications over routable protocols can withstand the delay introduced by electronic access controls. Examples of excluded time-sensitive communications are those communications which may necessitate the tripping of a breaker within a few cycles (sub-second response times) to protect BES assets. The SDT intent is a Responsible Entity using this technology is not expected to implement the electronic access controls in a situation where it would prohibit the proper function in the proper timeframe.

Requirement R1 Part 1.2:

Rationale

The SDT is proposing a new Requirement, CIP-005-8 Requirement R1, Part 1.2. The purpose of this requirement is to permit only needed communications to and from the Management Interfaces, denying all other communications, of the systems that are providing the protection of BES Cyber Systems in part 1.1; namely SCI that is independently identified (not a part of an “all-in” scenario and thus is isolating systems of different impact levels from each other) and EACMS that are enforcing an ESP. As these are vital controls to performing the isolation/segmentation between systems of differing impact levels, the access to the Management Interface whereby these controls could be compromised is to be protected.

Requirement R1 Part 1.3:

Rationale

As the same technologies used in on-premise virtualization are used by cloud vendors hosting systems from many different customers, the methods used to separate the management plane from the data plane developed quickly as systems moving to the cloud increased. For a cloud-based hosting facility to be successful, the tenants must share hardware resources (SCI as defined here) but have no ability to access or modify other tenants or their configuration. Cloud technology was forced to enhance existing methods and develop new methods to accomplish this separation. SCI presents the same issue for in-house (on-premise) virtualization environments to prevent users of various systems hosted on the SCI from affecting each other or the SCI’s configuration. CIP-005-8 Requirement R1 Part 1.3 addresses this risk within the CIP standards.

The SDT is proposing this new Requirement R1, Part 1.3 that applies to SCI that is independently identified (not a part of an “all-in” scenario and thus is isolating systems of different impact levels from each other). As virtualized servers, networks, switches, firewalls, and storage are logical constructs, controlling communications to the Management Interfaces of these systems becomes imperative. Communication with the Management Interfaces can allow users to create, modify, or delete objects or entire infrastructures, or move objects from one network to another. Therefore, administrative level or “management access” to the SCI is critical to the security and reliability of the hosted systems. By isolating the Management Interfaces of these devices from the larger audience of users that can communicate with the hosted tenant systems, the attack surface of the SCI is reduced to the group of users with administrative access. The intent is users of a BCS hosted on an SCI that is identified independently and hosting other VCAs of differing impact levels should be prevented from having any access to the Management Interface of the underlying SCI. For example, a user accessing a low impact BCS on SCI should have no ability to pivot from that system to the Management Interface and thus impact a higher impact BCS.

This new Requirement part therefore requires the denial of network communications to the Management Interfaces of SCI that is independently identified (not a part of an “all-in” scenario and thus is isolating systems of different impact levels from each other) from the hosted BCS VCA's on the SCI. It does not preclude a separate VCA that hosts the SCI Management Interface from being used to manage the SCI as that is not an applicable system from part 1.1, however it must still meet requirement part 1.2 as well as part 1.3. A separate VCA hosting only a Management Interface can be allowed necessary access from part 1.2 for administrative users, but all access from any hosted BCS must be denied per part 1.3.

Requirement R1 Part 1.4:

Rationale

Requirement R1 Part 1.4 was written to address the issue of "Super ESPs" with high or medium impact BCS at Control Centers that extend a single ESP beyond one PSP. This often applies to virtualized Control Center environments that implement network adjacency to allow workloads to automatically move from one physical location to another to increase BCS resiliency between primary and backup Control Centers.

In summary, Requirement 1 Part 1.4 within CIP-005-8 requires that data traversing communication links between the two PSPs be protected to preserve its integrity and confidentiality. This new requirement part works in conjunction with the new 4.2.3.3 exemption in the CIP standards that exempts the Cyber Systems associated with such communication links since the data is required to be protected per this requirement. Also, the requirement part that formerly was CIP-006-6, Requirement 1, Part 1.10 has been removed from CIP-006 and incorporated into this new 1.4 requirement part. This consolidates the protections of an ESP and its components that extend outside of a PSP into one requirement part within one standard.

Communications equipment associated with communications links (e.g., equipment belonging to carriers) is exempted from the CIP standards with the 4.2.3.2 exemption, however that only applies to equipment between discrete ESPs. However, in this extended ESP situation where a single ESP spans different sites or PSPs, that exemption does not apply and the potential exists for data to traverse a connection that uses third-party communications equipment that is unprotected inside an ESP. The SDT chose to create Requirement R1 Part 1.4 to enforce confidentiality and integrity controls (such as encryption) on the data that traverses PSPs that is within the same ESP that works in conjunction with the new 4.2.3.3 exemption. In this case where communication equipment is used to extend a single ESP to more than one PSP, the confidentiality and integrity controls required in CIP-005-8 Requirement R1 Part 1.4 isolate any protected data from access through the communications equipment.

This Requirement Part applies to the data that traverses between PSPs. The SDT also combined CIP-006-6 Requirement R1 Part 1.10) into this Requirement Part to incorporate cabling and non-programmable communication components that are not protected within a PSP with the intent to protect data moving across the state as well as data traversing cabling that crosses the hall outside of the PSP. This consolidates these two requirements on protecting an ESP that spans differing PSPs into one requirement. The requirement language specifically exempts the data that falls under CIP-012 Requirements in order to avoid the potential for double jeopardy as well as the time-sensitive protection or control functions as described in CIP-005-8 Requirement R1 Part 1.1 above.

Requirement R1 Part 1.5:

Rationale

The SDT included "SCI identified independently supporting an Applicable System above" to the scope of the requirement part to ensure that controls regarding Dial-up Connectivity are applicable to SCI as well.

Requirement R1 Part 1.6:

Rationale

The SDT made changes to specify that the known or suspected malicious communication detection is for Internet Protocol (IP) based traffic that enters or leaves the required ESP. Products available to implement this malicious communication detection are usually based on IP traffic (as defined in RFC 791 and upon which TCP and UDP reside).

Requirement R2:

General Considerations for Requirement R2.

External Routable Connectivity (ERC) and Interactive Remote Access (IRA)

The ERC and IRA definitions are changing substantively in order to:

1. Incorporate new models such as Zero Trust where a security perimeter is not necessarily a network perimeter and ESP's become very granular based on policies that can be established at "people to resource" levels rather than IP address levels.
2. Recognize those CIP Systems that are of an increased risk due to their "reachability" via ERC and that have IRA available to them even if they are serial-only, non-routable devices.
3. Continue to limit scope of requirement parts to those locations that have a high enough level of remote connectivity to support the requirement. Locations that have connectivity such as non-routable serial leased circuits should not have to increase their level of remote connectivity and attack surface to meet security requirements.

One issue from the V5TAG transfer document in the SDT's scope is that of a BCA that only speaks non-routable protocols over a serial port. These BCAs are not connected to a network with a routable protocol themselves and therefore can be considered to not be within an ESP and thus not have ERC or IRA. However, these BCAs can have interactive user access using those serial connections. The SDT's intent is to clarify that IRA can occur to a device with only a serial, non-routable connection through subsequent IP-to-serial conversions and be subject to CIP-005-8 Requirement R2. For example, the intent is to clearly cover situations where a serial-only, non-routable BCA, such as a digital relay in a substation, has its serial communication from a 'console port' converted to IP or other routable protocols thus allowing IRA from users outside the substation to use a routable protocol to interact with the serial device and to require the CIP-005-8 Requirement R2 protection for that IRA.

In modifying the Intermediate Systems definitions, the SDT removed related requirement-style language ("The Intermediate System must not be located inside the Electronic Security Perimeter"). The SDT clarified the objective in CIP-005-8 Requirement R2 that all IRA must be *through* an Intermediate System and added Requirement Part 2.6.2 that addresses the location of the Intermediate System through an objective-based requirement.

See the "CIP Definitions and Exemptions Technical Rationale" document for further explanation of the changes to the R2 related definitions.

The scoping of R2 has been clarified to "all IRA and vendor remote access" and the applicability of several Requirement Parts was updated for virtualized environments to include SCI identified independently.

Requirement R2 Part 2.1:

Rationale

The Applicable Systems section of this requirement was updated to include SCI identified independently (SCI identified in the "all-in" scenario from CIP-002 is already included as part of the BCS). This was done to ensure that the same safeguards for remote access methods and technologies exist for the applicable SCI as for the high and medium impact BCS and associated PCA being hosted on that SCI. Backwards compatibility with CIP-005-7 is maintained for entities that do not currently use SCI.

The inclusion of the SCI is intended to target the Management Interfaces (included in SCI definition) of the associated SCI. This is to ensure that the management of the SCI being used to support BCS is also protected in an equivalent manner.

The SDT has added to the scope of this Requirement Part 2.1 any EACMS that enforces the ESP for Applicable Systems in Part 1.1. The intent is to require IRA protections (Intermediate System, multi-factor authentication, etc.) for those users who are managing an EACMS that enforces an ESP, such as firewalls, policy enforcement points, or network switches with ACLs or VLANs that enforce an ESP. The intent is that such remote access from users that is 'to' (not 'through') the EACMS to configure the ESP requires the IRA protections.

The requirement language itself was simplified. Note the definitions of IRA and Intermediate System have been updated. Please note that the definition of IRA was changed to include serial communications connections. This change maintains backwards compatibility with CIP-005-7 except where serial connectivity is being used for IRA.

The required location of an Intermediate System was within the definition previously. The definition of Intermediate System has been simplified and the requirement as to its location is now within the requirement itself (Part 2.6.2) rather than within the definition.

Requirement R2 Part 2.2:

Rationale

The Applicable Systems was changed to "Intermediate Systems used to access Applicable Systems of Part 2.1". This change better reflects that this requirement is associated with the Intermediate System itself.

The requirement was changed from a specific technical based requirement for encryption to an objective based requirement to protect confidentiality and integrity of the IRA session between the Intermediate System and the remote client. The proposed language of this requirement accounts for the possibility that other equally effective methods could be developed and deployed. This objective also keeps methods from being used that are merely obfuscation methods (XOR, ROT13, etc.) or deprecated encryption methods (DES with 56-bit keys) that no longer actually protect the confidentiality and integrity of the IRA session.

The changed requirement is backwards compatible with the CIP-005-7 except where outdated encryption methods have been used.

Requirement R2 Part 2.3:

Rationale

The Applicable Systems was changed to "Intermediate Systems used to access Applicable Systems of Part 2.1". This change better reflects that this requirement is associated with the Intermediate System itself. This change also clarifies where the requirement for multifactor authentication should be applied (multi-factor authentication to the Intermediate System).

The changed requirement is backwards compatible with the CIP-005-7 except where serial connection-based IRA is being utilized.

Requirement R2 Part 2.4 – 2.5:

Rationale

The Applicable Systems section of this requirement was updated to include SCI identified independently (SCI identified in the “all-in” scenario from CIP-002 is already included as part of the BCS), in instances where vendor remote access is allowed to the SCI (including its Management Interfaces). The Applicable Systems were also modified such that only those with vendor remote access are in scope and thus need to have one or more methods for CIP-005-8 Requirement R2 Parts 2.4 and 2.5.

The requirements themselves have not been changed. Note that the requirement includes both vendor-based IRA and system-to-system access.

Requirement R2 Part 2.6:

Rationale

This is a new requirement that applies to Intermediate Systems that are required by CIP-005-8 Requirement R2 Part 2.1. The intent of this new requirement is to further protect the BCS from the Intermediate System by reducing the attack surface between the two. Intermediate Systems have an externally accessible interface that may be used by external parties such as vendors or entity support staff using IRA across an Internet connection to support a remote site. Since Intermediate Systems by nature provide IRA from a less-trusted network, a degree of separation from the higher-trust systems they are protecting is necessary in case the Intermediate System is compromised. Previously, this risk was addressed not in an actual requirement but within the glossary definition of Intermediate System (“…must not be located inside the ESP”). The SDT has removed this from the definition and included a security objective in CIP-005-8 Requirement R2 Part 2.6.2 to permit only needed and controlled communications between the Intermediate System and the Applicable Systems it is providing IRA to.

In order to mitigate the risk of a compromised virtualized Intermediate System (VCA) hosted on SCI, Requirement CIP-005-8 Requirement R2 Part 2.6.1 restricts CPU and memory sharing on SCI to only its associated SCI and other Intermediate Systems. In summary, CIP-005-8 Requirement R2 Part 2.6.1 is intended to mitigate the risk associated with “side channel” based attack vectors where it could be possible to compromise the Intermediate System VCA from an external source and then subsequently access other CIP System VCAs running on the same hypervisor within the SCI.

Requirement R3

Rationale

The Applicable Systems section of CIP-005-8 Requirement R3 was updated to include “SCI identified independently supporting an Applicable System above” to ensure the same safeguards for vendor-initiated remote connections exist for the applicable SCI. Backwards compatibility with CIP-005-7 is maintained for entities that do not currently use SCI.

Former Background Section from Reliability Standard CIP-005-7

The section **6. Background** has been retired and removed from the Standard, and preserved by cutting and pasting as-is below.

Background

Standard CIP-005 exists as part of a suite of CIP Standards related to cyber security, which require the initial identification and categorization of BCS and require a minimum level of organizational, operational and procedural controls to mitigate risk to BCS.

Most requirements open with, "*Each Responsible Entity shall implement one or more documented [processes, plan, etc.] that include the applicable items in [Table Reference].*" The referenced table requires the applicable items in the procedures for the requirement's common subject matter.

The term *documented processes* refers to a set of required instructions specific to the Responsible Entity and to achieve a specific outcome. This term does not imply any particular naming or approval structure beyond what is stated in the requirements. An entity should include as much as it believes necessary in its documented processes, but it must address the applicable requirements in the table.

The terms *program* and *plan* are sometimes used in place of *documented processes* where it makes sense and is commonly understood. For example, documented processes describing a response are typically referred to as *plans* (i.e., incident response plans and recovery plans). Likewise, a security plan can describe an approach involving multiple procedures to address a broad subject matter.

Similarly, the term *program* may refer to the organization's overall implementation of its policies, plans, and procedures involving a subject matter. Examples in the standards include the personnel risk assessment program and the personnel training program. The full implementation of the CIP Cyber Security Standards could also be referred to as a program. However, the terms *program* and *plan* do not imply any additional requirements beyond what is stated in the standards.

Responsible Entities can implement common controls that meet requirements for multiple high and medium impact BCS. For example, a single training program could meet the requirements for training personnel across multiple BCS.

Measures for the initial requirement are simply the documented processes themselves. Measures in the table rows provide examples of evidence to show documentation and implementation of applicable items in the documented processes. These measures serve to provide guidance to entities in acceptable records of compliance and should not be viewed as an all-inclusive list.

Throughout the standards, unless otherwise stated, bulleted items in the requirements and measures are items that are linked with an "or," and numbered items are items that are linked with an "and."

Many references in the Applicability section use a threshold of 300 MW for UFLS and UVLS. This particular threshold of 300 MW for UVLS and UFLS was provided in Version 1 of the CIP Cyber Security Standards. The threshold remains at 300 MW since it is specifically addressing UVLS and UFLS, which are last ditch efforts to save the Bulk Electric System. A review of UFLS tolerances defined within regional reliability standards for UFLS program requirements to date indicates that the historical value of 300 MW represents an adequate and reasonable threshold value for allowable UFLS operational tolerances.

"Applicable Systems" Columns in Tables:

Each table has an “Applicable Systems” column to further define the scope of systems to which a specific requirement row applies. The CSO706 SDT adapted this concept from the National Institute of Standards and Technology (“NIST”) Risk Management Framework as a way of applying requirements more appropriately based on impact and connectivity characteristics. The following conventions are used in the “Applicability Systems” column as described.

- **High Impact BES Cyber Systems** – Applies to BES Cyber Systems categorized as high impact according to the CIP-002 identification and categorization processes.
- **High Impact BES Cyber Systems with Dial-up Connectivity** – Only applies to high impact BES Cyber Systems with Dial-up Connectivity.
- **High Impact BES Cyber Systems with External Routable Connectivity** – Only applies to high impact BES Cyber Systems with External Routable Connectivity. This also excludes Cyber Assets in the BES Cyber System that cannot be directly accessed through External Routable Connectivity.
- **Medium Impact BES Cyber Systems** – Applies to BES Cyber Systems categorized as medium impact according to the CIP-002 identification and categorization processes.
- **Medium Impact BES Cyber Systems at Control Centers** – Only applies to medium impact BES Cyber Systems located at a Control Center.
- **Medium Impact BES Cyber Systems with Dial-up Connectivity** – Only applies to medium impact BES Cyber Systems with Dial-up Connectivity.
- **Medium Impact BES Cyber Systems with External Routable Connectivity** – Only applies to medium impact BES Cyber Systems with External Routable Connectivity. This also excludes Cyber Assets in the BES Cyber System that cannot be directly accessed through External Routable Connectivity.
- **Protected Cyber Assets (PCA)** – Applies to each Protected Cyber Asset associated with a referenced high impact BES Cyber System or medium impact BES Cyber System.
- **Electronic Access Points (EAP)** – Applies at Electronic Access Points associated with a referenced high impact BES Cyber System or medium impact BES Cyber System.
- **Physical Access Control Systems (PACS)** – Applies to each Physical Access Control System associated with a referenced high impact BES Cyber System or medium impact BES Cyber System.
- **Electronic Access Control or Monitoring Systems (EACMS)** – Applies to each Electronic Access Control or Monitoring System associated with a referenced high impact BES Cyber System or medium impact BES Cyber System. Examples may include, but are not limited to, firewalls, authentication servers, and log monitoring and alerting systems.

Technical Rationale for Reliability Standard CIP-005-7

Introduction

This document explains the technical rationale and justification for the proposed Reliability Standard CIP-005-7. It provides stakeholders and the ERO Enterprise with an understanding of the technology and technical requirements in the Reliability Standard. This Technical Rationale and Justifications for CIP-005-7 is not a Reliability Standard and should not be considered mandatory and enforceable.

Section “4. Applicability” of the standards provides important information for Responsible Entities to determine the scope of the applicability of the CIP Cyber Security Requirements.

Section “4.1. Functional Entities” is a list of NERC functional entities to which the standard applies. If the entity is registered as one or more of the functional entities listed in Section 4.1, then the NERC CIP Cyber Security Standards apply. Note that there is a qualification in this Section that restricts the applicability in the case of Distribution Providers to only those that own certain types of systems and equipment listed in 4.2.

Furthermore, Section “4.2. Facilities” defines the scope of the Facilities, systems, and equipment owned by the Responsible Entity, as qualified in Section 4.1, that is subject to the requirements of the standard. As specified in the exemption section 4.2.3.5, this standard does not apply to Responsible Entities that do not have High Impact or Medium Impact BES Cyber Systems under CIP-002-5’s categorization. In addition to the set of Bulk Electric System (BES) Facilities, Control Centers, and other systems and equipment, the list includes the set of systems and equipment owned by Distribution Providers. While the NERC Glossary term “Facilities” already includes the BES characteristic, the additional use of the term BES here is meant to reinforce the scope of applicability of these Facilities where it is used, especially in this applicability scoping section. This in effect sets the scope of Facilities, systems, and equipment that is subject to the standards.

Updates to this document now include the Project 2019-03 – Cyber Security Supply Chain Risks Standard Drafting Team’s (SDT’s) intent in drafting changes to the requirements.

The Federal Energy Regulatory Commission (the Commission) issued Order No. 850 on October 18, 2018, calling for modifications to the Supply Chain Suite of Standards to address Electronic Access Control or Monitoring Systems (EACMS), specifically those system that provide electronic access control or monitoring to high and medium impact BES Cyber Systems. In addition, NERC also recommended revising the Supply Chain Standards in its May 17, 2019 NERC Cyber Security Supply Chain Risk Report to address Physical Access Control Systems (PACS) that provide physical access control to high and medium impact BES Cyber Systems.

The Project 2019-03 SDT drafted Reliability Standard CIP-005-7 to require Responsible Entities to meet the directives set forth in the Commission’s Order No. 850 and the NERC Cyber Security Supply Chain Risk Report.

Additionally, the Project 2019-03 SDT removed Interchange Coordinator or Interchange Authority as that registration has been retired.

New and Modified Terms Used in NERC Reliability Standards

CIP-005-7 uses the following definition(s), which are cited below for reference when reading the technical rational that follows.

Proposed Modified Terms: None

Proposed New Terms: None

Requirement R1

General Considerations for Requirement R1

The ESP serves to control traffic at the external electronic boundary of the BES Cyber System. It provides a first layer of defense for network-based attacks as it limits reconnaissance of targets, restricts and prohibits traffic to a specified rule set, and assists in containing any successful attacks.

Summary of Changes: CIP-005, Requirement R1 has taken more of a focus on the discrete Electronic Access Points, rather than the logical "perimeter."

CIP-005 (V1 through V4), Requirement R1.2 has been deleted from V5. This requirement was definitional in nature and used to bring dial-up modems using non-routable protocols into the scope of CIP-005. The non-routable protocol exclusion no longer exists as a blanket CIP-002 filter for applicability in V5, therefore there is no need for this requirement.

CIP-005 (V1 through V4), Requirement R1.1 and R1.3 were also definitional in nature and have been deleted from V5 as separate requirements but the concepts were integrated into the definitions of ESP and Electronic Access Point ("EAP").

Reference to prior version: (Part 1.1) CIP-005-4, R1

Change Rationale: (Part 1.1)
Explicitly clarifies that BES Cyber Assets connected via routable protocol must be in an Electronic Security Perimeter.

Reference to prior version: (Part 1.2) CIP-005-4, R1

Change Rationale: (Part 1.2)
Changed to refer to the defined term Electronic Access Point and BES Cyber System.

Reference to prior version: (Part 1.3) CIP-005-4, R2.1

Change Rationale: (Part 1.3)
Changed to refer to the defined term Electronic Access Point and to focus on the entity knowing and having a reason for what it allows through the EAP in both inbound and outbound directions.

Reference to prior version: (Part 1.4) CIP-005-4, R2.3

Change Rationale: (Part 1.4)
Added clarification that dial-up connectivity should perform authentication so that the BES Cyber System is not directly accessible with a phone number only.

Reference to prior version: (Part 1.5) CIP-005-4, R1

Change Rationale: (Part 1.5)
Per FERC Order No. 706, Paragraphs 496-503, ESPs need two distinct security measures such that the Cyber Assets do not lose all perimeter protection if one measure fails or is misconfigured. The Order makes clear this is not simple redundancy of firewalls, thus the SDT has decided to add the security measure of malicious traffic inspection as a requirement for these ESPs.

Requirement R1

CIP-005-5, Requirement R1 requires segmenting of BES Cyber Systems from other systems of differing trust levels by requiring controlled Electronic Access Points between the different trust zones. Electronic Security Perimeters are also used as a primary defense layer for some BES Cyber Systems that may not inherently have sufficient cyber security functionality, such as devices that lack authentication capability.

All applicable BES Cyber Systems that are connected to a network via a routable protocol must have a defined Electronic Security Perimeter (ESP). Even standalone networks that have no external connectivity to other networks must have a defined ESP. The ESP defines a zone of protection around the BES Cyber System, and it also provides clarity for entities to determine what systems or Cyber Assets are in scope and what requirements they must meet. The ESP is used in:

- Defining the scope of ‘Associated Protected Cyber Assets’ that must also meet certain CIP requirements.
- Defining the boundary in which all of the Cyber Assets must meet the requirements of the highest impact BES Cyber System that is in the zone (the ‘high water mark’).

The CIP Cyber Security Standards do not require network segmentation of BES Cyber Systems by impact classification. Many different impact classifications can be mixed within an ESP. However, all of the Cyber Assets and BES Cyber Systems within the ESP must be protected at the level of the highest impact BES Cyber System present in the ESP (i.e., the “high water mark”) where the term “Protected Cyber Assets” is used. The CIP Cyber Security Standards accomplish the “high water mark” by associating all other Cyber Assets within the ESP, even other BES Cyber Systems of lesser impact, as “Protected Cyber Assets” of the highest impact system in the ESP.

For example, if an ESP contains both a high impact BES Cyber System and a low impact BES Cyber System, then each Cyber Asset of the low impact BES Cyber System are “Associated Protected Cyber Assets” of the high impact BES Cyber System and must meet all the requirements with that designation in the applicability columns of the requirement tables.

If there is routable connectivity across the ESP into any Cyber Asset, then an Electronic Access Point (EAP) must control traffic into and out of the ESP.

The EAP should control both inbound and outbound traffic. The standard added outbound traffic control, as it is a prime indicator of compromise and a first level of defense against zero-day vulnerability-based attacks. If Cyber Assets within the ESP become compromised and attempt to communicate to unknown hosts outside the ESP (usually ‘command and control’ hosts on the Internet, or compromised ‘jump hosts’ within the Responsible Entity’s other networks acting as intermediaries), the EAPs should function as a first level of defense in stopping the exploit. The SDT’s intent is that the Responsible Entity knows what other Cyber Assets or ranges of addresses a BES Cyber System needs to communicate with and limits the communication to that known range. The SDT’s intent is not for Responsible Entities to document the inner workings of stateful firewalls, where connections initiated in one direction are allowed a return path. The intent is to know and document what systems can talk to what other systems or ranges of systems on the other side of the EAP, such that rouge connections can be detected and blocked.

This requirement applies only to communications for which access lists and ‘deny by default’ type requirements can be universally applied, which today are those that employ routable protocols. Direct serial, non-routable connections are not included as there is no perimeter or firewall type security that should be universally mandated across all entities and all serial communication situations. There is no firewall or perimeter capability for an RS232 cable run between two Cyber Assets. Without a clear ‘perimeter type’ security control that can be applied in practically every circumstance, such a requirement would mostly generate technical feasibility exceptions (“TFEs”) rather than increased security.

As for dial-up connectivity, the Standard Drafting Team's intent of this requirement is to prevent situations where only a phone number can establish direct connectivity to the BES Cyber Asset. If a dial-up modem is implemented in such a way that it simply answers the phone and connects the line to the BES Cyber Asset with no authentication of the calling party, it is a vulnerability to the BES Cyber System. The requirement calls for some form of authentication of the calling party before completing the connection to the BES Cyber System. If the dial-up connectivity is used for Interactive Remote Access, then Requirement R2 also applies.

The standard adds a requirement to detect malicious communications for Control Centers. This is in response to FERC Order No. 706, Paragraphs 496-503, where ESPs are required to have two distinct security measures such that the BES Cyber Systems do not lose all perimeter protection if one measure fails or is misconfigured. The Order makes clear that this is not simply redundancy of firewalls, thus the SDT has decided to add the security measure of malicious traffic inspection as a requirement for these ESPs.

Requirement R2

General Considerations for Requirement R2

Registered Entities use Interactive Remote Access to access Cyber Assets to support and maintain control systems networks. Discovery and announcement of vulnerabilities for remote access methods and technologies, that were previously thought secure and in use by a number of electric sector entities, necessitate changes to industry security control standards. Currently, no requirements are in effect for management of secure remote access to Cyber Assets to be afforded the NERC CIP protective measures. Inadequate safeguards for remote access can allow unauthorized access to the organization's network, with potentially serious consequences. Additional information is provided in ***Guidance for Secure Interactive Remote Access*** published by NERC in July 2011.

Remote access control procedures must provide adequate safeguards through robust identification, authentication and encryption techniques. Remote access to the organization's network and resources should only be permitted providing that authorized users are authenticated, data is encrypted across the network, and privileges are restricted.

The Intermediate System serves as a proxy for the remote user. Rather than allowing all the protocols the user might need to access Cyber Assets inside the Electronic Security Perimeter to traverse from the Electronic Security Perimeter to the remote computer, only the protocol required for remotely controlling the jump host is required. This allows the firewall rules to be much more restrictive than if the remote computer was allowed to connect to Cyber Assets within the Electronic Security Perimeter directly. The use of an Intermediate System also protects the Cyber Asset from vulnerabilities on the remote computer.

The use of multi-factor authentication provides an added layer of security. Passwords can be guessed, stolen, hijacked, found, or given away. They are subject to automated attacks including brute force attacks, in which possible passwords are tried until the password is found, or dictionary attacks, where words and word combinations are tested as possible passwords.
But if a password or PIN must be supplied along with a one-time password supplied by a token, a fingerprint, or some other factor, the password is of no value unless the other factor(s) used for authentication are acquired along with it.

Encryption is used to protect the data that is sent between the remote computer and the Intermediate System. Data encryption is important for anyone who wants or needs secure data transfer. Encryption is needed when there is a risk of unauthorized interception of transmissions on the communications link. This is especially important when using the Internet as the communication means.

Summary of Changes: This is a new requirement to continue the efforts of the Urgent Action team for Project 2010-

15: Expedited Revisions to CIP-005-3.

Reference to prior version: (Part 2.1) New

Change Rationale: (Part 2.1)
This is a new requirement to continue the efforts of the Urgent Action team for Project 2010-15: Expedited Revisions to CIP-005-3.

Reference to prior version: (Part 2.2) CIP-007-5, R3.1

Change Rationale: (Part 2.2)
This is a new requirement to continue the efforts of the Urgent Action team for Project 2010-15: Expedited Revisions to CIP-005-3. The purpose of this part is to protect the confidentiality and integrity of each Interactive Remote Access session.

Reference to prior version: (Part 2.3) CIP-007-5, R3.2

Change Rationale: (Part 2.3)
This is a new requirement to continue the efforts of the Urgent Action team for Project 2010-15: Expedited Revisions to CIP-005-3. The multi-factor authentication methods are also the same as those identified in the Homeland Security Presidential Directive 12 (HSPD-12), issued August 12, 2007.

Requirement R3

Requirement Part 3.1 and Part 3.2 Vendor Remote Access Management for EACMS and PACS

The 2019-03 SDT added Requirement R3 to contain the requirements for all types of vendor remote access management for EACMS and PACS (i.e. system to system, user to system). EACMS were added based on FERC order 850 paragraph 5 where FERC ordered NERC to create a drafting team to add these devices. EACMS were added based on the risks FERC noted in paragraph 4, where a Department of Homeland Security Industrial Control System-Cyber Emergency Response Team (DHS ICS-CERT) said firewalls (normally defined as an EACMS) is the “first line of defense within an Industry Control System (ICS) network environment”. The compromise of those devices that control access management could provide an outsider the “keys to the front door” of the ESP where BES Cyber Systems reside. An intruder holding the “keys to the front door” could use those “keys” to enter the ESP or modify the access controls to allow others to bypass authorization.

In Requirement R3 Part 3.1 and Part 3.2, the word "connection" is the mechanism for a user or a system to interact with an EAMCS or PACS for the purpose of authenticating.

In Requirement R3 Part 3.1 and Part 3.2, the word "authenticate" is the mechanism for the EACMS or PACS to identify the user or device. This permits the EACMS or PACS to first perform its function to authenticate the user or device that is connecting, which in turn permits the entity to delineate or differentiate vendor-initiated connections from other remote access connections. This new proposed language is not prescriptive as to how authentication must occur to permit administrative and technical methods.

In Requirement R3 Part 3.2, the word "control" provides the entity flexibility to allow the vendor to reconnect under a specific set of conditions, established by the entity, where the reconnection is necessary to support critical operations of the entity. If the entity determines that they do not want to allow or does not need to allow a reconnection they can employ means to stop any reconnection.

The term *vendor(s)* as used in the standard is limited to those persons, companies, or other organizations with whom the Responsible Entity, or its affiliates, contract with to supply BES Cyber Systems and related services. It does not include other NERC registered entities providing reliability services (e.g., Balancing Authority or Reliability Coordinator services pursuant to NERC Reliability Standards). A *vendor,* as used in the standard, may include: (i) developers or manufacturers of information systems, system components, or information system services; (ii) product resellers; or (iii) system integrators.

Since remotely compromised PACS still require physical presence to exploit BES Cyber Systems, the SDT conducted extensive dialogue and considerations for the addition of PACS. The SDT concluded the risk posed to BES reliability by a compromised, misused, degraded, or unavailable PACS warranted their inclusion as an applicable Cyber Asset. Further, the inclusion of PACS:

1. addresses the Commission's remaining concern stated in FERC Order No. 850 P 6. that, "…the exclusion of these components may leave a gap in the supply chain risk management Reliability Standards.",
2. addresses the expectations of FERC Order No. 850 P 24. "…to direct that NERC evaluate the cybersecurity supply chain risks presented by PACS and PCAs in the study of cybersecurity supply chain risks directed by the NERC BOT in its resolutions of August 10, 2017.", and
3. directly aligns with NERC's recommendation to include PACS as documented in NERC's final report on "*Cyber Security Supply Chain Risks*"[2].

NERC's final report on "*Cyber Security Supply Chain Risks*", states on page 4, "The NERC CIP Reliability Standards provide a risk-based, defense-in-depth approach to securing the BES against cyber and physical security threats." PACS are intended to manage physical threats to BES Cyber Systems, thus protecting BES Cyber Systems against compromise that could lead to misoperation or instability in the BES.

Additionally, NERC states on page 15 of their final report on "*Cyber Security Supply Chain Risks*" that, "In addition, a threat actor must be physically present at the facility in order to exploit the vulnerability created by a compromised PACS system. A threat actor may also need to bypass several physical accesses or monitoring controls that have not been compromised in order to gain access." While a cyber-compromised PACSs may not in and of itself represent an immediate 15-minute adverse impact to the reliability of the BES, it could demonstrate a threat Actor's intention to gain fully unauthorized electronic access.

While other Reliability Standards mitigate certain security risks relating to PACS none address supply chain risk. Based on this analysis the SDT included PACS within the applicable section of both Requirement Parts 3.1 and 3.2.

An additional aspect of the NERC Supply Chain Report, the SDT considered was the risk associated with the access control vs. access monitoring functions of both EACMS and PACS. While both types of systems, under the current definitions, have various functional activities they perform, the NERC Supply Chain Report pointed to the increased risk of the access control function beyond the access monitoring function. The SDT considered limiting the scope of the requirements to only those access control functions, however chose to stay with the currently approved definition of both EACMS and PACS. The SDT concluded staying with approved definitions would introduce less confusion. Additionally, an attempt to change the EACMS and PACS definition was outside the 2019-03 SAR.

Entities may or may not allow remote access into any of its systems, (BES Cyber Systems, EACMS or PACS), however if remote access is allowed, options to determine remote access connection(s) and capability to disable remote access connection(s) is required.

---

Technical Rational for Reliability Standard CIP-005-6

This section contains a "cut and paste" of the Technical Rationale components of the former Guidelines and Technical Basis (GTB) as-is of from CIP-005-6 standard to preserve any historical references. Similarly, former GTB content providing compliance guidance can be found in a separate Implementation Guidance document for this standard.

Section 4 – Scope of Applicability of the CIP Cyber Security Standards

Section "4. Applicability" of the standards provides important information for Responsible Entities to determine the scope of the applicability of the CIP Cyber Security Requirements.

Section "4.1. Functional Entities" is a list of NERC functional entities to which the standard applies. If the entity is registered as one or more of the functional entities listed in Section 4.1, then the NERC CIP Cyber Security Standards apply. Note that there is a qualification in Section that restricts the applicability in the case of Distribution Providers to only those that own certain types of systems and equipment listed in 4.2.

Furthermore, Section "4.2. Facilities" defines the scope of the Facilities, systems, and equipment owned by the Responsible Entity, as qualified in Section 4.1, that is subject to the requirements of the standard. As specified in the exemption section 4.2.3.5, this standard does not apply to Responsible Entities that do not have High Impact or Medium Impact BES Cyber Systems under CIP-002-5's categorization. In addition to the set of BES Facilities, Control Centers, and other systems and equipment, the list includes the set of systems and equipment owned by Distribution Providers. While the NERC Glossary term "Facilities" already includes the BES characteristic, the additional use of the term BES here is meant to reinforce the scope of applicability of these Facilities where it is used, especially in this applicability scoping section. This in effect sets the scope of Facilities, systems, and equipment that is subject to the standards.

Requirement R1:

CIP-005-5, Requirement R1 requires segmenting of BES Cyber Systems from other systems of differing trust levels by requiring controlled Electronic Access Points between the different trust zones. Electronic Security Perimeters are also used as a primary defense layer for some BES Cyber Systems that may not inherently have sufficient cyber security functionality, such as devices that lack authentication capability.

All applicable BES Cyber Systems that are connected to a network via a routable protocol must have a defined Electronic Security Perimeter (ESP). Even standalone networks that have no external connectivity to other networks must have a defined ESP. The ESP defines a zone of protection around the BES Cyber System, and it also provides clarity for entities to determine what systems or Cyber Assets are in scope and what requirements they must meet. The ESP is used in:

- Defining the scope of 'Associated Protected Cyber Assets' that must also meet certain CIP requirements.
- Defining the boundary in which all of the Cyber Assets must meet the requirements of the highest impact BES Cyber System that is in the zone (the 'high water mark').

The CIP Cyber Security Standards do not require network segmentation of BES Cyber Systems by impact classification. Many different impact classifications can be mixed within an ESP. However, all of the Cyber Assets and BES Cyber Systems within the ESP must be protected at the level of the highest impact BES Cyber System present in the ESP (i.e., the "high water mark") where the term "Protected Cyber Assets" is used. The CIP Cyber Security Standards accomplish the "high water mark" by associating all other Cyber Assets within the ESP, even other BES Cyber Systems of lesser impact, as "Protected Cyber Assets" of the highest impact system in the ESP.

For example, if an ESP contains both a high impact BES Cyber System and a low impact BES Cyber System, each Cyber Asset of the low impact BES Cyber System is an “Associated Protected Cyber Asset” of the high impact BES Cyber System and must meet all requirements with that designation in the applicability columns of the requirement tables.

If there is routable connectivity across the ESP into any Cyber Asset, then an Electronic Access Point (EAP) must control traffic into and out of the ESP.

Responsible Entities should know what traffic needs to cross an EAP and document those reasons to ensure the EAPs limit the traffic to only those known communication needs. These include, but are not limited to, communications needed for normal operations, emergency operations, support, maintenance, and troubleshooting.

The EAP should control both inbound and outbound traffic. The standard added outbound traffic control, as it is a prime indicator of compromise and a first level of defense against zero day vulnerability-based attacks. If Cyber Assets within the ESP become compromised and attempt to communicate to unknown hosts outside the ESP (usually ‘command and control’ hosts on the Internet, or compromised ‘jump hosts’ within the Responsible Entity’s other networks acting as intermediaries), the EAPs should function as a first level of defense in stopping the exploit. This does not limit the Responsible Entity from controlling outbound traffic at the level of granularity that it deems appropriate, and large ranges of internal addresses may be allowed. The SDT’s intent is that the Responsible Entity knows what other Cyber Assets or ranges of addresses a BES Cyber System needs to communicate with and limits the communications to that known range. For example, most BES Cyber Systems within a Responsible Entity should not have the ability to communicate through an EAP to any network address in the world, but should probably be at least limited to the address space of the Responsible Entity, and preferably to individual subnet ranges or individual hosts within the Responsible Entity’s address space. The SDT’s intent is not for Responsible Entities to document the inner workings of stateful firewalls, where connections initiated in one direction are allowed a return path. The intent is to know and document what systems can talk to what other systems or ranges of systems on the other side of the EAP, such that rogue connections can be detected and blocked.

This requirement applies only to communications for which access lists and ‘deny by default’ type requirements can be universally applied, which today are those that employ routable protocols. Direct serial, non-routable connections are not included as there is no perimeter or firewall type security that should be universally mandated across all entities and all serial communication situations. There is no firewall or perimeter capability for an RS232 cable run between two Cyber Assets. Without a clear ‘perimeter type’ security control that can be applied in practically every circumstance, such a requirement would mostly generate technical feasibility exceptions (“TFEs”) rather than increased security.

As for dial-up connectivity, the Standard Drafting Team’s intent of this requirement is to prevent situations where only a phone number can establish direct connectivity to the BES Cyber Asset. If a dial-up modem is implemented in such a way that it simply answers the phone and connects the line to the BES Cyber Asset with no authentication of the calling party, it is a vulnerability to the BES Cyber System. The requirement calls for some form of authentication of the calling party before completing the connection to the BES Cyber System. If the dial-up connectivity is used for Interactive Remote Access, then Requirement R2 also applies.

The standard adds a requirement to detect malicious communications for Control Centers. This is in response to FERC Order No. 706, Paragraphs 496-503, where ESPs are required to have two distinct security measures such that the BES Cyber Systems do not lose all perimeter protection if one measure fails or is misconfigured. The Order makes clear that this is not simply redundancy of firewalls, thus the SDT has decided to add the security measure of malicious traffic inspection as a requirement for these ESPs.

Rationale:

During the development of this standard, references to prior versions of the CIP standards and rationale for the requirements and their parts were embedded within the standard. Upon BOT approval, that information was moved to this section.

Rationale for R1:

The Electronic Security Perimeter ("ESP") serves to control traffic at the external electronic boundary of the BES Cyber System. It provides a first layer of defense for network based attacks as it limits reconnaissance of targets, restricts and prohibits traffic to a specified rule set, and assists in containing any successful attacks.

Summary of Changes: CIP-005, Requirement R1 has taken more of a focus on the discrete Electronic Access Points, rather than the logical "perimeter."

CIP-005 (V1 through V4), Requirement R1.2 has been deleted from V5. This requirement was definitional in nature and used to bring dial-up modems using non-routable protocols into the scope of CIP-005. The non-routable protocol exclusion no longer exists as a blanket CIP-002 filter for applicability in V5, therefore there is no need for this requirement.

CIP-005 (V1 through V4), Requirement R1.1 and R1.3 were also definitional in nature and have been deleted from V5 as separate requirements but the concepts were integrated into the definitions of ESP and Electronic Access Point ("EAP").

Reference to prior version: (Part 1.1) CIP-005-4, R1

Change Rationale: (Part 1.1)
Explicitly clarifies that BES Cyber Assets connected via routable protocol must be in an Electronic Security Perimeter.

Reference to prior version: (Part 1.2) CIP-005-4, R1

Change Rationale: (Part 1.2)
Changed to refer to the defined term Electronic Access Point and BES Cyber System.

Reference to prior version: (Part 1.3) CIP-005-4, R2.1

Change Rationale: (Part 1.3)
Changed to refer to the defined term Electronic Access Point and to focus on the entity knowing and having a reason for what it allows through the EAP in both inbound and outbound directions.

Reference to prior version: (Part 1.4) CIP-005-4, R2.3

Change Rationale: (Part 1.4)
Added clarification that dial-up connectivity should perform authentication so that the BES Cyber System is not directly accessible with a phone number only.

Reference to prior version: (Part 1.5) CIP-005-4, R1

Change Rationale: (Part 1.5)
Per FERC Order No. 706, Paragraphs 496-503, ESPs need two distinct security measures such that the Cyber Assets do not lose all perimeter protection if one measure fails or is misconfigured. The Order makes clear this is not simple redundancy of firewalls, thus the SDT has decided to add the security measure of malicious traffic inspection as a requirement for these ESPs.

Requirement R2:

See Secure Remote Access Reference Document (see remote access alert).

Rationale for R2:

Registered Entities use Interactive Remote Access to access Cyber Assets to support and maintain control systems networks. Discovery and announcement of vulnerabilities for remote access methods and technologies, that were previously thought secure and in use by a number of electric sector entities, necessitate changes to industry security control standards. Currently, no requirements are in effect for management of secure remote access to Cyber Assets to be afforded the NERC CIP protective measures. Inadequate safeguards for remote access can allow unauthorized access to the organization's network, with potentially serious consequences. Additional information is provided in ***Guidance for Secure Interactive Remote Access*** published by NERC in July 2011.

Remote access control procedures must provide adequate safeguards through robust identification, authentication and encryption techniques. Remote access to the organization's network and resources will only be permitted providing that authorized users are authenticated, data is encrypted across the network, and privileges are restricted.

The Intermediate System serves as a proxy for the remote user. Rather than allowing all the protocols the user might need to access Cyber Assets inside the Electronic Security Perimeter to traverse from the Electronic Security Perimeter to the remote computer, only the protocol required for remotely controlling the jump host is required. This allows the firewall rules to be much more restrictive than if the remote computer was allowed to connect to Cyber Assets within the Electronic Security Perimeter directly. The use of an Intermediate System also protects the Cyber Asset from vulnerabilities on the remote computer.

The use of multi-factor authentication provides an added layer of security. Passwords can be guessed, stolen, hijacked, found, or given away. They are subject to automated attacks including brute force attacks, in which possible passwords are tried until the password is found, or dictionary attacks, where words and word combinations are tested as possible passwords.
But if a password or PIN must be supplied along with a one-time password supplied by a token, a fingerprint, or some other factor, the password is of no value unless the other factor(s) used for authentication are acquired along with it.

Encryption is used to protect the data that is sent between the remote computer and the Intermediate System. Data encryption is important for anyone who wants or needs secure data transfer. Encryption is needed when there is a risk of unauthorized interception of transmissions on the communications link. This is especially important when using the Internet as the communication means.

Summary of Changes: This is a new requirement to continue the efforts of the Urgent Action team for Project 2010-15: Expedited Revisions to CIP-005-3.

Reference to prior version: (Part 2.1) New

Change Rationale: (Part 2.1)
This is a new requirement to continue the efforts of the Urgent Action team for Project 2010-15: Expedited Revisions to CIP-005-3.

Reference to prior version: (Part 2.2) CIP-007-5, R3.1

Change Rationale: (Part 2.2)
This is a new requirement to continue the efforts of the Urgent Action team for Project 2010-15: Expedited Revisions to CIP-005-3. The purpose of this part is to protect the confidentiality and integrity of each Interactive Remote Access session.

Reference to prior version: (Part 2.3) CIP-007-5, R3.2

Change Rationale: (Part 2.3)
This is a new requirement to continue the efforts of the Urgent Action team for Project 2010-15: Expedited Revisions to CIP-005-3. The multi-factor authentication methods are also the same as those identified in the Homeland Security Presidential Directive 12 (HSPD-12), issued August 12, 2007.

Change Rationale: (Part 2.4 and 2.5)
Requirement R2 Parts 2.4 and 2.5 addresses Order No. 829 directives for controls on vendor-initiated remote access to BES Cyber Systems covering both user-initiated and machine-to machine vendor remote access (P. 51). The objective is to mitigate potential risks of a compromise at a vendor during an active remote access session with a Responsible Entity from impacting the BES.

The objective of Requirement R2 Part 2.4 is for entities to have visibility of active vendor remote access sessions (including Interactive Remote Access and system-to-system remote access) that are taking place on their system. This scope covers all remote access sessions with vendors. The obligation in Part 2.4 requires entities to have a method to determine active vendor remote access sessions. While not required, a solution that identifies all active remote access sessions, regardless of whether they originate from a vendor, would meet the intent of this requirement. The objective of Requirement R2 Part 2.5 is for entities to have the ability to disable active remote access sessions in the event of a system breach as specified in Order No. 829 (P. 52).

Technical Rationale for Reliability Standard CIP-006-7

Introduction

This document explains the technical rationale and justification for the proposed Reliability Standard CIP-006-7. It provides stakeholders and the ERO Enterprise with an understanding of the technology and technical requirements in the Reliability Standard. This Technical Rationale and Justifications for CIP-006-7 is not a Reliability Standard and should not be considered mandatory and enforceable.

Updates to this document now include the Project 2016-02 – Modifications to CIP Standards Drafting Team's (SDT's) intent in drafting changes to the requirements.

Background

The Version 5 Transition advisory Group (V5TAG), which consists of representatives from NERC, Regional Entities, and industry stakeholders, was formed to issue guidance regarding possible methods to achieve compliance with the CIP V5 standards and to support industry's implementation activities. During the course of the V5TAG's activities, the V5TAG identified certain issues with the CIP Reliability Standards that were more appropriately addressed by a standard drafting team (SDT). The V5TAG developed the V5TAG Transfer Document to explain the issues and recommend that they be considered in future development activity. As Project 2016-02 was formed to address the directives in FERC Order 822 issued on January 21, 2016, that team also received addressing the V5TAG issues as part of its Standard Authorization Request (SAR).

One of the areas of issue was virtualization. The V5TAG Transfer document said, "The CIP Version 5 standards do not specifically address virtualization. However, because of the increasing use of virtualization in industrial control system environments, questions around treatment of virtualization within the CIP Standards are due for consideration. The SDT should consider revisions to CIP-005 and the definitions of Cyber Asset and Electronic Access Point that make clear the permitted architecture and address the security risks of network, server and storage virtualization technologies."

New and Modified Terms and Applicability

This standard uses new or modified terms and contains new or modified exemptions in Section 4 Applicability. The rationale for this global content can be found in "CIP Definitions and Exemptions Technical Rationale" document for reference when reading the technical rationale that follows.

Requirement R1

Rationale

The SDT added the option (known as the "all-in" scenario) for entities to group SCI within a BCS it supports; Therefore, to enable CIP-006-7 for virtualization, the SDT added "SCI identified independently supporting an Applicable System above…" each of the Parts in Applicable Systems for Requirement R1 to account for the alternative option (See the CIP-002 Technical Rationale document for a description of the options for identifying SCI and reasons an entity may choose between the options.)

The SDT chose not to renumber Parts 1.1 – 1.3 of Requirement R1 due to the undue administrative impact to entity's documented programs caused by such renumbering. As a result, Part 1.1 through 1.3 remain constructed in an additive order as the impact or connectivity to said Applicable System increases. The list of Applicable Systems had become lengthy and confusing within this construct, so in an effort to bring clarity, the SDT was mindful to streamline the Applicable Systems through exclusionary references to other Parts. This approach assures the appropriate scoping is retained within this construct without creating double jeopardy, while bringing clarity and brevity to the Applicable Systems column for each Part. The results are as follows:

Applicable Systems:

Requirement R1 Part 1.1: the SDT added "SCI identified independently supporting an Applicable System above, not included in the Applicable Systems of Part 1.2 or Part 1.3"

Requirement R1 Part 1.2: the SDT added "SCI identified independently supporting an Applicable System above, not included in the Applicable Systems of Part 1.3"

Requirement R1 Part 1.3 – 1.9: the SDT added "SCI identified independently supporting an Applicable System above"

Per System Capability vs Technical Feasibility:

Requirement R1 Part 1.3: The SDT chose to remove the reliance on a Technical Feasibility Exception in favor of the updated term "per system capability." Rationale: The SDT contends that the term still requires an entity to document the limit to the system's capability with regards to the requirement language, while not incurring the additional documentation overhead of a Technical Feasibility Exception.

CIP Exceptional Circumstances (CEC):

The SDT also evaluated where CIP Exceptional Circumstances (CEC) should be included, and has added this provision to the following requirement parts:

Requirement R1 Part 1.8: Rationale: Responsible Entities may not be able to log entry of each individual with authorized unescorted physical access into each Physical Security Perimeter (PSP) if a facility that contains the PSP or Physical Access Control System is damaged or destroyed.

Requirement R1 Part 1.9: Rationale: Responsible Entities may not be able to retain access logs of entry of individuals into each PSP if a facility that contains the PSP or Physical Access Control System is damaged or destroyed.

Consolidation:

Requirement R1 Part 1.10: The SDT deleted Requirement R1 Part 1.10 from CIP-006-7 because it is incorporated into CIP-005-8 Requirement R1 Part 1.4.

Requirement R2 – Requirement R3

Rationale

The SDT added the option (known as the "all-in" scenario) for entities to group SCI within a BCS it supports; Therefore, to enable CIP-006-7 for virtualization, the SDT added "SCI identified independently supporting an Applicable System above" each of the Parts in Applicable Systems for Requirement R2 – Requirement R3 to account for the alternative option (See the CIP-002 Technical Rationale document for a description of the options for identifying SCI and reasons an entity may choose between the options.)

Requirement R1 Part 3.1: To accommodate for the variant construct of Applicable systems in Requirement R3 Part 3.1 specifically, the phrase “identified independently supporting” was used in each SCI bullet beneath “Physical Access Control Systems (PACS)” and “Locally mounted hardware or devices at the Physical Security Perimeter”.

Former Background Section from Reliability Standard CIP-006-6

The section **6. Background** has been retired and removed from the Standard, and preserved by cutting and pasting as-is below.

Background

Standard CIP-006 exists as part of a suite of CIP Standards related to cyber security, which require the initial identification and categorization of BES Cyber Systems and require a minimum level of organizational, operational and procedural controls to mitigate risk to BES Cyber Systems.

Most requirements open with, "*Each Responsible Entity shall implement one or more documented [processes, plan, etc.] that include the applicable items in [Table Reference].*" The referenced table requires the applicable items in the procedures for the requirement's common subject matter.

The term *documented processes* refers to a set of required instructions specific to the Responsible Entity and to achieve a specific outcome. This term does not imply any particular naming or approval structure beyond what is stated in the requirements. An entity should include as much as it believes necessary in its documented processes, but it must address the applicable requirements in the table.

The terms *program* and *plan* are sometimes used in place of *documented processes* where it makes sense and is commonly understood. For example, documented processes describing a response are typically referred to as *plans* (i.e., incident response plans and recovery plans). Likewise, a security plan can describe an approach involving multiple procedures to address a broad subject matter.

Similarly, the term *program* may refer to the organization's overall implementation of its policies, plans and procedures involving a subject matter. Examples in the standards include the personnel risk assessment program and the personnel training program. The full implementation of the CIP Cyber Security Standards could also be referred to as a program. However, the terms *program* and *plan* do not imply any additional requirements beyond what is stated in the standards.

Responsible Entities can implement common controls that meet requirements for multiple high and medium impact BES Cyber Systems. For example, a single training program could meet the requirements for training personnel across multiple BES Cyber Systems.

Measures for the initial requirement are simply the documented processes themselves. Measures in the table rows provide examples of evidence to show documentation and implementation of applicable items in the documented processes. These measures serve to provide guidance to entities in acceptable records of compliance and should not be viewed as an all-inclusive list.

Throughout the standards, unless otherwise stated, bulleted items in the requirements and measures are items that are linked with an "or," and numbered items are items that are linked with an "and."

Many references in the Applicability section use a threshold of 300 MW for UFLS and UVLS. This particular threshold of 300 MW for UVLS and UFLS was provided in Version 1 of the CIP Cyber Security Standards. The threshold remains at 300 MW since it is specifically addressing UVLS and UFLS, which are last ditch efforts to save the Bulk Electric System. A review of UFLS tolerances defined within regional reliability standards for UFLS program requirements to date indicates that the historical value of 300 MW represents an adequate and reasonable threshold value for allowable UFLS operational tolerances.

"Applicable Systems" Columns in Tables:

Each table has an “Applicable Systems” column to further define the scope of systems to which a specific requirement row applies. The CSO706 SDT adapted this concept from the National Institute of Standards and Technology (“NIST”) Risk Management Framework as a way of applying requirements more appropriately based on impact and connectivity characteristics. The following conventions are used in the “Applicable Systems” column as described.

- **High Impact BES Cyber Systems** – Applies to BES Cyber Systems categorized as high impact according to the CIP-002-5.1 identification and categorization processes.
- **Medium Impact BES Cyber Systems** – Applies to BES Cyber Systems categorized as medium impact according to the CIP-002-5.1 identification and categorization processes.
- **Medium Impact BES Cyber Systems without External Routable Connectivity** – Only applies to medium impact BES Cyber Systems without External Routable Connectivity.
- **Medium Impact BES Cyber Systems with External Routable Connectivity** – Only applies to medium impact BES Cyber Systems with External Routable Connectivity. This also excludes Cyber Assets in the BES Cyber System that cannot be directly accessed through External Routable Connectivity.
- **Electronic Access Control or Monitoring Systems (EACMS)** – Applies to each Electronic Access Control or Monitoring System associated with a referenced high impact BES Cyber System or medium impact BES Cyber System. Examples may include, but are not limited to, firewalls, authentication servers, and log monitoring and alerting systems.
- **Physical Access Control Systems (PACS)** – Applies to each Physical Access Control System associated with a referenced high impact BES Cyber System or medium impact BES Cyber System.

Technical Rational for Reliability Standard CIP-006-6

This section contains a “cut and paste” of the former Guidelines and Technical Basis (GTB) as-is of from CIP-006-6 standard to preserve any historical references. No modifications have been made.

Guidelines and Technical Basis

Section 4 – Scope of Applicability of the CIP Cyber Security Standards

Section “4. Applicability” of the standards provides important information for Responsible Entities to determine the scope of the applicability of the CIP Cyber Security Requirements.

Section “4.1. Functional Entities” is a list of NERC functional entities to which the standard applies. If the entity is registered as one or more of the functional entities listed in Section 4.1, then the NERC CIP Cyber Security Standards apply. Note that there is a qualification in Section 4.1 that restricts the applicability in the case of Distribution Providers to only those that own certain types of systems and equipment listed in 4.2.

Section “4.2. Facilities” defines the scope of the Facilities, systems, and equipment owned by the Responsible Entity, as qualified in Section 4.1, that is subject to the requirements of the standard. As specified in the exemption section 4.2.3.5, this standard does not apply to Responsible Entities that do not have High Impact or Medium Impact BES Cyber Systems under CIP-002-5.1’s categorization. In addition to the set of BES Facilities, Control Centers, and other systems and equipment, the list includes the set of systems and equipment owned by Distribution Providers. While the NERC Glossary term “Facilities” already includes the BES characteristic, the additional use of the term BES here is meant to reinforce the scope of applicability of these Facilities where it is used, especially in this applicability scoping section. This in effect sets the scope of Facilities, systems, and equipment that is subject to the standards.

General:

While the focus of this Reliability Standard has shifted away from the definition and management of a completely enclosed “six-wall” boundary, it is expected that in many instances a six-wall boundary will remain a primary mechanism for controlling, alerting, and logging access to BES Cyber Systems. Taken together, these controls outlined below will effectively constitute the physical security plan to manage physical access to BES Cyber Systems.

Requirement R1:

Methods of physical access control include:

- Card Key: A means of electronic access where the access rights of the card holder are predefined in a computer database. Access rights may differ from one perimeter to another.

- Special Locks: These include, but are not limited to, locks with “restricted key” systems, magnetic locks that can be operated remotely, and “man-trap” systems.
- Security Personnel: Personnel responsible for controlling physical access who may reside on-site or at a monitoring station.
- Other Authentication Devices: Biometric, keypad, token, or other equivalent devices that control physical access into the PSP.

Methods to monitor physical access include:

- Alarm Systems: Systems that alarm to indicate interior motion or when a door, gate, or window has been opened without authorization. These alarms must provide for notification within 15 minutes to individuals responsible for response.
- Human Observation of Access Points: Monitoring of physical access points by security personnel who are also controlling physical access.

Methods to log physical access include:

- Computerized Logging: Electronic logs produced by the Responsible Entity’s selected access control and alerting method.
- Video Recording: Electronic capture of video images of sufficient quality to determine identity.
- Manual Logging: A log book or sign-in sheet, or other record of physical access maintained by security or other personnel authorized to control and monitor physical access.

The FERC Order No. 706, Paragraph 572, directive discussed utilizing two or more different and complementary physical access controls to provide defense in depth. It does not require two or more PSPs, nor does it exclude the use of layered perimeters. Use of two-factor authentication would be acceptable at the same entry points for a non-layered single perimeter. For example, controls for a sole perimeter could include either a combination of card key and pin code (something you know and something you have), or a card key and biometric scanner (something you have and something you are), or a physical key in combination with a guard-monitored remote camera and door release, where the “guard” has adequate information to authenticate the person the guard is observing or talking to prior to permitting access (something you have and something you are). The two-factor authentication could be implemented using a single Physical Access Control System but more than one authentication method must be utilized. For physically layered protection, a locked gate in combination with a locked control-building could be acceptable, provided no single authenticator (e.g., key or card key) would provide access through both.

Entities may choose for certain PACS to reside in a PSP controlling access to applicable BES Cyber Systems. For these PACS, there is no additional obligation to comply with Requirement Parts 1.1, 1.6 and 1.7 beyond what is already required for the PSP.

The new requirement part CIP-006-6, Requirement R1, Part 1.10 responds to the directive found in FERC Order No. 791, Paragraph 150. The requirement intends to protect cabling and nonprogrammable communication components that are within an ESP, but extend outside of a PSP. This protection, similar to the FERC Approved NERC Petition on the interpretation on CIP-006-2 from PacifiCorp, must be accomplished either by physically protecting the cabling and components that leave a PSP (such as by conduit or secured cable trays) or through data encryption, circuit monitoring, or equally effective logical protections. It is intended that the physical protections reduce the possibility of tampering or allowing direct access to the nonprogrammable devices. Conduit, secured cable trays, and secured communication closets are examples of these types of protections. These physical security measures should be implemented in such a way that they would provide some mechanism to detect or recognize that someone could have tampered with the cabling and non-programmable components. This could be something as simple as a padlock on a communications closet where the entity would recognize if the padlock had been cut off. Alternatively, this protection may also be accomplished through the use of armored cabling or via the stainless steel or aluminum tube protecting the fiber inside an optical ground wire (OPGW) cable. In using any of these methods, care should be taken to protect the entire length of the cabling including any termination points that may be outside of a defined PSP.

This requirement part only covers those portions of cabling and nonprogrammable communications components that are located outside of the PSP, but inside the ESP. Where this cabling and non-programmable communications components exist inside the PSP, this requirement part no longer applies.

The requirement focuses on physical protection of the communications cabling and components as this is a requirement in a physical security standard and the gap in protection identified by FERC in Order 791 is one of physical protections. However, the requirement part recognizes that there is more than one way to provide protection to communication cabling and nonprogrammable components. In particular, the requirement provides a mechanism for entities to select an alternative to physical security protection that may be chosen in a situation where an entity cannot implement physical security or simply chooses not to implement physical security. The entity is under no obligation to justify or explain why it chose logical protections over physical protections identified in the requirement.

The alternative protective measures identified in the CIP-006-6 R1, Part 1.10 (encryption and circuit monitoring) were identified as acceptable alternatives in NERC petition of the PacifiCorp Interpretation of CIP-006-2 which was approved by FERC (RD10-13-000). If an entity chooses to implement an “an equally effective logical protection” in lieu of one of the protection mechanisms identified in the standard, the entity would be expected to document how the protection is equally effective. NERC explained in its petition of the PacifiCorp Interpretation of CIP-006-2 that the measures are relevant to access or physical tampering. Therefore, the entity may choose to discuss how its protection may provide detection of tampering. The entity may also choose to explain how its protection is equivalent to the other logical options identified in the standard in terms of the CIA triad (confidentiality, integrity, and availability). The entity may find value in reviewing their plans prior to implementation with the regional entity, but there is no obligation to do so.

The intent of the requirement is not to require physical protection of third party components, consistent with FERC Order 791-A. The requirement allows flexibility in that the entity has control of how to design its ESP and also has the ability to extend its ESP outside its PSP via the logical mechanisms specified in CIP-006-6 Requirement 1, Part 1.10 such as encryption (which is an option specifically identified in FERC Order 791-A). These mechanisms should provide sufficient protections to an entity's BES Cyber Systems while not requiring controls to be implemented on third-party components when entities rely on leased third-party communications.

In addition to the cabling, the components in scope of this requirement part are those components outside of a PSP that could otherwise be considered a BES Cyber Asset or Protected Cyber Asset except that they do not meet the definition of Cyber Asset because they are nonprogrammable. Examples of these nonprogrammable components include, but are not limited to, unmanaged switches, hubs, patch panels, media converters, port savers, and couplers.

Requirement R2:

The logging of visitors should capture each visit of the individual and does not need to capture each entry or exit during that visit. This is meant to allow a visitor to temporarily exit the PSP to obtain something they left in their vehicle or outside the area without requiring a new log entry for each and every entry during the visit.

The SDT also determined that a point of contact should be documented who can provide additional details about the visit if questions arise in the future. The point of contact could be the escort, but there is no need to document everyone that acted as an escort for the visitor.

Requirement R3:

This includes the testing of locally mounted hardware or devices used in controlling, alerting or logging access to the PSP. This includes motion sensors, electronic lock control mechanisms, and badge readers which are not deemed to be part of the Physical Access Control System but are required for the protection of the BES Cyber Systems.

Rationale:

During development of this standard, text boxes were embedded within the standard to explain the rationale for various parts of the standard. Upon BOT approval, the text from the rationale text boxes was moved to this section.

Rationale for Requirement R1:

Each Responsible Entity shall ensure that physical access to all BES Cyber Systems is restricted and appropriately managed. Entities may choose for certain Physical Access Control Systems (PACS) to reside in a PSP (PSP) controlling access to applicable BES Cyber Systems. For these PACS, there is no additional obligation to comply with Requirement R1, Parts 1.1, 1.6 and 1.7 beyond what is already required for the PSP.

Regarding Requirement R1, Part 1.10, when cabling and other nonprogrammable components of a Control Center's communication network cannot be secured in a PSP, steps must be taken to ensure the integrity of the BES Cyber Systems. Exposed communication pathways outside of a PSP necessitate that physical or logical protections be installed to reduce the likelihood that man-in-the-middle attacks could compromise the integrity of their connected BES Cyber Assets or PCAs that are required to reside within PSPs. While it is anticipated that priority consideration will be given to physically securing the cabling and nonprogrammable communications components, the SDT understands that configurations arise when physical access restrictions are not ideal and Responsible Entities are able to reasonably defend their physically exposed communications components through specific additional logical protections.

Rationale for Requirement R2:

To control when personnel without authorized unescorted physical access can be in any PSPs protecting BES Cyber Systems or Electronic Access Control or Monitoring Systems, as applicable in Table R2.

Rationale for Requirement R3:

To ensure all Physical Access Control Systems and devices continue to function properly.

Technical Rationale for Reliability Standard CIP-007-7

Introduction

This document explains the technical rationale and justification for the proposed Reliability Standard CIP-007-7. It provides stakeholders and the ERO Enterprise with an understanding of the technology and technical requirements in the Reliability Standard. This Technical Rationale and Justifications for CIP-007-7 is not a Reliability Standard and should not be considered mandatory and enforceable.

Updates to this document now include the Project 2016-02 – Modifications to CIP Standards Drafting Team's (SDT's) intent in drafting changes to the requirements.

Background

The V5TAG, which consists of representatives from NERC, Regional Entities, and industry stakeholders, was formed to issue guidance regarding possible methods to achieve compliance with the CIP V5 standards and to support industry's implementation activities. During the course of the V5TAG's activities, the V5TAG identified certain issues with the CIP Reliability Standards that were more appropriately addressed by a standard drafting team (SDT). The V5TAG developed the V5TAG Transfer Document to explain the issues and recommend that they be considered in future development activity. As Project 2016-02 was formed to address the directives in FERC Order 822 issued on January 21, 2016, that team also received addressing the V5TAG issues as part of its Standard Authorization Request (SAR).

One of the areas of issue was virtualization. The V5TAG Transfer document said, "The CIP Version 5 standards do not specifically address virtualization. However, because of the increasing use of virtualization in industrial control system environments, questions around treatment of virtualization within the CIP Standards are due for consideration. The SDT should consider revisions to CIP-005 and the definitions of Cyber Asset and Electronic Access Point that make clear the permitted architecture and address the security risks of network, server and storage virtualization technologies."

New and Modified Terms and Applicability

This standard uses new or modified terms and contains new or modified exemptions in Section 4 Applicability. The rationale for this global content can be found in "CIP Definitions and Exemptions Technical Rationale.pdf" for reference when reading the technical rationale that follows.

General Considerations
Requirement R1
General Considerations for Requirement R1

Independently identified Shared Cyber Infrastructure (SCI) is mutually exclusive from BES Cyber System (BCS) by definition. To enable CIP-007-7 for virtualization, the SDT added SCI identified independently and related it to the BCS and associated Cyber Assets already listed in Applicable Systems. This approach keeps the SCI applicability parallel to each existing variant of medium impact BCS (i.e. Medium impact BCS vs. Medium impact BCS with External Routable Connectivity (ERC) vs. Medium impact BCS at Control Centers etc.)

Change Rationale Requirement R1:

The SDT has changed the name of the R1 table to “System Hardening” to more clearly reflect the security objective of the entries in the table which is to harden the applicable systems through limiting access to logical and physical ports, and to control where certain VCAs can instantiate through host affinity rules.

The SDT chose to include “SCI identified independently…” language in the Applicable Systems column of the requirement part in order to ensure that controls which are applicable to the hardware portion of a physical Cyber Asset would remain applicable to the hardware supporting the Virtual Cyber Assets (VCA) used in applicable BCS, EACMS, PACS or PCAs.

Change Rationale Requirement R1 Part 1.1: Requirement R1 Part 1.1 adds the clarifier of Internet Protocol (IP) to the port references in order to ensure only those network accessible IP ports are within scope of this requirement. This was done in order to ensure ports such as those associated with non-IP network communications (such as with a SAN over Fiber Channel) do not fall within scope of the Requirement Part. Additionally, the option to rely on the service, if the IP port is not known, has been added to the Requirement Part.

The SDT chose to remove the reliance on a Technical Feasibility Exception in favor of the updated term “per system capability”. The SDT contends that the term still requires an entity to document the limit to the system’s capability with regards to the requirement language, while not incurring the additional documentation overhead of a Technical Feasibility Exception.

Change Rationale Requirement R1 Part 1.3:

Requirement R1 Part 1.3 is a new requirement intended to apply host affinity controls to SCI identified independently. The risk associated with an SCI identified independently is such that it may host non-CIP Systems, and therefore must be protected at a higher level than those SCI that are included within the BCS, EACMS or PACS that they support. This is one of the controls added for SCI identified independently that serves as an additional hardening control required due to this higher risk.

Requirement R2

Change Rationale Requirement R2:

The SDT chose to include "SCI identified independently…" language in the Applicable Systems column of the requirement part in order to ensure that controls which are applicable to the hardware portion of a physical Cyber Asset would remain applicable to the hardware supporting the Virtual Cyber Assets (VCA) used in applicable BCS, EACMS, PACS or PCAs.

The SDT made conforming changes where necessary with Requirement R2 to remove reliance on the Cyber Asset term, choosing to reference the system instead.

Backward Compatibility

CIP-007-7 Requirement R2 retains backward compatibility for entities without SCI identified independently.

The SDT intends that entities take full advantage of their virtualization infrastructure in order to ease the overhead associated with patch management. While many of the entity's existing processes will remain the same, (such as those associated with tracking the source of security patches, evaluation of the applicability of available patches and mitigation plans for those applicable patches that cannot be installed) new or modified processes around the installation of patches can be used (for example, parent images, remediation VLANs, etc.)

Parent Images

One of the interesting nuances of virtualization is the concept of parent/child relationships.

Some VCAs utilize a "parent image" type methodology where the specific VCA software and operating system is merely a child instance of a parent image. In such cases, the application of security patches to the parent image also applies the same changes to any children of that image. As there may be many child instances, the administrative overhead associated with patching of those instances can be greatly reduced.

Dormant Instances

There are times when VCAs are not being used and are idle. Physical instances of the assets are always left up and running in order to receive applicable patches, software updates, configuration updates, etc.

Leveraging the built in virtualization features allows idle resources to be reassigned to tasks at hand without incurring additional overhead of tracking which dormant virtual instances require patching. Dormant virtual instances are just files with the saved state of the VCA. Dormant instances are not VCAs themselves nor Applicable Systems until they become active instances again.

Where a dormant virtual instance is also the child instance of a parent image, the application of security patches to the parent image will also make the same changes automatically when needed to any out of date dormant child virtual instances when they are restarted.

In most cases, a dormant virtual child instance is made active again on a remediation type network where any missing security patches (compared to the parent image) are automatically applied before it is placed back into active service.

Saved Images

Similar to dormant child images, saved child images or snapshots may be also used as functional backups for CIP-009 purposes in order to provide fast restoration and better availability. If an active VCA becomes corrupted, a saved image can be made active where the application of any missing security patches (compared to the parent image) can be automatically applied, through remediation, before being placed back into active service.

Requirement R3

Change Rationale Requirement R3:

The SDT chose to modify the name of the Table in R3 from Malicious Code Prevention to the term used by the National Institute of Standards & Technology (NIST), Malicious Code Protection, as that more accurately clarifies the security objective of protecting BCS from malicious code.

The SDT chose to include “SCI identified independently…” language in the Applicable Systems column of the requirement part in order to ensure that controls which are applicable to the hardware portion of a physical Cyber Asset would remain applicable to the hardware supporting the Virtual Cyber Assets (VCA) used in applicable BCS, EACMS, PACS or PCAs.

Requirement R4

Change Rationale Requirement R4:

The SDT chose to include “SCI identified independently…” language in the Applicable Systems column of the requirement part in order to ensure that controls which are applicable to the hardware portion of a physical Cyber Asset would remain applicable to the hardware supporting the Virtual Cyber Assets (VCA) used in applicable BCS, EACMS, PACS or PCAs.

Change Rationale Requirement R4 Part 4.1:

The SDT determined the entire structure of the “at the BES Cyber System level (per BES Cyber System capability) or at the Cyber Asset level (per Cyber Asset capability)” language could be simplified to “per system capability” since the Applicable Systems column clarifies what systems are included.

Additionally, the SDT chose to insert the word “security” as a clarifier to which events are to be logged.

Change Rationale Requirement R4 Part 4.2:

The SDT applied conforming changes to the Requirement Part language to remove the reliance on the “Cyber Asset” term, as well as the ambiguity that would have existed if the term “BES Cyber System” were left in place while the Applicability Column included SCI.

Change Rationale Requirement R4 Part 4.3:

The SDT also chose to remove the reliance on a Technical Feasibility Exception from Part 4.3 in favor of the updated term “per system capability”. The SDT contends that the term still requires an entity to document the limit to the system’s capability with regards to the requirement language, while not incurring the additional documentation overhead of a Technical Feasibility Exception.

Requirement R5

Change Rationale Requirement R5:

The SDT chose to include “SCI identified independently…” language in the Applicable Systems column of the requirement part in order to ensure that controls which are applicable to the hardware portion of a physical Cyber Asset would remain applicable to the hardware supporting the Virtual Cyber Assets (VCA) used in applicable BCS, EACMS, PACS or PCAs.

Change Rationale Requirement R5 Parts 5.1, and 5.6 – 5.7:

The SDT chose to remove the reliance on Technical Feasibility Exception in favor of the updated term “per system capability”. The SDT contends that the term still requires an entity to document the limit to the system’s capability with regards to the requirement language, while not incurring the additional documentation overhead of a Technical Feasibility Exception.

Change Rationale Requirement R5 Part 5.5:

The SDT applied conforming changes to the Requirement Part language to remove the reliance on the “Cyber Asset” term, replacing it with a reference to the Applicable Systems.

Former Background Section from Reliability Standard CIP-007-6

The section **6. Background** has been retired and removed from the Standard, and preserved by cutting and pasting as-is below.

Background

Standard CIP-005 exists as part of a suite of CIP Standards related to cyber security, which require the initial identification and categorization of BES Cyber Systems and require a minimum level of organizational, operational and procedural controls to mitigate risk to BES Cyber Systems.

Most requirements open with, "*Each Responsible Entity shall implement one or more documented [processes, plan, etc.] that include the applicable items in [Table Reference].*" The referenced table requires the applicable items in the procedures for the requirement's common subject matter.

The term *documented processes* refers to a set of required instructions specific to the Responsible Entity and to achieve a specific outcome. This term does not imply any particular naming or approval structure beyond what is stated in the requirements. An entity should include as much as it believes necessary in its documented processes, but it must address the applicable requirements in the table.

The terms *program* and *plan* are sometimes used in place of *documented processes* where it makes sense and is commonly understood. For example, documented processes describing a response are typically referred to as *plans* (i.e., incident response plans and recovery plans). Likewise, a security plan can describe an approach involving multiple procedures to address a broad subject matter.

Similarly, the term *program* may refer to the organization's overall implementation of its policies, plans, and procedures involving a subject matter. Examples in the standards include the personnel risk assessment program and the personnel training program. The full implementation of the CIP Cyber Security Standards could also be referred to as a program. However, the terms *program* and *plan* do not imply any additional requirements beyond what is stated in the standards.

Responsible Entities can implement common controls that meet requirements for multiple high and medium impact BES Cyber Systems. For example, a single training program could meet the requirements for training personnel across multiple BES Cyber Systems.

Measures for the initial requirement are simply the documented processes themselves. Measures in the table rows provide examples of evidence to show documentation and implementation of applicable items in the documented processes. These measures serve to provide guidance to entities in acceptable records of compliance and should not be viewed as an all-inclusive list.

Throughout the standards, unless otherwise stated, bulleted items in the requirements and measures are items that are linked with an "or," and numbered items are items that are linked with an "and."

Many references in the Applicability section use a threshold of 300 MW for UFLS and UVLS. This particular threshold of 300 MW for UVLS and UFLS was provided in Version 1 of the CIP Cyber Security Standards. The threshold remains at 300 MW since it is specifically addressing UVLS and UFLS, which are last ditch efforts to save the Bulk Electric System. A review of UFLS tolerances defined within regional reliability standards for UFLS program requirements to date indicates that the historical value of 300 MW represents an adequate and reasonable threshold value for allowable UFLS operational tolerances.

"Applicable Systems" Columns in Tables:

Each table has an "Applicable Systems" column to further define the scope of systems to which a specific requirement row applies. The CSO706 SDT adapted this concept from the National Institute of Standards and Technology ("NIST") Risk Management Framework as a way of applying requirements more appropriately based on impact and connectivity characteristics. The following conventions are used in the "Applicability Systems" column as described.

- **High Impact BES Cyber Systems** – Applies to BES Cyber Systems categorized as high impact according to the CIP-002-5.1 identification and categorization processes.
- **Medium Impact BES Cyber Systems** – Applies to BES Cyber Systems categorized as medium impact according to the CIP-002-5.1 identification and categorization processes.
- **Medium Impact BES Cyber Systems at Control Centers** – Only applies to medium impact BES Cyber Systems located at a Control Center.
- **Medium Impact BES Cyber Systems with External Routable Connectivity** – Only applies to medium impact BES Cyber Systems with External Routable Connectivity. This also excludes Cyber Assets in the BES Cyber System that cannot be directly accessed through External Routable Connectivity.
- **Electronic Access Control or Monitoring Systems (EACMS)** – Applies to each Electronic Access Control or Monitoring System associated with a referenced high impact BES Cyber System or medium impact BES Cyber System. Examples may include, but are not limited to, firewalls, authentication servers, and log monitoring and alerting systems.
- **Physical Access Control Systems (PACS)** – Applies to each Physical Access Control System associated with a referenced high impact BES Cyber System or medium impact BES Cyber System.
- **Protected Cyber Assets (PCA)** – Applies to each Protected Cyber Asset associated with a referenced high impact BES Cyber System or medium impact BES Cyber System.

Technical Rational for Reliability Standard CIP-007-6

This section contains a "cut and paste" of the former Guidelines and Technical Basis (GTB) as-is of from CIP-007-6 standard to preserve any historical references. No modifications have been made.

Guidelines and Technical Basis

Section 4 – Scope of Applicability of the CIP Cyber Security Standards

Section "4. Applicability" of the standards provides important information for Responsible Entities to determine the scope of the applicability of the CIP Cyber Security Requirements.

Section "4.1. Functional Entities" is a list of NERC functional entities to which the standard applies. If the entity is registered as one or more of the functional entities listed in Section 4.1, then the NERC CIP Cyber Security Standards apply. Note that there is a qualification in Section 4.1 that restricts the applicability in the case of Distribution Providers to only those that own certain types of systems and equipment listed in 4.2.

Section "4.2. Facilities" defines the scope of the Facilities, systems, and equipment owned by the Responsible Entity, as qualified in Section 4.1, that is subject to the requirements of the standard. As specified in the exemption section 4.2.3.5, this standard does not apply to Responsible Entities that do not have High Impact or Medium Impact BES Cyber Systems under CIP-002-5.1's categorization. In addition to the set of BES Facilities, Control Centers, and other systems and equipment, the list includes the set of systems and equipment owned by Distribution Providers. While the NERC Glossary term "Facilities" already includes the BES characteristic, the additional use of the term BES here is meant to reinforce the scope of applicability of these Facilities where it is used, especially in this applicability scoping section. This in effect sets the scope of Facilities, systems, and equipment that is subject to the standards.

Requirement R1:

Requirement R1 exists to reduce the attack surface of Cyber Assets by requiring entities to disable known unnecessary ports. The SDT intends for the entity to know what network accessible ("listening") ports and associated services are accessible on their assets and systems, whether they are needed for that Cyber Asset's function, and disable or restrict access to all other ports.

1.1. This requirement is most often accomplished by disabling the corresponding service or program that is listening on the port or configuration settings within the Cyber Asset. It can also be accomplished through using host-based firewalls, TCP_Wrappers, or other means on the Cyber Asset to restrict access. Note that the requirement is applicable at the Cyber Asset level. The Cyber Assets are those which comprise the applicable BES Cyber Systems and their associated Cyber Assets. This control is another layer in the defense against network-based attacks, therefore the SDT intends that the control be on the device itself, or positioned inline in a non-bypassable manner. Blocking ports at the ESP border does not substitute for this device level requirement. If a device has no provision for disabling or restricting logical ports on the device (example - purpose built devices that run from firmware with no port configuration available) then those ports that are open are deemed 'needed.'

1.2. Examples of physical I/O ports include network, serial and USB ports external to the device casing. BES Cyber Systems should exist within a Physical Security Perimeter in which case the physical I/O ports have protection from unauthorized access, but it may still be possible for accidental use such as connecting a modem, connecting a network cable that bridges networks, or inserting a USB drive. Ports used for 'console commands' primarily means serial ports on Cyber Assets that provide an administrative interface.

The protection of these ports can be accomplished in several ways including, but not limited to:

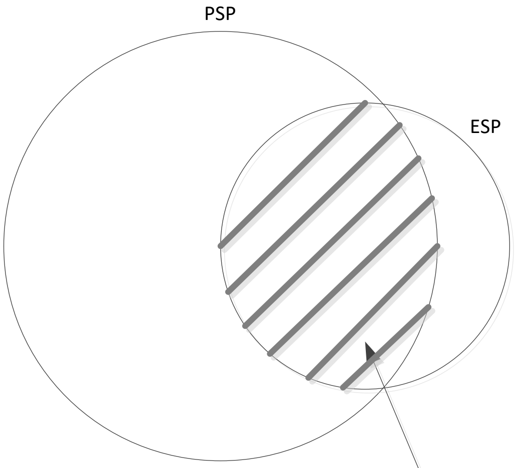
- Disabling all unneeded physical ports within the Cyber Asset's configuration
- Prominent signage, tamper tape, or other means of conveying that the ports should not be used without proper authorization
- Physical port obstruction through removable locks

The network ports included in the scope of this requirement part are not limited to those on the BES Cyber System itself. The scope of physical network ports includes those ports that may exist on nonprogrammable devices such as unmanaged switches, hubs, or patch panels.

This is a 'defense in depth' type control and it is acknowledged that there are other layers of control (the PSP for one) that prevent unauthorized personnel from gaining physical access to these ports. Even with physical access, it has been pointed out there are other ways to circumvent the control. This control, with its inclusion of means such as signage, is not meant to be a preventative control against intruders. Signage is indeed a directive control, not a preventative one. However, with a defense-in-depth posture, different layers and types of controls are required throughout the standard with this providing another layer for depth in Control Center environments. Once physical access has been achieved through the other preventative and detective measures by authorized personnel, a directive control that outlines proper behavior as a last line of defense is appropriate in these highest risk areas. In essence, signage would be used to remind authorized users to "think before you plug anything into one of these systems" which is the intent. This control is not designed primarily for intruders, but for example the authorized employee who intends to plug his possibly infected smartphone into an operator console USB port to charge the battery.

The Applicable Systems column was updated on CIP-007-6 Requirement 1, Part 1.2 to include "Nonprogrammable communication components located inside both a PSP and an ESP." This should be interpreted to apply to only those nonprogrammable communication components that are inside both an ESP and a PSP in combination, not those components that are in only one perimeter as can be illustrated in the following diagram:

Location of Nonprogrammable Communication Components



Applicability of CIP-007-6 R1, Part 1.2 for Nonprogrammable Communication Components

Requirement R2:

The SDT's intent of Requirement R2 is to require entities to know, track, and mitigate the known software vulnerabilities associated with their BES Cyber Assets. It is not strictly an "install every security patch" requirement; the main intention is to "be aware of in a timely manner and manage all known vulnerabilities" requirement.

Patch management is required for BES Cyber Systems that are accessible remotely as well as standalone systems. Standalone systems are vulnerable to intentional or unintentional introduction of malicious code. A sound defense-in-depth security strategy employs additional measures such as physical security, malware prevention software, and software patch management to reduce the introduction of malicious code or the exploit of known vulnerabilities.

One or multiple processes could be utilized. An overall assessment process may exist in a top tier document with lower tier documents establishing the more detailed process followed for individual systems. Lower tier documents could be used to cover BES Cyber System nuances that may occur at the system level.

2.1. The Responsible Entity is to have a patch management program that covers tracking, evaluating, and installing cyber security patches. The requirement applies to patches only, which are fixes released to handle a specific vulnerability in a hardware or software product. The requirement covers only patches that involve cyber security fixes and does not cover patches that are purely functionality related with no cyber security impact. Tracking involves processes for notification of the availability of new cyber security patches for the Cyber Assets. Documenting the patch source in the tracking portion of the process is required to determine when the assessment timeframe clock starts. This requirement handles the situation where security patches can come from an original source (such as an operating system vendor), but must be approved or certified by another source (such as a control system vendor) before they can be assessed and applied in order to not jeopardize the availability or integrity of the control system. The source can take many forms. The National Vulnerability Database, Operating System vendors, or Control System vendors could all be sources to monitor for release of security related patches, hotfixes, and/or updates. A patch source is not required for Cyber Assets that have no updateable software or firmware (there is no user accessible way to update the internal software or firmware executing on the Cyber Asset), or those Cyber Assets that have no existing source of patches such as vendors that no longer exist. The identification of these sources is intended to be performed once unless software is changed or added to the Cyber Asset's baseline.

2.2. Responsible Entities are to perform an assessment of security related patches within 35 days of release from their monitored source. An assessment should consist of determination of the applicability of each patch to the entity's specific environment and systems. Applicability determination is based primarily on whether the patch applies to a specific software or hardware component that the entity does have installed in an applicable Cyber Asset. A patch that applies to a service or component that is not installed in the entity's environment is not applicable. If the patch is determined to be non-applicable, that is documented with the reasons why and the entity is compliant. If the patch is applicable, the assessment can include a determination of the risk involved, how the vulnerability can be remediated, the urgency and timeframe of the remediation, and the steps the entity has previously taken or will take. Considerable care must be taken in applying security related patches, hotfixes, and/or updates or applying compensating measures to BES Cyber System or BES Cyber Assets that are no longer supported by vendors. It is possible security patches, hotfixes, and updates may reduce the reliability of the system, and entities should take this into account when determining the type of mitigation to apply. The Responsible Entities can use the information provided in the Department of Homeland Security "Quarterly Report on Cyber Vulnerabilities of Potential Risk to Control Systems" as a source. The DHS document "Recommended Practice for Patch Management of Control Systems" provides guidance on an evaluative process. It uses severity levels determined using the Common Vulnerability Scoring System Version 2. Determination that a security related patch, hotfix, and/or update poses too great a risk to install on a system or is not applicable due to the system configuration should not require a TFE.

When documenting the remediation plan measures it may not be necessary to document them on a one to one basis. The remediation plan measures may be cumulative. A measure to address a software vulnerability may involve disabling a particular service. That same service may be exploited through other software vulnerabilities. Therefore disabling the single service has addressed multiple patched vulnerabilities.

2.3. The requirement handles the situations where it is more of a reliability risk to patch a running system than the vulnerability presents. In all cases, the entity either installs the patch or documents (either through the creation of a new or update of an existing mitigation plan) what they are going to do to mitigate the vulnerability and when they are going to do so. There are times when it is in the best interest of reliability to not install a patch, and the entity can document what they have done to mitigate the vulnerability. For those security related patches that are determined to be applicable, the Responsible Entity must within 35 days either install the patch, create a dated mitigation plan which will outline the actions to be taken or those that have already been taken by the Responsible Entity to mitigate the vulnerabilities addressed by the security patch, or revise an existing mitigation plan. Timeframes do not have to be designated as a particular calendar day but can have event designations such as "at next scheduled outage of at least two days duration." "Mitigation plans" in the standard refers to internal documents and are not to be confused with plans that are submitted to Regional Entities in response to violations.

2.4. The entity has been notified of, has assessed, and has developed a plan to remediate the known risk and that plan must be implemented. Remediation plans that only include steps that have been previously taken are considered implemented upon completion of the documentation. Remediation plans that have steps to be taken to remediate the vulnerability must be implemented by the timeframe the entity documented in their plan. There is no maximum timeframe in this requirement as patching and other system changes carries its own risk to the availability and integrity of the systems and may require waiting until a planned outage. In periods of high demand or threatening weather, changes to systems may be curtailed or denied due to the risk to reliability.

Requirement R3:

3.1. Due to the wide range of equipment comprising the BES Cyber Systems and the wide variety of vulnerability and capability of that equipment to malware as well as the constantly evolving threat and resultant tools and controls, it is not practical within the standard to prescribe how malware is to be addressed on each Cyber Asset. Rather, the Responsible Entity determines on a BES Cyber System basis which Cyber Assets have susceptibility to malware intrusions and documents their plans and processes for addressing those risks and provides evidence that they follow those plans and processes. There are numerous options available including traditional antivirus solutions for common operating systems, white-listing solutions, network isolation techniques, Intrusion Detection/Prevention (IDS/IPS) solutions, etc. If an entity has numerous BES Cyber Systems or Cyber Assets that are of identical architecture, they may provide one process that describes how all the like Cyber Assets are covered. If a specific Cyber Asset has no updateable software and its executing code cannot be altered, then that Cyber Asset is considered to have its own internal method of deterring malicious code.

3.2. When malicious code is detected on a Cyber Asset within the applicability of this requirement, the threat posed by that code must be mitigated. In situations where traditional antivirus products are used, they may be configured to automatically remove or quarantine the malicious code. In white-listing situations, the white-listing tool itself can mitigate the threat as it will not allow the code to execute, however steps should still be taken to remove the malicious code from the Cyber Asset. In some instances, it may be in the best interest of reliability to not immediately remove or quarantine the malicious code, such as when availability of the system may be jeopardized by removal while operating and a rebuild of the system needs to be scheduled. In that case, monitoring may be increased and steps taken to insure the malicious code cannot communicate with other systems. In some instances the entity may be working with law enforcement or other governmental entities to closely monitor the code and track the perpetrator(s). For these reasons, there is no maximum timeframe or method prescribed for the removal of the malicious code, but the requirement is to mitigate the threat posed by the now identified malicious code.

Entities should also have awareness of malware protection requirements for Transient Cyber Assets and Removable Media (“transient devices”) in CIP-010-2. The protections required here in CIP-007-6, Requirement R3 complement, but do not meet, the additional obligations for transient devices.

3.3. In instances where malware detection technologies depend on signatures or patterns of known attacks, the effectiveness of these tools against evolving threats is tied to the ability to keep these signatures and patterns updated in a timely manner. The entity is to have a documented process that includes the testing and installation of signature or pattern updates. In a BES Cyber System, there may be some Cyber Assets that would benefit from the more timely installation of the updates where availability of that Cyber Asset would not jeopardize the availability of the BES Cyber System's ability to perform its function. For example, some HMI workstations where portable media is utilized may benefit from having the very latest updates at all times with minimal testing. Other Cyber Assets should have any updates thoroughly tested before implementation where the result of a 'false positive' could harm the availability of the BES Cyber System. The testing should not negatively impact the reliability of the BES. The testing should be focused on the update itself and if it will have an adverse impact on the BES Cyber System. Testing in no way implies that the entity is testing to ensure that malware is indeed detected by introducing malware into the environment. It is strictly focused on ensuring that the update does not negatively impact the BES Cyber System before those updates are placed into production.

Requirement R4:

Refer to NIST 800-92 and 800-137 for additional guidance in security event monitoring.

4.1. In a complex computing environment and faced with dynamic threats and vulnerabilities, it is not practical within the standard to enumerate all security-related events necessary to support the activities for alerting and incident response. Rather, the Responsible Entity determines which computer generated events are necessary to log, provide alerts and monitor for their particular BES Cyber System environment.

Specific security events already required in Version 4 of the CIP Standards carry forward in this version. This includes access attempts at the Electronic Access Points, if any have been identified for a BES Cyber Systems. Examples of access attempts include: (i) blocked network access attempts, (ii) successful and unsuccessful remote user access attempts, (iii) blocked network access attempts from a remote VPN, and (iv) successful network access attempts or network flow information.

User access and activity events include those events generated by Cyber Assets within the Electronic Security Perimeter that have access control capability. These types of events include: (i) successful and unsuccessful authentication, (ii) account management, (iii) object access, and (iv) processes started and stopped.

It is not the intent of the SDT that if a device cannot log a particular event that a TFE must be generated. The SDT's intent is that if any of the items in the bulleted list (for example, user logouts) can be logged by the device then the entity must log that item. If the device does not have the capability of logging that event, the entity remains compliant.

4.2. Real-time alerting allows the cyber system to automatically communicate events of significance to designated responders. This involves configuration of a communication mechanism and log analysis rules. Alerts can be configured in the form of an email, text message, or system display and alarming. The log analysis rules can exist as part of the operating system, specific application or a centralized security event monitoring system. On one end, a real-time alert could consist of a set point on an RTU for a login failure, and on the other end, a security event monitoring system could provide multiple alerting communications options triggered on any number of complex log correlation rules.

The events triggering a real-time alert may change from day to day as system administrators and incident responders better understand the types of events that might be indications of a cyber-security incident. Configuration of alerts also must balance the need for responders to know an event occurred with the potential inundation of insignificant alerts. The following list includes examples of events a Responsible Entity should consider in configuring real-time alerts:

- Detected known or potential malware or malicious activity
- Failure of security event logging mechanisms

- Login failures for critical accounts
- Interactive login of system accounts
- Enabling of accounts
- Newly provisioned accounts
- System administration or change tasks by an unauthorized user
- Authentication attempts on certain accounts during non-business hours
- Unauthorized configuration changes
- Insertion of Removable Media in violation of a policy

4.3 Logs that are created under Part 4.1 are to be retained on the applicable Cyber Assets or BES Cyber Systems for at least 90 days. This is different than the evidence retention period called for in the CIP standards used to prove historical compliance. For such audit purposes, the entity should maintain evidence that shows that 90 days were kept historically. One example would be records of disposition of event logs beyond 90 days up to the evidence retention period.

4.4. Reviewing logs at least every 15 days (approximately every two weeks) can consist of analyzing a summarization or sampling of logged events. NIST SP800-92 provides a lot of guidance in periodic log analysis. If a centralized security event monitoring system is used, log analysis can be performed top-down starting with a review of trends from summary reports. The log review can also be an extension of the exercise in identifying those events needing real-time alerts by analyzing events that are not fully understood or could possibly inundate the real-time alerting.

Requirement R5:

Account types referenced in this guidance typically include:

- Shared user account: An account used by multiple users for normal business functions by employees or contractors. Usually on a device that does not support Individual User Accounts.
- Individual user account: An account used by a single user.
- Administrative account: An account with elevated privileges for performing administrative or other specialized functions. These can be individual or shared accounts.
- System account: Accounts used to run services on a system (web, DNS, mail etc.). No users have access to these accounts.
- Application account: A specific system account, with rights granted at the application level often used for access into a Database.
- Guest account: An individual user account not typically used for normal business functions by employees or contractors and not associated with a specific user. May or may not be shared by multiple users.
- Remote access account: An individual user account only used for obtaining Interactive Remote Access to the BES Cyber System.
- Generic account: A group account set up by the operating system or application to perform specific operations. This differs from a shared user account in that individual users do not receive authorization for access to this account type.

5.1 Reference the Requirement’s rationale.

5.2 Where possible, default and other generic accounts provided by a vendor should be removed, renamed, or disabled prior to production use of the Cyber Asset or BES Cyber System. If this is not possible, the passwords must be changed from the default provided by the vendor. Default and other generic accounts remaining enabled must be documented. For common configurations, this documentation can be performed at a BES Cyber System or more general level.

5.3 Entities may choose to identify individuals with access to shared accounts through the access authorization and provisioning process, in which case the individual authorization records suffice to meet this Requirement Part. Alternatively, entities may choose to maintain a separate listing for shared accounts. Either form of evidence achieves the end result of maintaining control of shared accounts.

5.4. Default passwords can be commonly published in vendor documentation that is readily available to all customers using that type of equipment and possibly published online.

The requirement option to have unique password addresses cases where the Cyber Asset generates or has assigned pseudo-random default passwords at the time of production or installation. In these cases, the default password does not have to change because the system or manufacturer created it specific to the Cyber Asset.

5.5. Interactive user access does not include read-only information access in which the configuration of the Cyber Asset cannot change (e.g. front panel displays, web-based reports, etc.). For devices that cannot technically or for operational reasons perform authentication, an entity may demonstrate all interactive user access paths, both remote and local, are configured for authentication. Physical security suffices for local access configuration if the physical security can record who is in the Physical Security Perimeter and at what time.

Technical or procedural enforcement of password parameters are required where passwords are the only credential used to authenticate individuals. Technical enforcement of the password parameters means a Cyber Asset verifies an individually selected password meets the required parameters before allowing the account to authenticate with the selected password. Technical enforcement should be used in most cases when the authenticating Cyber Asset supports enforcing password parameters. Likewise, procedural enforcement means requiring the password parameters through procedures. Individuals choosing the passwords have the obligation of ensuring the password meets the required parameters.

Password complexity refers to the policy set by a Cyber Asset to require passwords to have one or more of the following types of characters: (1) lowercase alphabetic, (2) uppercase alphabetic, (3) numeric, and (4) non-alphanumeric or “special” characters (e.g. #, $, @, &), in various combinations.

5.6 Technical or procedural enforcement of password change obligations are required where passwords are the only credential used to authenticate individuals. Technical enforcement of password change obligations means the Cyber Asset requires a password change after a specified timeframe prior to allowing access. In this case, the password is not required to change by the specified time as long as the Cyber Asset enforces the password change after the next successful authentication of the account. Procedural enforcement means manually changing passwords used for interactive user access after a specified timeframe.

5.7 Configuring an account lockout policy or alerting after a certain number of failed authentication attempts serves to prevent unauthorized access through an online password guessing attack. The threshold of failed authentication attempts should be set high enough to avoid false-positives from authorized users failing to authenticate. It should also be set low enough to account for online password attacks occurring over an extended period of time. This threshold may be tailored to the operating environment over time to avoid unnecessary account lockouts.

Entities should take caution when configuring account lockout to avoid locking out accounts necessary for the BES Cyber System to perform a BES reliability task. In such cases, entities should configure authentication failure alerting.

Rationale:

During development of this standard, text boxes were embedded within the standard to explain the rationale for various parts of the standard. Upon BOT approval, the text from the rationale text boxes was moved to this section.

Rationale for Requirement R1:

The requirement is intended to minimize the attack surface of BES Cyber Systems through disabling or limiting access to unnecessary network accessible logical ports and services and physical I/O ports.

In response to FERC Order No. 791, specifically FERC's reference to NIST 800-53 rev. 3 security control PE-4 in paragraph 149, Part 1.2 has been expanded to include PCAs and nonprogrammable communications components. This increase in applicability expands the scope of devices that receive the protection afforded by the defense-in-depth control included in Requirement R1, Part 1.2.

The applicability is limited to those nonprogrammable communications components located both inside a PSP and an ESP in order to allow for a scenario in which a Responsible Entity may implement an extended ESP (with corresponding logical protections identified in CIP-006, Requirement R1, Part 1.10). In this scenario, nonprogrammable components of the communication network may exist out of the Responsible Entity's control (i.e. as part of the telecommunication carrier's network).

Rationale for Requirement R2:

Security patch management is a proactive way of monitoring and addressing known security vulnerabilities in software before those vulnerabilities can be exploited in a malicious manner to gain control of or render a BES Cyber Asset or BES Cyber System inoperable.

Rationale for Requirement R3:

Malicious code prevention has the purpose of limiting and detecting the addition of malicious code onto the applicable Cyber Assets of a BES Cyber System. Malicious code (viruses, worms, botnets, targeted code such as Stuxnet, etc.) may compromise the availability or integrity of the BES Cyber System.

Rationale for Requirement R4:

Security event monitoring has the purpose of detecting unauthorized access, reconnaissance and other malicious activity on BES Cyber Systems, and comprises of the activities involved with the collection, processing, alerting and retention of security-related computer logs. These logs can provide both (1) the detection of an incident and (2) useful evidence in the investigation of an incident. The retention of security-related logs is intended to support post-event data analysis.

Audit processing failures are not penalized in this requirement. Instead, the requirement specifies processes which must be in place to monitor for and notify personnel of audit processing failures.

Rationale for Requirement R5:

To help ensure that no authorized individual can gain electronic access to a BES Cyber System until the individual has been authenticated, i.e., until the individual's logon credentials have been validated. Requirement R5 also seeks to reduce the risk that static passwords, where used as authenticators, may be compromised.

Requirement Part 5.1 ensures the BES Cyber System or Cyber Asset authenticates individuals that can modify configuration information. This requirement addresses the configuration of authentication. The authorization of individuals is addressed elsewhere in the CIP Cyber Security Standards. Interactive user access does not include read-only information access in which the configuration of the Cyber Asset cannot change (e.g. front panel displays, web-based reports, etc.). For devices that cannot technically or for operational reasons perform authentication, an entity may demonstrate all interactive user access paths, both remote and local, are configured for authentication. Physical security suffices for local access configuration if the physical security can record who is in the Physical Security Perimeter and at what time.

Requirement Part 5.2 addresses default and other generic account types. Identifying the use of default or generic account types that could introduce vulnerabilities has the benefit ensuring entities understand the possible risk these accounts pose to the BES Cyber System. The Requirement Part avoids prescribing an action to address these accounts because the most effective solution is situation specific, and in some cases, removing or disabling the account could have reliability consequences.

Requirement Part 5.3 addresses identification of individuals with access to shared accounts. This Requirement Part has the objective of mitigating the risk of unauthorized access through shared accounts. This differs from other CIP Cyber Security Standards Requirements to authorize access. An entity can authorize access and still not know who has access to a shared account. Failure to identify individuals with access to shared accounts would make it difficult to revoke access when it is no longer needed. The term “authorized” is used in the requirement to make clear that individuals storing, losing, or inappropriately sharing a password is not a violation of this requirement.

Requirement 5.4 addresses default passwords. Changing default passwords closes an easily exploitable vulnerability in many systems and applications. Pseudo-randomly system generated passwords are not considered default passwords.

For password-based user authentication, using strong passwords and changing them periodically helps mitigate the risk of successful password cracking attacks and the risk of accidental password disclosure to unauthorized individuals. In these requirements, the drafting team considered multiple approaches to ensuring this requirement was both effective and flexible enough to allow Responsible Entities to make good security decisions. One of the approaches considered involved requiring minimum password entropy, but the calculation for true information entropy is more highly complex and makes several assumptions in the passwords users choose. Users can pick poor passwords well below the calculated minimum entropy.

The drafting team also chose to not require technical feasibility exceptions for devices that cannot meet the length and complexity requirements in password parameters. The objective of this requirement is to apply a measurable password policy to deter password cracking attempts, and replacing devices to achieve a specified password policy does not meet this objective. At the same time, this requirement has been strengthened to require account lockout or alerting for failed login attempts, which in many instances better meets the requirement objective.

The requirement to change passwords exists to address password cracking attempts if an encrypted password were somehow attained and also to refresh passwords which may have been accidentally disclosed over time. The requirement permits the entity to specify the periodicity of change to accomplish this objective. Specifically, the drafting team felt determining the appropriate periodicity based on a number of factors is more effective than specifying the period for every BES Cyber System in the Standard. In general, passwords for user authentication should be changed at least annually. The periodicity may increase in some cases. For example, application passwords that are long and pseudo-randomly generated could have a very long periodicity. Also, passwords used only as a weak form of application authentication, such as accessing the configuration of a relay may only need to be changed as part of regularly scheduled maintenance.

The Cyber Asset should automatically enforce the password policy for individual user accounts. However, for shared accounts in which no mechanism exists to enforce password policies, the Responsible Entity can enforce the password policy procedurally and through internal assessment and audit.

Requirement Part 5.7 assists in preventing online password attacks by limiting the number of guesses an attacker can make. This requirement allows either limiting the number of failed authentication attempts or alerting after a defined number of failed authentication attempts. Entities should take caution in choosing to limit the number of failed authentication attempts for all accounts because this would allow the possibility for a denial of service attack on the BES Cyber System.

Technical Rationale for Reliability Standard CIP-008-7

Introduction

This document explains the technical rationale and justification for the proposed Reliability Standard CIP-008-7. It provides stakeholders and the ERO Enterprise with an understanding of the technology and technical requirements in the Reliability Standard. This Technical Rationale and Justifications for CIP-008-7 is not a Reliability Standard and should not be considered mandatory and enforceable.

Updates to this document now include the Project 2016-02 – Modifications to CIP Standards Drafting Team's (SDT's) intent in drafting changes to the requirements.

Background

The Version 5 Transition advisory Group (V5TAG), which consists of representatives from NERC, Regional Entities, and industry stakeholders, was formed to issue guidance regarding possible methods to achieve compliance with the CIP V5 standards and to support industry's implementation activities. During the course of the V5TAG's activities, the V5TAG identified certain issues with the CIP Reliability Standards that were more appropriately addressed by a standard drafting team (SDT). The V5TAG developed the V5TAG Transfer Document to explain the issues and recommend that they be considered in future development activity. As Project 2016-02 was formed to address the directives in FERC Order 822 issued on January 21, 2016, that team also received the V5TAG issues as part of its Standard Authorization Request (SAR).

One of the areas of issue was virtualization. The V5TAG Transfer document said, "The CIP Version 5 standards do not specifically address virtualization. However, because of the increasing use of virtualization in industrial control system environments, questions around treatment of virtualization within the CIP Standards are due for consideration. The SDT should consider revisions to CIP-005 and the definitions of Cyber Asset and Electronic Access Point that make clear the permitted architecture and address the security risks of network, server and storage virtualization technologies."

New and Modified Terms and Applicability

This standard uses new or modified terms and contains new or modified exemptions in Section 4 Applicability. The rationale for this global content can be found in "CIP Definitions and Exemptions Technical Rationale" document for reference when reading the technical rationale that follows.

Requirement R1 – Requirement R4

Rationale

The Project 2016-02 SDT made conforming changes to Reliability Standard CIP-008-6 to align incident reporting and response planning requirements with the virtualization changes.

The SDT added the option (known as the "all-in" scenario) for entities to group SCI within a BCS it supports; Therefore, to enable CIP-008-7 for virtualization, the SDT added "SCI identified independently supporting an Applicable System above" each of the Parts in Applicable Systems for Requirement R1 – Requirement R4 to account for the alternative option (See the CIP-002 Technical Rationale document for a description of the options for identifying SCI and reasons an entity may choose between the options.)

Requirement R4

Rationale

The Project 2016-02 SDT made updates to reflect the change from the National Cybersecurity and Communications integration Center (NCCIC) to its successor organization Cybersecurity & Infrastructure Security Agency (CISA), and deleted the superfluous footnote in favor of deference to the Requirement language, which already states, “or their successors”.

Former Background Section from Reliability Standard CIP-008-6

The section **6. Background** has been retired and removed from the Standard, and preserved by cutting and pasting as-is below.

Background

Standard CIP-008 exists as part of a suite of CIP Standards related to cyber security. CIP-002 requires the initial identification and categorization of BES Cyber Systems. CIP-003, CIP-004, CIP-005, CIP-006, CIP-007, CIP-008, CIP-009, CIP-010, and CIP-011 require a minimum level of organizational, operational, and procedural controls to mitigate risk to BES Cyber Systems.

Most requirements open with, "*Each Responsible Entity shall implement one or more documented [processes, plan, etc.] that include the applicable items in [Table Reference].*" The referenced table requires the applicable items in the procedures for the requirement's common subject matter.

The term *documented processes* refers to a set of required instructions specific to the Responsible Entity and to achieve a specific outcome. This term does not imply any particular naming or approval structure beyond what is stated in the requirements. An entity should include as much as it believes necessary in its documented processes, but must address the applicable requirements in the table.

The terms *program* and *plan* are sometimes used in place of *documented processes* where it is commonly understood. For example, documented processes describing a response are typically referred to as *plans* (i.e., incident response plans and recovery plans). Likewise, a security plan can describe an approach involving multiple procedures to address a broad subject matter.

Similarly, the term *program* may refer to the organization's overall implementation of its policies, plans and procedures involving a particular subject matter. Examples in the standards include the personnel risk assessment program and the personnel training program. The full implementation of the CIP Cyber Security Standards could also be referred to as a program. However, the terms *program* and *plan* do not imply any additional requirements beyond what is stated in the standards.

Responsible Entities can implement common controls that meet requirements for multiple high and medium impact BES Cyber Systems. For example, a single training program could meet the requirements for training personnel across multiple BES Cyber Systems.

Measures for the initial requirement are simply the documented processes themselves. Measures in the table rows provide examples of evidence to show documentation and implementation of applicable items in the documented processes. These measures serve to provide guidance to entities in acceptable records of compliance and should not be viewed as an all-inclusive list.

Throughout the standards, unless otherwise stated, bulleted items in the requirements and measures are items that are linked with an "or," and numbered items are items that are linked with an "and."

Many references in the Applicability section use a threshold of 300 MW for UFLS and UVLS. This particular threshold of 300 MW for UVLS and UFLS was provided in Version 1 of the CIP Cyber Security Standards. The threshold remains at 300 MW since it is specifically addressing UVLS and UFLS, which are last ditch efforts to save the Bulk Electric System. A review of UFLS tolerances defined within regional reliability standards for UFLS program requirements to date indicates that the historical value of 300 MW represents an adequate and reasonable threshold value for allowable UFLS operational tolerances.

“Applicable Systems” Columns in Tables:

Each table has an “Applicable Systems” column to further define the scope of systems to which a specific requirement row applies. The CSO706 SDT adapted this concept from the National Institute of Standards and Technology (“NIST”) Risk Management Framework as a way of applying requirements more appropriately based on impact and connectivity characteristics. The following conventions are used in the “Applicable Systems” column as described.

High Impact BES Cyber Systems – Applies to BES Cyber Systems categorized as high impact according to the CIP-002 identification and categorization processes.

Medium Impact BES Cyber Systems – Applies to BES Cyber Systems categorized as medium impact according to the CIP-002 identification and categorization processes.

Technical Rationale for Reliability Standard CIP-008-6

Introduction

This document explains the technical rationale and justification for the proposed Reliability Standard CIP-008-6. It provides stakeholders and the ERO Enterprise with an understanding of the technology and technical requirements in the Reliability Standard. It also contains information on the Standard Drafting Team's (SDT's) intent in drafting the requirements. This Technical Rationale and Justification for CIP-008-6 is not a Reliability Standard and should not be considered mandatory and enforceable.

On July 19, 2018, the Federal Energy Regulatory Commission (FERC or Commission) issued Order No. 848. In this Order FERC directed the North American Electric Reliability Corporation (NERC) to "develop and submit modifications to the Reliability Standards to require the reporting of Cyber Security Incidents that compromise, or attempt to compromise, a responsible entity's Electronic Security Perimeter (ESP) or associated Electronic Access and Control or Monitoring System (EACMS)." (Order 848, Paragraph 1)

In response to the directive in Order No. 848, the Project 2018-02 SDT drafted Reliability Standard CIP-008-6 to require Responsible Entities to implement methods augmenting the mandatory reporting of Cyber Security Incidents to include: "(1) responsible entities must report Cyber Security Incidents that compromise, or attempt to compromise, a responsible entity's ESP; (2) required information in Cyber Security Incident reports should include certain minimum information to improve the quality of reporting and allow for ease of comparison by ensuring that each report included specified fields of information; (3) filing deadlines for Cyber Security Incident reports should be established once a compromise or disruption to reliable BES operation, or an attempted compromise or disruption, is identified by a responsible entity; and (4) Cyber Security Incident reports should continue to be sent to the Electricity Information Sharing and Analysis Center (E-ISAC), rather than the Commission, but the reports should also be sent to the Department of Homeland Security (DHS) Industrial Control System Cyber Emergency Response Team (ICS-CERT)." (Order 848, Paragraph 3)[1]

New and Modified Terms Used in NERC Reliability Standards

CIP-006-6 uses the following definition(s), which are cited below for reference when reading the technical rationale that follows.

Proposed Modified Terms:

Cyber Security Incident

A malicious act or suspicious event that:

- *For a high or medium impact BES Cyber System, compromises, or attempts to compromise the, (1) an Electronic Security Perimeter, (2) a Physical Security Perimeter, or (3) an Electronic Access Control or Monitoring System; or*
- *Disrupts, or attempts to disrupt, the operation of a BES Cyber System.*

In response to FERC Order 848, Paragraph 1, the SDT modified the Cyber Security Incident definition to include Electronic Access Control or Monitoring Systems (EACMS) associated with high or medium impact BES Cyber Systems, in response to the Order.

---

[1] The National Cybersecurity and Communications Integration Center (NCCIC) is the successor organization of the Industrial Control Systems Cyber Emergency Response Team (ICS-CERT). In 2017, NCCIC realigned its organizational structure and integrated like functions previously performed independently by the ICS-CERT and the United States Computer Emergency Readiness Team (US-CERT).

The addition of high and medium impact BES Cyber Systems considers the potential unintended consequences with the use of the existing definition in CIP-003-7. It also provides clarity that only low impact BES Cyber Systems are included within the definition. ESP or EACMs that may be defined by an entity for low impact BES Cyber Systems are not part of the definition.

An attempt to disrupt the operation of a BES Cyber System is meant to include, among other things, a compromise of a single BES Cyber Asset within a BES Cyber System. For example, malware discovered on a BES Cyber Asset is an attempt to disrupt the operation of that BES Cyber System.

Reportable Cyber Security Incident

A Cyber Security Incident that compromised or disrupted:

- *A BES Cyber System that performs one or more reliability tasks of a functional entity;*
- *An Electronic Security Perimeter of a high or medium impact BES Cyber System; or*
- *An Electronic Access Control or Monitoring System of a high or medium impact BES Cyber Systems.*

The Reportable Cyber Security Incident definition was modified to comply with FERC Order 848. In response to Paragraph 54 of the Order, the SDT modified the definition to include incidents that compromised or disrupted an ESP or an EACMS. The team also added the qualifying clause for “A BES Cyber System that performs one or more reliability tasks of a functional entity” to clarify what was compromised or disrupted, thus not extending the scope to Protected Cyber Assets (PCAs). In response to comments, the SDT left the entire definition of BES Cyber system in Reportable Cyber Security Incident to provide clarity.

It is also important to understand the relationship between the two definitions, the requirement language, and how they work in concert to classify events and conditions at varied levels of significance as the Registered Entity executes its process and applies its defined criteria to determine if reporting is required.

Electronic Access Control or Monitoring Systems (EACMS)

The drafting team spent significant time discussing this topic among its members, through industry outreach, and with FERC staff. The team believes by not specifically referencing the five functions in Order 848, we have reduced complexity and made compliance with the Standard achievable. The drafting team asserts that the five functions are equivalent to the current definition of EACMS in the NERC Glossary of Terms. If entities have questions about application of the EACMS definition, the drafting team advises entities to discuss those questions directly with NERC.

Requirements R1, R2, and R3

General Considerations for Requirement R1, Requirement R2, and Requirement R3

FERC Order 848, Paragraph 1, directs modifications to Reliability Standards to require reporting of incidents that compromise, or attempt to compromise a responsible entity's ESP or associated EACMS. The intent of the SDT was to minimize the changes within CIP-008 and address the required modifications. To do this, the SDT added "and their associated EACMS" to the "Applicable Systems" column for Requirements R1, R2, and R3.

To add clarity to "attempts to compromise," the drafting team created Part 1.2.1 to require entities to establish and document their process to include criteria to evaluate and define attempts to compromise. This requirement maps to Requirement 4 Part 4.2, which requires entities to use that entity-defined process for determining which incidents entities must report.

The use of the language describing Cyber Security Incident(s) as being "an attempt to compromise, as determined by applying the criteria from Part 1.2.1, one or more systems identified in the 'Applicable Systems'" column for the Part is meant to clarify which Cyber Assets are in scope for attempts to compromise reporting by entities. This language is used throughout the standard.

Moving Parts of Requirement R1 to Requirement R4

To minimize the changes to Requirement R1, the SDT created Requirement R4 and consolidated all the CIP-008-6 reporting requirements. The SDT deleted Requirement R1 Part 1.2 reporting requirements from CIP-008-5, and moved them to Requirement R4 for this purpose.

Inclusion of "Successor Organizations" throughout the Requirement Parts

The SDT recognizes that organizations are constantly evolving to meet emerging needs, and may re-organize or change their names over time. The ICS-CERT has completed its name change to the National Cybersecurity and Communications Integration Center (NCCIC) Industrial Control Systems. The E-ISAC previously re-branded its name and may again in the future. By following Requirement R4 references to E-ISAC and NCCIC with "or their successors" the SDT is ensuring that Requirement R4 can be implemented even if the names of E-ISAC and NCCIC change or a different agency takes over their current roles.

Requirement R4

General Considerations for Requirement R4

Requirement R4 is a new requirement focused on mandatory reporting of Reportable Cyber Security Incidents and includes attempts to compromise systems in the "Applicable Systems" column. Previously, CIP-008-5 defined reporting requirements for Reportable Cyber Security Requirements (Requirement R1 Part 1.2) only.

Required Reportable Incident Attributes

Requirement R4.1 specifies that initial notifications and updates must include three attributes: 1) functional impact, 2) attack vector used, and 3) level of intrusion achieved or attempted. These attributes are taken directly from the Order. (FERC Order No. 848, paragraph 89).

The SDT understands that some or all of these attributes may be unknown at time of initial notification. To account for this scenario the SDT included "to the extent known" in the requirement language. There is an expectation that update reporting will be done as new information is determined or unknown attributes become known by the entity. There could be cases, due to operational need, that all the attributes may never be known, if this case presents itself that information should be reported.

Methods for Submitting Notifications

Requirement R4 Part 4.2 allows responsible entities to submit notification using any method supported by E-ISAC and NCCIC. The SDT did not prescribe a particular reporting method or format to allow responsible entities' personnel to focus on incident response itself and not the method or format of reporting. It is important to note the report must contain the three attributes required in Requirement R4 Part 4.1 as they are known, regardless of reporting method or format.

Notification Timing

Requirement R4 Part 4.2 specifies two timelines for initial notification submission; one hour for Reportable Cyber Security Incidents; and end of next calendar day for attempts to compromise systems in the "Applicable Systems" column. Paragraph 3 of FERC Order No 848 directly states that reporting deadlines must be established. Paragraph 89 further states that "timelines that are commensurate with the adverse impact to the BES that loss, compromise, or misuse of those BES Cyber Systems could have on the reliable operation of the BES."

- *Reportable Cyber Security Incidents* – The SDT wrote Requirement R4 Part R4.2 to use a one hour deadline for reporting of these events because incidents in this category include successful compromise of ESP(s), EACMS, or BES Cyber System(s). One hour is referenced directly in FERC Order No 848 paragraph 89 and is also the current reporting requirement in CIP-008-5.
- *Cyber Security Incident that was an attempt to compromise one or more systems identified in the "Applicable Systems" column* - Due to the lower severity of these unsuccessful attempts at compromising ESP(s), EACMS, or BES Cyber System(s), the SDT proposed a longer reporting timeframe. The intent behind the decision to add "By the end of the next calendar day" (11:59 pm local time) was to give responsible entities additional time to gather facts prior to notifications for the less severe attempts to compromise Applicable Systems. It is important to note that compliance timing begins with the entity's determination that attempt to compromise meets the process they defined in Requirement R1 Part 1.2.1.

The SDT understands initial notification may not have all the details when first submitted. It is expected, however, that information that has been determined is reported within the notification deadlines. Additionally, it is important to note the wording in Requirement R4 Part 4.2. The "compliance clock" for the report timing begins when the Responsible Entity executes its process from Requirement R1 Part 1.2.1 and a determination has been made that the type of incident which has occurred qualifies as reportable.

Technical rationale taken from the Guidelines and Technical Basis (GTB) CIP-008-5 Requirement 1 provides additional justification for the SDT to maintain the one hour timeframe for Reportable Cyber Security Incidents.

> *"The reporting obligations for Reportable Cyber Security Incidents require at least a preliminary notice to the ES-ISAC within one hour after determining that a Cyber Security Incident is reportable (not within one hour of the Cyber Security Incident, an important distinction). This addition is in response to the directive addressing this issue in FERC Order No. 706, paragraphs 673 and 676, to report within one hour (at least preliminarily). This standard does not require a complete report within an hour of determining that a Cyber Security Incident is reportable, but at least preliminary notice, which may be a phone call, an email, or sending a Web-based notice. The standard does not require a specific timeframe for completing the full report."*

In 2007, the Electricity Information Sharing and Analysis Center (E-ISAC) was known as the Electricity Sector Information Sharing and Analysis Center (ES-ISAC). Its voluntary procedures required the reporting of a cyber-incident within one hour of an incident. CIP-008-1 required entities to report to the ES-ISAC.

In FERC Order No. 706[2] (July 18, 2008), the Commission concluded that the one-hour reporting limit was reasonable [P 663]. The Commission further stated that it was leaving the details to NERC, but it wanted the reporting timeframe to run from the "**discovery**" of the incident by the entity, and not the actual **"occurrence"** of the incident [P 664].

CIP-008-2 and CIP-008-3 were silent regarding the required timeframe for reporting, but it was specifically addressed in CIP-008-5. In the October 26, 2012, redlined version of CIP-008-5, the proposed language for initial notification originally specified "one hour from **identification**" of an incident. This aligned with the Commission's decision in Order No. 706, for the clock to start with the discovery of an incident. However, the Standard Drafting Team changed "one hour from identification" to "one hour from the **determination** of a Reportable Cyber Security Incident". This language was subsequently approved and incorporated into CIP-008-5.

These changes, from "occurrence" to "discovery" to "determination," provide the additional time needed for the entity to apply its specifically created process(es) for determining whether a Cyber Security Incident rises to the level of required reporting. This determination timeframe may include a preliminary investigation of the incident which will provide useful information to other entities to help defend against similar attacks.

---

[2] 2008, Federal Energy Regulatory Commission, Mandatory Reliability Standards for Critical Infrastructure Protection, Order No. 706.

Notification Updates

Requirement R4 Part 4.3 requires that Responsible Entities submit updates for the required attributes upon determination of new or changed attribute information, if any. The SDT added this language to provide entities sufficient time to determine attribute information, which may be unknown at the time of initial notification, and which may change as more information is gathered. The intent of Requirement R4 Part 4.3 is to provide a method for Responsible Entities to report new information over time as their investigations progress. NOTE: The SDT does not intend updates specified in Requirement R4. Part 4.3 to expose responsible entities to potential violations if, for example, initial and updated notification on the same attribute have different information. This is expected since knowledge of attributes may change as investigations proceed. Rather, the intent of Requirement R4 Part 4.3 is to have a mechanism to report incident information to E-ISAC and NCCIC (and thereby industry) upon determination of each required attribute.

The intent is that the entity report what is known and document the reason not all attributes could become known and ultimately be reported in conditions where, e.g. a Cyber Asset was restored completely, removing all forensic evidence in order to restore operations, which caused the entity to conclude its investigation without having a complete knowledge of the three required attributes.

The SDT asserts that nothing included in the new reporting Requirement R4, precludes the entity from continuing to provide any voluntary sharing they may already be conducting today.

Technical Rationale for Reliability Standard CIP-008-5

This section contains the Guidelines and Technical basis as a “cut and paste” from CIP-008-5 standard to preserve any historical references.

Section “4. Applicability” of the standards provides important information for Responsible Entities to determine the scope of the applicability of the CIP Cyber Security Requirements.

Section “4.1. Functional Entities” is a list of NERC functional entities to which the standard applies. If the entity is registered as one or more of the functional entities listed in Section 4.1, then the NERC CIP Cyber Security Standards apply. Note that there is a qualification in Section 4.1 that restricts the applicability in the case of Distribution Providers to only those that own certain types of systems and equipment listed in 4.2. Furthermore,

Section “4.2. Facilities” defines the scope of the Facilities, systems, and equipment owned by the Responsible Entity, as qualified in Section 4.1, that is subject to the requirements of the standard. As specified in the exemption section 4.2.3.5, this standard does not apply to Responsible Entities that do not have High Impact or Medium Impact BES Cyber Systems under CIP-002-5’s categorization. In addition to the set of BES Facilities, Control Centers, and other systems and equipment, the list includes the set of systems and equipment owned by Distribution Providers. While the NERC Glossary term “Facilities” already includes the BES characteristic, the additional use of the term BES here is meant to reinforce the scope of applicability of these Facilities where it is used, especially in this applicability scoping section. This in effect sets the scope of Facilities, systems, and equipment that is subject to the standards.

Requirement R1:

The reporting obligations for Reportable Cyber Security Incidents require at least a preliminary notice to the ES-ISAC within one hour after determining that a Cyber Security Incident is reportable (not within one hour of the Cyber Security Incident, an important distinction). This addition is in response to the directive addressing this issue in FERC Order No. 706, paragraphs 673 and 676, to report within one hour (at least preliminarily). This standard does not require a complete report within an hour of determining that a Cyber Security Incident is reportable, but at least preliminary notice, which may be a phone call, an email, or sending a Web-based notice. The standard does not require a specific timeframe for completing the full report.

Requirement R2:

Requirement R2 ensures entities periodically test the Cyber Security Incident response plan. This includes the requirement in Part 2.2 to ensure the plan is actually used when testing. The testing requirements are specifically for Reportable Cyber Security Incidents.

Entities may use an actual response to a Reportable Cyber Security Incident as a substitute for exercising the plan annually. Otherwise, entities must exercise the plan with a paper drill, tabletop exercise, or full operational exercise.

In addition to the requirements to implement the response plan, Part 2.3 specifies entities must retain relevant records for Reportable Cyber Security Incidents. There are several examples of specific types of evidence listed in the measure.

Requirement R3:

This requirement ensures entities maintain Cyber Security Incident response plans. There are two requirement parts that trigger plan updates: (1) lessons learned from Part 3.1 and (2) organizational or technology changes from Part 3.2.

The documentation of lessons learned from Part 3.1 is associated with each Reportable Cyber Security Incident and involves the activities as illustrated in Figure 1, below. The deadline to document lessons learned starts after the completion of the incident in recognition that complex incidents on complex systems can take a few days or weeks to complete response activities. It is possible to have a *Reportable Cyber Security Incident* without any documented lessons learned. In such cases, the entity must retain documentation of the absence of any lessons learned associated with the *Reportable Cyber Security Incident*.

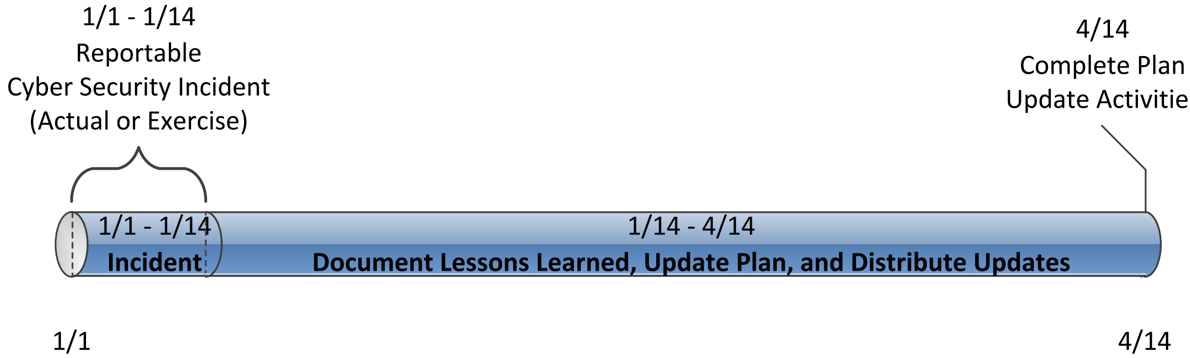

Figure 1: CIP-008-5 R3 Timeline for Reportable Cyber Security Incidents

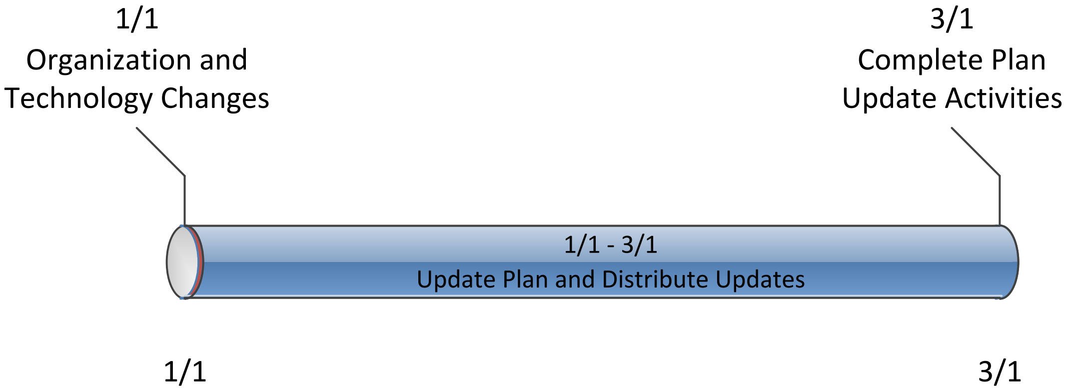
The activities necessary to complete the lessons learned include updating the plan and distributing those updates.

The plan change requirement in Part 3.2 is associated with organization and technology changes referenced in the plan and involves the activities illustrated in Figure 2, below. Organizational changes include changes to the roles and responsibilities people have in the plan or changes to the response groups or individuals.

Figure 2: Timeline for Plan Changes in 3.2



Rationale for R1:

The implementation of an effective Cyber Security Incident response plan mitigates the risk to the reliable operation of the BES caused as the result of a Cyber Security Incident and provides feedback to Responsible Entities for improving the security controls applying to BES Cyber Systems. Preventative activities can lower the number of incidents, but not all incidents can be prevented. A preplanned incident response capability is therefore necessary for rapidly detecting incidents, minimizing loss and destruction, mitigating the weaknesses that were exploited, and restoring computing services.

Summary of Changes: Wording changes have been incorporated based primarily on industry feedback to more specifically describe required actions.

Reference to prior version: (Part 1.1) CIP-008, R1.1

Change Description and Justification: (Part 1.1)
"Characterize" has been changed to "identify" for clarity. "Response actions" has been changed to "respond to" for clarity.

Reference to prior version: (Part 1.2) CIP-008, R1.1

Change Description and Justification: (Part 1.2)
Addresses the reporting requirements from previous versions of CIP-008. This requirement part only obligates entities to have a process for determining Reportable Cyber Security Incidents. Also addresses the directive in FERC Order No. 706, paragraphs 673 and 676 to report within one hour (at least preliminarily).

Reference to prior version: (Part 1.3) CIP-008, R1.2

Change Description and Justification: (Part 1.3)
Replaced incident response teams with incident response "groups or individuals" to avoid the interpretation that roles and responsibilities sections must reference specific teams.

Reference to prior version: (Part 1.4) CIP-008, R1.2

Change Description and Justification: (Part 1.4)
Conforming change to reference new defined term Cyber Security Incidents.

Rationale for R2:

The implementation of an effective Cyber Security Incident response plan mitigates the risk to the reliable operation of the BES caused as the result of a Cyber Security Incident and provides feedback to Responsible Entities for improving the security controls applying to BES Cyber Systems. This requirement ensures implementation of the response plans. Requirement Part 2.3 ensures the retention of incident documentation for post event analysis.

This requirement obligates entities to follow the Cyber Security Incident response plan when an incident occurs or when testing, but does not restrict entities from taking needed deviations from the plan. It ensures the plan represents the actual response and does not exist for documentation only.

Summary of Changes: Added testing requirements to verify the Responsible Entity's response plan's effectiveness and consistent application in responding to a Cyber Security Incident(s) impacting a BES Cyber System.

Reference to prior version: (Part 2.1) CIP-008, R1.6

Change Description and Justification: (Part 2.1)
Minor wording changes; essentially unchanged.

Reference to prior version: (Part 2.2) CIP-008, R1.6

Change Description and Justification: (Part 2.2)
Allows deviation from plan(s) during actual events or testing if deviations are recorded for review.

Reference to prior version: (Part 2.3) CIP-008, R2

Change Description and Justification: (Part 2.3)
Removed references to the retention period because the Standard addresses data retention in the Compliance Section.

Rationale for R3:

Conduct sufficient reviews, updates and communications to verify the Responsible Entity's response plan's effectiveness and consistent application in responding to a Cyber Security Incident(s) impacting a BES Cyber System. A separate plan is not required for those requirement parts of the table applicable to High or Medium Impact BES Cyber Systems. If an entity has a single Cyber Security Incident response plan and High or Medium Impact BES Cyber Systems, then the additional requirements would apply to the single plan.

Summary of Changes: Changes here address the FERC Order 706, Paragraph 686, which includes a directive to perform after-action review for tests or actual incidents and update the plan based on lessons learned. Additional changes include specification of what it means to review the plan and specification of changes that would require an update to the plan.

Reference to prior version: (Part 3.1) CIP-008, R1.5

Change Description and Justification: (Part 3.1)
Addresses FERC Order 706, Paragraph 686 to document test or actual incidents and lessons learned.

Reference to prior version: (Part 3.2) CIP-008, R1.4

Change Description and Justification: (Part 3.2)
Specifies the activities required to maintain the plan. The previous version required entities to update the plan in response to any changes. The modifications make clear the changes that would require an update

Technical Rationale for Reliability Standard CIP-009-7

Introduction

This document explains the technical rationale and justification for the proposed Reliability Standard CIP-009-7. It provides stakeholders and the ERO Enterprise with an understanding of the technology and technical requirements in the Reliability Standard. This Technical Rationale and Justifications for CIP-009-7 is not a Reliability Standard and should not be considered mandatory and enforceable.

Updates to this document now include the Project 2016-02 – Modifications to CIP Standards Drafting Team's (SDT's) intent in drafting changes to the requirements.

Background

The Version 5 Transition advisory Group (V5TAG), which consists of representatives from NERC, Regional Entities, and industry stakeholders, was formed to issue guidance regarding possible methods to achieve compliance with the CIP V5 standards and to support industry's implementation activities. During the course of the V5TAG's activities, the V5TAG identified certain issues with the CIP Reliability Standards that were more appropriately addressed by a standard drafting team (SDT). The V5TAG developed the V5TAG Transfer Document to explain the issues and recommend that they be considered in future development activity. As Project 2016-02 was formed to address the directives in FERC Order 822 issued on January 21, 2016, that team also received addressing the V5TAG issues as part of its Standard Authorization Request (SAR).

One of the areas of issue was virtualization. The V5TAG Transfer document said, "The CIP Version 5 standards do not specifically address virtualization. However, because of the increasing use of virtualization in industrial control system environments, questions around treatment of virtualization within the CIP Standards are due for consideration. The SDT should consider revisions to CIP-005 and the definitions of Cyber Asset and Electronic Access Point that make clear the permitted architecture and address the security risks of network, server and storage virtualization technologies."

New and Modified Terms and Applicability

This standard uses new or modified terms and contains new or modified exemptions in Section 4 Applicability. The rationale for this global content can be found in "CIP Definitions and Exemptions Technical Rationale" document for reference when reading the technical rationale that follows.

Requirement R1 – Requirement R3

Rationale

The Project 2016-02 SDT made conforming changes to Reliability Standard CIP-009-7 to align recovery planning requirements with the virtualization changes.

The SDT added the option (known as the “all-in” scenario) for entities to group SCI within a BCS it supports. Therefore, to enable CIP-009-7 for virtualization, the SDT added “SCI identified independently supporting an Applicable System above” each of the Parts in Applicable Systems for Requirement R1 – Requirement R3 to account for the alternative option (See the CIP-002 Technical Rationale document for a description of the options for identifying SCI and reasons an entity may choose between the options.) Additionally, the use of the term BES Cyber System has been replaced with “Applicable System” within the requirement language of Requirement R1 Part 1.3 and Requirement R2 Part 2.2 to align the requirement with the applicability for each Requirement Part.

Former Background Section from Reliability Standard CIP-009-6

The section **6. Background** has been retired and removed from the Standard, and preserved by cutting and pasting as-is below.

Background

Standard CIP-009 exists as part of a suite of CIP Standards related to cyber security, which require the initial identification and categorization of BES Cyber Systems and require a minimum level of organizational, operational, and procedural controls to mitigate risk to BES Cyber Systems.

Most requirements open with, "*Each Responsible Entity shall implement one or more documented [processes, plan, etc.] that include the applicable items in [Table Reference].*" The referenced table requires the applicable items in the procedures for the requirement's common subject matter.

The term *documented processes* refers to a set of required instructions specific to the Responsible Entity and to achieve a specific outcome. This term does not imply any particular naming or approval structure beyond what is stated in the requirements.

An entity should include as much as it believes necessary in their documented processes, but they must address the applicable requirements in the table.

The terms *program* and *plan* are sometimes used in place of *documented processes* where it makes sense and is commonly understood. For example, documented processes describing a response are typically referred to as *plans* (i.e., incident response plans and recovery plans). Likewise, a security plan can describe an approach involving multiple procedures to address a broad subject matter.

Similarly, the term *program* may refer to the organization's overall implementation of its policies, plans and procedures involving a subject matter. Examples in the standards include the personnel risk assessment program and the personnel training program. The full implementation of the CIP Cyber Security Standards could also be referred to as a program. However, the terms *program* and *plan* do not imply any additional requirements beyond what is stated in the standards.

Responsible Entities can implement common controls that meet requirements for multiple high and medium impact BES Cyber Systems. For example, a single training program could meet the requirements for training personnel across multiple BES Cyber Systems.

Measures for the initial requirement are simply the documented processes themselves. Measures in the table rows provide examples of evidence to show documentation and implementation of applicable items in the documented processes. These measures serve to provide guidance to entities in acceptable records of compliance and should not be viewed as an all-inclusive list.

Throughout the standards, unless otherwise stated, bulleted items in the requirements and measures are items that are linked with an "or," and numbered items are items that are linked with an "and."

Many references in the Applicability section use a threshold of 300 MW for UFLS and UVLS. This particular threshold of 300 MW for UVLS and UFLS was provided in Version 1 of the CIP Cyber Security Standards. The threshold remains at 300 MW since it is specifically addressing UVLS and UFLS, which are last ditch efforts to save the Bulk Electric System. A review of UFLS tolerances defined within regional reliability standards for UFLS program requirements to date indicates that the historical value of 300 MW represents an adequate and reasonable threshold value for allowable UFLS operational tolerances.

"Applicable Systems" Columns in Tables:

Each table has an "Applicable Systems" column to further define the scope of systems to which a specific requirement row applies. The CSO706 SDT adapted this concept from the National Institute of Standards and Technology ("NIST") Risk Management Framework as a way of applying requirements more appropriately based on impact and connectivity characteristics. The following conventions are used in the "Applicable Systems" column as described.

- **High Impact BES Cyber Systems** – Applies to BES Cyber Systems categorized as high impact according to the CIP-002-5.1 identification and categorization processes.
- **Medium Impact BES Cyber Systems** – Applies to BES Cyber Systems categorized as medium impact according to the CIP-002-5.1 identification and categorization processes.
- **Medium Impact BES Cyber Systems at Control Centers** – Only applies to BES Cyber Systems located at a Control Center and categorized as medium impact according to the CIP-002-5.1 identification and categorization processes.
- **Electronic Access Control or Monitoring Systems (EACMS)** – Applies to each Electronic Access Control or Monitoring System associated with a referenced high impact BES Cyber System or medium impact BES Cyber System. Examples include, but are not limited to firewalls, authentication servers, and log monitoring and alerting systems.
- **Physical Access Control Systems (PACS)** – Applies to each Physical Access Control System associated with a referenced high impact BES Cyber System or medium impact BES Cyber System with External Routable Connectivity.

Technical Rationale for Reliability Standard CIP-009-6

This section contains a "cut and paste" of the former Guidelines and Technical Basis (GTB) as-is of from CIP-009-6 standard to preserve any historical references. No modifications have been made.

Guidelines and Technical Basis

Section 4 – Scope of Applicability of the CIP Cyber Security Standards

Section "4. Applicability" of the standards provides important information for Responsible Entities to determine the scope of the applicability of the CIP Cyber Security Requirements.

Section "4.1. Functional Entities" is a list of NERC functional entities to which the standard applies. If the entity is registered as one or more of the functional entities listed in Section 4.1, then the NERC CIP Cyber Security Standards apply. Note that there is a qualification in Section 4.1 that restricts the applicability in the case of Distribution Providers to only those that own certain types of systems and equipment listed in 4.2.

Section "4.2. Facilities" defines the scope of the Facilities, systems, and equipment owned by the Responsible Entity, as qualified in Section 4.1, that is subject to the requirements of the standard. As specified in the exemption section 4.2.3.5, this standard does not apply to Responsible Entities that do not have High Impact or Medium Impact BES Cyber Systems under CIP-002-5.1's categorization. In addition to the set of BES Facilities, Control Centers, and other systems and equipment, the list includes the set of systems and equipment owned by Distribution Providers. While the NERC Glossary term "Facilities" already includes the BES characteristic, the additional use of the term BES here is meant to reinforce the scope of applicability of these Facilities where it is used, especially in this applicability scoping section. This in effect sets the scope of Facilities, systems, and equipment that is subject to the standards.

Requirement R1:

The following guidelines are available to assist in addressing the required components of a recovery plan:

- NERC, Security Guideline for the Electricity Sector: Continuity of Business Processes and Operations Operational Functions, September 2011, online at http://www.nerc.com/docs/cip/sgwg/Continuity%20of%20Business%20and%20Operational%20Functions%20FINAL%20102511.pdf
- National Institute of Standards and Technology, Contingency Planning Guide for Federal Information Systems, Special Publication 800-34 revision 1, May 2010, online at http://csrc.nist.gov/publications/nistpubs/800-34-rev1/sp800-34-rev1_errata-Nov11-2010.pdf

The term recovery plan is used throughout this Reliability Standard to refer to a documented set of instructions and resources needed to recover reliability functions performed by BES Cyber Systems. The recovery plan may exist as part of a larger business continuity or disaster recovery plan, but the term does not imply any additional obligations associated with those disciplines outside of the Requirements.

A documented recovery plan may not be necessary for each applicable BES Cyber System. For example, the short-term recovery plan for a BES Cyber System in a specific substation may be managed on a daily basis by advanced power system applications such as state estimation, contingency and remedial action, and outage scheduling. One recovery plan for BES Cyber Systems should suffice for several similar facilities such as those found in substations or power plants.

For Part 1.1, the conditions for activation of the recovery plan should consider viable threats to the BES Cyber System such as natural disasters, computing equipment failures, computing environment failures, and Cyber Security Incidents. A business impact analysis for the BES Cyber System may be useful in determining these conditions.

For Part 1.2, entities should identify the individuals required for responding to a recovery operation of the applicable BES Cyber System.

For Part 1.3, entities should consider the following types of information to recover BES Cyber System functionality:

1. Installation files and media;
2. Current backup tapes and any additional documented configuration settings;
3. Documented build or restoration procedures; and
4. Cross site replication storage.

For Part 1.4, the processes to verify the successful completion of backup processes should include checking for: (1) usability of backup media, (2) logs or inspection showing that information from current, production system could be read, and (3) logs or inspection showing that information was written to the backup media. Test restorations are not required for this Requirement Part. The following backup scenarios provide examples of effective processes to verify successful completion and detect any backup failures:

- Periodic (e.g. daily or weekly) backup process – Review generated logs or job status reports and set up notifications for backup failures.
- Non-periodic backup process– If a single backup is provided during the commissioning of the system, then only the initial and periodic (every 15 months) testing must be done. Additional testing should be done as necessary and can be a part of the configuration change management program.
- Data mirroring – Configure alerts on the failure of data transfer for an amount of time specified by the entity (e.g. 15 minutes) in which the information on the mirrored disk may no longer be useful for recovery.
- Manual configuration information – Inspect the information used for recovery prior to storing initially and periodically (every 15 months). Additional inspection should be done as necessary and can be a part of the configuration change management program.

The plan must also include processes to address backup failures. These processes should specify the response to failure notifications or other forms of identification.

For Part 1.5, the recovery plan must include considerations for preservation of data to determine the cause of a Cyber Security Incident. Because it is not always possible to initially know if a Cyber Security Incident caused the recovery activation, the data preservation procedures should be followed until such point a Cyber Security Incident can be ruled out. CIP-008 addresses the retention of data associated with a Cyber Security Incident.

Requirement R2:

A Responsible Entity must exercise each BES Cyber System recovery plan every 15 months. However, this does not necessarily mean that the entity must test each plan individually. BES Cyber Systems that are numerous and distributed, such as those found at substations, may not require an individual recovery plan and the associated redundant facilities since reengineering and reconstruction may be the generic response to a severe event. Conversely, there is typically one control center per bulk transmission service area that requires a redundant or backup facility. Because of these differences, the recovery plans associated with control centers differ a great deal from those associated with power plants and substations.

A recovery plan test does not necessarily cover all aspects of a recovery plan and failure scenarios, but the test should be sufficient to ensure the plan is up to date and at least one restoration process of the applicable cyber systems is covered.

Entities may use an actual recovery as a substitute for exercising the plan every 15 months. Otherwise, entities must exercise the plan with a paper drill, tabletop exercise, or operational exercise. For more specific types of exercises, refer to the FEMA Homeland Security Exercise and Evaluation Program (HSEEP). It lists the following four types of discussion-based exercises: seminar, workshop, tabletop, and games. In particular, it defines that, “A tabletop exercise involves key personnel discussing simulated scenarios in an informal setting. [Table top exercises (TTX)] can be used to assess plans, policies, and procedures.”

The HSEEP lists the following three types of operations-based exercises: Drill, functional exercise, and full-scale exercise. It defines that, “[A] full-scale exercise is a multi-agency, multi-jurisdictional, multi-discipline exercise involving functional (e.g., joint field office, Emergency operation centers, etc.) and ‘boots on the ground’ response (e.g., firefighters decontaminating mock victims).”

For Part 2.2, entities should refer to the backup and storage of information required to recover BES Cyber System functionality in Requirement Part 1.3. This provides additional assurance that the information will actually recover the BES Cyber System as necessary. For most complex computing equipment, a full test of the information is not feasible. Entities should determine the representative sample of information that provides assurance in the processes for Requirement Part 1.3. The test must include steps for ensuring the information is useable and current. For backup media, this can include testing a representative sample to make sure the information can be loaded, and checking the content to make sure the information reflects the current configuration of the applicable Cyber Assets.

Requirement R3:

This requirement ensures entities maintain recovery plans. There are two requirement parts that trigger plan updates: (1) lessons learned and (2) organizational or technology changes.

The documentation of lessons learned is associated with each recovery activation, and it involves the activities as illustrated in Figure 1, below. The deadline to document lessons learned starts after the completion of the recovery operation in recognition that complex recovery activities can take a few days or weeks to complete. The process of conducting lessons learned can involve the recovery team discussing the incident to determine gaps or areas of improvement within the plan. It is possible to have a recovery activation without any documented lessons learned. In such cases, the entity must retain documentation of the absence of any lessons learned associated with the recovery activation.

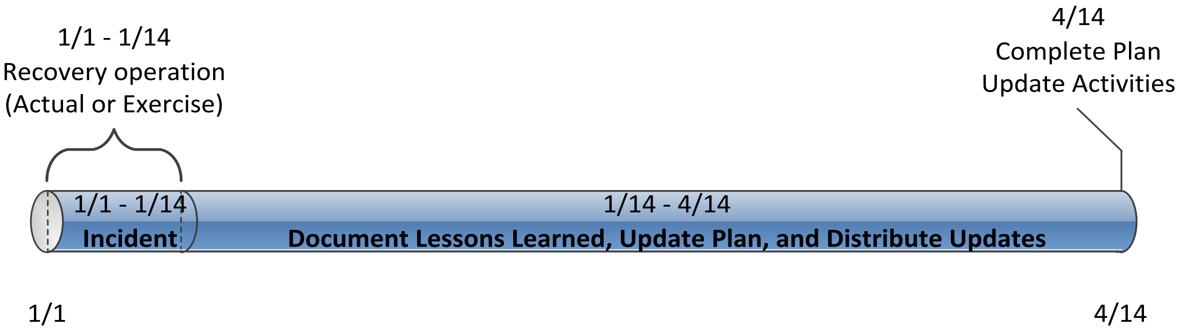

Figure 1: CIP-009-6 R3 Timeline

The activities necessary to complete the lessons learned include updating the plan and distributing those updates. Entities should consider meeting with all of the individuals involved in the recovery and documenting the lessons learned as soon after the recovery activation as possible. This allows more time for making effective updates to the plan, obtaining any necessary approvals, and distributing those updates to the recovery team.

The plan change requirement is associated with organization and technology changes referenced in the plan and involves the activities illustrated in Figure 2, below. Organizational changes include changes to the roles and responsibilities people have in the plan or changes to the response groups or individuals. This may include changes to the names or contact information listed in the plan. Technology changes affecting the plan may include referenced information sources, communication systems, or ticketing systems.

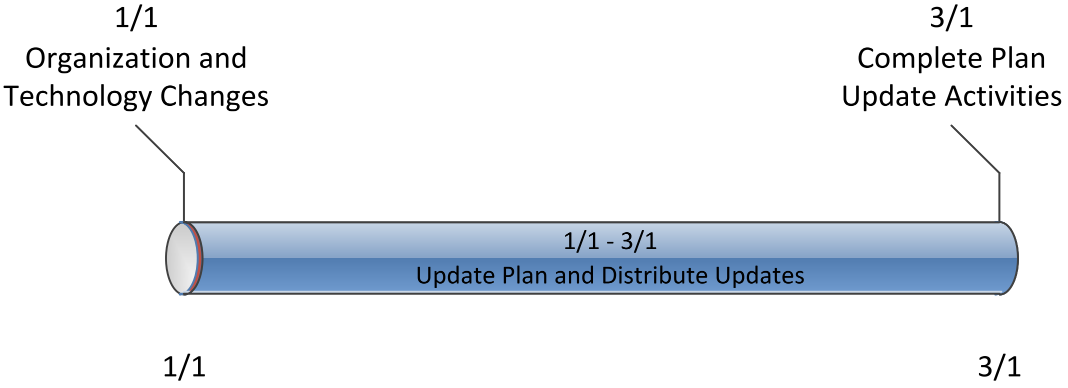

Figure 2: Timeline for Plan Changes in 3.2

When notifying individuals of response plan changes, entities should keep in mind that recovery plans may be considered BES Cyber System Information, and they should take the appropriate measures to prevent unauthorized disclosure of recovery plan information. For example, the recovery plan itself, or other sensitive information about the recovery plan, should be redacted from Email or other unencrypted transmission.

Rationale:

During development of this standard, text boxes were embedded within the standard to explain the rationale for various parts of the standard. Upon BOT approval, the text from the rationale text boxes was moved to this section.

Rationale for Requirement R1:

Preventative activities can lower the number of incidents, but not all incidents can be prevented. A preplanned recovery capability is, therefore, necessary for rapidly recovering from incidents, minimizing loss and destruction, mitigating the weaknesses that were exploited, and restoring computing services so that planned and consistent recovery action to restore BES Cyber System functionality occurs.

Rationale for Requirement R2:

The implementation of an effective recovery plan mitigates the risk to the reliable operation of the BES by reducing the time to recover from various hazards affecting BES Cyber Systems. This requirement ensures continued implementation of the response plans.

Requirement Part 2.2 provides further assurance in the information (e.g. backup tapes, mirrored hot-sites, etc.) necessary to recover BES Cyber Systems. A full test is not feasible in most instances due to the amount of recovery information, and the Responsible Entity must determine a sampling that provides assurance in the usability of the information.

Rationale for Requirement R3:

To improve the effectiveness of BES Cyber System recovery plan(s) following a test, and to ensure the maintenance and distribution of the recovery plan(s). Responsible Entities achieve this by (i) performing a lessons learned review in 3.1 and (ii) revising the plan in 3.2 based on specific changes in the organization or technology that would impact plan execution. In both instances when the plan needs to change, the Responsible Entity updates and distributes the plan.

Technical Rationale for Reliability Standard CIP-010-5

Introduction

This document explains the technical rationale and justification for the proposed Reliability Standard CIP-010-5. It provides stakeholders and the ERO Enterprise with an understanding of the technology and technical requirements in the Reliability Standard. This Technical Rationale and Justifications for CIP-010-5 is not a Reliability Standard and should not be considered mandatory and enforceable.

Updates to this document now include the Project 2016-02 – Modifications to CIP Standards Drafting Team's (SDT's) intent in drafting changes to the requirements.

Background

The Version 5 Transition advisory Group (V5TAG), which consists of representatives from NERC, Regional Entities, and industry stakeholders, was formed to issue guidance regarding possible methods to achieve compliance with the CIP V5 standards and to support industry's implementation activities. During the course of the V5TAG's activities, the V5TAG identified certain issues with the CIP Reliability Standards that were more appropriately addressed by a standard drafting team (SDT). The V5TAG developed the V5TAG Transfer Document to explain the issues and recommend that they be considered in future development activity. As Project 2016-02 was formed to address the directives in FERC Order 822 issued on January 21, 2016, that team also received the V5TAG issues as part of its Standard Authorization Request (SAR).

One of the areas of issue was virtualization. The V5TAG Transfer document said, "The CIP Version 5 standards do not specifically address virtualization. However, because of the increasing use of virtualization in industrial control system environments, questions around treatment of virtualization within the CIP Standards are due for consideration. The SDT should consider revisions to CIP-005 and the definitions of Cyber Asset and Electronic Access Point that make clear the permitted architecture and address the security risks of network, server and storage virtualization technologies."

New and Modified Terms and Applicability

This standard uses new or modified terms and contains new or modified exemptions in Section 4 Applicability. The rationale for this global content can be found in "CIP Definitions and Exemptions Technical Rationale" document for reference when reading the technical rational that follows.

The proposed changes in CIP-010-5 from the Project 2016-02 SDT concern the use of several facets of virtualization technologies. Virtualization allows for such technologies as new controls for Shared Cyber Infrastructure (SCI), remediation VLANs, parent/child images, and dormant virtual machines (VMs). Enabling and clarifying the use of these technologies is the basis of the proposed changes in CIP-010-5. A general introduction to each of these technologies follows.

Shared Cyber Infrastructure (SCI)

Virtualization abstracts the software layers (the OS and applications) from the underlying hardware to allow for hardware to be shared among several Virtual Cyber Assets (VCAs). Hypervisors include security controls to keep these workloads logically isolated from one another and their requirements are within other CIP standards such as CIP-005. However, with any type of shared infrastructure, the need for change management requirements is elevated for those security controls that allow for the 'shared' in SCI. Such controls are added to the change management requirements in CIP-010-5.

Remediation VLAN

Remediation VLAN is a term used to describe a logical network segment in which a computing device can be isolated from other production systems and examined to ensure the integrity and validity of the configuration and software installed on the device before it is permitted to transition to the production network segment.

This examination is policy driven, meaning that the administrator is able to configure what the minimum requirements are for admission to the production network. Examples of this might be minimum operating system patch levels or recent anti-virus definitions.

If during the examination of the computing device, it is found to not comply with the requirements defined in the policy, an administrator may intervene to manually remediate the deficiencies, or the system which was used to examine the device may communicate the deficiencies to the device with instructions on how to remediate itself in an automated fashion. After the remediation actions are taken, the computing device can request to be re-examined and if the requirements dictated by the policy are now met, it will be permitted access to the production network segment.

Parent/Child Images

When a VCA is ‘powered on’, it instantiates (“boots”) from a disk image file. Since the boot ‘disk’ is a file and not physical disk, many individual VCAs can use the same “parent” image as the basis for their own “child” image. Among other things, this allows for patching of an OS to occur to a parent image and the child images then pick up that patched image upon their next instantiation.

Dormant VMs

A VCA that is not instantiated (i.e. not ‘booted up’ and executing) is a dormant VM. It exists not as a traditional cyber asset, but simply as a file. VCA’s can be created for specialized purposes such as to run troubleshooting tools and only be instantiated when needed with long periods of times in between, during which they exist as a file. They are not up and running and on the network where they are managed and patched on a regular basis. However, these can go hand-in-hand with remediation VLANs which would bring them up to date as soon as they do instantiate but before they have access to any other systems.

General Considerations

SCI is mutually exclusive from Cyber Assets (CA) by definition. To enable CIP-010-5 for virtualization, the SDT evaluated the existing Applicable Systems and added SCI that supports each applicable BCS variant and associated Electronic Access Control or Monitoring Systems (EACMS), Physical Access Control Systems (PACS), or (Protected Cyber Assets (PCAs) already listed in Applicable Systems. This approach keeps the SCI applicability parallel to each existing variant of medium impact BCS (i.e. Medium Impact BCS vs. Medium Impact BCS with External Routable Connectivity (ERC) vs. Medium Impact BCS at Control Centers etc.).

Based on the updates to CIP-002 proposed with this version of CIP-010-5, SCI can be handled in two ways. A Registered Entity can choose to include the SCI within the CIP System it supports, and therefore treat it as a part of that system and apply all applicable CIP Requirements that apply to the CIP System it is included within. Alternatively, the SCI can be identified independently, which adds the flexibility to host multiple CIP Systems, even of differing impact ratings, however because of this flexibility, the SCI identified independently has additional controls which apply only to the SCI, and not the CIP Systems it supports.

Requirement R1

General Considerations for Requirement R1

In prior versions, CIP-010 Requirement R1 has required developing a baseline configuration that consisted of five (5) items (OS, installed and custom software, ports, patches). The baseline configuration was then used in the remainder of Requirement R1 and R2 as the basis of change management including testing. At a high level, the current Requirement Part 1.1 was to develop a baseline config, Requirement R1 Part 1.2 was to authorize and document changes to the items in the baseline config, and Requirement R1 Part 1.3 was to update the baseline config within a specific timeframe of a change. This tended to focus the requirement on documenting past changes.

In CIP-010-5, as the SDT considered the more policy-based and automated virtualization technologies discussed in the previous section, the SDT determined to change the focus of Requirement R1 towards a security objective of authorizing upcoming changes rather than maintaining a baseline configuration. Maintaining baseline configurations remains one possible "how", but it is no longer the only prescribed "how." The phrase "baseline configuration" has been removed from CIP-010-5 as a result. This maintains compatibility with current state but allows flexibility for virtualization technologies. This also ensures the focus is not on documenting past changes but the authorization of current or future changes, thus making the requirement forward looking with a clearer security objective.

Rationale for Requirement R1 Part 1.1

The original CIP-010 Requirement R1 Part 1.1 included establishing a baseline configuration for assets that included a set of items that would then be monitored for changes in the remaining parts of Requirement R1. This process is continued in the replacement for Requirement R1 and its Parts, however the documentation requirement (CIP-010-4 Requirement R1 Part 1.1) is no longer focused on a documentation only activity. While a Responsible Entity can benefit from documenting the configuration or the various elements of Requirement R1 Part 1.1 (1.1.1 – 1.1.4) this is no longer a requirement on its own. Maintaining this documentation is now one possible control to use to ensure changes to those elements are managed as required.

Additional changes were introduced to allow for or enable further use of virtualization. Specifically, the addition of "images used to derive operating systems or firmware" found in Requirement Part 1.1.1 is accounting for the concept of virtualized systems based on a "parent image." These images may be updated separately from a derived virtual machine and become active as soon as the virtual machine is rebooted. In this case, changes to this parent image must follow the management requirements found in Requirement R1.

Dormant VMs was another change with the current focus on baseline documentation, since the dormant VM is really just a file on disk, and as such cannot impact the BES until it is instantiated, at which time it must be compliant with the requirement. In many cases dormant VMs are patched to current prior to being added to the "production" network. By focusing the Part 1.1. requirement on the authorization to change as opposed to documentation of a current configuration, the challenge is mitigated. The Registered Entity must still know what is current, in order to know they must authorize a change, but the obligation to keep documentation up to date for a dormant VM is removed.

Additionally, the SDT noted that with the shift from a documentation requirement to a change authorization requirement, the bulk of the changes to the OS and installed software will be security patches. In this light, the inclusion of installed security patches in the list of items to authorize changes to would be duplicative, and provide no security benefit. Security Patches will be authorized through the authorization to change the OS or installed software through the installation of a security patch.

Rationale for Requirement R1 Part 1.2

Specific configuration items are included which apply only to SCI. These exist because the SDT determined that SCI that hosts BCS or associated EACMS, PACS or PCAs have controls that apply to specific configuration items relevant only to SCI.

Requirement R1 Part 1.2 is a new addition in order to require the authorization of changes to SCI configuration as it pertains to other required security controls (such as in CIP-005). The sharing of infrastructure puts a premium on the management of the security controls that enforce the logical isolation between tenants and the services the SCI itself uses. These areas that should fall under a CIP-010 management program are contained in Requirement R1 Part 1.2.

The SDT chose to include “SCI identified independently supporting…” language in the Applicable Systems column of the requirement part in order to ensure that controls which are applicable to the hardware portion of a physical Cyber Asset would remain applicable to the hardware supporting the VCAs used in BCS, EACMS, PACS or PCAs. This inclusion also re-emphasizes the criticality of the SCI, due to its inherent capability to affect multiple hosted systems, which could be a significantly broader impact than an individual physical Cyber Asset’s supporting hardware’s impact on the individual Cyber Asset itself.

Additionally, SCI typically includes supporting management capabilities which allow for the requirement part to be fulfilled on the SCI itself, without reliance on the hosted BCS, EACMS, PACS, or PCAs, and should therefore be the focus of Requirement R1 Part 1.1.

Rationale for Requirement R1 Part 1.3

The SDT chose to include “SCI identified independently supporting…” language in the Applicable Systems column of the requirement part in order to ensure that controls which are applicable to the hardware portion of a physical Cyber Asset would remain applicable to the hardware supporting the VCAs used in BCS, EACMS, PACS or PCAs. This inclusion also re-emphasizes the criticality of the SCI, due to its inherent capability to affect multiple hosted systems, which could be a significantly broader impact than an individual physical Cyber Asset’s supporting hardware’s impact on the individual Cyber Asset itself.

Additionally, SCI typically includes supporting management capabilities which allow for the requirement part to be fulfilled on the SCI itself, without reliance on the hosted BCS, EACMS, PACS, or PCAs, and should therefore be the focus of Requirement R1 Part 1.3.

The addition of “For each change *to the items listed in Part 1.1*” is used to scope the changes to only those listed in Requirement R1 Part 1.1, as a replacement to “deviations from the existing baseline configuration”, of applicable systems.

The addition of CIP Exceptional Circumstances (CEC) to Requirement R1 Part 1.3.1 was made because verification and documentation of cyber security controls prior to emergency change could impede Responsible Entities' efforts to recover from events or conditions that qualify as CEC.

Rationale for Requirement R1 Part 1.4

The addition of "For each change *to the items listed in Part 1.1 or Part 1.2*" is used to scope the changes to only those listed in Requirement R1 Part 1.1 or 1.2, as a replacement to "deviations from the existing baseline configuration", of applicable systems.

The SDT chose to remove the reliance on a "Technical Feasibility Exception" in favor of the updated term "per system capability." The SDT contends that the term still requires an entity to document the limit to the system's capability with regards to the requirement language, while not incurring the additional documentation overhead of a Technical Feasibility Exception (TFE).

Additionally, the SDT chose to add to the phrase "that minimizes adverse effects" with "and differences with the production environment" to eliminate the dependency on baseline configuration. The SDT also enabled CIP-010-5 for the use of Remediation VLANs for testing. This Remediation VLAN is not be considered a part of the production BCS environment and could help facilitate a secure means of testing prior to implementing the change in the production BCS environment.

The addition of CEC to Requirement R1 Part 1.4.1 was made because testing in a test environment and documenting test results may impede Responsible Entities' efforts to recover from events or conditions that qualify as CEC.

Rationale for Requirement R1 Part 1.5

The SDT chose to include "SCI identified independently supporting…" language in the Applicable Systems column of the requirement part in order to ensure that controls which are applicable to the hardware portion of a physical Cyber Asset would remain applicable to the hardware supporting the VCAs used in BCS, EACMS, PACS or PCAs. This inclusion also re-emphasizes the criticality of the SCI, due to its inherent capability to affect multiple hosted systems, which could be a significantly broader impact than an individual physical Cyber Asset's supporting hardware's impact on the individual Cyber Asset itself.

Additionally, SCI typically includes supporting management capabilities which allow for the requirement part to be fulfilled on the SCI itself, without reliance on the hosted BCS and should therefore be the focus of Requirement R1 Part 1.4.

The removal of "deviations from the existing baseline configuration" is a conforming change, with direct references to the specific Requirement R1 Part 1.1, sub-parts 1.1.1, and 1.1.2.

Requirement R2

General Considerations for Requirement R2

The SDT chose to include "SCI identified independently supporting…" language in the Applicable Systems column of the requirement part in order to ensure that controls which are applicable to the hardware portion of a physical Cyber Asset would remain applicable to the hardware supporting the VCAs used in BCS, EACMS, PACS or PCAs. This inclusion also re-emphasizes the criticality of the SCI, due to its inherent capability to affect multiple hosted systems, which could be a significantly broader impact than an individual physical Cyber Asset's supporting hardware's impact on the individual Cyber Asset itself.

The SDT has added the term "unauthorized" into Requirement R2 Part 2.1 to focus it on the risk of unauthorized changes. Many implementations will perform this task by monitoring all changes and looking for unauthorized changes within that population. However, if a way to filter out authorized changes can be implemented and an entity is able then to monitor just unauthorized changes that should fulfill the requirement.

Requirement R3

General Considerations for Requirement R3

The SDT chose to include "SCI identified independently supporting…" language in the Applicable Systems column of the requirement part in order to ensure that controls which are applicable to the hardware portion of a physical Cyber Asset would remain applicable to the hardware supporting the VCAs used in BCS, EACMS, PACS or PCAs. This inclusion also re-emphasizes the criticality of the SCI, due to its inherent capability to affect multiple hosted systems, which could be a significantly broader impact than an individual physical Cyber Asset's supporting hardware's impact on the individual Cyber Asset itself.

Additionally, SCI typically includes supporting management capabilities which allow for the requirement part to be fulfilled on the SCI itself, without reliance on the hosted BCS, EACMS, PACS, or PCAs, and should therefore be a target of this requirement part itself.

Rationale for Requirement R3 Part 3.1

Conforming changes only to Applicable Systems (see General Considerations for Requirement R3 above).

Rationale for Requirement R3 Part 3.2

The SDT chose to remove the reliance on a "Technical Feasibility Exception" in favor of the updated term "per system capability". The SDT contends that the term still requires an entity to document the limit to the system's capability with regards to the requirement language, while not incurring the additional documentation overhead of a TFE.

In Requirement R3 Part 3.2.1, conforming changes have been made to remove the baseline configuration dependency.

Rationale for Requirement R3 Part 3.3

The timing of when to enforce this requirement part has been an interesting chicken and egg problem. With the inclusion of the language "Prior to becoming a new Applicable System…" the SDT feels it has resolved this issue, and established that before the new system has applicability, i.e. it has an impact to the BES, this requirement part must be fulfilled.

The changes to the Protected Cyber Asset (PCA) definition, and the proposed change mentioned above to the requirement part language, should enable the use of remediation VLANs. The concept of "before connecting to a production environment…" is no longer part if this requirement language.

The requirements have been expanded to assure that virtual machines and their associated infrastructure are properly assessed before they can have an impact to the BES.

Rationale for Requirement R3 Part 3.4

Conforming changes only (see General Considerations for Requirement R3 above).

Requirement R4

General Considerations for Requirement R4

The SDT updated R4 to include associated SCI into the scope of the Transient Cyber Assets (TCA) and Removable Media required plans. The SDT also updated Attachment 1, such that the scope was broadened from a Cyber Asset only solution.

Former Background Section from Reliability Standard CIP-010-4

The section **6. Background** has been retired and removed from the Standard, and preserved by cutting and pasting as-is below.

Background

Standard CIP-010 exists as part of a suite of CIP Standards related to cyber security, which require the initial identification and categorization of BES Cyber Systems and require a minimum level of organizational, operational and procedural controls to mitigate risk to BES Cyber Systems.
Most requirements open with, "*Each Responsible Entity shall implement one or more documented [processes, plan, etc.] that include the applicable items in [Table Reference].*" The referenced table requires the applicable items in the procedures for the requirement's common subject matter.

The term *documented processes* refers to a set of required instructions specific to the Responsible Entity and to achieve a specific outcome. This term does not imply any particular naming or approval structure beyond what is stated in the requirements. An entity should include as much as it believes necessary in its documented processes, but it must address the applicable requirements in the table.

The terms *program* and *plan* are sometimes used in place of *documented processes* where it makes sense and is commonly understood. For example, documented processes describing a response are typically referred to as *plans* (i.e., incident response plans and recovery plans). Likewise, a security plan can describe an approach involving multiple procedures to address a broad subject matter.

Similarly, the term *program* may refer to the organization's overall implementation of its policies, plans, and procedures involving a subject matter. Examples in the standards include the personnel risk assessment program and the personnel training program. The full implementation of the CIP Cyber Security Standards could also be referred to as a program. However, the terms *program* and *plan* do not imply any additional requirements beyond what is stated in the standards.

Responsible Entities can implement common controls that meet requirements for multiple high and medium impact BES Cyber Systems. For example, a single training program could meet the requirements for training personnel across multiple BES Cyber Systems.

Measures for the initial requirement are simply the documented processes themselves. Measures in the table rows provide examples of evidence to show documentation and implementation of applicable items in the documented processes. These measures serve to provide guidance to entities in acceptable records of compliance and should not be viewed as an all-inclusive list.

Throughout the standards, unless otherwise stated, bulleted items in the requirements and measures are items that are linked with an "or," and numbered items are items that are linked with an "and."

Many references in the Applicability section use a threshold of 300 MW for UFLS and UVLS. This particular threshold of 300 MW for UVLS and UFLS was provided in Version 1 of the CIP Cyber Security Standards. The threshold remains at 300 MW since it is specifically addressing UVLS and UFLS, which are last ditch efforts to save the Bulk Electric System. A review of UFLS tolerances defined within regional reliability standards for UFLS program requirements to date indicates that the historical value of 300 MW represents an adequate and reasonable threshold value for allowable UFLS operational tolerances.

“Applicable Systems” Columns in Tables:

Each table has an “Applicable Systems” column to further define the scope of systems to which a specific requirement row applies. The CSO706 SDT adapted this concept from the National Institute of Standards and Technology (“NIST”) Risk Management Framework as a way of applying requirements more appropriately based on impact and connectivity characteristics. The following conventions are used in the “Applicability Systems” column as described.

- **High Impact BES Cyber Systems** – Applies to BES Cyber Systems categorized as high impact according to the CIP-002 identification and categorization processes.
- **Medium Impact BES Cyber Systems** – Applies to BES Cyber Systems categorized as medium impact according to the CIP-002 identification and categorization processes.
- **Electronic Access Control or Monitoring Systems (EACMS)** – Applies to each Electronic Access Control or Monitoring System associated with a referenced high impact BES Cyber System or medium impact BES Cyber System. Examples may include, but are not limited to, firewalls, authentication servers, and log monitoring and alerting systems.
- **Physical Access Control Systems (PACS)** – Applies to each Physical Access Control System associated with a referenced high impact BES Cyber System or medium impact BES Cyber System.
- **Protected Cyber Assets (PCA)** – Applies to each Protected Cyber Asset associated with a referenced high impact BES Cyber System or medium impact BES Cyber System.

Technical Rationale for Reliability Standard CIP-010-4

Introduction

This document explains the technical rationale and justification for the proposed Reliability Standard CIP-010-4. It provides stakeholders and the ERO Enterprise with an understanding of the technology and technical requirements in the Reliability Standard. This Technical Rationale and Justification for CIP-010-4 is not a Reliability Standard and should not be considered mandatory and enforceable.

The Federal Energy Regulatory Commission (the Commission) issued Order No. 850[1] on October 18, 2018, calling for modifications to the Supply Chain Suite of Standards, in which the summary on page 1 states, "…the Commission directs NERC to develop and submit modifications to the supply chain risk management Reliability Standards so that the scope of the Reliability Standards include Electronic Access Control and Monitoring Systems." In addition, NERC also recommended revising the Supply Chain Standards in its May 17, 2019 NERC Cyber Security Supply Chain Risk Report, Staff Report and Recommended Actions[2], to address Physical Access Control Systems (PACS) that provide physical access control to high and medium impact BES Cyber Systems.

The Project 2019-03 SDT drafted Reliability Standard CIP-010-4 to require responsible entities to meet the directives set forth in the Commission's Order No. 850 and the NERC Cyber Security Supply Chain Risk Report.

New and Modified Terms Used on NERC Reliability Standards

CIP-010-4 uses the following definition(s), which are cited below for reference when reading the technical rational that follows.

Proposed Modified Terms: None

Proposed New Terms: None

Requirement R1

General Considerations for Requirement R1

FERC Order 850, Paragraph 5 and Paragraph 30 directed modifications to Reliability Standard CIP-010-3 Requirement R1 to address supply chain risk management for Electronic Access Control or Monitoring Systems (EACMS) for high and medium impact BES Cyber Systems. In addition, NERC also recommended revising the Supply Chain Standards to address PACS that provide physical access control (excluding alarming and logging) to high and medium impact BES Cyber Systems, and modifications were addressed by the 2019-03 SDT.

Rationale for Requirement R1

The configuration change management processes are intended to prevent unauthorized modifications to BES Cyber Systems.

Requirement R1 Part 1.6 addresses directives in Order No. 829 for verifying software integrity and authenticity prior to installation in BES Cyber Systems (P. 48). The objective of verifying software integrity and authenticity is to ensure that the software being installed in the BES Cyber System was not modified without the awareness of the software supplier and is not counterfeit.

Requirement R1 Part 1.6 addresses directives in Order No. 850 for verifying software integrity and authenticity prior to installation of an EACMS (P. 5 and P.30), and PACS from the NERC Cyber Security Supply Chain Risk Report[3] recommendation. The objective of verifying software integrity and authenticity is to ensure that the software being installed on EACMS and PACS was not modified without the awareness of the software supplier and is not counterfeit.

Due to the nature of PACS and the potential need for physical presence, the SDT conducted extensive dialogue and consideration for the addition of PACS to the requirements, the SDT concluded the risk posed to BES reliability by a compromised, misused, degraded, or unavailable PACS warrants the inclusion of PACS as an applicable Cyber Asset category for supply chain risk management controls. Further, the inclusion of PACS:

1. addresses the Commission's remaining concern stated in FERC Order No. 850 P 6. that, "…the exclusion of these components may leave a gap in the supply chain risk management Reliability Standards.",
2. is consistent with the expectations of FERC Order No. 850 P 24. "…to direct that NERC evaluate the cybersecurity supply chain risks presented by PACS and PCAs in the study of cybersecurity supply chain risks directed by the NERC BOT in its resolutions of August 10, 2017.", and
3. directly aligns with NERC's recommendation to include PACS as documented in NERC's final report on "*Cyber Security Supply Chain Risks"*[4].

In further support of the SDT's decision to include PACS, as cited on page 4 of NERC's final report on "*Cyber Security Supply Chain Risks*", "The NERC CIP Reliability Standards provide a risk-based, defense-in-depth approach to securing the BES against cyber and physical security threats." While this statement appears in the context of EACMS, it acknowledges physical security threats equally; therefore, the concept is transferable and applicable to PACS, which serve as an integral component to a strategy involving layers of detective and preventive security controls. PACS are intended to manage physical access to BES Cyber Systems in support of protecting BES Cyber Systems against compromise that could lead to misoperation or instability in the BES and are implemented with that specific intention to protect the BES Cyber System.

[4] NERC, "Cyber Security Supply Chain Risks, Staff Report and Recommended Actions", May 17, 2019.
https://www.nerc.com/pa/comp/SupplyChainRiskMitigationProgramDL/NERC%20Supply%20Chain%20Final%20Report%20(20190517).pdf

Additionally, NERC states on page 15 of their final report on "*Cyber Security Supply Chain Risks"* that, "In addition, a threat actor must be physically present at the facility in order to exploit the vulnerability created by a compromised PACS system. A threat actor may also need to bypass several physical access or monitoring controls that have not been compromised in order to gain access." While it might be a fair point that a cyber-compromised PACSs may not in and of itself represent an immediate 15-minute adverse impact to the reliability of the BES, it stands to reason that a threat actor's intention to gain unauthorized electronic access to a PACS does so 1) with the knowledge of it being an initial deliberate action to facilitate undetected reconnaissance, and 2) further undetected methodical compromise and intentional harm to the BES Cyber Systems the PACS is intended to protect.

Furthermore, a precedent is set in CIP-006-6 Requirement R1 Part 1.5 that recognizes the importance of PACS, its functions, and the timeliness of information provided by these systems by requiring issuance of an alarm or alert in response to detected unauthorized access through a physical access point into a Physical Security Perimeter (PSP) to incident response personnel within 15 minutes of detection. This strict timeline suggests that compromised physical security poses an imminent threat to the associated BES Cyber System and the reliable operation of the BES Facilities it serves.

The SDT agrees that NERC correctly refers to various Reliability Standards that mitigate certain security risks relating to PACS; however, the SDT asserts that these existing requirements do not address risk associated to the supply chain and therefore do not sufficiently mitigate that risk.

An additional aspect of the NERC Supply Chain Report, the SDT risks associated with the different aspects of both EACMS and PACS. The NERC Supply Chain Report pointed to the increased risk of the control portion of both EACMS and PACS, and the SDT considered limiting the scope of the requirements to only those EACMS and PACS that perform the control functions. However, since the current approved definitions includes both control and monitoring for EACMS and control, logging and alerting for PACS, the SDT concluded it would introduce less confusion by referring to the authoritative term. The SDT did not attempt a change in definition due to the wide spread use of both EACMS and PACS within all the standards, and did not have authorization within its SAR to modify all of those standards.

Baseline Configuration

The concept of establishing a Cyber Asset's baseline configuration is meant to provide clarity on requirement language found in previous CIP standard versions. Modification of any item within an applicable Cyber Asset's baseline configuration provides the triggering mechanism for when entities must apply change management processes.

Baseline configurations in CIP-010 consist of five different items: Operating system/firmware, commercially available software or open-source application software, custom software, logical network accessible port identification, and security patches. Operating system information identifies the software and version that is in use on the Cyber Asset. In cases where an independent operating system does not exist (such as for a protective relay), then firmware information should be identified. Commercially available or open-source application software identifies applications that were intentionally installed on the cyber asset. The use of the term "intentional" was meant to ensure that only software applications that were determined to be necessary for Cyber Asset use should be included in the baseline configuration. The SDT does not intend for notepad, calculator, DLL, device drivers, or other applications included in an operating system package as commercially available or open-source application software to be included. Custom software installed may include scripts developed for local entity functions or other custom software developed for a specific task or function for the entity's use. If additional software was intentionally installed and is not commercially available or open-source, then this software could be considered custom software. If a specific device needs to communicate with another device outside the network, communications need to be limited to only the devices that need to communicate per the requirement in CIP-007-6. Those ports which are accessible need to be included in the baseline. Security patches applied would include all historical and current patches that have been applied on the cyber asset. While CIP-007-6 Requirement R2, Part 2.1 requires entities to track, evaluate, and install security patches, CIP-010 Requirement R1, Part 1.1.5 requires entities to list all applied historical and current patches.

Cyber Security Controls

The use of cyber security controls refers specifically to controls referenced and applied according to CIP-005 and CIP-007. The concept presented in the relevant requirement sub-parts in CIP-010 R1 is that an entity is to identify/verify controls from CIP-005 and CIP-007 that could be impacted for a change that deviates from the existing baseline configuration. The SDT does not intend for Responsible Entities to identify/verify all controls located within CIP-005 and CIP-007 for each change. The Responsible Entity is only to identify/verify those control(s) that could be affected by the baseline configuration change. For example, changes that affect logical network ports would only involve CIP-007 R1 (Ports and Services), while changes that affect security patches would only involve CIP-007 R2 (Security Patch Management). The SDT chose not to identify the specific requirements from CIP-005 and CIP-007 in CIP-010 language as the intent of the related requirements is to be able to identify/verify any of the controls in those standards that are affected as a result of a change to the baseline configuration. The SDT believes it possible that all requirements from CIP-005 and CIP-007 may be identified for a major change to the baseline configuration, and therefore, CIP-005 and CIP-007 was cited at the standard-level versus the requirement-level.

Test Environment

The language for use of a testing environment for deviations from baseline configuration was chosen deliberately in order to allow for individual elements of a BES Cyber System at a Control Center to be modeled that may not otherwise be able to be replicated or duplicated exactly.

Software Verification

The concept of verifying the identity of the software source and the integrity of the software obtained from the software source helps prevent the introduction of malware or counterfeit software. This reduces the likelihood that an attacker could exploit legitimate vendor patch management processes to deliver compromised software updates or patches to a BES Cyber System. The SDT intends for Responsible Entities to provide controls for verifying the baseline elements updated by vendors. It is important to note that this is not limited to only security patches.

Requirement R2

Rationale for Requirement R2

The configuration monitoring processes are intended to detect unauthorized modifications to BES Cyber Systems.

Baseline Monitoring

The SDT's intent of R2 is to require automated monitoring of the BES Cyber System. However, the SDT understands that there may be some Cyber Assets where automated monitoring may not be possible

Requirement R3

Rationale for Requirement R3

The vulnerability assessment processes are intended to act as a component in an overall program to periodically ensure the proper implementation of cyber security controls as well as to continually improve the security posture of BES Cyber Systems.

The vulnerability assessment performed for this requirement may be a component of deficiency identification, assessment, and correction.

Vulnerability Assessments

The Responsible Entity should note that the requirement provides a distinction between paper and active vulnerability assessments. The justification for this distinction is well-documented in FERC Order No. 706 and its associated Notice of Proposed Rulemaking.

Requirement R4

Rationale for Requirement R4

Requirement R4 responds to the directive in FERC Order No. 791, at Paragraphs 6 and 136, to address security-related issues associated with Transient Cyber Assets and Removable Media used on a temporary basis for tasks such as data transfer, vulnerability assessment, maintenance, or troubleshooting. These tools are potential vehicles for transporting malicious code into a facility and subsequently into Cyber Assets or BES Cyber Systems. To mitigate the risks associated with such tools, Requirement R4 was developed to accomplish the following security objectives:

- Preventing unauthorized access or malware propagation to BES Cyber Systems through Transient Cyber Assets or Removable Media; and
- Preventing unauthorized access to BES Cyber System Information through Transient Cyber Assets or Removable Media.
- Requirement R4 incorporates the concepts from other CIP requirements in CIP-010-2 and CIP-007-6 to help define the requirements for Transient Cyber Assets and Removable Media.

Summary of Changes

All requirements related to Transient Cyber Assets and Removable Media are included within a single standard, CIP-010. Due to the newness of the requirements and definition of asset types, the SDT determined that placing the requirements in a single standard would help ensure that entities were able to quickly identify the requirements for these asset types. A separate standard was considered for these requirements. However, the SDT determined that these types of assets would be used in relation to change management and vulnerability assessment processes and should, therefore, be placed in the same standard as those processes.

Transient Cyber Assets and Removable Media

Because most BES Cyber Assets and BES Cyber Systems are isolated from external public or untrusted networks, Transient Cyber Assets and Removable Media are a means for cyber-attack. Transient Cyber Assets and Removable Media are often the only way to transport files to and from secure areas to maintain, monitor, or troubleshoot critical systems. To protect the BES Cyber Assets and BES Cyber Systems, entities are required to document and implement a plan for how they will manage the use of Transient Cyber Assets and Removable Media. The approach of defining a plan allows the Responsible Entity to document the processes that are supportable within its organization and in alignment with its change management processes.

Transient Cyber Assets and Removable Media are those devices connected temporarily to: (1) a BES Cyber Asset, (2) a network within an ESP, or (3) a Protected Cyber Asset. Transient Cyber Assets and Removable Media do not provide BES reliability services and are not part of the BES Cyber Asset to which they are connected.

Transient Cyber Assets can be one of many types of devices from a specially-designed device for maintaining equipment in support of the BES to a platform such as a laptop, desktop, or tablet that may just interface with or run applications that support BES Cyber Systems and is capable of transmitting executable code. Removable Media in scope of this requirement can be in the form of floppy disks, compact disks, USB flash drives, external hard drives, and other flash memory cards/drives that contain nonvolatile memory.

While the definitions of Transient Cyber Asset and Removable Media include a conditional provision that requires them to be connected for 30 days or less, Section 1.1 of Attachment 1 allows the Responsible Entity to include provisions in its plan(s) that allow continuous or on-demand treatment and application of controls independent of the connected state. Please note that for on-demand treatment, the requirements only apply when Transient Cyber Assets and Removable Media are being connected to a BES Cyber System or Protected Cyber Asset. Once the transient device is disconnected, the requirements listed herein are not applicable until that Transient Cyber Asset or Removable Media is to be reconnected to the BES Cyber Asset or Protected Cyber Asset.

The attachment was created to specify the capabilities and possible security methods available to Responsible Entities based upon asset type, ownership, and management.

With the list of options provided in Attachment 1 for each control area, the entity has the discretion to use the option(s) that is most appropriate. This includes documenting its approach for how and when the entity manages or reviews the Transient Cyber Asset under its control or under the control of parties other than the Responsible Entity.

Vulnerability Mitigation

The terms “mitigate”, “mitigating”, and “mitigation” are used in the sections in Attachment 1 to address the risks posed by malicious code, software vulnerabilities, and unauthorized use when connecting Transient Cyber Assets and Removable Media. Mitigation in this context does not require that each vulnerability is individually addressed or remediated, as many may be unknown or not have an impact on the system to which the Transient Cyber Asset or Removable Media is connected. Mitigation is meant to reduce security risks presented by connecting the Transient Cyber Asset.

Per Transient Cyber Asset Capability

As with other CIP standards, the requirements are intended for an entity to use the method(s) that the system is capable of performing. The use of “per Transient Cyber Asset capability” is to eliminate the need for a Technical Feasibility Exception when it is understood that the device cannot use a method(s). For example, for malicious code, many types of appliances are not capable of implementing antivirus software; therefore, because it is not a capability of those types of devices, implementation of the antivirus software would not be required for those devices.

Attachment 1

Requirement R4, Attachment 1, Section 1 - Transient Cyber Asset(s) Managed by the Responsible Entity

Section 1.1: Entities have a high level of control for the assets that they manage. The requirements listed herein allow entities the flexibility to either pre-authorize an inventory of devices or authorize devices at the time of connection or use a combination of these methods. The devices may be managed individually or by group.

Section 1.2: Entities are to document and implement their process(es) to authorize the use of Transient Cyber Assets for which they have direct management. The Transient Cyber Assets may be listed individually or by asset type.

Requirement R4, Attachment 1, Section 2 - Transient Cyber Asset(s) Managed by a Party Other than the Responsible Entity

The attachment also recognizes the lack of control for Transient Cyber Assets that are managed by parties other than the Responsible Entity. However, this does not obviate the Responsible Entity's responsibility to ensure that methods have been deployed to deter, detect, or prevent malicious code on Transient Cyber Assets it does not manage. The requirements listed herein allow entities the ability to review the assets to the best of their capability and to meet their obligations.

Section 2.3: Determine whether additional mitigation actions are necessary, and implement such actions prior to connecting the Transient Cyber Asset managed by a party other than the Responsible Entity. The intent of this section is to ensure that after conducting the selected review from Sections 2.1 and 2.2, if there are deficiencies that do not meet the Responsible Entity's security posture, the other party is required to complete the mitigations prior to connecting their devices to an applicable system.

Requirement R4, Attachment 1, Section 3 - Removable Media

Entities have a high level of control for Removable Media that are going to be connected to their BES Cyber Assets.

Section 3.2: Entities are to document and implement their process(es) to mitigate the introduction of malicious code through the use of one or more method(s) to detect malicious code on the Removable Media before it is connected to a BES Cyber Asset. When using the method(s) to detect malicious code, it is expected to occur from a system that is not part of the BES Cyber System to reduce the risk of propagating malicious code into the BES Cyber System network or onto one of the BES Cyber Assets. If malicious code is discovered, it must be removed or mitigated to prevent it from being introduced into the BES Cyber Asset or BES Cyber System. Frequency and timing of the methods used to detect malicious code were intentionally excluded from the requirement because there are multiple timing scenarios that can be incorporated into a plan to mitigate the risk of malicious code. The entities must use the method(s) to detect malicious code on Removable Media before it is connected to the BES Cyber Asset. The timing dictated and documented in the entity's plan should reduce the risk of introducing malicious code to the BES Cyber Asset or Protected Cyber Asset.

For Section 3.2.1, the Cyber Asset used to perform the malicious code detection must be outside of the BES Cyber System or Protected Cyber Asset.

Technical Rationale for Reliability Standard CIP-010-3

This section contains a "cut and paste" of the Technical Rationale components of the former Guidelines and Technical Basis (GTB) as-is of from CIP-010-3 standard to preserve any historical references. Similarly, former GTB content providing compliance guidance can be found in a separate Implementation Guidance document for this standard.

Section 4 – Scope of Applicability of the CIP Cyber Security Standards:

Section "4. Applicability" of the standards provides important information for Responsible Entities to determine the scope of the applicability of the CIP Cyber Security Requirements.

Section "4.1. Functional Entities" is a list of NERC functional entities to which the standard applies. If the entity is registered as one or more of the functional entities listed in Section 4.1, then the NERC CIP Cyber Security Standards apply. Note that there is a qualification in Section 4.1 that restricts the applicability in the case of Distribution Providers to only those that own certain types of systems and equipment listed in 4.2.

Section "4.2. Facilities" defines the scope of the Facilities, systems, and equipment owned by the Responsible Entity, as qualified in Section 4.1, that is subject to the requirements of the standard. As specified in the exemption section 4.2.3.5, this standard does not apply to Responsible Entities that do not have High Impact or Medium Impact BES Cyber Systems under CIP-002-5.1's categorization. In addition to the set of BES Facilities, Control Centers, and other systems and equipment, the list includes the set of systems and equipment owned by Distribution Providers. While the NERC Glossary term "Facilities" already includes the BES characteristic, the additional use of the term BES here is meant to reinforce the scope of applicability of these Facilities where it is used, especially in this applicability scoping section. This in effect sets the scope of Facilities, systems, and equipment that is subject to the standards.

Requirement R1:

Baseline Configuration

The concept of establishing a Cyber Asset's baseline configuration is meant to provide clarity on requirement language found in previous CIP standard versions. Modification of any item within an applicable Cyber Asset's baseline configuration provides the triggering mechanism for when entities must apply change management processes.

Baseline configurations in CIP-010 consist of five different items: Operating system/firmware, commercially available software or open-source application software, custom software, logical network accessible port identification, and security patches. Operating system information identifies the software and version that is in use on the Cyber Asset. In cases where an independent operating system does not exist (such as for a protective relay), then firmware information should be identified. Commercially available or open-source application software identifies applications that were intentionally installed on the cyber asset. The use of the term "intentional" was meant to ensure that only software applications that were determined to be necessary for Cyber Asset use should be included in the baseline configuration. The SDT does not intend for notepad, calculator, DLL, device drivers, or other applications included in an operating system package as commercially available or open-source application software to be included. Custom software installed may include scripts developed for local entity functions or other custom software developed for a specific task or function for the entity's use. If additional software was intentionally installed and is not commercially available or open-source, then this software could be considered custom software. If a specific device needs to communicate with another device outside the network, communications need to be limited to only the devices that need to communicate per the requirement in CIP-007-6. Those ports which are accessible need to be included in the baseline. Security patches applied would include all historical and current patches that have been applied on the cyber asset. While CIP-007-6 Requirement R2, Part 2.1 requires entities to track, evaluate, and install security patches, CIP-010 Requirement R1, Part 1.1.5 requires entities to list all applied historical and current patches.

Cyber Security Controls

The use of cyber security controls refers specifically to controls referenced and applied according to CIP-005 and CIP-007. The concept presented in the relevant requirement sub-parts in CIP-010 R1 is that an entity is to identify/verify controls from CIP-005 and CIP-007 that could be impacted for a change that deviates from the existing baseline configuration. The SDT does not intend for Responsible Entities to identify/verify all controls located within CIP-005 and CIP-007 for each change. The Responsible Entity is only to identify/verify those control(s) that could be affected by the baseline configuration change. For example, changes that affect logical network ports would only involve CIP-007 R1 (Ports and Services), while changes that affect security patches would only involve CIP-007 R2 (Security Patch Management). The SDT chose not to identify the specific requirements from CIP-005 and CIP-007 in CIP-010 language as the intent of the related requirements is to be able to identify/verify any of the controls in those standards that are affected as a result of a change to the baseline configuration. The SDT believes it possible that all requirements from CIP-005 and CIP-007 may be identified for a major change to the baseline configuration, and therefore, CIP-005 and CIP-007 was cited at the standard-level versus the requirement-level.

Test Environment

The Control Center test environment (or production environment where the test is performed in a manner that minimizes adverse effects) should model the baseline configuration, but may have a different set of components.

Additionally, the Responsible Entity should note that wherever a test environment (or production environment where the test is performed in a manner that minimizes adverse effects) is mentioned, the requirement is to “model” the baseline configuration and not duplicate it exactly. This language was chosen deliberately in order to allow for individual elements of a BES Cyber System at a Control Center to be modeled that may not otherwise be able to be replicated or duplicated exactly.

Software Verification

The concept of software verification (verifying the identity of the software source and the integrity of the software obtained from the software source) is a key control in preventing the introduction of malware or counterfeit software. This objective is intended to reduce the likelihood that an attacker could exploit legitimate vendor patch management processes to deliver compromised software updates or patches to a BES Cyber System. The intent of the SDT is for Responsible Entities to provide controls for verifying the baseline elements that are updated by vendors. It is important to note that this is not limited to only security patches.

Requirement R2:

The SDT’s intent of R2 is to require automated monitoring of the BES Cyber System. However, the SDT understands that there may be some Cyber Assets where automated monitoring may not be possible. For that reason, automated technical monitoring was not explicitly required, and a Responsible Entity may choose to accomplish this requirement through manual procedural controls.

Requirement R3:

The Responsible Entity should note that the requirement provides a distinction between paper and active vulnerability assessments. The justification for this distinction is well-documented in FERC Order No. 706 and its associated Notice of Proposed Rulemaking.

Requirement R4:

Because most BES Cyber Assets and BES Cyber Systems are isolated from external public or untrusted networks, Transient Cyber Assets and Removable Media are a means for cyber-attack. Transient Cyber Assets and Removable Media are often the only way to transport files to and from secure areas to maintain, monitor, or troubleshoot critical systems. To protect the BES Cyber Assets and BES Cyber Systems, entities are required to document and implement a plan for how they will manage the use of Transient Cyber Assets and Removable Media. The approach of defining

a plan allows the Responsible Entity to document the processes that are supportable within its organization and in alignment with its change management processes.

Transient Cyber Assets and Removable Media are those devices connected temporarily to: (1) a BES Cyber Asset, (2) a network within an ESP, or (3) a Protected Cyber Asset. Transient Cyber Assets and Removable Media do not provide BES reliability services and are not part of the BES Cyber Asset to which they are connected.

Transient Cyber Assets can be one of many types of devices from a specially-designed device for maintaining equipment in support of the BES to a platform such as a laptop, desktop, or tablet that may just interface with or run applications that support BES Cyber Systems and is capable of transmitting executable code. Removable Media in scope of this requirement can be in the form of floppy disks, compact disks, USB flash drives, external hard drives, and other flash memory cards/drives that contain nonvolatile memory.

While the definitions of Transient Cyber Asset and Removable Media include a conditional provision that requires them to be connected for 30 days or less, Section 1.1 of Attachment 1 allows the Responsible Entity to include provisions in its plan(s) that allow continuous or on-demand treatment and application of controls independent of the connected state. Please note that for on-demand treatment, the requirements only apply when Transient Cyber Assets and Removable Media are being connected to a BES Cyber System or Protected Cyber Asset. Once the transient device is disconnected, the requirements listed herein are not applicable until that Transient Cyber Asset or Removable Media is to be reconnected to the BES Cyber Asset or Protected Cyber Asset.

The attachment was created to specify the capabilities and possible security methods available to Responsible Entities based upon asset type, ownership, and management.

With the list of options provided in Attachment 1 for each control area, the entity has the discretion to use the option(s) that is most appropriate. This includes documenting its approach for how and when the entity manages or reviews the Transient Cyber Asset under its control or under the control of parties other than the Responsible Entity. The entity should avoid implementing a security function that jeopardizes reliability by taking actions that would negatively impact the performance or support of the Transient Cyber Asset, BES Cyber Asset, or Protected Cyber Asset.

Vulnerability Mitigation

The terms “mitigate”, “mitigating”, and “mitigation” are used in the sections in Attachment 1 to address the risks posed by malicious code, software vulnerabilities, and unauthorized use when connecting Transient Cyber Assets and Removable Media. Mitigation in this context does not require that each vulnerability is individually addressed or remediated, as many may be unknown or not have an impact on the system to which the Transient Cyber Asset or Removable Media is connected. Mitigation is meant to reduce security risks presented by connecting the Transient Cyber Asset.

Per Transient Cyber Asset Capability

As with other CIP standards, the requirements are intended for an entity to use the method(s) that the system is capable of performing. The use of “per Transient Cyber Asset capability” is to eliminate the need for a Technical Feasibility Exception when it is understood that the device cannot use a method(s). For example,, for malicious code, many types of appliances are not capable of implementing antivirus software; therefore, because it is not a capability of those types of devices, implementation of the antivirus software would not be required for those devices.

Requirement R4, Attachment 1, Section 1 - Transient Cyber Asset(s) Managed by the Responsible Entity

Section 1.1: Entities have a high level of control for the assets that they manage. The requirements listed herein allow entities the flexibility to either pre-authorize an inventory of devices or authorize devices at the time of connection or use a combination of these methods. The devices may be managed individually or by group.

Section 1.2: Entities are to document and implement their process(es) to authorize the use of Transient Cyber Assets for which they have direct management. The Transient Cyber Assets may be listed individually or by asset type. To meet this requirement part, the entity is to document the following:

1.2.1 User(s), individually or by group/role, allowed to use the Transient Cyber Asset(s). This can be done by listing a specific person, department, or job function. Caution: consider whether these user(s) must also have authorized electronic access to the applicable system in accordance with CIP-004.

1.2.2 Locations where the Transient Cyber Assets may be used. This can be done by listing a specific location or a group of locations.

1.2.3 The intended or approved use of each individual, type, or group of Transient Cyber Asset. This should also include the software or application packages that are authorized with the purpose of performing defined business functions or tasks (e.g., used for data transfer, vulnerability assessment, maintenance, or troubleshooting purposes), and approved network interfaces (e.g., wireless, including near field communication or Bluetooth, and wired connections). Activities, and software or application packages, not specifically listed as acceptable should be considered as prohibited. It may be beneficial to educate individuals through the CIP-004 Security Awareness Program and Cyber Security Training Program about authorized and unauthorized activities or uses (e.g., using the device to browse the Internet or to check email or using the device to access wireless networks in hotels or retail locations).

Section 1.3: Entities are to document and implement their process(es) to mitigate software vulnerabilities posed by unpatched software through the use of one or more of the protective measures listed. This needs to be applied based on the capability of the device. Recognizing there is a huge diversity of the types of devices that can be included as Transient Cyber Assets and the advancement in software vulnerability management solutions, options are listed that include the alternative for the entity to use a technology or process that effectively mitigates vulnerabilities.

- Security patching, including manual or managed updates provides flexibility to the Responsible Entity to determine how its Transient Cyber Asset(s) will be used. It is possible for an entity to have its Transient Cyber Asset be part of an enterprise patch process and receive security patches on a regular schedule or the entity can verify and apply security patches prior to connecting the Transient Cyber Asset to an applicable Cyber Asset. Unlike CIP-007, Requirement R2, there is no expectation of creating dated mitigation plans or other documentation other than what is necessary to identify that the Transient Cyber Asset is receiving appropriate security patches.
- Live operating system and software executable only from read-only media is provided to allow a protected operating system that cannot be modified to deliver malicious software. When entities are creating custom live operating systems, they should check the image during the build to ensure that there is not malicious software on the image.
- System hardening, also called operating system hardening, helps minimize security vulnerabilities by removing all non-essential software programs and utilities and only installing the bare necessities that the computer needs to function. While other programs may provide useful features, they can provide "back-door" access to the system, and should be removed to harden the system.

- When selecting to use other methods that mitigate software vulnerabilities to those listed, entities need to have documentation that identifies how the other method(s) meet the software vulnerability mitigation objective.

Section 1.4: Entities are to document and implement their process(es) to mitigate malicious code through the use of one or more of the protective measures listed. This needs to be applied based on the capability of the device. As with vulnerability management, there is diversity of the types of devices that can be included as Transient Cyber Assets and the advancement in malicious code protections. When addressing malicious code protection, the Responsible Entity should address methods deployed to deter, detect, or prevent malicious code. If malicious code is discovered, it must be removed or mitigated to prevent it from being introduced into the BES Cyber Asset or BES Cyber System. Entities should also consider whether the detected malicious code is a Cyber Security Incident.

- Antivirus software, including manual or managed updates of signatures or patterns, provides flexibility just as with security patching, to manage Transient Cyber Asset(s) by deploying antivirus or endpoint security tools that maintain a scheduled update of the signatures or patterns. Also, for devices that do not regularly connect to receive scheduled updates, entities may choose to scan the Transient Cyber Asset prior to connection to ensure no malicious software is present.
- Application whitelisting is a method of authorizing only the applications and processes that are necessary on the Transient Cyber Asset. This reduces the opportunity that malicious software could become resident, much less propagate, from the Transient Cyber Asset to the BES Cyber Asset or BES Cyber System.
- Restricted communication to limit the exchange of data to only the Transient Cyber Asset and the Cyber Assets to which it is connected by restricting or disabling serial or network (including wireless) communications on a managed Transient Cyber Asset can be used to minimize the opportunity to introduce malicious code onto the Transient Cyber Asset while it is not connected to BES Cyber Systems. This renders the device unable to communicate with devices other than the one to which it is connected.
- When selecting to use other methods that mitigate the introduction of malicious code to those listed, entities need to have documentation that identifies how the other method(s) meet the mitigation of the introduction of malicious code objective.

Section 1.5: Entities are to document and implement their process(es) to protect and evaluate Transient Cyber Assets to ensure they mitigate the risks that unauthorized use of the Transient Cyber Asset may present to the BES Cyber System. The concern addressed by this section is the possibility that the Transient Cyber Asset could be tampered with, or exposed to malware, while not in active use by an authorized person. Physical security of the Transient Cyber Asset is certainly a control that will mitigate this risk, but other tools and techniques are also available. The bulleted list of example protections provides some suggested alternatives.

- For restricted physical access, the intent is that the Transient Cyber Asset is maintained within a Physical Security Perimeter or other physical location or enclosure that uses physical access controls to protect the Transient Cyber Asset.
- Full disk encryption with authentication is an option that can be employed to protect a Transient Cyber Asset from unauthorized use. However, it is important that authentication be required to decrypt the device. For example, pre-boot authentication, or power-on authentication, provides a secure, tamper-proof environment external to the operating system as a trusted authentication layer. Authentication prevents data from being read from the hard disk until the user has confirmed they have the correct password or other credentials. By performing the authentication prior to the system decrypting and booting, the risk that an unauthorized person may manipulate the Transient Cyber Asset is mitigated.

- Multi-factor authentication is used to ensure the identity of the person accessing the device. Multi-factor authentication also mitigates the risk that an unauthorized person may manipulate the Transient Cyber Asset.
- In addition to authentication and pure physical security methods, other alternatives are available that an entity may choose to employ. Certain theft recovery solutions can be used to locate the Transient Cyber Asset, detect access, remotely wipe, and lockout the system, thereby mitigating the potential threat from unauthorized use if the Transient Cyber Asset was later connected to a BES Cyber Asset. Other low tech solutions may also be effective to mitigate the risk of using a maliciously-manipulated Transient Cyber Asset, such as tamper evident tags or seals, and executing procedural controls to verify the integrity of the tamper evident tag or seal prior to use.
- When selecting to use other methods that mitigate the risk of unauthorized use to those listed, entities need to have documentation that identifies how the other method(s) meet the mitigation of the risk of unauthorized use objective.

Requirement R4, Attachment 1, Section 2 - Transient Cyber Asset(s) Managed by a Party Other than the Responsible Entity

The attachment also recognizes the lack of control for Transient Cyber Assets that are managed by parties other than the Responsible Entity. However, this does not obviate the Responsible Entity's responsibility to ensure that methods have been deployed to deter, detect, or prevent malicious code on Transient Cyber Assets it does not manage. The requirements listed herein allow entities the ability to review the assets to the best of their capability and to meet their obligations.

Section 2.1: Entities are to document and implement their process(es) to mitigate software vulnerabilities through the use of one or more of the protective measures listed.

- Conduct a review of the Transient Cyber Asset managed by a party other than the Responsible Entity to determine whether the security patch level of the device is adequate to mitigate the risk of software vulnerabilities before connecting the Transient Cyber Asset to an applicable system.
- Conduct a review of the other party's security patching process. This can be done either at the time of contracting but no later than prior to connecting the Transient Cyber Asset to an applicable system. Just as with reviewing the security patch level of the device, selecting to use this approach aims to ensure that the Responsible Entity has mitigated the risk of software vulnerabilities to applicable systems.
- Conduct a review of other processes that the other party uses to mitigate the risk of software vulnerabilities. This can be reviewing system hardening, application whitelisting, virtual machines, etc.
- When selecting to use other methods to mitigate software vulnerabilities to those listed, entities need to have documentation that identifies how the other method(s) meet mitigation of the risk of software vulnerabilities.

Section 2.2: Entities are to document and implement their process(es) to mitigate the introduction of malicious code through the use of one or more of the protective measures listed.

- Review the use of antivirus software and signature or pattern levels to ensure that the level is adequate to the Responsible Entity to mitigate the risk of malicious software being introduced to an applicable system.
- Review the antivirus or endpoint security processes of the other party to ensure that their processes are adequate to the Responsible Entity to mitigate the risk of introducing malicious software to an applicable system.

- Review the use of application whitelisting used by the other party to mitigate the risk of introducing malicious software to an applicable system.
- Review the use of live operating systems or software executable only from read-only media to ensure that the media is free from malicious software itself. Entities should review the processes to build the read-only media as well as the media itself.
- Review system hardening practices used by the other party to ensure that unnecessary ports, services, applications, etc. have been disabled or removed. This will limit the chance of introducing malicious software to an applicable system.

Section 2.3: Determine whether additional mitigation actions are necessary, and implement such actions prior to connecting the Transient Cyber Asset managed by a party other than the Responsible Entity. The intent of this section is to ensure that after conducting the selected review from Sections 2.1 and 2.2, if there are deficiencies that do not meet the Responsible Entity's security posture, the other party is required to complete the mitigations prior to connecting their devices to an applicable system.

Requirement R4, Attachment 1, Section 3 - Removable Media

Entities have a high level of control for Removable Media that are going to be connected to their BES Cyber Assets.

Section 3.1: Entities are to document and implement their process(es) to authorize the use of Removable Media. The Removable Media may be listed individually or by type.

- Document the user(s), individually or by group/role, allowed to use the Removable Media. This can be done by listing a specific person, department, or job function. Authorization includes vendors and the entity's personnel. Caution: consider whether these user(s) must have authorized electronic access to the applicable system in accordance with CIP-004.
- Locations where the Removable Media may be used. This can be done by listing a specific location or a group/role of locations.

Section 3.2: Entities are to document and implement their process(es) to mitigate the introduction of malicious code through the use of one or more method(s) to detect malicious code on the Removable Media before it is connected to a BES Cyber Asset. When using the method(s) to detect malicious code, it is expected to occur from a system that is not part of the BES Cyber System to reduce the risk of propagating malicious code into the BES Cyber System network or onto one of the BES Cyber Assets. If malicious code is discovered, it must be removed or mitigated to prevent it from being introduced into the BES Cyber Asset or BES Cyber System. Frequency and timing of the methods used to detect malicious code were intentionally excluded from the requirement because there are multiple timing scenarios that can be incorporated into a plan to mitigate the risk of malicious code. The entities must use the method(s) to detect malicious code on Removable Media before it is connected to the BES Cyber Asset. The timing dictated and documented in the entity's plan should reduce the risk of introducing malicious code to the BES Cyber Asset or Protected Cyber Asset.

For Section 3.2.1, the Cyber Asset used to perform the malicious code detection must be outside of the BES Cyber System or Protected Cyber Asset.

Rationale:

During development of this standard, text boxes were embedded within the standard to explain the rationale for various parts of the standard. Upon BOT approval, the text from the rationale text boxes was moved to this section.

Rationale for Requirement R1:

The configuration change management processes are intended to prevent unauthorized modifications to BES Cyber Systems.

Requirement R1 Part 1.6 addresses directives in Order No. 829 for verifying software integrity and authenticity prior to installation in BES Cyber Systems (P. 48). The objective of verifying software integrity and authenticity is to ensure that the software being installed in the BES Cyber System was not modified without the awareness of the software supplier and is not counterfeit.

Rationale for Requirement R2:

The configuration monitoring processes are intended to detect unauthorized modifications to BES Cyber Systems.

Rationale for Requirement R3:

The vulnerability assessment processes are intended to act as a component in an overall program to periodically ensure the proper implementation of cyber security controls as well as to continually improve the security posture of BES Cyber Systems.

The vulnerability assessment performed for this requirement may be a component of deficiency identification, assessment, and correction.

Rationale for Requirement R4:

Requirement R4 responds to the directive in FERC Order No. 791, at Paragraphs 6 and 136, to address security-related issues associated with Transient Cyber Assets and Removable Media used on a temporary basis for tasks such as data transfer, vulnerability assessment, maintenance, or troubleshooting. These tools are potential vehicles for transporting malicious code into a facility and subsequently into Cyber Assets or BES Cyber Systems. To mitigate the risks associated with such tools, Requirement R4 was developed to accomplish the following security objectives:

- Preventing unauthorized access or malware propagation to BES Cyber Systems through Transient Cyber Assets or Removable Media; and
- Preventing unauthorized access to BES Cyber System Information through Transient Cyber Assets or Removable Media.
- Requirement R4 incorporates the concepts from other CIP requirements in CIP-010-2 and CIP-007-6 to help define the requirements for Transient Cyber Assets and Removable Media.

Summary of Changes:

All requirements related to Transient Cyber Assets and Removable Media are included within a single standard, CIP-010. Due to the newness of the requirements and definition of asset types, the SDT determined that placing the requirements in a single standard would help ensure that entities were able to quickly identify the requirements for these asset types. A separate standard was considered for these requirements. However, the SDT determined that these types of assets would be used in relation to change management and vulnerability assessment processes and should, therefore, be placed in the same standard as those processes

Technical Rationale for Reliability Standard CIP-011-Y

Introduction

This document explains the technical rationale and justification for the proposed Reliability Standard CIP-011-Y. It provides stakeholders and the ERO Enterprise with an understanding of the technology and technical requirements in the Reliability Standard. This Technical Rationale and Justifications for CIP-011-Y is not a Reliability Standard and should not be considered mandatory and enforceable.

Updates to this document now include the Project 2016-02 – Modifications to CIP Standards Drafting Team's (SDT's) intent in drafting changes to the requirements.

Background

The Version 5 Transition advisory Group (V5TAG), which consists of representatives from NERC, Regional Entities, and industry stakeholders, was formed to issue guidance regarding possible methods to achieve compliance with the CIP V5 standards and to support industry's implementation activities. During the course of the V5TAG's activities, the V5TAG identified certain issues with the CIP Reliability Standards that were more appropriately addressed by a standard drafting team (SDT). The V5TAG developed the V5TAG Transfer Document to explain the issues and recommend that they be considered in future development activity. As Project 2016-02 was formed to address the directives in FERC Order 822 issued on January 21, 2016, that team also received the V5TAG issues as part of its Standard Authorization Request (SAR).

One of the areas of issue was virtualization. The V5TAG Transfer document said, "The CIP Version 5 standards do not specifically address virtualization. However, because of the increasing use of virtualization in industrial control system environments, questions around treatment of virtualization within the CIP Standards are due for consideration. The SDT should consider revisions to CIP-005 and the definitions of Cyber Asset and Electronic Access Point that make clear the permitted architecture and address the security risks of network, server and storage virtualization technologies."

New and Modified Terms and Applicability

This standard uses new or modified terms and contains new or modified exemptions in Section 4 Applicability. The rationale for this global content can be found in "CIP Definitions and Exemptions Technical Rationale" document for reference when reading the technical rational that follows.

General Considerations

The Project 2016-02 SDT made conforming changes to Reliability Standard CIP-011-Y to align information protection requirements with the virtualization changes.

Requirement R1 and R2

Rationale

The SDT added the option (known as the “all-in” scenario) for entities to group SCI within a BCS it supports; Therefore, to enable CIP-011-Y for virtualization, the SDT added “SCI identified independently supporting an Applicable System above” each of the Parts in Applicable Systems for Requirement R1 – Requirement R2 to account for the alternative option (See the CIP-002 Technical Rationale document for a description of the options for identifying SCI and reasons an entity may choose between the options.)

Requirement R2 Part 2.1

Requirement R2 Part 2.1 is an objective level requirement focused on protecting BES Cyber System Information (BCSI) rather than ‘Cyber Assets’ and ‘storage media’, and modified to include Requirement R2 Part 2.2. This modification creates necessary flexibility, allowing for cryptographic erasure in scenarios where BCSI cannot be mapped to particular disks within virtualized storage, and where BCSI is stored on SCI employing deduplication. This adjustment is also future-looking to better position CIP-011 for the enablement of cloud type scenarios where the disks are owned and/or managed by a third-party as a service to the entity for its BCSI storage, analysis, or use.

Requirement R2 Part 2.2

Requirement R2 Part 2.2 has been deleted because it was consolidated into Requirement R2 Part 2.1.

Former Background Section from Reliability Standard CIP-011-2

The section **6. Background** has been retired and removed from the Standard, and preserved by cutting and pasting as-is below.

Background

Standard CIP-011 exists as part of a suite of CIP Standards related to cyber security, which require the initial identification and categorization of BES Cyber Systems and require a minimum level of organizational, operational, and procedural controls to mitigate risk to BES Cyber Systems.

Most requirements open with, "*Each Responsible Entity shall implement one or more documented [processes, plan, etc.] that include the applicable items in [Table Reference].*" The referenced table requires the applicable items in the procedures for the requirement's common subject matter.
The term *documented processes* refers to a set of required instructions specific to the Responsible Entity and to achieve a specific outcome. This term does not imply any particular naming or approval structure beyond what is stated in the requirements. An entity should include as much as it believes necessary in its documented processes, but it must address the applicable requirements in the table.

The terms *program* and *plan* are sometimes used in place of *documented processes* where it makes sense and is commonly understood. For example, documented processes describing a response are typically referred to as *plans* (i.e., incident response plans and recovery plans). Likewise, a security plan can describe an approach involving multiple procedures to address a broad subject matter.

Similarly, the term *program* may refer to the organization's overall implementation of its policies, plans and procedures involving a subject matter. Examples in the standards include the personnel risk assessment program and the personnel training program. The full implementation of the CIP Cyber Security Standards could also be referred to as a program. However, the terms *program* and *plan* do not imply any additional requirements beyond what is stated in the standards.

Responsible Entities can implement common controls that meet requirements for multiple high and medium impact BES Cyber Systems. For example, a single training program could meet the requirements for training personnel across multiple BES Cyber Systems.

Measures for the initial requirement are simply the documented processes themselves. Measures in the table rows provide examples of evidence to show documentation and implementation of applicable items in the documented processes. These measures serve to provide guidance to entities in acceptable records of compliance and should not be viewed as an all-inclusive list.

Throughout the standards, unless otherwise stated, bulleted items in the requirements and measures are items that are linked with an "or," and numbered items are items that are linked with an "and."

Many references in the Applicability section use a threshold of 300 MW for UFLS and UVLS. This particular threshold of 300 MW for UVLS and UFLS was provided in Version 1 of the CIP Cyber Security Standards. The threshold remains at 300 MW since it is specifically addressing UVLS and UFLS, which are last ditch efforts to save the BES. A review of UFLS tolerances defined within regional reliability standards for UFLS program requirements to date indicates that the historical value of 300 MW represents an adequate and reasonable threshold value for allowable UFLS operational tolerances.

“Applicable Systems” Columns in Tables: Each table has an “Applicable Systems” column to further define the scope of systems to which a specific requirement row applies. The CSO706 SDT adapted this concept from the National Institute of Standards and Technology (“NIST”) Risk Management Framework as a way of applying requirements more appropriately based on impact and connectivity characteristics. The following conventions are used in the “Applicable Systems” column as described.

- **High Impact BES Cyber Systems** – Applies to BES Cyber Systems categorized as high impact according to the CIP-002-5.1 identification and categorization processes.
- **Medium Impact BES Cyber Systems** – Applies to BES Cyber Systems categorized as medium impact according to the CIP-002-5.1 identification and categorization processes.
- **Electronic Access Control or Monitoring Systems (EACMS)** – Applies to each Electronic Access Control or Monitoring System associated with a referenced high impact BES Cyber System or medium impact BES Cyber System. Examples may include, but are not limited to, firewalls, authentication servers, and log monitoring and alerting systems.
- **Physical Access Control Systems (PACS)** – Applies to each Physical Access Control System associated with a referenced high impact BES Cyber System or medium impact BES Cyber System with External Routable Connectivity.
- **Protected Cyber Assets (PCA)** – Applies to each Protected Cyber Asset associated with a referenced high impact BES Cyber System or medium impact BES Cyber System.

Technical Rational for Reliability Standard CIP-011-2

This section contains a "cut and paste" of the former Guidelines and Technical Basis (GTB) as-is of from CIP-011-2 standard to preserve any historical references. No modifications have been made.

Guidelines and Technical Basis

Section 4 – Scope of Applicability of the CIP Cyber Security Standards

Section "4. Applicability" of the standards provides important information for Responsible Entities to determine the scope of the applicability of the CIP Cyber Security Requirements.

Section "4.1. Functional Entities" is a list of NERC functional entities to which the standard applies. If the entity is registered as one or more of the functional entities listed in Section 4.1, then the NERC CIP Cyber Security Standards apply. Note that there is a qualification in Section 4.1 that restricts the applicability in the case of Distribution Providers to only those that own certain types of systems and equipment listed in 4.2.

Section "4.2. Facilities" defines the scope of the Facilities, systems, and equipment owned by the Responsible Entity, as qualified in Section 4.1, that is subject to the requirements of the standard. As specified in the exemption section 4.2.3.5, this standard does not apply to Responsible Entities that do not have High Impact or Medium Impact BES Cyber Systems under CIP-002-5.1's categorization. In addition to the set of BES Facilities, Control Centers, and other systems and equipment, the list includes the set of systems and equipment owned by Distribution Providers. While the NERC Glossary term "Facilities" already includes the BES characteristic, the additional use of the term BES here is meant to reinforce the scope of applicability of these Facilities where it is used, especially in this applicability scoping section. This in effect sets the scope of Facilities, systems, and equipment that is subject to the standards.

Requirement R1:

Responsible Entities are free to utilize existing change management and asset management systems. However, the information contained within those systems must be evaluated, as the information protection requirements still apply.

The justification for this requirement is pre-existing from previous versions of CIP and is also documented in FERC Order No. 706 and its associated Notice of Proposed Rulemaking.

This requirement mandates that BES Cyber System Information be identified. The Responsible Entity has flexibility in determining how to implement the requirement. The Responsible Entity should explain the method for identifying the BES Cyber System Information in their information protection program. For example, the Responsible Entity may decide to mark or label the documents. Identifying separate classifications of BES Cyber System Information is not specifically required. However, a Responsible Entity maintains the flexibility to do so if they desire. As long as the Responsible Entity's information protection program includes all applicable items, additional classification levels (e.g., confidential, public, internal use only, etc.) can be created that go above and beyond the requirements. If the entity chooses to use classifications, then the types of classifications used by the entity and any associated labeling should be documented in the entity's BES Cyber System Information Program.

The Responsible Entity may store all of the information about BES Cyber Systems in a separate repository or location (physical and/or electronic) with access control implemented. For example, the Responsible Entity's program could document that all information stored in an identified repository is considered BES Cyber System Information, the program may state that all information contained in an identified section of a specific repository is considered BES Cyber System Information, or the program may document that all hard copies of information are stored in a secured area of the building. Additional methods for implementing the requirement are suggested in the measures section. However, the methods listed in measures are not meant to be an exhaustive list of methods that the entity may choose to utilize for the identification of BES Cyber System Information.

The SDT does not intend that this requirement cover publicly available information, such as vendor manuals that are available via public websites or information that is deemed to be publicly releasable.

Information protection pertains to both digital and hardcopy information. R1.2 requires one or more procedures for the protection and secure handling BES Cyber System Information, including storage, transit, and use. This includes information that may be stored on Transient Cyber Assets or Removable Media.

The entity's written Information Protection Program should explain how the entity handles aspects of information protection including specifying how BES Cyber System Information is to be securely handled during transit in order to protect against unauthorized access, misuse, or corruption and to protect confidentiality of the communicated BES Cyber System Information. For example, the use of a third-party communication service provider instead of organization-owned infrastructure may warrant the use of encryption to prevent unauthorized disclosure of information during transmission. The entity may choose to establish a trusted communications path for transit of BES Cyber System Information. The trusted communications path would utilize a logon or other security measures to provide secure handling during transit. The entity may employ alternative physical protective measures, such as the use of a courier or locked container for transmission of information. It is not the intent of this standard to mandate the use of one particular format for secure handling during transit.

A good Information Protection Program will document the circumstances under which BES Cyber System Information can be shared with or used by third parties. The organization should distribute or share information on a need-to-know basis. For example, the entity may specify that a confidentiality agreement, non-disclosure arrangement, contract, or written agreement of some kind concerning the handling of information must be in place between the entity and the third party. The entity's Information Protection Program should specify circumstances for sharing of BES Cyber System Information with and use by third parties, for example, use of a non-disclosure agreement. The entity should then follow their documented program. These requirements do not mandate one specific type of arrangement.

Requirement R2:

This requirement allows for BES Cyber Systems to be removed from service and analyzed with their media intact, as that should not constitute a release for reuse. However, following the analysis, if the media is to be reused outside of a BES Cyber System or disposed of, the entity must take action to prevent the unauthorized retrieval of BES Cyber System Information from the media.

The justification for this requirement is pre-existing from previous versions of CIP and is also documented in FERC Order No. 706 and its associated Notice of Proposed Rulemaking.

If an applicable Cyber Asset is removed from the Physical Security Perimeter prior to action taken to prevent the unauthorized retrieval of BES Cyber System Information or destroying the data storage media, the Responsible Entity should maintain documentation that identifies the custodian for the data storage media while the data storage media is outside of the Physical Security Perimeter prior to actions taken by the entity as required in R2.

Media sanitization is the process used to remove information from system media such that reasonable assurance exists that the information cannot be retrieved or reconstructed. Media sanitization is generally classified into four categories: Disposal, clearing, purging, and destroying. For the purposes of this requirement, disposal by itself, with the exception of certain special circumstances, such as the use of strong encryption on a drive used in a SAN or other media, should never be considered acceptable. The use of clearing techniques may provide a suitable method of sanitization for media that is to be reused, whereas purging techniques may be more appropriate for media that is ready for disposal.

The following information from NIST SP800-88 provides additional guidance concerning the types of actions that an entity might take to prevent the unauthorized retrieval of BES Cyber System Information from the Cyber Asset data storage media:

> Clear: One method to sanitize media is to use software or hardware products to overwrite storage space on the media with non-sensitive data. This process may include overwriting not only the logical storage location of a file(s) (e.g., file allocation table) but also may include all addressable locations. The security goal of the overwriting process is to replace written data with random data. Overwriting cannot be used for media that are damaged or not rewriteable. The media type and size may also influence whether overwriting is a suitable sanitization method [SP 800-36].
>
> Purge: Degaussing and executing the firmware Secure Erase command (for ATA drives only) are acceptable methods for purging. Degaussing is exposing the magnetic media to a strong magnetic field in order to disrupt the recorded magnetic domains. A degausser is a device that generates a magnetic field used to sanitize magnetic media. Degaussers are rated based on the type (i.e., low energy or high energy) of magnetic media they can purge. Degaussers operate using either a strong permanent magnet or an electromagnetic coil. Degaussing can be an effective method for purging damaged or inoperative media, for purging media with exceptionally large storage capacities, or for quickly purging diskettes. [SP 800-36] Executing the firmware Secure Erase command (for ATA drives only) and degaussing are examples of acceptable methods for purging. Degaussing of any hard drive assembly usually destroys the drive as the firmware that manages the device is also destroyed.

> Destroy: There are many different types, techniques, and procedures for media destruction. Disintegration, Pulverization, Melting, and Incineration are sanitization methods designed to completely destroy the media. They are typically carried out at an outsourced metal destruction or licensed incineration facility with the specific capabilities to perform these activities effectively, securely, and safely. Optical mass storage media, including compact disks (CD, CD-RW, CD-R, CD-ROM), optical disks (DVD), and MO disks, must be destroyed by pulverizing, crosscut shredding or burning.
>
> In some cases such as networking equipment, it may be necessary to contact the manufacturer for proper sanitization procedure.

It is critical that an organization maintain a record of its sanitization actions to prevent unauthorized retrieval of BES Cyber System Information. Entities are strongly encouraged to review NIST SP800-88 for guidance on how to develop acceptable media sanitization processes.

Rationale

During development of this standard, text boxes were embedded within the standard to explain the rationale for various parts of the standard. Upon BOT approval, the text from the rationale text boxes was moved to this section.

Rationale for Requirement R1:

The SDT's intent of the information protection program is to prevent unauthorized access to BES Cyber System Information.

Rationale for Requirement R2:

The intent of the BES Cyber Asset reuse and disposal process is to prevent the unauthorized dissemination of BES Cyber System Information upon reuse or disposal.

Technical Rationale for Reliability Standard CIP-013-3

Introduction

This document explains the technical rationale and justification for the proposed Reliability Standard CIP-013-3. It provides stakeholders and the ERO Enterprise with an understanding of the technology and technical requirements in the Reliability Standard. This Technical Rationale and Justifications for CIP-013-3 is not a Reliability Standard and should not be considered mandatory and enforceable.

Updates to this document now include the Project 2016-02 – Modifications to CIP Standards Drafting Team's (SDT's) intent in drafting changes to the requirements.

Background

The Version 5 Transition advisory Group (V5TAG), which consists of representatives from NERC, Regional Entities, and industry stakeholders, was formed to issue guidance regarding possible methods to achieve compliance with the CIP V5 standards and to support industry's implementation activities. During the course of the V5TAG's activities, the V5TAG identified certain issues with the CIP Reliability Standards that were more appropriately addressed by a standard drafting team (SDT). The V5TAG developed the V5TAG Transfer Document to explain the issues and recommend that they be considered in future development activity. As Project 2016-02 was formed to address the directives in FERC Order 822 issued on January 21, 2016, that team also received the V5TAG issues as part of its Standard Authorization Request (SAR).

One of the areas of issue was virtualization. The V5TAG Transfer document said, "The CIP Version 5 standards do not specifically address virtualization. However, because of the increasing use of virtualization in industrial control system environments, questions around treatment of virtualization within the CIP Standards are due for consideration. The SDT should consider revisions to CIP-005 and the definitions of Cyber Asset and Electronic Access Point that make clear the permitted architecture and address the security risks of network, server and storage virtualization technologies."

New and Modified Terms and Applicability

This standard uses new or modified terms and contains new or modified exemptions in Section 4 Applicability. The rationale for this global content can be found in "CIP Definitions and Exemptions Technical Rationale" document for reference when reading the technical rationale that follows.

Requirement R1

Rationale

The Project 2016-02 SDT made conforming changes to Reliability Standard CIP-013-3 to align supply chain risk management requirements with the virtualization changes.

The SDT added the option (known as the "all-in" scenario) for entities to group SCI within a BCS it supports; Therefore, to enable CIP-013-3 for virtualization, the SDT added "SCI identified independently supporting these BCS or their associated EACMS and PACS" to account for the alternative option (See the CIP-002 Technical Rationale document for a description of the options for identifying SCI and reasons an entity may choose between the options.) Additionally, the SDT simplified the applicability in Requirement R1 Parts 1.1-1.2 by replacing the long list of Applicable Systems with a reference to the list in the parent Requirement R1 through the use of this language, "of systems listed in R1".

Technical Rationale for Reliability Standard CIP-013-2

This section contains a “cut and paste” of the Technical Rationale for CIP-013-2 standard to preserve any historical references.

Introduction

This document explains the technical rationale and justification for the proposed Reliability Standard CIP-013-2. It provides stakeholders and the ERO Enterprise with an understanding of the technology and technical requirements in the Reliability Standard. It also contains information on Project 2019-03 Cyber Security Supply Chain Risks Standard Drafting Team’s (SDT’s) intent in drafting the requirements. This Technical Rationale and Justification for CIP-013-2 is not a Reliability Standard and should not be considered mandatory and enforceable.

The Federal Energy Regulatory Commission (the Commission) issued Order No. 850 on October 18, 2018, calling for modifications to the Supply Chain Suite of Standards to address Electronic Access Control or Monitoring Systems (EACMS), specifically those systems that provide electronic access control or monitoring to high and medium impact BES Cyber Systems. In addition, NERC also recommended revising the Supply Chain Standards in its May 17, 2019 NERC Cyber Security Supply Chain Risk Report to address Physical Access Control Systems (PACS) that provide physical access control to high and medium impact BES Cyber Systems.

The Project 2019-03 SDT drafted Reliability Standard CIP-013-2 to require responsible entities to meet the directives set forth in the Commission’s Order No. 850 and the NERC Cyber Security Supply Chain Risk Report.

New and Modified Terms Used on NERC Reliability Standards

CIP-013-2 uses the following definition(s), which are cited below for reference when reading the technical rationale that follows.

Proposed Modified Terms: None

Proposed New Terms: None

Requirement R1 and R2

General Considerations for Requirements R1 and R2

The Requirement addresses Order No. 829 directives for entities to develop and implement a plan(s) that includes processes for mitigating cyber security risks in the supply chain. The plan(s) is required to address the following four objectives (Order No. 829 at P. 45):

(1) Software integrity and authenticity;

(2) Vendor remote access;

(3) Information system planning; and

(4) Vendor risk management and procurement controls.

The cyber security risk management plan(s) specified in Requirement R1 apply to high and medium impact BES Cyber Systems. FERC Order 850, Paragraph 5 and Paragraph 30, directs modifications to Reliability Standards to include EACMS associated with medium and high impact BES Cyber Systems within the scope of the Supply Chain Risk Management Standards. In addition, NERC also recommended revising the Supply Chain Standards in its May 17,

2019 NERC Cyber Security Supply Chain Risk Report [1](Chapter 3, pages 12-15) to address PACS that provide physical access control to high and medium impact BES Cyber Systems.

Implementation of the cyber security risk management plan(s) does not require the Responsible Entity to renegotiate or abrogate existing contracts (including amendments to master agreements and purchase orders), consistent with Order No. 829 (P. 36).-

Due to the nature of PACS and the potential need for physical presence, the SDT conducted extensive dialogue and consideration for the addition of PACS to the requirements. The SDT concluded the risk posed to BES reliability by a compromised, misused, degraded, or unavailable PACS warrants the inclusion of PACS as an applicable Cyber Asset category for supply chain risk management controls.

Further, the inclusion of PACS:

1. addresses the Commission's remaining concern stated in FERC Order No. 850 P 6. that, "…the exclusion of these components may leave a gap in the supply chain risk management Reliability Standards.",
2. addresses the expectations of FERC Order No. 850 P 24. "…to direct that NERC evaluate the cybersecurity supply chain risks presented by PACS and PCAs in the study of cybersecurity supply chain risks directed by the NERC BOT in its resolutions of August 10, 2017.", and
3. directly aligns with NERC's recommendation to include PACS as documented in NERC's final report on "*Cyber Security Supply Chain Risks"*[2].

In further support of the SDT's decision to include PACS, as cited on page 4 of NERC's final report on "*Cyber Security Supply Chain Risks*", "The NERC CIP Reliability Standards provide a risk-based, defense-in-depth approach to securing the BES against cyber and physical security threats." While this statement appears in the context of EACMS, it acknowledges physical security threats equally; therefore, the concept is transferable and applicable to PACS, which serve as an integral component to a strategy involving layers of detective and preventive security controls. PACS are intended to manage physical access to BES Cyber Systems in support of protecting BES Cyber Systems against compromise that could lead to misoperation or instability in the BES and are implemented with that specific intention to protect the BES Cyber System.

Additionally, NERC states on page 15 of their final report on "*Cyber Security Supply Chain Risks"* that, "In addition, a threat actor must be physically present at the facility in order to exploit the vulnerability created by a compromised PACS system. A threat actor may also need to bypass several physical access or monitoring controls that have not been compromised in order to gain access." While a cyber-compromised PACSs may not in and of itself represent an immediate 15-minute adverse impact to the reliability of the BES, it could demonstrate a threat Actor's intention to gain fully unauthorized electronic access. With electronic access to the PACS an initial deliberate action to facilitate reconnaissance and intentional harm to the BES Cyber Systems.

Furthermore, there is precedent set in CIP-006-6 Requirement R1 Part 1.5 that speaks to a recognized importance of PACS, its functions, and the timeliness of information provided by these systems by requiring issuance of an alarm or alert in response to detected unauthorized access through a physical access point into a PSP to incident response personnel within 15 minutes of detection. This strict timeline suggests imminent threat that compromised physical security poses to the associated BES Cyber System and the reliable operation of the BES Facilities it serves.

---

[1] NERC, "Cyber Security Supply Chain Risks, Staff Report and Recommended Actions", May 17, 2019. https://www.nerc.com/pa/comp/SupplyChainRiskMitigationProgramDL/NERC%20Supply%20Chain%20Final%20Report%20(20190517).pdf

[2] NERC, "Cyber Security Supply Chain Risks, Staff Report and Recommended Actions", May 17, 2019. https://www.nerc.com/pa/comp/SupplyChainRiskMitigationProgramDL/NERC%20Supply%20Chain%20Final%20Report%20(20190517).pdf

The SDT agrees that NERC correctly refers to various Reliability Standards that mitigate certain security risks relating to PACS; however, the SDT asserts that these existing requirements do not address risk associated to the supply chain and therefore do not sufficiently mitigate that risk.

An additional aspect of the NERC Supply Chain Report the SDT considered was around the risk associated with the different aspects of both EACMS and PACS. While both types of systems, under the current definitions, have various functional activities they perform, the NERC Supply Chain Report pointed to the increased risk of the control function. The SDT considered limiting the scope of the requirements to only control functions, however chose to stay with the currently approved definitions of both EACMS and PACS. The SDT concluded staying with approved definitions would introduce less confusion. Additionally an attempt to change the EACMS and PACS definitions was outside the 2019-03 SAR.

Rational for Requirement 1 and Requirement 2

Requirement R1 Part 1.1 addresses the directive in Order No. 829 (P.56) and Order 850 (P.5) for identification and documentation of cyber security risks in the planning and development processes related to the procurement of medium and high impact BES Cyber Systems, and their associated EACMS and PACS. The security objective is to ensure entities consider cyber security risks to the BES from vendor products or services resulting from: (i) procuring and installing vendor equipment and software; and (ii) transitions from one vendor(s) to another vendor(s); and options for mitigating these risks when planning for BES Cyber Systems.

Requirement R1 Part 1.2 addresses the directive in Order No. 829 for procurement controls to address the provision and verification of security concepts in future contracts for BES Cyber Systems (P. 59). The objective of Part 1.2 is for entities to include these topics in their plans so that procurement and contract negotiation processes address the applicable risks. Implementation of the entity's plan related to Part 1.2 may be accomplished through the entity's procurement and contract negotiation processes. For example, entities can implement the plan by including applicable procurement items from their plan in Requests for Proposals (RFPs), negotiations with vendors, or requests submitted to entities negotiating on behalf of the Responsible Entity such as in cooperative purchasing agreements. Obtaining specific controls in the negotiated contract may not be feasible and is not considered failure to implement an entity's plan. Although the expectation is that Responsible Entities would enforce the security-related provisions in the contract based on the terms and conditions of that contract, such contract enforcement and vendor performance or adherence to the negotiated contract is not subject to this Reliability Standard.

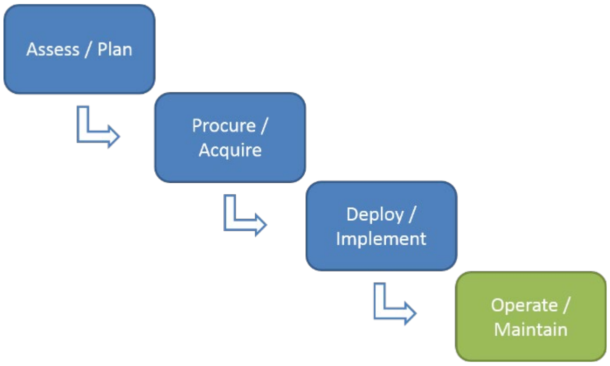
The objective of verifying software integrity and authenticity (Part 1.2.5) is to help ensure that software installed on BES Cyber Systems is not modified prior to installation without the awareness of the software supplier and is not counterfeit. Part 1.2.5 is not an operational requirement for entities to perform such verification; instead, it requires entities to address the software integrity and authenticity issue in its contracting process to provide the entity the means by which to perform such verification under CIP-010-3.

The use of remote access in Part 1.2.6 includes vendor-initiated authenticated remote connections and system to system remote connections for EACMS and PACS; and vendor-initiated IRA and system to system access to BCS and PCAs.

The term *vendor(s)* as used in the standard is limited to those persons, companies, or other organizations with whom the Responsible Entity, or its affiliates, contract with to supply BES Cyber Systems and related services. It does not include other NERC registered entities providing reliability services (e.g., Balancing Authority or Reliability Coordinator services pursuant to NERC Reliability Standards). A *vendor,* as used in the standard, may include: (i) developers or manufacturers of information systems, system components, or information system services; (ii) product resellers; or (iii) system integrators.

Collectively, the provisions of CIP-013-2 address an entity's controls for managing cyber security risks to BES Cyber Systems during the planning, acquisition, and deployment phases of the system life cycle, as shown below.

Notional BES Cyber System Life Cycle



Requirement R3

General Considerations for Requirement R3

The requirement addresses Order No. 829 directives for entities periodically to reassess selected supply chain cyber security risk management controls (P. 46).

Entities perform periodic assessment to keep plans up-to-date and address current and emerging supply chain-related concerns and vulnerabilities. Examples of sources of information that the entity could consider include guidance or information issued by:

- NERC or the E-ISAC
- ICS-CERT
- Canadian Cyber Incident Response Centre (CCIRC)

Responsible Entities are not required to renegotiate or abrogate existing contracts (including amendments to master agreements and purchase orders) when implementing an updated plan (i.e., the note in Requirement R2 applies to implementation of new plans and updated plans).

Technical Rational for Reliability Standard CIP-013-1

This section contains a “cut and paste” of the Technical Rationale components of the former Guidelines and Technical Basis (GTB) as-is of from CIP-013-1 standard to preserve any historical references. Similarly, former GTB content providing compliance guidance can be found in a separate Implementation Guidance document for this standard.

Rationale

Requirement R1:

The proposed Requirement addresses Order No. 829 directives for entities to implement a plan(s) that includes processes for mitigating cyber security risks in the supply chain. The plan(s) is required to address the following four objectives (Order No. 829 at P. 45):

(1) Software integrity and authenticity;

(2) Vendor remote access;

(3) Information system planning; and

(4) Vendor risk management and procurement controls.

The cyber security risk management plan(s) specified in Requirement R1 apply to high and medium impact BES Cyber Systems.

Implementation of the cyber security risk management plan(s) does not require the Responsible Entity to renegotiate or abrogate existing contracts (including amendments to master agreements and purchase orders), consistent with Order No. 829 (P. 36).-

Requirement R1 Part 1.1 addresses the directive in Order No. 829 for identification and documentation of cyber security risks in the planning and development processes related to the procurement of BES Cyber Systems (P. 56). The security objective is to ensure entities consider cyber security risks to the BES from vendor products or services resulting from: (i) procuring and installing vendor equipment and software; and (ii) transitions from one vendor(s) to another vendor(s); and options for mitigating these risks when planning for BES Cyber Systems.

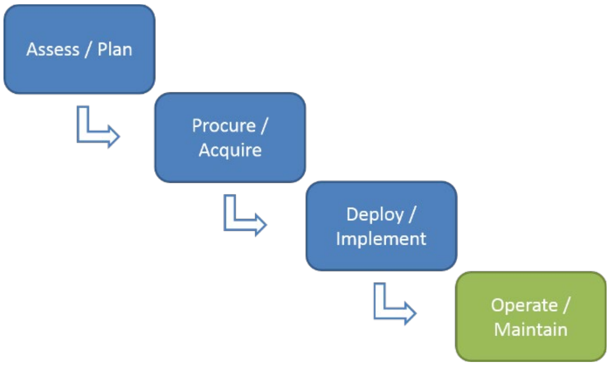
Requirement R1 Part 1.2 addresses the directive in Order No. 829 for procurement controls to address the provision and verification of security concepts in future contracts for BES Cyber Systems (P. 59). The objective of Part 1.2 is for entities to include these topics in their plans so that procurement and contract negotiation processes address the applicable risks. Implementation of the entity's plan related to Part 1.2 may be accomplished through the entity's procurement and contract negotiation processes. For example, entities can implement the plan by including applicable procurement items from their plan in Requests for Proposals (RFPs), negotiations with vendors, or requests submitted to entities negotiating on behalf of the Responsible Entity such as in cooperative purchasing agreements. Obtaining specific controls in the negotiated contract may not be feasible and is not considered failure to implement an entity's plan. Although the expectation is that Responsible Entities would enforce the security-related provisions in the contract based on the terms and conditions of that contract, such contract enforcement and vendor performance or adherence to the negotiated contract is not subject to this Reliability Standard.

The objective of verifying software integrity and authenticity (Part 1.2.5) is to help ensure that software installed on BES Cyber Systems is not modified prior to installation without the awareness of the software supplier and is not counterfeit. Part 1.2.5 is not an operational requirement for entities to perform such verification; instead, it requires entities to address the software integrity and authenticity issue in its contracting process to provide the entity the means by which to perform such verification under CIP-010-3.

The term *vendor(s)* as used in the standard is limited to those persons, companies, or other organizations with whom the Responsible Entity, or its affiliates, contract with to supply BES Cyber Systems and related services. It does not include other NERC registered entities providing reliability services (e.g., Balancing Authority or Reliability Coordinator services pursuant to NERC Reliability Standards). A *vendor,* as used in the standard, may include: (i) developers or manufacturers of information systems, system components, or information system services; (ii) product resellers; or (iii) system integrators.

Collectively, the provisions of CIP-013-1 address an entity's controls for managing cyber security risks to BES Cyber Systems during the planning, acquisition, and deployment phases of the system life cycle, as shown below.

Notional BES Cyber System Life Cycle



Requirement R2:

The proposed requirement addresses Order No. 829 directives for entities to periodically reassess selected supply chain cyber security risk management controls (P. 46).

Entities perform periodic assessment to keep plans up-to-date and address current and emerging supply chain-related concerns and vulnerabilities. Examples of sources of information that the entity could consider include guidance or information issued by:

- NERC or the E-ISAC
- ICS-CERT
- Canadian Cyber Incident Response Centre (CCIRC)

Responsible Entities are not required to renegotiate or abrogate existing contracts (including amendments to master agreements and purchase orders) when implementing an updated plan (i.e., the note in Requirement R2 applies to implementation of new plans and updated plans).

Standards Announcement

Project 2016-02 Modifications to CIP Standards | Virtualization

Formal Comment Period Extended, Now Open through September 1, 2021

Now Available

Due to numerous requests received from industry, the 45-day formal comment period for the **CIP Virtualization suite of standards (outlined below)** has been extended and is now open through **8 p.m. Eastern, Wednesday, September 1, 2021**.

The standard drafting team's considerations of the responses received from the previous comment period are reflected in these drafts of the standards.

- CIP-002-7 - Cyber Security – BES Cyber System Categorization
- CIP-003-Y - Cyber Security – Security Management Controls
- CIP-004-Y - Cyber Security – Personnel & Training
- CIP-005-8 - Cyber Security – BES Cyber System Logical Isolation
- CIP-006-7 - Cyber Security – Physical Security of BES Cyber Systems
- CIP-007-7 - Cyber Security – Systems Security Management
- CIP-008-7 - Cyber Security – Incident Reporting and Response Planning
- CIP-009-7 - Cyber Security – Recovery Plans for BES Cyber Systems
- CIP-010-5 - Cyber Security – Configuration Change Management and Vulnerability Assessments
- CIP-011-Y - Cyber Security – Information Protection
- CIP-013-3 - Cyber Security – Supply Chain Risk Management

Commenting

Use the Standards Balloting and Commenting System (SBS) to submit comments. An unofficial Word version of the comment form is posted on the project page**.**

- *Contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern) for problems regarding accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out.*
- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*

- *Please be mindful of ballot and comment period closing dates. We ask to* ***allow at least 48 hours*** *for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts* ***prior to the last day*** *of a comment/ballot period.*

Next Steps

Additional ballots for the standards and non-binding polls of the associated Violation Risk Factors and Violation Severity Levels will be conducted **August 23 – September 1, 2021**.

For information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Senior Standards Developer, Jordan Mallory (via email) or at (404) 446-2589. Subscribe to this project's observer mailing list by selecting "NERC Email Distribution Lists" from the "Service" drop-down menu and specify “Project 2016-02 Modifications to CIP Standards Observer List” in the Description Box.

There were 93 sets of responses, including comments from approximately 218 different people from approximately 137 companies representing 10 of the Industry Segments as shown in the table on the following pages.

Questions

1. Are the two options for identification of SCI within CIP-002 clear and is it understood that when SCI is included in the CIP Systems that it is treated like the CIP System, it is a part of for CIP Requirement Applicability?

2. The Applicable Systems column may include "SCI identified independently…" Is this clear or is additional clarification (such as "SCI identified as supporting, but not part of…") needed?

3. The SDT modified the ERC definition to reference "outside the asset containing". This is to allow scoping based on connectivity of the logging systems as required by CIP-007 Requirement R4 as well as the scoping of requirement parts in CIP-004 and CIP-006 based on risk. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

4. The SDT proposes that the modified ESP definition can be used for both traditional firewall based networks, as well as future networks such as zero trust. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

5. The SDT modified the IRA definition based on industry comments. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

6. The SDT modified the Management Interface definition based on industry comments. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

7. As discussed in the CIP Definitions and Exemptions Technical Rationale (TR), the SDT believes that the use of configurations or policy in the modified ESP definition can reduce the burden of documenting ESPs in a zero trust environment. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

8. The SDT added new and revised several defined terms to incorporate virtualization and future technologies within the CIP Standards. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

9. The SDT revised CIP-002 based on industry comments. Do you agree with the proposed changes to the CIP-002 Reliability Standard? If not, please provide the basis for your disagreement and an alternate proposal.

10. The SDT revised CIP-005 based on industry comments. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

11. The SDT revised CIP-007 based on industry comments. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

12. The SDT revised CIP-010 based on industry comments. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

13. The SDT revised CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013 (conforming changes) based on industry comments. Do you agree with the proposed changes to these Reliability Standards? If not, please provide the basis for your disagreement and an alternate proposal.

14. Please provide any additional comments for the SAR drafting team to consider, if desired.

Comment	
The proposed definition of CIP System is confusing. Dominion Energy recommends removing CIP System from the proposed defined terms and all references to the CIP System defined term throughout the definitions. Dominion Energy recommends addressing the issues of applicability it appears the CIP System definition was intending to do at the Standard level.

Consider modification of SCI to be based on the Cyber Asset definition. SCI's basis on the "programmable electronic devices" terminology makes it unclear as to what type of devices are the intended target of the standard. CIP-002 provides guidance for identification and classification of BCS (grouping of BCAs). Other associated cyber assets are classified based on their connectivity, protection and relationship to the BCAs. Suggest remove SCI identification from CIP-002.

Comment	
The current definitions and requirement language place BCS, which are groups of Cyber Assets, at the same level as SCI. SCI is likely to be handled as individual devices. This adds complexity both to the CIP-002 R1 compliance process as well as creates complexity for CIP-002 R2.2 approval processes. Duke Energy requests that the SDT add a definition and update requirements to leverage the concept of an SCI Group (SCIG). This would establish parity between the BCA -> BCS relationship with SCI -> SCIG. This also further simplifies applicability in the downstream standards from the current "High Impact BES Cyber Systems (BCS) and their associated: EACMS; PACS; and PCA" with a separate line for "SCI identified independently supporting an Applicable System above" to "High Impact BES Cyber Systems (BCS) and their associated: EACMS; PACS; PCA; and SCIG". Further, the CIP-002 language can now be simplified to the following, which retains closer parity with current language while still addressing the SDT's intentions: "Identify each of the high impact BES Cyber Systems, if any, and associated Shared Cyber Infrastructure Groups, if any, according to Attachment 1, Section 1 at each asset".

We believe the options are mostly clear and acceptable with the exception of the phrase “independent SCI supporting” either high or medium impact. It is unclear and confusing how an SCI can be both independent and supporting simultaneously. The proposed revised definition of BES Cyber System already would make it clear that SCI is to be included in CIP scope if applicable. We recommend removing the second bullet point entirely from both R1.1 and R1.2.

The identification of SCI is not clear within CIP-002, nor is it understood that SCI should be high-water marked to the highest impact applicable system that is sharing its infrastructure. The only thing that makes this clear is the definition of CIP System, which term is not used within CIP-002.

The identification of SCI included in a CIP System is clear but the identification of Management Systems included in SCI is unclear. For the all-in scenario, with Provider1 as an example, the Provider management Cyber Asset would typically be outside the ESP currently. With the new all-in, that CA would be a Management Interface, and would then be included as part of the SCI per the SCI 'including Management Interfaces' definition, which would then pull the CA into the BCS, making it a BCA, so it can no longer be outside of the ESP.

It is confusing to understand the definition of Shared Cyber Infrastrure (SCI) and therefore the overall requirement is unclear. While significant education to industry would improve this, it is extremely dependent on interpretation by stakeholders and auditors.

Texas RE does not agree that the two options for identification of SCI are clear. The distinction between SCI included in a BES Cyber System (BCS) and SCI operating independently adds an unnecessary level of complexity to the standards. Texas RE recommends there be only one option, which is to categorize SCI as meeting the definitions of the VCAs they are hosting and subsequently include the SCI within BCS, Electronic Access Control or Monitoring Systems (EACMS), Physical Access Control Systems (PACS) and Protected Cyber Assets (PCAs), as applicable. Additionally, Texas RE recommends that registered entities be required to identify all BCS, as well as their associated EACMS, PACS, and PCAs, as applicable. System (PM5) and system component (CM-8) inventory are both controls from NIST 800-53 Rev. 5. Texas RE is concerned CIP-002-7 would be less effective if registered entities are not required to implement the full suite of the system and component inventory protections in a manner consistent with these requirements.

In support of NPCC RSC comments.	

Request clarification when a SCI supports both high impact BES and medium impact BES. Is that SCI high watermarked to the high impact?

Request clarification of “it is a part of for CIP Requirement Applicability?” Is there a missing word? Should the language be “it is a part of it for CIP Requirement Applicability?”

Request clarification of the or in 1.3. Is the entity identifying low impact BCS or supporting SCI or both?

Request clarification of the 1.3 parenthetical. Is the entity required to provide an asset list for either low impact BCS or supporting SCI?

We don’t understand how to categorize a Shared Cyber Infrastructure. The SDT seems to make a distinction between two types of SCI, one type is supporting, and the other type is independent supporting. Our hypothesis is that a “supporting SCI” is for BCS (BCA/PCA) and that an “independent supporting SCI” is for associated Electronic Access Control or Monitoring Systems (EACMS), Physical Access Control Systems (PACS)).

In both cases, the SCI is the categorization labels, like BCA, PCA, EACMS, PACS, TCA.

Yet in the Applicable Systems column in the other CIPs, the SDT seem to make a distinction between the SCI, for example

CIP-005 R1.5 1.5 … PACS hosted on SCI … SCI identified independently…

CIP-007 R1.1 SCI identified independently supporting.

Clarification is needed.

Are the two options for identification SCI required? Is there a difference in the controls that we want to apply?

We suggest simplifying the language or add more precision. Example:

Per Attachment 1, Section 1, identify each high impact BES Cyber System as either of the following, if any, at each asset; High Impact BCS and their associated Electronic Access Control or Monitoring Systems (EACMS), Physical Access Control Systems (PACS), Protected Cyber Assets (PCAs) or SCI.

Furthermore, in the definition of SCI the PCA is not listed. Is this intentional? Wouldn’t be possible to have a PCA supported by an SCI? We suggest that the SDT review the SCI / VCA/ PCA definitions, adjust the applicability and the requirements.

Reference SCI: One or more programmable electronic devices, including the software and Management Interfaces, that share: • CPU and memory resources with one or more Virtual Cyber Assets identified as a BCA, EACMS, or PACS; or

Comment

While AEP agrees with the inclusion of this CIP-002 mechanism (the term CIP Systems) for including the associated applicable systems (EACMS, PACS, and PCAs) as a means to have a singular requirement for the identification of EACMS, PACS and PCAs, the current language appears to limit the identification of only those virtual systems (and underlying infrastructure) related to EACMS, PACS and PCAs. We believe this leaves a gap for the identification of those physical systems performing the same function(s). We recommend SDT to add clarifying language to allow for the identification of both physical and virtual systems as EACMS, PACS and PCAs under CIP-002.

Comment

IESO supports the comments submitted to all the questions by both NPCC and ISO/RTO Council

Request clarification when a SCI supports both high impact BES and medium impact BES. Is that SCI high watermarked to the high impact?

Request clarification of “it is a part of for CIP Requirement Applicability?” Is there a missing word? Should the language be “it is a part of it for CIP Requirement Applicability?”

Request clarification of the or in 1.3. Is the entity identifying low impact BCS or supporting SCI or both?

Request clarification of the 1.3 parenthetical. Is the entity required to provide an asset list for either low impact BCS or supporting SCI?

We don’t understand how to categorize a Shared Cyber Infrastructure. The SDT seems to make a distinction between two types of SCI, one type is supporting, and the other type is independent supporting. Our hypothesis is that a “supporting SCI” is for BCS (BCA/PCA) and that an “independent supporting SCI” is for associated Electronic Access Control or Monitoring Systems (EACMS), Physical Access Control Systems (PACS)).

In both cases, the SCI is the categorization labels, like BCA, PCA, EACMS, PACS, TCA.

Yet in the Applicable Systems column in the other CIPs, the SDT seem to make a distinction between the SCI, for example

CIP-005 R1.5 1.5 … PACS hosted on SCI … SCI identified independently…

CIP-007 R1.1 SCI identified independently supporting.

Clarification is needed.

Are the two options for identification SCI required? Is there a difference in the controls that we want to apply?

We suggest simplifying the language or add more precision. Example:

Per Attachment 1, Section 1, identify each high impact BES Cyber System as either of the following, if any, at each asset; High Impact BCS and their associated Electronic Access Control or Monitoring Systems (EACMS), Physical Access Control Systems (PACS), Protected Cyber Assets (PCAs) or SCI.

Furthermore, in the definition of SCI the PCA is not listed. Is this intentional? Wouldn't be possible to have a PCA supported by an SCI? We suggest that the SDT review the SCI / VCA/ PCA definitions, adjust the applicability and the requirements.

Answer	No
Document Name	Independently Identified SCI.jpg

Comment

The phrases "supporting SCI" and "independent SCI supporting" are not clear and should be removed from CIP-002. Resulting from SCI definition, SCI should be either a CIP cyber asset or no-CIP cyber asset, therefore SCI shouldn't appear in CIP-002 and Applicable Systems of CIP-003 to CIP-013. SCI should be used for identifying additional BCAs, EACMS, PACS or PCAs that could be missed in the virtualization environment.

For the proposed All-in-Scenario, SCI should be identified as a BCA, EACMS, PACS or PCA rather than a new classification of CIP cyber asset. For example, if a SCI can initialize, deploy and configure a BCA, it should be categorized as a BCA since it can remove a virtual BCA thus having an impact to the BES within 15 minutes. Similarly, if a SCI can initialize, deploy and configure an EACMS, it should be categorized as an EACMS since it can remove the virtual EACMS thus having electronic control function.

For independently Identified SCI as SDT proposed below, for the right side SCI, if the right SCI containing Management Interface can initialize, deploy and configure a CIP Cyber Asset, it should be categorized as a CIP cyber asset (See our comments above). If the right-side SCI hosts VCA that is a CIP cyber asset regardless of the impact rating, the right side SCI should be identified as the same impact CIP cyber asset it hosts. The right side SCI is out of CIP scope only: (1) if all VCAs it hosts are non-CIP cyber assets, this SCI would be out of CIP scope thus no need to be identified; (2) If it is used only to configure high impact network policy, it would be out of CIP scope since out of band management for CIP cyber assets is not required by the current CIP requirements scope and the SAR

Based on our comments above, the "SCI" and "independently Identified SCI" are not needed to be identified in CIP-002 since the SCI or independently Identified SCI either is a CIP cyber asset or out of CIP scope.

SEE ATTACHED DOCUMENT FOR PHOTO.

Resulting from our comments above, we recommend revising definitions of BCA, EACMS, PACS and PCA to include SCI so SCI would not be identified as another independently applicable CIP cyber asset. Our proposed changes align with FERC and NERC's security objectives and the SDT's goal to address cyber security risks to the reliability of the BES from virtualization technologies, while having less impact on the entities existing CIP programs, processes and documentation. Entities can use their existing CIP cyber asset identification processes to identify BCAs, EACMS, PACS and PCAs based on SCI and Management Interface language to address virtualization. If the responsible entities don't have virtualization, they wouldn't need to identify any additional CIP cyber assets at all.

Recommendations:

1. Restore the CIP-002 R1 and its Parts resulting from our proposed definitions changes below.

2. We propose the following changes to the new or existing definitions:

SCI:

SDT Proposed SCI definition

One or more programmable electronic devices, including the software and Management Interfaces, that share:

- CPU and memory resources with one or more Virtual Cyber Assets identified as a BCA, EACMS, or PACS; or
- storage resources with any part of a BES Cyber System or their associated EACMS or PACS.

Each SCI is either:

- included in one or more BES Cyber Systems, EACMS, or PACS; or
- identified independently.

SCI does not include the supported VCA or CA with which it shares its resources.

NSRF Proposed Changes to the Definition

One or more programmable electronic devices, including the software and Management Interfaces in those devices, that share:

- CPU and memory resources with one or more Virtual Cyber Assets identified as a BCA, EACMS, PACS or PCA; or
- storage resources with any part of a BES Cyber System or their associated EACMS, PACS or PCA.

This includes devices that contain Management Interfaces for virtualization management.

SCI does not include the supported VCA or CA with which it shares its resources.

Rationale: In the SDT proposed SCI definition, the device containing Management Interface is left out and is not identified as a CIP cyber part of SCI even though the management interface is in scope. For example, vCenter containing Management Interface, but it is not identified as a CIP cyber asset and is not protected. Also, PCA is missing from the SCI definition. In our proposed changes, it is not necessary to identify SCI independently since SCI would be identified as one of CIP Cyber Assets.

Management Interface:

SDT Proposed SCI definition

A user interface, logical interface, or dedicated physical port that is used to:

- Control the processes of initializing, deploying, and configuring Shared Cyber Infrastructure; or
- Provide lights-out management capabilities; or
- Configure an Electronic Security Perimeter;

excluding physical user interfaces (e.g., power switch, touch panel, etc.).

Our Proposed Changes to the Definition

A user interface, logical interface, or dedicated physical port that is used to:

- Initialize, deploy, and configure BCA, EACMS, PACS, or PCA; or
- Control the processes of initializing, deploying, and configuring Shared Cyber Infrastructure; or
- Configure EAP of an Electronic Security Perimeter; or
- Configure EACMS that controls all communications to and from the BCS unless ESP model is used.

excluding physical user interfaces (e.g., power switch, touch panel, etc.). (See our rationale in Q6).

Rationale: In our view, the definition should focus on “in scope” CIP management interfaces. The term “Provide lights-out management capabilities” is not clear and should be removed since this criterion itself cannot make a management interface fall within CIP scope.

Also, the Management Interface on the SCI is absent. We have added a bullet in our proposed definition to address it.

Furthermore, we suggest edits to include:

a) changing configure an ESP to configure an EAP

b) adding configure EACMS to address the zero-trust mode based on our comments in Q4.

BCA:

SDT Proposed SCI definition

A Cyber Asset or Virtual Cyber Asset, that if rendered unavailable, degraded, or misused would, within 15 minutes of its required operation, misoperation, or non-operation, adversely impact one or more Facilities, systems, or equipment, which, if destroyed, degraded , or otherwise rendered unavailable when needed, would affect the reliable operation of the Bulk Electric System. Redundancy of affected Facilities, systems, and equipment shall not be considered when determining adverse impact. Each BES Cyber Asset is included in one or more BES Cyber Systems.

Our Proposed Changes to the Definition

A Cyber Asset or Virtual Cyber Asset, that if rendered unavailable, degraded, or misused would, within 15 minutes of its required operation, misoperation, or non-operation, adversely impact one or more Facilities, systems, or equipment, which, if destroyed, degraded, or otherwise rendered unavailable when needed, would affect the reliable operation of the Bulk Electric System. Redundancy of affected Facilities, systems, and equipment shall not be considered when determining adverse impact. Each BES Cyber Asset is included in one or more BES Cyber Systems. This includes SCI that is used for initializing, deploying and configuring BCAs or storing information for the real-time operation of BCAs.

Rationale: In our view, if a SCI meets BCA criteria, it must be identified as a BCA.

EACMS:

SDT Proposed SCI definition

Cyber Assets, Virtual Cyber Assets, or Shared Cyber Infrastructure (SCI) that perform electronic access control or electronic access monitoring of the Electronic Security Perimeter(s) or BES Cyber Systems or SCI. This includes Intermediate Systems and SCI grouped, by the Responsible Entity, in the EACMS it supports.

Our Proposed Changes to the Definition

Cyber Assets or Virtual Cyber Assets that perform electronic access control or electronic access monitoring of the Electronic Security Perimeter(s) or BES Cyber Systems. This includes Intermediate Systems and SCI that is used for initializing, deploying and configuring EACMS or storing information for the real-time operation of EACMS.

Rationale: A SCI supporting EACMS doesn't make it to be part of EACMS. For instance, if a SCI only stores historical information for EACMS, it could be a BCSI repository rather than part of EACMS. In our view, only a SCI that can initialize, deploy and configure EACMS should be identified as EACMS.

PACS:

SDT Proposed SCI definition

Cyber Assets, Virtual Cyber Assets, or Shared Cyber Infrastructure (SCI) (including SCI grouped, by the Responsible Entity, in the Physical Access Control Systems it supports) that control, alert, or log access to the Physical Security Perimeter(s), exclusive of locally mounted hardware or devices at the Physical Security Perimeter such as motion sensors, electronic lock control mechanisms, and badge readers.

Our Proposed Changes to the Definition

Cyber Assets or Virtual Cyber Assets that control, alert, or log access to the Physical Security Perimeter(s), exclusive of locally mounted hardware or devices at the Physical Security Perimeter such as motion sensors, electronic lock control mechanisms, and badge readers. This includes SCI that is used for initializing, deploying and configuring PACS or storing information for the real-time operation of PACS.

Rationale: A SCI supporting PACS doesn't make it to be part of PACS. For instance, if a SCI only stores historical information for PACS, it could be a BCSI repository rather than part of PACS. In our view, only a SCI that can initialize, deploy and configure PACS should be identified as PACS.

PCA:

SDT Proposed SCI definition

One or more Cyber Assets or Virtual Cyber Assets that:

- Are within an Electronic Security Perimeter but are not part of the highest impact BES Cyber System within the same Electronic Security Perimeter; or
- Share CPU or memory with any part of a BES Cyber System, excluding Virtual Cyber Assets that are being actively remediated prior to introduction to the Electronic Security Perimeter.

Our Proposed Changes to the Definition

One or more Cyber Assets or Virtual Cyber Assets that:

- Are within an Electronic Security Perimeter but are not part of the highest impact BES Cyber System within the same Electronic Security Perimeter; or
- Share CPU or memory with any part of a BES Cyber System, EACMS, PACS or PCA; or

This includes SCI that is used for initializing, deploying and configuring PCA or storing information for the real-time operation of PCA.

Rationale: In the SDT proposed PCA definition, if the bullet 2 is for identifying PCA that shares resources with BCS, the ESP should be irrelevant. Also, it is not clear what the remediation actions are and why the one-time remediation makes it out of scope, noting that the compliance is an ongoing basis and the remediation shouldn't exclude a VCA from CIP scope. Furthermore, if SDT intends to protect non-CIP cyber assets that share the CPU or memory with CIP cyber assets, EACMS, PACS and PCA sharing resources with non-CIP cyber assets should also be considered rather than only BCS.

CA: Restore the CA definition.

Rationale: Given that SCI is defined as a programmable device, it meets the CA definition and should be treated as one type of CAs rather than excluding it from CA definition.

VCA: A logical instance of an operating system or firmware including software, data and virtual hardware on the logical instance hosted on a physical Cyber Asset.

BCS: Restore BCS definition.

Rationale: BCS should only include BCAs not other CIP cyber assets. Given that SCI could be an EACM, PACS or PCR, it shouldn't be included in BCS definition.

CIP System: This definition is not needed based on our proposed changes above.

Rationale: CIP System won't work for the CIP requirements since not each requirement applies to all CIP cyber assets that are included in the CIP System and the requirement has to specified which CIP cyber asset would apply.

ERC: Restore ERC definition since it is still effective (see our rationale in Q3).

EAP: Restore the definition

Rationale: Given that the current EAP is still clear and doesn't exclude policy-based rules, there is no need to modify EAP definition.

ESP: Restore ESP definition since it is still effective for the perimeter-based network protection (see the rationale in Q4).

IRA:

SDT Proposed SCI definition

User-initiated real-time access by a person from outside of the Responsible Entity's Electronic Security Perimeters (ESP) using a routable protocol:

- to a Cyber System within an ESP;
- through a Cyber Asset or Virtual Cyber Asset that is converting communications from a routable protocol to a non-routable protocol to a Cyber System not within an Electronic Security Perimeter;
- To Management Interfaces of Shared Cyber Infrastructure; or
- To Management Interfaces of an Electronic Access Control or Monitoring Systems that enforces an ESP.

Our Proposed Changes to the Definition

User-initiated interactive access by a person employing a remote access client or other remote access technology using a routable protocol. (This includes cases where a routable protocol is converted to a non-routable protocol)

Remote access originates from a Cyber Asset or Virtual Cyber Asset that is:

a. not an Intermediate System

b. is not located within any of the Responsible Entity's Electronic Security Perimeter(s) or,

c. at a defined Electronic Access Point (EAP).

Interactive remote access does not include system-to-system process communications. (See our rationale in Q5).

Rationale: IRA definition should only define what remote access constitutes an IRA and shouldn't include the accessed end devices. The IRA accessed cyber assets should be addressed in the requirements rather than in the IRA definition. We propose to add additional language to clarify the routable protocol converting to non-routable still falls within IRA definition since the current IRA definition is not clear on this. The current IRA definition states the user-initiated access using a routable protocol and doesn't say all communication sessions need to be routable.

Intermediate System: Restore the IS definition since the current definition is clear and no need to redefine it.

Rationale: The proposed IS definition starts from "EACMS", which is not correct logically. A Cyber Asset should meet the IS definition and then becomes an EACMS. Otherwise an IS can be missed if it is not an EACMS originally.

BCSI: Restore the definition based on our proposed definition changes above.

Cyber Security Incident: Restore the definition based on our proposed definition changes above.

PSP: Restore the definition based on our proposed definition changes above.

Removable Medium: Restore the definition based on our proposed definition changes above.

Reportable Cyber Security Incident: Restore the definition based on our proposed definition changes above.

TCA: Restore the definition based on our proposed definition changes above.

We believe the options are mostly clear and acceptable with the exception of the phrase "independent SCI supporting" either high or medium impact. It is unclear and confusing how an SCI can be both independent and supporting simultaneously. The proposed revised definition of BES Cyber System already would make it clear that SCI is to be included in CIP scope if applicable. We recommend removing the second bullet point entirely from both R1.1 and R1.2.

The options for SCI association within CIP-002 may be clear, but the handling of SCI involving EACMS cases is not clear from CIP-002 since that standard is limited to assessment of HIGH, MEDIUM and LOW impact BCS cases.

We thank the SDT for it’s work but believe the changes to definitions will create greatly impact existing entity’s policies, procedures and documentation and increase administrative overhead when some basic changes can be drafted which will a) retain and address the issue of virtualization, b) allow entity’s the flexibility to identify risks and implement appropriate security controls, and c) clarify language for regulators and industry alike. The current drafts create much administrative overhead because it requires entity’s using virtual platforms to parse out subcomponents and assign risk to establish compliance for such components. As entity’s move to cloud environments this will not be possible and therefore it is more practical to allow entity’s to identify their systems, assess risk and categorize them based on hardware profiles. SCI does little to clarify and define. In general, WAPA recommends a focus on individual hardware components and software enforcment policies (AAA). For example, an entity could consider an ESXi platform a single BCS (or BCA) which contains VCAs. Just a perspective.

The phrases “supporting SCI” and “independent SCI supporting” are not clear and should be removed from CIP-002. Recommend that SCI should be either categorized as a CIP Cyber Asset or not a CIP Cyber Asset (Hardware based decision). SCI shouldn’t appear in CIP-002 and Applicable Systems of CIP-003 to CIP-013. SCI should be evaluated using the criteria of a BCAs, EACMS, PACS or PCAs which can be missed in the virtualization environment.

For the proposed All-in-Scenario, SCI should be identified based on hardware such as BCA, EACMS, PACS or PCA rather than a new classification of CIP cyber asset. Creating separate definitions for SCI is tantamount to identifying hard drives and PCI cards as separate BCA and this will require entity’s a great deal of administrative overhead.

Secondly, SCI that can initialize, deploy and configure a BCA should be categorized as a BCA since it has a high risk profile - can remove a virtual BCA and impact to the BES within 15 minutes. Similarly, if a SCI can initialize, deploy and configure an EACMS and should be categorized as an EACMS since it can remove the virtual EACMS and it’s functions.

For independently Identified SCI proposed in the right box diagram below, SCI with an active Management Interface can initialize, deploy and configure a CIP Cyber Asset. This further supports the case for categorization based on hardware and not sub-components.

If the right-side SCI hosts VCA such as a CIP cyber asset regardless of the impact rating, the right side SCI should be identified as the same impact CIP cyber asset it hosts. It has the capability to impact the BES in 15 minutes. The right side SCI is out of CIP scope only: (1) if all VCAs it hosts are non-CIP cyber assets, this SCI would be out of CIP scope thus no need to be identified; (2) If it is used only to configure high impact network policy, it would be out of CIP scope since out of band management for CIP cyber assets is not required by the current CIP requirements scope and the SAR

Based on our comments above, the “SCI” and “independently Identified SCI” are not needed to be identified in CIP-002 since the SCI or independently Identified SCI either is a CIP BES Cyber Asset or not in scope.

We recommend revising definitions of BCA, EACMS, PACS and PCA to include SCI. Our proposed changes align with FERC and NERC’s security objectives and the SDT’s goal to address cyber security risks to the reliability of the BES from virtualization technologies, while having less impact on the entities existing CIP programs, processes and documentation. Entities can use their existing CIP cyber asset identification processes to identify BCAs, EACMS, PACS and PCAs based on SCI and Management Interface language to address virtualization. If the responsible entities don’t have virtualization, they wouldn’t need to identify any additional CIP cyber assets at all.

Recommendations:

1. Restore the CIP-002 R1 and its Parts resulting from our proposed definitions changes below.
2. We propose the following changes to the new or existing definitions:

SCI: One or more programmable electronic devices, including the software and Management Interfaces in those devices, that share:

- CPU and memory resources with one or more Virtual Cyber Assets identified as a BCA, EACMS, PACS or PCA; or
- storage resources with any part of a BES Cyber System or their associated EACMS, PACS or PCA.

- Includes devices that contain Management Interfaces for virtualization management.
- SCI does not include the supported VCA or CA with which it shares its resources.

Basis for this Recommendation: PCA is missing from the SCI definition. In our proposed changes, it is not necessary to identify SCI independently since SCI would be identified as a CIP Cyber Asset(s).

Management Interface: A user interface, logical interface, or dedicated physical port that is used to:

- Initialize, deploy, and configure BCA, EACMS, PACS, or PCA; or
- Control the processes of initializing, deploying, and configuring Shared Cyber Infrastructure; or
- Configure EAP of an Electronic Security Perimeter; or
- Configure EACMS that controls all communications to and from the BCS unless ESP model is used.
- Excludes physical user interfaces (e.g., power switch, touch panel, etc.). (Refer to Q6).

Basis for this Recommendation: the definition should focus on “in scope” CIP management interfaces. The term “Provide lights-out management capabilities” is not clear and should be removed since this criterion itself cannot make a management interface fall within CIP scope.

- Also, the Management Interface on the SCI is absent. We have added a bullet in our proposed definition to address it.
- Furthermore, we suggest edits to include:
- a) changing configure an ESP to configure an EAP
- b) adding configure EACMS to address the zero-trust mode based on our comments in Q4

CA: Restore the CA definition.

Basis of this Recommendation: If SCI is defined as a programmable device, it meets the definition of a CA and should be treated as one type of CA’s rather than excluding it from CA definition.

VCA: A logical instance of an operating system or firmware including software, data and virtual hardware on the logical instance hosted on a physical Cyber Asset.

BCS: Restore BCS definition.

Basis of this Recommendation: BCS should only include BCAs not other CIP cyber assets. Given that SCI could be an EACM, PACS or PCR, it shouldn’t be included in BCS definition.

CIP System: This definition is not needed based on our proposed changes above.

Basis of this Recommendation: CIP System won't work for the CIP requirements since not each requirement applies to all CIP cyber assets that are included in the CIP System and the requirement has to specified which CIP cyber asset would apply.

ERC: Restore ERC definition since it is still effective (see our rationale in Q3).

EAP: Restore the definition

Rationale: Given that the current EAP is still clear and doesn't exclude policy-based rules, there is no need to modify EAP definition.

ESP: Restore ESP definition since it is still effective for the perimeter-based network protection (see the rationale in Q4).

IRA: User-initiated interactive access by a person employing a remote access client or other remote access technology using a routable protocol. (This includes cases where a routable protocol is converted to a non-routable protocol)

Remote access originates from a Cyber Asset or Virtual Cyber Asset that is:

3. not an Intermediate System
4. is not located within any of the Responsible Entity's Electronic Security Perimeter(s) or,
5. at a defined Electronic Access Point (EAP).

- Interactive remote access does not include system-to-system process communications. (See our rationale in Q5).

Basis for this Recommendation: IRA definition should only define what remote access constitutes as IRA and shouldn't include the accessed end devices. IRA accessed Cyber Assets should be addressed in the requirements rather than in the IRA definition. Recommend additional language to clarify the routable protocol converting to non-routable that falls within IRA definition - since the current IRA definition is not clear on this anyway. The current IRA definition states the user-initiated access using a routable protocol and doesn't refer to communication sessions needing to be routable.

Intermediate System: Restore the IS definition since the current definition is clear and no need to redefine it.

Basis for this Recommendation: The proposed IS definition starts from "EACMS", which is not correct logically. A Cyber Asset should meet the IS definition and then becomes an EACMS. Otherwise an IS can be missed if it is not an EACMS originally.

BCSI: Restore the definition based on our proposed definition changes above.

Cyber Security Incident: Restore the definition based on our proposed definition changes above.

PSP: Restore the definition based on our proposed definition changes above.

Removable Medium: Restore the definition based on our proposed definition changes above.

Reportable Cyber Security Incident: Restore the definition based on our proposed definition changes above.

TCA: Restore the definition based on our proposed definition changes above.

ERCOT supports the IRC SRC comments and offers these additional comments:

- R1.1, bullet 1: Under the current version of CIP-002, there is no specific requirement to identify specific types of Cyber Assets applicable to the remaining CIP standards; it is implied at best. Going beyond the BCS identification into identifying specific Cyber Asset types, like Shared Cyber Infrastructure, is a change in to the fundamentals of CIP-002 and takes us back to CIP v1-v4 and the very granular level of Cyber Asset identification. The SDT should determine if all Cyber Asset types should be identified in CIP-002 or not. Each Cyber Asset type under the CIP standards is important in its role, including the SCI. If the SDT does not think that all Cyber Asset types should be addressed, SCI should be removed from this standard.
- R1.1, bullet 2: Please clarify the use of “independent.” It is unclear what this means. Independent of what?
- ERCOT recommends that no changes be made to requirement R1 in CIP-002.

While the expectation is clear with regard to what needs to be protected and why, what is not clear is what is required to achieve compliance with CIP-002 R1.1 requirements.

The requirement requires the identification of BCS as either “including any supporting SCI as part of the BCS” or with “independent SCI supporting any part of the high impact BCS or its associated Electronic Access Control or Monitoring Systems (EACMS), Physical Access Control Systems (PACS) or Protected Cyber Assets (PCAs).” This does not allow for the identification of BCS independent of having SCI, and therefore doesn’t account for non-virtualized environments.

The requirements and measures of CIP-002 do not sufficiently detail what is required to demonstrate compliance. The requirements are to create a list that identifies “each [BCS] as either” including supporting SCI or having independent SCI. However, the independent SCI details an association to EACMS, PACS, PCA. The requirement expects an identification of “BES Cyber Systems” but the sub-bullets imply an expectation to identify SCI and corresponding asset/system classifications. The measures and technical rationale provide no additional clarity other than creating lists. Is the expectation to simply provide identification that the identified BCS either include SCI or are supported by SCI (e.g. Yes/No or Checkbox), or is the expectation to explicitly identify and categorize SCI that meet this criteria (e.g. “1.) ABC High Impact BCS; 2.) CDE High Impact EACMS SCI”). If the expectation is to classify SCI, what should be the approach for classifying SCI that supports multiple classifications (e.g. EACMS and PACS)?

Request clarification when a SCI supports both high impact BES and medium impact BES. Is that SCI high watermarked to the high impact?

Request clarification of “it is a part of for CIP Requirement Applicability?” Is there a missing word? Should the language be “it is a part of it for CIP Requirement Applicability?”

Request clarification of the or in 1.3. Is the entity identifying low impact BCS or supporting SCI or both?

Request clarification of the 1.3 parenthetical. Is the entity required to provide an asset list for either low impact BCS or supporting SCI?

We don’t understand how to categorize a Shared Cyber Infrastructure. The SDT seems to make a distinction between two types of SCI, one type is supporting, and the other type is independent supporting. Our hypothesis is that a “supporting SCI” is for BCS (BCA/PCA) and that an “independent supporting SCI” is for associated Electronic Access Control or Monitoring Systems (EACMS), Physical Access Control Systems (PACS)).

In both cases, the SCI is the categorization labels, like BCA, PCA, EACMS, PACS, TCA.

Yet in the Applicable Systems column in the other CIPs, the SDT seem to make a distinction between the SCI, for example

CIP-005 R1.5 1.5 … PACS hosted on SCI … SCI identified independently…

CIP-007 R1.1 SCI identified independently supporting.

Clarification is needed.

Are the two options for identification SCI required? Is there a difference in the controls that we want to apply?

We suggest simplifying the language or add more precision. Example:

Per Attachment 1, Section 1, identify each high impact BES Cyber System as either of the following, if any, at each asset; High Impact BCS and their associated Electronic Access Control or Monitoring Systems (EACMS), Physical Access Control Systems (PACS), Protected Cyber Assets (PCAs) or SCI.

Furthermore, in the definition of SCI the PCA is not listed. Is this intentional? Wouldn't be possible to have a PCA supported by an SCI? We suggest that the SDT review the SCI / VCA/ PCA definitions, adjust the applicability and the requirements.

Reference SCI: One or more programmable electronic devices, including the software and Management Interfaces, that share: • CPU and memory resources with one or more Virtual Cyber Assets identified as a BCA, EACMS, or PACS; or

ACES agrees when SCI is included in the CIP Systems it falls into scope of CIP requirements where SCI is an Applicable System. The issue is not with CIP-002's usage of SCI or its definition, but the definition of CIP System as it lacks the inclusion of VCAs which could lead to confusion. AEPC has signed on to ACES comments.

Yes. The two options for SCI identification are clear within the CIP-002 standard revisions. However, the SDT should provide implementation guidance including examples of how to document the SCI, whether included within the CIP System or independently. Additionally, it would be helpful if the SDT was able to provide Implementation Guidance that included a logic diagram depicting how the device classifications and embedded definitions like Management Interface and CIP System can be applied. In addition, the SDT has been clear that this project focuses on on-premise virtualization, however, many virtualization concepts, like SCI, could be interpreted as being related to use of cloud computing technologies. AWS suggests explicitly stating that the Standards do not apply to cloud within the Applicability section of CIP-002. If these updated Standards do not apply to cloud, it should be obvious to the reader.

This language can be misinterpreted. Recommend clarification. Current language is “SCI identified independently supporting an Applicable System.” Suggest adding a comma to distinguish between “identified independently” and “supporting.” Resulting in “SCI identified independently, supporting an Applicable System”

The context of the question isn't clear is this question a general question or it's pertaining to CIP-002.

Also, the question offers two choices; "Is this clear" or "is additional clarification needed" yet the choices are Yes/No.

So, our answer; is No, it's not clear and yes additional clarification is needed.

Our hypothesis is that it must be a general question. We are not sure of the value of identifying the SCI ("supporting SCI" vs an "independent supporting SCI"), the SCI should be controlled and own requirements.

If the SDT maintains its distinction, they should enforce two types of categorizations and the requirements should be defined with those two types of categorizations in mind.

The process for the independent identification of SCI is not clear and needs additional clarification. EEI notes that within the VSLs for CIP-002, "independently identified SCI" is mentioned 27 times, yet no explanation is provided as to what it means or how this is to be accomplished.

It is also not clear what is meant by the term "independent SCI". This term is prominently used in Requirement R1, subpart 1.1 and 1.2 (bullet 2) but not explained. EEI asks that the SDT either define the term or use another term that is more widely understood.

Note: While EEI has identified our concern related to the use of SCI identified independently in CIP-002, this phrase is used throughout the CIP standards. For this reason, the SDT should provide more clarity to this term.

ERCOT supports the IRC SRC comments and offers these additional comments:

- Clarify "identified independently supporting". It is unclear what this means. Independent of what?
- Listing the SCI in the applicable systems columns contradicts what was done in the definition of BES Cyber System. The proposed definition of BES Cyber System already includes SCI but does not have the same qualifiers as in the applicable systems column.

Pamela Hunter - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - SERC, Group Name Southern Company

Answer	No
Document Name	

Comment

Southern agrees that "SCI identified independently" is clear and no additional clarification of that particular phrase is needed. However, Southern is concerned with the lack of clarity around SCI that does not host a BES Cyber System and is not within an ESP. Specifically, the inclusion of EACMS and PACS within the definition of SCI (and SCI within the EACMS and PACS definitions). As an example, an entity may have a VCA that is involved in processing access control logs. If this is an example of the "M" in EACMS (see discussion of this on Q14), and any part of the process executes as a VCA, then is the entire SCI now in scope? If so, what about backup systems that copy off snapshots of VCA for backup and thus may "share storage resources" with an EACMS? It is not clear where the scope of this "EACMS" ends. Southern believes there is clarity and simplicity for SCI that hosts a BCS and is in an ESP, but suggests scoping SCI to that which hosts a BCS and creating separate requirements to specifically address access to the mgt plane of an EACMS or PACS, for example (however, see Q14 as even that is problematic with the broadness of EACMS). This would be much more straightforward than treating SCI outside the ESP the same as SCI hosting a BCS.

Southern proposes the following alternative language for defining SCI, EACMS and PACS:

SCI: One or more programmable electronic devices, including the software and Management Interfaces, that share:

- CPU and memory resources with one or more Virtual Cyber Assets identified as a BCA; or
- storage resources with any part of a BES Cyber System.

Each SCI is either:

- included in one or more BES Cyber Systems; or
- identified independently.

SCI does not include the supported VCA or CA with which it shares its resources.

EACMS: Cyber Assets or Virtual Cyber Assets that perform electronic access control or electronic access monitoring of the Electronic Security Perimeter(s) or BES Cyber Systems or SCI. This includes Intermediate Systems.

PACS: Cyber Assets or Virtual Cyber Assets that control, alert, or log access to the Physical Security Perimeter(s), exclusive of locally mounted hardware or devices at the Physical Security Perimeter such as motion sensors, electronic lock control mechanisms, and badge readers.

While it is clear to those that have been following this project and or understand virtualization technologies and how it is used, a non-technical person may need more clarification. Further, “SCI identified independently…” the information provided in the most recent webinar was much clearer than what reads in the standards and Technical Rationale, but that is not binding. While both try to explain it, we don’t feel the Technical Rationale and glossary term does enough to distinguish exactly what is intended by the SDT. Secondly, CIP-002 R1.x doesn’t use the same verbiage. For example, “A XXXX impact BCS and independent SCI supporting any part of the XXXX impact BCS...” This should read: “A XXXX impact BCS and any SCI identified independently… supporting any part of the XXXX impact BCS...” We do feel these two classifications could work for industry, but need significant and binding definitions and distinctions with technical basis so entities can avoid misclassification of SCI.

The draft language is not clear. We assume that the phrase means SCI not declared as part of a BCA, PCA, EACMS, or PACS but it supports the BCA, PCA, EACMS, or PACS function (for example, a BCA can be run on VM system and the VM system will be defined as SCI, and the SCI can be declared as only SCI and not a dual declaration as a BCA and a SCI). However, this is only an assumption. How can SCI can both be independent and supporting any part of a BES Cyber System? If SCI supports any part of a BES Cyber System then it is not independent and is supporting.

Not clear on how the SCI is defined in this scenario. For the definition of "SCI identified indepently" is unclear what is meant by this definition, and is not clearly spelled out but an assumption is made. It appears to be assumed that the phrase means SCI not declared as part of a BCA, PCA, EACMS or PACS but it supports the BCA, PCA, EACMS, or PACS function. Would like this clearly spelled out by defintion and by each of the Applicable Systems column.

Additional clarification is needed.

Recommend spelling out "Shared Cyber Infrastructure" and its acronym within the standard text.

Recommend including the definition within the text, or make a statement in the text directing to the definition in the definition list.

The language “SCI identified independently” is not clear and should be removed from CIP-002 to CIP-013 (see our comments 1 in Q1). Resulting from our proposed changes to the definitions in Q1, the language “SCI identified independently” is no longer needed. A SCI should be identified either as one of the existing CIP cyber assets or out of CIP cyber asset scope.

This is not clear. We assume that the phrase means SCI not declared as part of a BCA, PCA, EACMS, or PACS but it supports the BCA, PCA, EACMS, or PACS function (for example, a BCA can be run on VM system and the VM system will be defined as SCI, and the SCI can be declared as only SCI and not a dual declaration as a BCA and a SCI). However, this is only an assumption.

Further, the phrase “independent SCI supporting any part of the … BCS” is confusing. It is not clear how an SCI can both be independent and supporting any part of a BES Cyber System. On its face it would seem that if an SCI supports any part of a BES Cyber System then it is not independent and is supporting.

We acknowledge the SDT’s attempt to avoid a “hall of mirrors” scenario where it could be interpreted that a device serving as an EACMS is required to have its own EACMS. However we also feel this situation may already occur today in some audits and not just a possibility going forward in the future. We recommend modifying existing definitions of BES Cyber System, BES Cyber Asset, and/or EACMS (ex. including an exclusionary phrase that an EACMS does not require its own EACMS).

This language can be misinterpreted. Recommend clarification. Current language is “SCI identified independently supporting an Applicable System.” Suggest adding a comma to distinguish between “identified independently” and “supporting.” Resulting in “SCI identified independently, supporting an Applicable System”

The context of the question isn’t clear is this question a general question or it’s pertaining to CIP-002.

Also, the question offers two choices; “Is this clear” or “is additional clarification needed” yet the choices are Yes/No.

So, our answer; is No, it’s not clear and yes additional clarification is needed.

Our hypothesis is that it must be a general question. We are not sure of the value of identifying the SCI (“supporting SCI” vs an “independent supporting SCI”), the SCI should be controlled and own requirements.

If the SDT maintains its distinction, they should enforce two types of categorizations and the requirements should be defined with those two types of categorizations in mind.

The definition of Shared Cyber Infrastructure (SCI) will be better explained with the term “SCI identified as supporting, but not part of…”.

BC Hydro requests that SDT provide more clarity around the concept of "not part of.." to better understand the separation point between whether an SCI is considered supporting but not actually part of BCAs, PCAs, EACMS or PACS.

BC Hydro also requests that SDT include a couple of practical examples to explain this concept within the Technical Rationale and proposed definition of SCI.

SIGE finds the language “SCI identified independently supporting an Applicable System above” confusing. It is confusing because “SCI identified independently” is a process, and CIP-002-7 R1.1 uses the term “independent SCI” when it asks to identify, “A high impact BCS and independent SCI supporting …” When stated in this context, the phrase “independent SCI” is a thing that can be defined. SIGE proposes that the Applicable Systems column should state “Independent SCI that supports an Applicable System above” and that “independent SCI” can be defined or explained as “a Cyber System identified separately from the BCS, EACMS, PACS, and/or PCA it supports.”

While it is clear to those that have been following this project and or understand virtualization technologies and how it is used, a non-technical person may need more clarification. Further, “SCI identified independently…” the information provided in the most recent webinar was much clearer than what reads in the standards and Technical Rationale, but that is not binding. While both try to explain it, we don’t feel the Technical Rationale and glossary term does enough to distinguish exactly what is intended by the SDT.

Secondly, CIP-002 R1.x doesn’t use the same verbiage. For example, “A XXXX impact BCS and independent SCI supporting any part of the XXXX impact BCS...” This should read: “A XXXX impact BCS and any SCI identified independently… supporting any part of the XXXX impact BCS...”

We do feel these two classifications could work for industry, but need significant and binding definitions and distinctions with technical basis so entities can avoid misclassification of SCI.

Introduction of the SCI Group concept as enumerated in response to Question 1 would provide the further clarity needed to address the relationship of devices identified as SCI to the BCS or SCIG of which they are a member. This additional clarity should be reinforced in the definitions, proposed as follows:

DUKE ENERGY PROPOSED DEFINITIONS FOR BCS, SCI, and SCIG:

BES Cyber System (BCS) - One or more BES Cyber Assets logically grouped by a Responsible Entity to perform one or more reliability tasks for a functional entity, including Shared Cyber Infrastructure that the Responsible Entity chooses to group into the BES Cyber System it supports.

Shared Cyber Infrastructure (SCI) - Programmable electronic devices, including the software and Management Interfaces, that share…(proposed bullets remain)… Each SCI is grouped by the Responsible Entity into one or more BCS or SCIG. SCI does not include the supported VCA or CA with which it shares its resources.

Shared Cyber Infrastructure Group (SCIG) - One or more Shared Cyber Infrastructure devices logically grouped by a Responsible Entity.

Additional clarification is required. Some SCI may provide underlying compute, storage, or network virtualization services, which is essential for the proper function of a BCS. Other SCI systems such as those providing overlays for management functions or monitoring, may not be required for real-time BCS functionality. Accordingly, that distinction, and provision of controls accordingly, would be beneficial in the associated glossary terms.

The Applicable System, “SCI identified independently” is ambiguous and unclear at best. Specifically, if SCI is hosting multiple Applicable Systems of different ratings, how is the SCI to be classified? Should it be high watermarked and protected to the highest rating of those Applicable Systems? If so, the SCI should be classified at the high watermark and be afforded the same protections as the Applicable System it supports - BCS, EACMS, PACS. The current definition and requirement is ambiguous which could result in an interpretation that applies BCS controls to an SCI that only supports EACMS or PACS. NRG requests the Standards Drafting Team provide more clarity between the two options: “All in” and “Identified SCI Option” as they seem to apply only when supporting a BCS and not in instances where SCI is hosting EACMS and/or PACS only. NRG disagrees with	

the Technical Rationale that requires logical isolation of SCI that hosts EACMS/PACS and no impact cyber systems. Within the context of the current CIP standards, there is no requirement for logical isolation between physical servers in this scenario.

The term "SCI identified independently" does not read intuitively without reading the guidance and technical rationale. Since those documents are not auditable, it must stand on its own and needs more revision to be more clear. Consider developing an additional defined term and classification: "Independent SCI" - "An SCI that is not identified as part of a BCS or its associated EACMS, PACS, or PCAs." This approach would keep the requirement language clean and include the needed guidance in the auditable parts of the standards and definitions.

Yes, it is clear that the “SCI identified independently” means that it is supporting any part of a high or medium impact BCS or associated EACMS, PACS or PCAs and is not included in the BCS. However, since “SCI identified independently…” is explicitly listed in the applicability columns, the other option for SCI to be included within the CIP System should also be explicitly stated. For example, “High Impact BCS, including supporting SCI, and their associated…”.

: **GSOC recommends revising the language in the definition of SCI such that it is clear to registered entities that “Each SCI must be identified as either…” As well, when SCI is addressed within other definitions, requirements, or applicable systems columns, consistent language should be used throughout, i.e., within the body of the standards, within the definitions, and between the definitions and the standards. As an example of inconsistencies identified in the new definitions, SCI is characterized as “supporting,” “included in,” or “grouped in/with” in various definitions, which usage may not comport with the terms used in the definition of SCI. Additionally, in CIP-002, SCI is referenced as “supporting” or “independent supporting,” but the term “supporting” is not utilized in the definition of SCI nor in its potential charcterizations as set forth in the definition. Finally, SCI reference language included in CIP-006 and other standards, at times, includes a clarifications to ensure exclusion of those SCI grouped into a BCS, but that language is also not consistently applied throughout the standards. To ensure clarity, it is recommended that the language utilized to reference SCIs is consistent throughout the definitions, throughout the standards, and between the definitions and standards.**

3. The SDT modified the ERC definition to reference “outside the asset containing”. This is to allow scoping based on connectivity of the logging systems as required by CIP-007 Requirement R4 as well as the scoping of requirement parts in CIP-004 and CIP-006 based on risk. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

Katie Connor - Duke Energy - 1,3,5,6 - SERC,RF

Answer	No
Document Name	

Comment

Duke has identified three concerns with the proposed ERC definition and underlying strategy:

First, the “outside the asset containing” language expands the current ambiguity in CIP-003 to High and Medium sites, allowing for auditor interpretation with respect to how communication that is translated or terminated through a bastion host locally at the asset should be assessed. It is not clear from the definitions whether the SDT intends that communication from an outside location that first terminates on a non-CIP System at the asset and then pivots to a CIP System at the asset is included in this ERC definition, or if that break in communication is basis to exclude the CIP System from the ERC applicability.

Second, use of the ERC definition to attempt to address security concerns associated with remote access to devices that are accessible based on Serial to IP conversion alone exacerbates the CIP-004, 006, and 007 scoping challenges noted by the SDT.

The ERO has socialized a better path forward using the IRA definition to ensure that devices accessible in this manner are correctly secured. This would be a better strategy for securing these assets while minimizing low-value compliance paperwork (e.g. documenting lack of syslog capability on a serial-only relay). This change would take the SDT's removal of ERC from the CIP-005 requirement language to its logical conclusion, removing the dependence on the ERC definition to define security posture and instead using it as a scoping tool. Refer to slides 9-11 in following presentation: https://www.nerc.com/pa/Stand/Project%20201602%20Modifications%20to%20CIP%20Standards%20RF/2016-02_ERC_and_IRA_Webinar_Slides_05072020.pdf

Third, the use of CIP Systems creates confusion as there are no ERC requirements applied to other classifications of devices that are included in the CIP Systems definition (e.g. EACMS, PACS, and TCA devices). Although simplicity in definitions is desirable, it would be clearer to spell out the system types that are relevant to the defined term (e.g. BCS, PCA, SCI).

Therefore, Duke proposes the following definition of ERC, which incorporates the SDT's improved "communicate" terminology while remaining focused on the ESP boundary as the point where the determination is made.

External Routable Connectivity (ERC) - The ability to communicate across a defined ESP via a bi-directional routable protocol connection.

It does not appear that the SDT's rationale regarding the shrinkage of the ESP in Zero Trust environments is likely to reach the intra-device level given that the CA, VCA, and SCI definitions remain device-centric. Therefore, Duke strongly feels that the fundamental change proposed by the SDT is not justified by the potential downside the SDT has identified.

Just as it has been problematic for entities with assets containing low impact BES Cyber Systems to identify where electronic access controls must be afforded for routable protocol, the use of a physical construct for where logical controls are implemented for CIP-004 and CIP-006 appears to further the problem. Consider the following two edit to the proposed ERC definition: The ability to communicate to a CIP System using a bi-directional routable protocol from a nonCIP System.

The lower-case ‘asset’ used in the definition really erodes the intent of ERC. This could allow an entity to not consider communication between corporate networks and BCS to be ERC if they are in the same building (‘asset’), for example at a Control Center. Alternative proposal: *The ability to communicate to a CIP System using a bi-directional routable protocol from a Cyber System that is not protected by an Electronic Security Perimeter located at the same asset. However, the alternate proposal still has a limitation on ‘asset’, which is an undefined term.*

AZPS feels that changing the language to “communicate to” instead of “accessing” has the potential to expand the scope of ERC unintentionally. Including “outside the asset containing the CIP system” leads to ambiguity while use of ESP helps clarify intent. The new definition suits virtual fully, but leaves vagueness and abiguity to physical aspects. AZPS respectfully recommends creating two separate definitions for physical and virtual.

The new language does not clarify where the border where bi-directional communication is considered. The current definition, which specifies the border to be at that EACMS (local firewall) is adequate for most cases. We understand that the definition needs to be adjusted to recognize implementation of zero trust models. However, clarifying that external routable connectivity is determined at the physical border of the asset would clearly identify where external routable connectivity is to be considered.

ACES does not agree with the reference “outside the asset containing” as a scoping mechanism for CIP-007 R4. We do not understand the correlation of ERC to CIP-007 logging or CIP-004 and CIP-006 risks. Using the “asset” as a scoping mechanism could lead to various interpretations and allow for loop holes for access. In our opinion, “outside the asset containing” is not necessary to define ERC. We feel ESP is still the proper scoping mechanism.

AEPC has signed on to ACES comments.

CEHE does not agree with the proposed change to the ERC definition because the phrase “from outside the asset containing the CIP System” is not clear. “Asset” is not a term in the NERC Glossary of Terms; therefore the definition cannot clarify precisely what “outside the asset” means. Is it a room, building, geographical location, or something else?

In addition, the proposed definition greatly expands the existing definition by changing from “BES Cyber System” to “CIP System” and by changing from “... to access …” to “… to communicate …”. However, this expansion can be controlled by specifying specific Cyber Systems in the requirements.

CEHE suggests maintaining the currently approved definition until a more clearly defined proposal is offered or “Asset” is added as a defined term in the NERC Glossary.

It’s not clear what is meant by the phrase “from outside the asset containing the CIP System.” This makes it sound like all CIP Systems must reside within a electronic security perimeter. It is unclear what it is that the SDT is attempting to accomplish with this wording or how it is allowing scoping based on connectivity of the logging systems as required by CIP-007. Further, the use of the term “asset,” with a lower case A, often causes confusion with “Cyber Asset” when discussing requirements with SMEs.

Rachel Coyne - Texas Reliability Entity, Inc. - 10

Answer	No

Document Name	
Comment	

Texas RE is concerned the new proposed changes to the ERC definition only focus on WAN and excludes LAN network communications. LAN and WAN network communications are both captured under the current definition. If the proposed changes are approved, registered entities could potentially argue that they have no ERC even though a bi-directional routable protocol connection is being utilized from LAN to LAN.

As such, this change could reduce the entities' overall security posture by placing such communications potentially outside the scope of the entities' CIP-program. For example, the proposed language for CIP-005 R2.1 includes in scope "medium impact BCS with ERC". Since the proposed ERC definition focuses on the term "asset", Texas RE is concerned that entities could potentially read the "asset" language to remove from scope BCAs such as operator consoles that are not accessible from outside the Control Center (that is, from outside the "asset"). Specifically, because there is no ERC from outside of the Control Center, it could be argued that the operator consoles no longer fall within the proposed ERC definition. As a result, important CIP protections such as the use of an Intermediate System to access those assets, physical protections, and personnel training requirements would be limited.

Given these concerns, Texas RE recommends retaining the current definition of ERC.

BC Hydro seeks more clarity on the term "asset" in relation to the reference "outside the asset containing." Specifically, it is not clear whether the term "asset" is meant to talk to individual BES Elements (i.e. a specific transformer, circuit breaker, etc.) or whether entities are given the latitude to define the boundaries of assets (i.e. could be based on defined physical boundaries of a broader transmission or generation station or a Control Centre). Recommend providing specific drawing examples similar to the models provided under the CIP-003-8 standard to help visualize through practical network architecture to characterize what would constitute ERC under this new proposed definition.

The modification to the definition to ERC brings serially connected OT Devices using a protocol-converter into scope for multiple CIP-007 requirements. In some instances, compliance with all CIP-007 requirements would be impossible. The use of a protocol converter does not facilitate centralized logging, review, and alarming (based on events). It simply facilitates data acquisition and IRA to these devices. We suggest not revising the definition of ERC, leaving the concept of a protocol break in place and require the protocol converter to either be categorized as a BCA, PCA or EACMS (depending on the circumstance). The serial OT device could still utilize the proposed definition for IRA to be in scope for CIP-005.

The proposed change to the ERC definition expands scope by making the boundary physical “asset” from the original electronic concept. ERC could happen within a room where two systems have discrete ESPs that communicate between each other.

Change the ability to “access” to “communicate to” to bring the connectivity rationale into the term.

Suggested definition - *The ability to communicate to a BES Cyber System from a Cyber Asset that is outside of its associated Electronic Security Perimeter via a bi-directional routable protocol connection.*

In support of NPCC RSC comments.	

We understand that “outside the asset containing” is a scoping mechanism.

Request clarification. This new language creates an implicit requirement that the trust boundary is now at the asset not the ESP. Did the SDT intend this implicit requirement?

We are confused by the proposed change. We do not understand the trust boundary change from ESP to asset. Request clarification of demarcation. Where is the electronic boundary? Where is the physical boundary?

Given this update, we believe the Medium Impact boundary is not as well defined as the Low Impact boundary. ERC means external to what?

The overall definition of ERC is

The ability to communicate to a CIP System using a bi-directional routable protocol from outside the asset containing the CIP System.

(The definition of CIP System is included for precision)

The ability to communicate to a CIP System (A Cyber System identified by the Responsible Entity as a BES Cyber System, Electronic Access Control or Monitoring System, Physical Access Control System, Shared Cyber Infrastructure, Protected Cyber Asset, or Transient Cyber Asset.) using a bi-directional routable protocol from outside the asset containing the CIP System (A Cyber System identified by the Responsible Entity as a BES Cyber System, Electronic Access Control or Monitoring System, Physical Access Control System, Shared Cyber Infrastructure, Protected Cyber Asset, or Transient Cyber Asset.).

We don’t see the added value of this “scoping” for CIP-007 R4, CIP-004, CIP-006. This definition includes additional asset types (EACMS, PACS, SCI, PCA, TCA) to the concept of ERC. One could think that future requirements could come forward, like for EACMS with ERC or even TCA with ERC, but it’s not the case.

In reference to CIP-007 R4, the text used is the following

Medium Impact BCS with External Routable Connectivity and their associated:

1. EACMS;

2. PACS; and

3. PCA

SCI identified independently supporting an Applicable System above

The ERC trigger is still based on the BCS.

If the understanding of asset (“the asset containing “) is equivalent to the following … i. Control Centers and backup Control Centers; ii. Transmission stations and substations; iii. Generation resources; iv. Systems and facilities critical to system restoration, including Blackstart Resources and Cranking Paths and initial switching requirements; v. RAS that support the reliable operation of the Bulk Electric System; and vi. For Distribution Providers, Protection Systems specified in Applicability section 4.2.1 above… the suggested definition is interesting.

Our comprehension is that if we have two HIGH/Medium-Impact BCS in the same Control Center (asset) using a bi-directional routable protocol to establish their communication and that any of those BCS doesn’t use a bi-directional routable protocol outside of the Control Center, the ERC definition wouldn’t be applied. Furthermore, if any of those two BCS would be using a bi-directional routable protocol outside of the asset of both BCS would be tagged as being ERC.

We suggest the removal of CIP System in the definition.

AEP does not support the proposed changes to the External Routable Connectivity (ERC) definition and is in support of EEI's comments. The new definition for ERC expands the scope by (1) replacing the defined term "BES Cyber System (BCS)" with a proposed new term "CIP System", and (2) changing "the ability to access …" to "the ability to communicate to …". In addition, AEP seeks additional clarification on "asset containing the CIP System". The term "asset" could be interpreted in many ways and could be a point of contention if an entity identified an "asset" at a fence line where an auditor may have a different opinion on where that line of demarcation for an "asset" might be drawn.

We disagree to modifying ERC definition. Given that the ESP is still effective and the language BCS with ERC and IRA are still used by STD in the revised requirements, ERC should be still ESP and BCS based rather than asset based. If using the physical boundary to identify ERC, it is hard to decide which BCS with ERC and which BCS without ERC, which would cause ERC identification issues and various interpretations. Also the asset boundary will cause the security risk since the highwater marking wouldn't apply within a physical boundary. Furthermore, physical boundary would cause audit issue since it is not a defined term. For instance, whether a generating station power house and its switchyard are treated as the same asset or separate asset will get the different results. In addition, the proposed ERC definition overreaches the goal of SAR since the revised ERC refers to CIP System which includes all types of CIP cyber assets. The SRA doesn't require entities to identify ERC for EACMS, PACS, and TCA that are outside ESP.

Recommendation: Restore the current ERC definition since it still fits the revised requirements.

Comment

Because the term and concept of ESP remains effective and the BCS language of ERC and IRA are used by STD in the revised requirements, ERC should remain ESP and BCS based rather than asset based. It is difficult to determine which BCS with ERC and which BCS without ERC would apply with the proposed language.

The asset boundary will cause a security risk since the highwater marking wouldn't apply within a physical boundary. Furthermore, physical boundary would cause audit issue since it is not a defined term. For instance, whether a generating station power house and its switchyard are treated as the same asset or separate asset will get the different results. - The proposed change for ERC is confusing, including March and August discussions with the SDT during outreach, for when a CIP System that serial converts RS-232 or RS-485 may extend ERC beyond the ESP to medium impact BCAs, PCAs and Non-CIP Cyber Asset. We do not understand the trust boundary change from ESP to asset. Request clarification of demarcation.
    - Where is the electronic boundary and how does it apply when not routable?
    - Where is the physical boundary when serial extends out of the substation to field devices?
    - When does ERC apply to a CIP System that is connected serially that was previously consider non-routable before the new proposed updates from Project 2016-02 SDT?
        - Please clarify the language that extends applicability to a CIP System using serial communication within the asset/site?

    - If the serial link can change the configuration of a BCA is the SDT intending Entities now have a BCA with ERC when previously the demarcation was the serial link?

- Please clarify how ERC is applied to standards when an SCI EACMS in a Medium Impact substation that provides conversion of ERC to serial for remote configuration support of RTU and Relays rated as Medium BCA along with Relays that are Low Impact BCA and Non-CIP System Relays how ERC is being applied when using serial communication has the proposed standard requirements intended that PSP and 15 month password changes now apply?

- Will applicability today for BCA with ERC apply going forward with the new proposed definitions and requirements to a BCS Medium Impact Relay connected serially that is being managed through RS-232?

- Does a Non-CIP System distribution Relay now become a PCA because it is connected to the Medium Impact Serial converter?

- The SDT ERC changes appears to be impacting the BROS process may require improved language in CIP-002 Attachment 1 as it cascades into other standards applicability requiring clarification:

    - CIP-002 R1 and R2 - Would Entities now need to identify BCA's that are serially connected and update CIP-002 BCS List to show these now as part of either SCADA or Protection with ERC?

    - CIP-004 R4.3 – Would electronic access to devices with ERC now be an entitlement to be mapped all serially connected devices requiring and role authorization?

    - CIP-005 R1.1 – Does the SDT expect that the ESP diagrams to now show serially connected devices within the substation house PSP and cables external out of the PSP to the devices in the structure including Transformers, CAP Banks, etc?

    - CIP-006 R1.2, 1.4, 1.7, 1.8, 1.9, 2.2, 2.3, 3.1 – Does the SDT intend that devices without ERC currently are outside a PSP (allowed by CIP-006 R1.1) will now with the proposed changes require the establishment of a PSP, with control, alerting, response, logging, visitor escort and system testing for serially connected IED in transformer cabinet for temperature monitoring, metering devices or other IEDs outside of the Station House PSP?

    - CIP-007 R1 – Please confirm the P1.1 Logical ports justification and details for serially connected CIP Systems are excluded but expectation of the physical wiring will be required for P1.2?

    - CIP-007 R4.2 – Please clarify the serial CIP System must now alert for failure of event logging.

    - CIP-007 R5.6 – Please clarify a serial CIP System such as an RTU or Relay that was a BCA or PCA without ERC now with the proposed change requires the password change every 15 months?

    - CIP-010 R1.1.4 – How will an Entity meet the baseline requirement for logical port open on each serially connected device or can a by device capability exclusion apply?

    - CIP-010 R1.2, 3, 4 – Do the proposed update require all the change management sub-requirements apply when a device is serially connected/disconnected to a network or moved within a network while still a serial device?

    - CIP-010 R3 – Please confirm the annual CVA including network discovery will require serial communication assessments throughout the site/facility/asset?

LCRA is concerned with bringing serial devices into scope as part of ‘Applicable System with ERC’. This would require the serial relays to comply with additional CIP requirements. Expanding the scope of ERC to serial-based devices could significantly increase implementation cost and require new tools/products to help with ensuring compliance. The changes needed to enforce Physical Security requirement CIP-006 R1.2 will require long lead times to implement especially for shared control houses.

Southern agrees with the concept but does not agree with the proposed language. “Asset” should be better defined as it is too ambiguous and many requirements’ scoping is based on clarity around ERC. Additionally, ERC has changed from being defined in terms of a BCS to a ‘CIP System’ which includes all named types of devices. If a BCS inside an “asset” is isolated, however there is a docked TCA on another network inside the 'asset', does the BCS inherit ERC because a “CIP System” can be accessed in the asset? As the boundary broadens and the target is any CIP System, it has lost focus on the ability to externally communicate with a BCS. Southern suggests that ERC be defined in terms of the BCS, not the overly broad “CIP System”.

ERCOT supports the IRC SRC comments and offers this additional comment:

- The proposed modification greatly expands the scope of the definition. “Asset” has historically referred to things like transmission, generation, etc. Before, ERC was limited to just BES Cyber System. Why is this needed with assets and systems that reside outside of an ESP? The definition also needs to accommodate technologies that do not use a routable protocol.

ATC supports the SDT’s intentions, however the proposed draft language is still somewhat unclear. For those reasons, ATC requests consideration of clearer language and perhaps supporting diagrams. One example of a question we’ve asked ourselves was: If you connect from a router (EACMS) to talk to a switch would that be ERC? Also, If my Control Center “asset” has several rooms and various subnets, and some devices are on a non-BCS subnet but still physically inside the “asset” containing the BCS, shouldn’t a routable connection from that device to a BCA be considered ERC?

Comment

EEI does not support the proposed change to the ERC definition because it expands the current definition by replacing the defined term BES Cyber System (BCS) with newly defined term “CIP System” and by changing from “... to access …” to “… to communicate …”. “Access” means the ability to make use of information (see NIST definition of access - https://csrc.nist.gov/glossary/term/access), while the term communicate has a much broader meaning and could be interpreted to mean that the act or ability to ping a device is now in scope.

Additionally, the use of the term “asset” within the context of the ERC definition raises potential compliance ambiguity and lack of uniformity that could result in different interpretations during an audit. To address these concerns, we offer the following:

The ability to access a BCS using a bidirectional routable protocol from outside the ESP that controls access to the BCS.

This is a substantial change to the definition of ERC that has a larger impact than in the context of addressing virtualized environments.

This is a large change to bring into scope assets that are protected by the ESPs in the past but did not have to meet ERC requirement since this connection did not enable IRA.

The proposed change to the ERC definition expands scope by making the boundary physical “asset” from the original electronic concept. ERC could happen within a room where two systems have discrete ESPs that communicate between each other. Change the ability to “access” to “communicate to” to bring the connectivity rationale into the term. Suggested definition - *The ability to communicate to a BES Cyber System from a Cyber Asset that is outside of its associated Electronic Security Perimeter via a bi-directional routable protocol connection.*

We understand that “outside the asset containing” is a scoping mechanism.

Request clarification. This new language creates an implicit requirement that the trust boundary is now at the asset not the ESP. Did the SDT intend this implicit requirement?

We are confused by the proposed change. We do not understand the trust boundary change from ESP to asset. Request clarification of demarcation. Where is the electronic boundary? Where is the physical boundary?

Given this update, we believe the Medium Impact boundary is not as well defined as the Low Impact boundary. ERC means external to what?

The overall definition of ERC is

The ability to communicate to a CIP System using a bi-directional routable protocol from outside the asset containing the CIP System.

(The definition of CIP System is included for precision)

The ability to communicate to a CIP System (A Cyber System identified by the Responsible Entity as a BES Cyber System, Electronic Access Control or Monitoring System, Physical Access Control System, Shared Cyber Infrastructure, Protected Cyber Asset, or Transient Cyber Asset.) using a bi-directional routable protocol from outside the asset containing the CIP System (A Cyber System identified by the Responsible Entity as a BES Cyber System, Electronic Access Control or Monitoring System, Physical Access Control System, Shared Cyber Infrastructure, Protected Cyber Asset, or Transient Cyber Asset.).

We don’t see the added value of this “scoping” for CIP-007 R4, CIP-004, CIP-006. This definition includes additional asset types (EACMS, PACS, SCI, PCA, TCA) to the concept of ERC. One could think that future requirements could come forward, like for EACMS with ERC or even TCA with ERC, but it’s not the case.

In reference to CIP-007 R4, the text used is the following

Medium Impact BCS with External Routable Connectivity and their associated:

1. EACMS;

2. PACS; and

3. PCA

SCI identified independently supporting an Applicable System above

The ERC trigger is still based on the BCS.

If the understanding of asset (“the asset containing “) is equivalent to the following … i. Control Centers and backup Control Centers; ii. Transmission stations and substations; iii. Generation resources; iv. Systems and facilities critical to system restoration, including Blackstart Resources and Cranking Paths and initial switching requirements; v. RAS that support the reliable operation of the Bulk Electric System; and vi. For Distribution Providers, Protection Systems specified in Applicability section 4.2.1 above… the suggested definition is interesting.

Our comprehension is that if we have two HIGH/Medium-Impact BCS in the same Control Center (asset) using a bi-directional routable protocol to establish their communication and that any of those BCS doesn’t use a bi-directional routable protocol outside of the Control Center, the ERC definition

wouldn't be applied. Furthermore, if any of those two BCS would be using a bi-directional routable protocol outside of the asset of both BCS would be tagged as being ERC. We suggest the removal of CIP System in the definition.

N&ST assumes this proposed revision is intended to bring into scope remote connections to serially-connected CIP Systems that traverse wide-area connections via TCP/IP before being converted, "locally," to serial. However, as written, it would exclude end-to-end routable connections from non-CIP Systems to CIP Systems established within a given asset (example: TCP/IP connection from a PC on corporate network to a CIP server in the same building behind an ESP on a CIP network). One loophole closed, another opened. N&ST believes the SDT should be able to address this problem by expanding the definition of ERC using an "either/or" format. ERC is either: "The ability to access a BES Cyber System from a Cyber Asset that is outside of its associated ESP via a bi-directional routable protocol connection; or "The ability to communicate to a serially-connected CIP System using a bi-directional routable protocol from outside the asset containing the CIP System."

Dominion Energy agrees with the reason for the reference “outside the asset containing…” but the definition itself does not help determine if ERC exists within a communication link that involves a routable protocol that is converted to serial protocol at the last leg of the link. However, based on the NERC SDT Webinar, presented on August 4, it appears that ERC exists in this kind of communication. One or more high level reference diagrams that illustrate the general concept of the modified term ERC, or some examples of the concept, in an Implementation Guidance document would be beneficial. While GSOC agrees with the intent of the change, it cannot support the proposed change as use of the generic term "asset" could cause confusion and inconsistency regarding the meaning of the term "asset" and its use across the body of standards. As an example, asset is utilized in CIP-002 and is meant to convey a physical facility or building. The generic use of "asset" within the new definition of ERC could, therefore, also be construed as referring to the physical building or facility in which a system is located, which is likely not the intended or	

only meaning. To reduce the potential for confusion, GSOC recommends that clarification be added to the definition of ‘ERC’ to ensure that the full intent and meaning of the term “asset” as used within the definition of ERC is clear and easily, consistently understood.

EEI agrees that the modified ESP definition can be used for both types of networks but seeks clarification regarding the inclusion of the phrase “and their associated PCAs”, which appears to be redundant to the second sentence in the definition. EEI notes that within the definition of CIP System, PCAs are clearly identified as a CIP System. We suggest the following as one possible solution: “A set of configurations or policies enforced by an EACMS that control routable protocol communications to or from any part of a BES Cyber System (BCS) and that groups BCS of the same impact rating.”	

Alternatively, the SDT might consider leveraging the defined term “Electronic Access Point (EAP)” rather than modifying the term ESP.

The phrase "control communication" is too broad; it could include any policy/configuration that configures anything that communicates (e.g., an internal API within an application). The definition needs additional clarity such that an ESP is in the networking realm and is controlling the ability to deliver packets to a BCS on the network, which we gather is the intent since host-based firewalls are excluded. We suggest modifying it to "control routable protocol communication" to clarify that an ESP is a network level construct (even in zero trust) concerned with delivery of packets. The grouping statement in the ESP definition is confusing as it switches to "CIP Systems" and only BCS have impact ratings. Suggest changing this to "These configurations or policies group BES Cyber Systems of the same impact rating with their associated PCAs". In addition, we believe this sentence is attempting to say the ESP is the ‘innermost’ policy or configuration controlling access to the BCS and therefore grouping BCS of like impact rating and their PCAs. We suggest making further clarifications to that end. An enterprise’s Internet facing firewalls play some role in ‘controlling communications’ to eventual groups of BCS that may be many network zones deep behind many firewalls that are not the CIP-005 ESP of today. However, there appears to be nothing in the definition or CIP-005 R1.1 that clearly states the ESP in question is the layer of segmentation/isolation method immediately ‘outside’ the BCS.

Comment	
The SDT is using the update to the definition as a mechanism to support zero-trust models, but the existing ESP definition does not preclude a Responsible Entity from applying the concept of zero-trust to its environment(s) in addition to its traditional ESP. The proposed modification does not obligate a Responsible Entity to adopt additional security controls. The statement in the Definitions and Exemptions Technical Rationale, “[i]n these models, the perimeter shrinks to increasingly more granular levels, potentially down to a process or resource level on a BCS and nothing on the network is trusted for unrestricted communications,” could be	

interpreted as meaning that traditional ESP-based perimeter security is not necessary or required. A Responsible Entity may choose to adopt a traditional ESP model, or a zero-trust model, without considering the benefits of a defense-in-depth approach that leverages both traditional perimeter-based security and zero-trust concepts.

AWS proposes the following language, “The logical border surrounding a network to which BES Cyber Systems are connected using a routable protocol that includes a set of configurations or policies enforced by an EACMS that controls communications to or from any part of a BES Cyber System. These configurations or policies group CIP Systems of the same impact rating and their associated PCAs.”

Detailed implementation guidance is necessary to support zero-trust and hybrid approaches.

Relative to the definition of ESP, GSOC is concerned that the second sentence proposed in the new definition is unnecessary and could cause confusion regarding its applicability beyond a virtualized environment. In particular, use of the term “group” could connote actions or protections beyond the traditional and intended meaning of ESP. As well, the second sentence appears to act as an additional requirement on the use of ESPs that would be better suited for inclusion in the actual requirements as set forth in CIP-005-8. GSOC recommends deleting the second sentence from the definition and re-capturing the concept (as applicable) in the language of CIP-005-8.

GSOC requests the addition of clarifying language in CIP-005-8 R1.2 that would reinforce the approach of utilizing a traditional approach to electronic security perimeters in addition to the language proposed “EACMS that enforces an ESP for the Applicable System…” Current proposed language could be interpreted to only apply to communications traversing an EACMS enforcing an ESP in a virtualized environment, without providing for requirements concerning the same traffic traversing a traditional ESP such as a firewall or similar device.

Comment

The modified ESP definition does not resolve the traditional firewall based network or future networks. The virtualization zero trust topology is underneath the ESP network and is a non-ESP model. It is configured in the virtualization layer prior to VCAs reaching the ESP network. IRA cannot be identified without an ESP boundary being defined since IRA is initiated outside ESP. Furthermore, the SDT proposed ESP definition would include routable and non-routable BCAs in which it overreaches the goal of SAR. In our view, the EAP is still effective for the ESP model to control communications to and from BCS using routable protocol inside an ESP. We recommend adding an alternative requirement in CIP-005 R1.1 to address the zero-trust model in which the ESP model is not used rather than revising ESP definition. Our proposed changes won’t affect the existing ESP definition and ESP related requirements while still addressing virtualization to meet the goal of SAR.

Recommendations:

1. Restore the current ESP definition since it is still effective for the perimeter-based routable network protection.
2. We propose the following changes for CIP-005 R1.1:
    i. All applicable Cyber Assets connected to a network via a routable protocol shall reside within a defined ESP where all External Routable Connectivity must be through an identified EAP that permits only needed inbound and outbound access and denies all other access by default including the reason for granting access, or
    ii. All BCAs connected to a network via a routable external protocol shall through an EACMS that controls all communications to and from BCAs unless ESP model is used.

    We agree that the proposed ESP definition can be used for both traditional firewall based networks, as well as future networks such as zero trust. However, the routable protocol qualifier was removed and the new ESP qualifier is an EACMS. The EACMS definition does not have a routable protocol/communication qualifier, and it references ESPs. This seems like a circular definition. Also, it is our understanding that the SDT does not intend to have requirements baked into definitions but with the proposed ESP definition, and changes to CIP-005, the definition is the only place EACMS are required. We propose the following changes:

ESP definition: A set of configurations or policies that controls communications to or from any part of a BES Cyber System. These configurations or policies group CIP Systems of the same impact rating and their associated PCAs.

New CIP-005-X R1 Part 1.X:

Applicable Systems

High Impact BES Cyber Systems and their associated PCA

Medium Impact BES Cyber Systems and their associated PCA

Requirements

1.X.1 - EACMSs must be implemented to enforce ESPs where communication leaves the ESP, or where SCI is used.

1.X.2 - EAPs must be identified for ESPs.

When the proposed ESP definition is applied in the proposed CIP-005-X R1 Part 1.1 there is another issue since the definition no longer has the routable protocol qualifier. See our response to Question #10 below for further explanation.

In our opinion it should be clarified that a BCA or PCA controlling access only to itself (such as a host-based firewall) does not qualify as an EACMS and likewise does not constitue an ESP, except in cases where zero-trust is being used in place of a traditional EACMS and Access Point (such as a firewall). We also support EEI's comments on this question.

Suggesting that the SD go back and make modifications to the definitions. We agree that the proposed ESP definition can be used for both traditional firewall based networks, as well as future networks such as zero trust. However, the routable protocol qualifier was removed and the new ESP qualifier is an EACMS. The EACMS definition does not have a routable protocol/communication qualifier, and it references ESPs. This seems like a circular definition. Also, it is our understanding that the SDT does not intend to have requirements baked into definitions but with the proposed ESP definition, and changes to CIP-005, the definition is the only place EACMS are required. We propose the following changes:

ESP definition: A set of configurations or policies that controls communications to or from any part of a BES Cyber System. These configurations or policies group CIP Systems of the same impact rating and their associated PCAs.

New CIP-005-X R1 Part 1.X:

Applicable Systems

High Impact BES Cyber Systems and their associated PCA

Medium Impact BES Cyber Systems and their associated PCA

Requirements

1.X.1 - EACMSs must be implemented to enforce ESPs where communication leaves the ESP, or where SCI is used.

1.X.2 - EAPs must be identified for ESPs.

When the proposed ESP definition is applied in the proposed CIP-005-X R1 Part 1.1 there is another issue since the definition no longer has the routable protocol qualifier.

While the modified ESP definition is a definite improvement with respect to support for future development of zero trust networking adoption, the measures associated with proposed CIP-005-8 R1 include specification of business reasons associated with the configuration identified in the definition. ISO-NE requests that the definition be updated to include the business reasons as a part of the ESP to clarify the relationship and the requirement to include such in the configuration and documentation related to ESP's.

We disagree with the modified ESP definition as it cannot resolve the traditional firewall based network and the future networks. The virtualization zero trust topology is underneath the ESP network and is a non-ESP model. It is configured in the virtualization layer prior to VCAs reaching the ESP network. Also, IRA cannot be identified without ESP boundary being defined since IRA is initiated outside ESP. Furthermore, the SDT proposed ESP definition would include routable and non-routable BCAs in which it overreaches the goal of SAR. In our view, the EAP is still effective for the ESP model to control communications to and from BCS using routable protocol inside an ESP. We recommend adding an alternative requirement in CIP-005	

R1.1 to address the zero-trust model in which the ESP model is not used rather than revising ESP definition. Our proposed changes won't affect the existing ESP definition and ESP related requirements while still addressing virtualization to meet the goal of SAR.

Recommendations:

1. Restore the current ESP definition since it is still effective for the perimeter-based routable network protection.

2. We propose the following changes for CIP-005 R1.1:

a. All applicable Cyber Assets connected to a network via a routable protocol shall reside within a defined ESP where all External Routable Connectivity must be through an identified EAP that permits only needed inbound and outbound access and denies all other access by default including the reason for granting access, or

b. All BCAs connected to a network via a routable protocol shall through an EACMS that controls all communications to and from BCAs unless ESP model is used.

While AEP agrees that the modified Electronic Security Perimeter (ESP) definition can be used for both type of networks (i.e., traditional firewall based networks, as well as future networks such as zero trust), we recommend the second sentence be removed. The second sentence, "These configurations or policies group CIP Systems of the same impact rating and their associated PCAs", seems to be an arbitrary statement that does not build upon the security requirement. A semantic argument could be made that once the configurations or policies are established, all CIP Systems inherit the highest water mark; however, prior to the establishment, the inherent risk of the associated CIP Systems could differ. We suggest removing the second sentence to avoid future confusive discussion.

Since the Glossary modifications are the foundation to all Standard changes, NERC should seek approval of the new terms prior to any changes being introduced in the Standards to reduce potential misunderstanding or misinterpretation of both the new definitions and modified Standards. This will also allow NERC, and industry, time to determine additional courses of action, reduce confusion, and reduce additional risk associated with such wholesale changes.

The proposed change ignores the concept of an isolated ESP network and instead requires an EACMS be deployed regardless to control communications between BCS, PCAs within the same network. The application of an EACMS in an isolated ESP network would add no extra protections or benefit for the purpose of controlling communications within the network given there are no Electronic Access Points applicable in relation to routable traffic from outside of the ESP or exiting the ESP.

BC Hydro recommends clarifying that the EACMS requirement portion of the definition be applicable only in cases where ERC may exist (i.e. discrete ESPs or extended ESPs).

New ESP definition would disallow including assets of lower impact ratings in a higher security environment, thus preventing the potential implementation of security best practices on Medium or Low impact assets. The new definition of ESP would also prevent the use of VLANs as a method of demonstrating isolation of BCS and other Cyber Assets as the Switches involved with managing of VLANs are often classified as BCAs and under the current CIP standards an asset classified as a BCA cannot be classified also as an EACMS, PCA or PACS.

There is no clear point of demarcation where the border of the ESP is defined, introducing significant concerns how the boundary of the CIP standard will be evaluated and enforced. Recommend retaining current definition. While not necessary, it may be appropriate to clarify that additional controls may be implemented within the security perimeter to limit communication ports inside of requirement CIP-007 R1.1

Comment

While we do not believe it to be the intent of the SDT, we disagree with the new definition(s) of EACMS and ESP as it is less clear what is and is not considered an ESP. Currently, a substation facility BCS that is not utilizing routable protocols, such as an RTU serially connected to several relays, is not classified as an ESP and subsequently, the RTU (which could be used as a central access point to the relays) would not be classified as an EACMS. This clarity is lost with the proposed definition changes.

Recommendation:

Electronic Security Perimeter (ESP) – The logical border surrounding a network to which BES Cyber Systems are connected using a routable protocol; or

A set of configurations or policies enforced by an EACMS that controls routable communications to or from any part of a BES Cyber System. These configurations or policies group CIP Systems of the same impact rating and their associated PCAs.

Electronic Access Control or Monitoring Systems (EACMS) – Cyber Assets, Virtual Cyber Assets, or Shared Cyber Infrastructure (SCI) that perform electronic access control or electronic access monitoring via routable protocols of the Electronic Security Perimeter(s) or BES Cyber Systems or SCI. This includes Intermediate Systems and SCI grouped by the Responsible Entity, in the EACMS it supports.

Comment

We agree that the proposed ESP definition can be used for both traditional firewall based networks, as well as future networks such as zero trust. However, the routable protocol qualifier was removed and the new ESP qualifier is an EACMS. The EACMS definition does not have a routable protocol/communication qualifier, and it references ESPs. This seems like a circular definition. Also, it is our understanding that the SDT does not intend to have requirements baked into definitions but with the proposed ESP definition, and changes to CIP-005, the definition is the only place EACMS are required. We propose the following changes:

ESP definition: A set of configurations or policies that controls communications to or from any part of a BES Cyber System. These configurations or policies group CIP Systems of the same impact rating and their associated PCAs.

New CIP-005-X R1 Part 1.X:

Applicable Systems

High Impact BES Cyber Systems and their associated PCA

Medium Impact BES Cyber Systems and their associated PCA

Requirements

1.X.1 - EACMSs must be implemented to enforce ESPs where communication leaves the ESP, or where SCI is used.

1.X.2 - EAPs must be identified for ESPs.

When the proposed ESP definition is applied in the proposed CIP-005-X R1 Part 1.1 there is another issue since the definition no longer has the routable protocol qualifier. See our response to Question #10 below for further explanation.

Katie Connor - Duke Energy - 1,3,5,6 - SERC,RF

Answer	No
Document Name	

Comment

Duke Energy agrees with the directional change but has identified several concerns with the proposed language.

First, the use of CIP Systems in the definition is in conflict with the use of BES Cyber System as the initial scoping in the definition, as it could be interpreted to require ESPs around EACMS and PACS that are outside the traditional ESP boundary on separate hardware. Further, this introduces a redundancy between the CIP Systems and PCA definitions.

Second, the use of the term policies is ambiguous in context and is likely to be conflicted with written policies (e.g. procedurally requiring password rotation). Policy-based access control is configured into the enforcing system, and therefore is inherently included in the configuration term. This should be made explicit in measures or guidance documents to ensure the intent to allow future policy-based access control is apparent.

Third, the inclusion of qualifiers to address the host-based firewall concern in the requirement language is inappropriate as it addresses specific solutions. A better means of addressing this concern would be to include qualifiers in the definition of ESP to ensure that the configurations enforcing the perimeter do not reside on a BES Cyber Asset.

DUKE ENERGY PROPOSED DEFINITION FOR ESP:

A set of configurations enforced by an EACMS that creates a logical boundary where communications to or from any part of a BES Cyber System and any PCA or SCIG associated with a BES Cyber System are controlled. All BCS, PCA, and SCIG included in an ESP have the same impact rating as the highest included device. The EACMS enforcing the ESP may not be part of a BES Cyber System.

BPA agrees that the modified definition is more flexible for future ESPs using a zero trust environment. However, additional language is needed to address whether the SDT still intends for standalone networks that have no external connectivity to other networks (”standalone networks”) to have a defined ESP.

Option 1: If standalone networks DO NOT require an ESP, please update the Technical Rationale to address standalone networks (as was traditionally done in the TR for CIP-005-6 and CIP-005-7).

Option 2: If standalone networks DO still require an ESP, the proposed definition requires all ESPs to be “enforced by an EACMS;” this will add a high burden for standalone networks. For example, a standalone ESP consisting of a local operator HMI (PCA, used for local review of SCADA alarms) connected to 2 local SCADA RTUs (BCAs) via a switch (PCA) would need to have an EACMS added in order to meet the letter of the requirement, but without gaining any security or protection.

Option 2 proposed language: move the “enforced by an EACMS” from the definition of an ESP, to a new requirement for BCS with ERC:

(1) Definition for Electronic Security Perimeter (ESP): A set of configurations or policies that controls communications to or from any part of a BES Cyber System. These configurations or policies group CIP Systems of the same impact rating and their associated PCAs.

Benefit: This would permit the isolated nature – or “configuration” – of the small local network to provide the control of communications to/from the BES Cyber System by simply excluding it.

(2) Add an additional requirement under CIP-005-8 R1.1 [hypothetically referenced here as R “1.1-A” for numbering clarity] for the EACMS portion:

Requirement: 1.1-A

Applicable Systems: BCS with ERC and their associated PCA Requirements: Utilize an EACMS to enforce the control of communications to or from any part of a BES Cyber System.

(3) Related update is needed to correct the Applicable Systems in R2.1: “EACMS that enforces an ESP for the Applicable Systems in Part 1.1-A.”

(4) Update the Technical Rationale (TR) to clarify for standalone networks (as was traditionally done in the **TR for CIP-005-6 and CIP-005-7**).

The proposed change to the ESP definition adds a significant amount of ambiguity. Within the context of the new definition, the term “Electronic Security Perimeter” doesn’t seem to apply. ESP references a “perimeter” and the definition doesn’t indicate a logical perimeter of any sort. If anything, the definition essentially becomes synonymous only with the policies or rulesets mandated by a firewall. NRG recommends reverting the ESP term back to its original definition.

We agree that the proposed change supports 1) traditional firewalls and 2) zero trust. However, the new language expands scope with “EACMS that controls communications to or from any part of a BES Cyber System.”

The new definition can be used for both traditional firewall-based networks, as well as future networks such as zero-trust but we don’t agree on the overall definition.

The suggested definition broadens the current scope, it implies the presence of an EACMS, thus requesting another cyber asset (We have a BCA: VCA and we have an EACMS: Firewall) unless the SDT wanted to permit the double categorization (BCA/EACMS: a VCA with an embedded firewall)

The language “that controls communications” isn’t consistent with the NERC CIP orientation, usage of the bi-directional routable protocol should be used because with the current language one could imply that serial, layer 2 communication needs to have a set of configurations or policies.

Also, the definition states that this is for a BES Cyber System (…any part of a BES Cyber System…), yet the definition mention CIP System (… policies group CIP Systems of the same …). The definition of CIP System includes more than BES Cyber System.

We suggest reviewing the definition.

The proposal could be A set of configurations or policies enforced those controls bi-directional routable protocol communications to or from any part of a BES Cyber System. These configurations or policies group BES Cyber System of the same impact rating and their associated PCAs. Reference: A set of configurations or policies enforced by an EACMS that controls communications to or from any part of a BES Cyber System. Texas RE agrees with the proposed definition of ESP. The SDT could, however, consider revision it to the following for clarification: • A boundary of protection set by configurations or policies enforced by an EACMS that controls communications to or from any part of a BES Cyber System. These configurations or policies group CIP Systems of the same impact rating and their associated PCAs Texas RE does note, however, that the proposed change to CIP-005 R1.1 explicitly states that host-based firewalls that only protect the host on which they reside are not a sufficient control to meet compliance with the requirement. Mass deployment of host-based firewalls is one method by which an organization can work toward implementing a zero-trust security model. The SDT may wish to consider this in the evaluation of its proposed ESP definition.

The new IRA definition could expand scope significantly. For instance, the second bullet within the proposed IRA definition – "through a Cyber Asset or Virtual Cyber Asset that is convering communications…" – could potentially bring into scope an operator at a Control Center increasing megawatts at a Medium without ERC plant and classify that scenario as IRA.

Suggest removing ‘Responsible Entity’s’ as it should still be considered IRA if a user at one entity, outside an ESP, connected remotely to another entity's ESP. Additionally, consider changing ‘person’ to Cyber Asset. The use of a person in the context being ‘outside an Electronic Security Perimeter’ does not make sense. Suggest the following - User-initiated real-time access from a Cyber Asset outside of the Electronic Security Perimeters (ESP) using a routable protocol: Bullets one and two are in the singular tense, consider changing bullets three and four from plural tense to single tense as well. Bullet three to – ‘To a Management Interface of a Shared Cyber Infrastructure; or’ and bullet four to – ‘To a Management Interface of an Electronic Access Control or Monitoring System that enforces an ESP.’

The use of ‘within an ESP’ doesn’t work with the new ESP definition. Alternative proposal: Replace ‘from outside of the Responsible Entity’s Electronic Security Perimeters’ with ‘from a Cyber Asset that is not protected by an Entity’s Electronic Security Perimeters’, and replace ‘within an ESP’ and ‘within an Electronic Security Perimeter’ with ‘protected by an Electronic Security Perimeter’. Additionally, focusing on Mangement Interfaces rather than SCI itself could allow access to the SCI through an additional port that doesn’t meet the definition of a Management Interface.

This definition introduces significant ambiguity and would rely excessively on non-enforcable Technical rationales and guidelines. As a result, it is subject to significant ambiguity. This ambiguity is further increased by the change in the definition of ESP that removes a clearly defined border of the ESP.

The definition of 'IRA' is unclear on the overall impact to the current infrastructure. Please further clarify as the second bullet "through a Cyber Asset or Virtual Cyber Asset that is converting communications from a routable protocol to a non-routable protocol to a Cyber System not within an Electronic Security Perimeter;" suggests that non-CIP devices will fall under the purview of this definition with the use of the NERC-defined term "Cyber System" being contained within the above language

CEHE does not agree with the proposed changes to the Interactive Remote Access definition because it seems to be unnecessarily confusing due to unneeded information within the definition.

The first bullet “to a Cyber System within an ESP” covers access to any Cyber System including its user interface ports. Therefore it is unnecessary to have the third and fourth bullet items. The third bullet specifies Management Interfaces of SCI, and similarly the fourth bullet specifies the Management Interfaces of the EACMS that enforces an ESP. However both SCI and EACMS are Cyber Systems which are covered by the first bullet.

The purpose of the fourth bullet is to capture remote access through a “serial to IP” device, and to achieve this the bullet item goes through a complex explanation on the conversion of routable to non-routable communications and Cyber Systems not in an ESP. The same thing can be accomplished by removing the phrase “using a routable protocol” from the first part of the definition. Then, to capture Cyber Systems not within an ESP, it seems that including “… Electronic Security Perimeter (ESP) or Physical Security Perimeter (PSP) …” would more clearly capture this.

In addition, CEHE understands that a cabinet can be a PSP, and someone standing outside of the cabinet and physically connecting to a system within a cabinet is not IRA. This situation is not a remote connection therefore is not IRA and may need to be explained in the technical rationale.

IRA should not be prescribed to only “a routable protocol”. It should include all methods by which this is accomplished, even by a dial-up connection. However, CIP-005-8 requirement R2 specifically excludes Dial-up Connectivity. This is how the process should work. The definition states what IRA is, and the requirements specify exactly what applies.

Based upon those thoughts CEHE proposes the following:

“A user initiated real-time electronic access by a person from outside of a Responsible Entity’s Electronic Security Perimeter (ESP) or Physical Security Perimeter (PSP) to a CIP System within the Responsible Entity’s ESP or PSP, either directly or through another Cyber Asset or Virtual Cyber Asset for the purpose of connecting to any of the CIP System’s user interfaces.”

As written and presented, there is a gap between what is system-to-system and what is Interactive Remote Access (IRA) with the new IRA definition. Entities often rely on IRA ports for system-to-system communication, but have not adequately enforced protections to ensure that the ports are not used by malicious actors regardless of whether a remote access client is available or used. Additional technical measures or controls should be added to ensure validity of communications to Applicable Systems. In addition, approval of CIP-005-8 would be conditional, based upon approval of the entire suite of new standards associated with virtualization and approval of SCI terminology and other definitions associated with virtualization as a whole.

In support of NPCC RSC comments.

Request clarification of the second bullet because it does not apply to any NERC CIP applicable system. Suggest changing from “through a Cyber Asset or Virtual Cyber Asset that is converting communications from a routable protocol to a non-routable protocol to a Cyber System not within an Electronic Security Perimeter;” to “to a Cyber System within an ESP, through a Cyber Asset or Virtual Cyber Asset that is converting communications from a routable protocol to a non-routable protocol from a Cyber System not within an Electronic Security Perimeter;”.

The new definition of ESP mentions an ESP is a …set of configurations or policies enforced by an EACMS… This definition doesn’t establish a boundary (logical border) so the language outside of the Responsible Entity’s Electronic Security Perimeters (ESP) or within an ESP doesn’t work.

The introduction of the converting functionality is interesting.

We suggest reviewing the definition of ESP/IRA/EAP.

Alternate proposal

User-initiated real-time access by a person outside of BES Cyber System, using a routable protocol:

• to a BES Cyber System;

• through a Cyber Asset or Virtual Cyber Asset that is converting communications from a routable protocol to a non-routable protocol to a BES Cyber System

• To Management Interfaces of a Shared Cyber Infrastructure; or

• To Management Interfaces of an Electronic Access Control or Monitoring Systems that enforce an ESP.

Reference

User-initiated real-time access by a person from outside of the Responsible Entity’s Electronic Security Perimeters (ESP). using a routable protocol:

• to a Cyber System within an ESP;

• through a Cyber Asset or Virtual Cyber Asset that is converting communications from a routable protocol to a non-routable protocol to a Cyber System not within an Electronic Security Perimeter;

• To Management Interfaces of a Shared Cyber Infrastructure; or

• To Management Interfaces of an Electronic Access Control or Monitoring Systems that enforce an ESP.

Response

JT Kuehne - AEP - 6

Answer	No
Document Name	

Comment

AEP believes additional clarity is needed to the proposed definition of Interactive Remote Access (IRA) and provides the following revised introduction sentence for consideration.

"A user initiated electronic access by a person from outside of a Responsible Entity's Electronic Security Perimeter (ESP) and Physical Security Perimeter (PSP) using a routable protocol to a CIP System within the Responsible Entity's ESP, either directly or through another Cyber Asset or Virtual Cyber Asset for the purpose of connecting to any of the CIP System's user interfaces. This includes access to:

- *Cyber Systems within an ESP;*
- *Through a Cyber Asset or Virtual Cyber Asset that is converting communications from a routable protocol to a non-routable protocol to a Cyber System not within an Electronic Security Perimeter*;
- *To Management Interfaces of a Shared Cyber Infrastructure; or*
- *To Management Interfaces of an Electronic Access Control or Monitoring Systems that enforce an ESP"*

We suggest "real-time" be stricken from the definition as we believe there is no function that would allow "a person" to interact with a system in any frame of time other than "real-time". While we recognize the attempt to establish that this would not include batch processing, it is our opinion that the batch would run system-to-system and would not qualify as "a person".

We are concerned with the implications of these changes in conjunction with the changes in definition to ESP, EACMS, and the addition of serial communication. To avoid confussin we believe this needs to be clarified within CIP-005 that CIP-005 IRA requirements do not apply to BCAs or PCAs controlling access only to themselves (such as host-based firewalls) when a traditional EACMS and Access Point (such as a site firewall) is being used.

- IRA with ERC has been confusing for Entities to understand when the conversion to serial devices appears to now be in scope if configurations may be impacted using serial thus requiring, for example password changes within 15 months.
    - Please provide more examples including transitioning BCA currently without ERC when it becomes BCA with ERC under the new proposed definitions and standards. How and where is the change applied and if it will be part of CIP-002?
- Does a Non-CIP System distribution Relay now become a PCA because it is connected to the Medium Impact Serial converter if it supports IRA?

Southern supports the changes concerning clarity for IP-serial conversions, but does not support the changes for Management Interfaces such as those on an “EACMS that enforces an ESP”. An Intermediate System is an EACMS that helps enforce an ESP which could open up a “Hall of Mirrors” scenario where an Intermediate System is required to access an Intermediate System. This hall of mirrors is stated in the Applicable Systems column of CIP-005 R2.1 (in the clean version of CIP-005 that was posted, which differs from the redline).

ERCOT supports the IRC SRC comments and offers these additional comments: • Bullet 2: This appears to be backwards. It reads like you are sending communications outside the ESP. • Bullet 3: Please clarify if “To Management Interfaces of a Shared Cyber Infrastructure” is only related to the Cyber Assets within the ESP. • Bullet 4: Adding “To Management Interfaces of an Electronic Access Control or Monitoring Systems that enforces an ESP” expands the scope of the existing definition by protecting more than just what resides inside the ESP.

Comments: EEI asks for additional clarity for the proposed definition of IRA. It is unclear why the definition includes “real-time” when the proposed definition specifically applies to access by a person. If “real-time” was inserted for a specific purpose, then the SDT should provide a clear explanation. Additionally, if “real-time” is needed, EEI recommends that the definition also include “IRA does not include system to system process communications or read-only access.”

“A user initiated real-time electronic access by a person from outside of a Responsible Entity’s Electronic Security Perimeter (ESP) or Physical Security Perimeter (PSP) using a routable protocol to a CIP System within the Responsible Entity’s ESP or PSP, either directly or through another Cyber Asset or Virtual Cyber Asset for the purpose of connecting to any of the CIP System’s user interfaces. This includes access to:

1. *Cyber Systems within an ESP;*
2. *Through a Cyber Asset or Virtual Cyber Asset that is converting communications from a routable protocol to a non-routable protocol to a Cyber System not within an Electronic Security Perimeter;*
3. *To Management Interfaces of a Shared Cyber Infrastructure; or*
4. *To Management Interfaces of an Electronic Access Control or Monitoring Systems that enforce an ESP”*
5. ***IRA does not include system to system process communications or read only access**.*

Request clarification of the second bullet because it does not apply to any NERC CIP applicable system. Suggest changing from “through a Cyber Asset or Virtual Cyber Asset that is converting communications from a routable protocol to a non-routable protocol to a Cyber System not within an Electronic Security Perimeter;” to “to a Cyber System within an ESP, through a Cyber Asset or Virtual Cyber Asset that is converting communications from a routable protocol to a non-routable protocol from a Cyber System not within an Electronic Security Perimeter;”.

The new definition of ESP mentions an ESP is a …set of configurations or policies enforced by an EACMS… This definition doesn’t establish a boundary (logical border) so the language outside of the Responsible Entity’s Electronic Security Perimeters (ESP) or within an ESP doesn’t work.

The introduction of the converting functionality is interesting.

We suggest reviewing the definition of ESP/IRA/EAP.

Alternate proposal

User-initiated real-time access by a person outside of BES Cyber System, using a routable protocol:

• to a BES Cyber System;

• through a Cyber Asset or Virtual Cyber Asset that is converting communications from a routable protocol to a non-routable protocol to a BES Cyber System

• To Management Interfaces of a Shared Cyber Infrastructure; or

• To Management Interfaces of an Electronic Access Control or Monitoring Systems that enforce an ESP.

Reference

User-initiated real-time access by a person from outside of the Responsible Entity’s Electronic Security Perimeters (ESP). using a routable protocol:

• to a Cyber System within an ESP;

• through a Cyber Asset or Virtual Cyber Asset that is converting communications from a routable protocol to a non-routable protocol to a Cyber System not within an Electronic Security Perimeter;

• To Management Interfaces of a Shared Cyber Infrastructure; or

• To Management Interfaces of an Electronic Access Control or Monitoring Systems that enforce an ESP.

N&ST believes the first sentence, "User-initiated real- time access by a person from outside of the Responsible Entity's Electronic Security Perimeters (ESP) using a routable protocol" fails to account for Responsible Entities that only have ESPs at some of their in-scope facilities or, in some instances (e.g., a TO with only serial Med Impact BCS) have no ESPs at all. Suggested change: "User-initiated real- time access by a person from outside of the Responsible Entity's Electronic Security Perimeters (ESPs) using a routable protocol, or "User-initiated real- time access by a person from outside of a Responsible Entity asset that contains only serially-connected BCS using a routable protocol… (etc.)"

Katie Connor - Duke Energy - 1,3,5,6 - SERC,RF

Answer	Yes
Document Name	

Comment

Duke Energy generally supports the SDT's direction, but suggests several changes to address various concerns:

Duke recommends that the second bullet be updated to read more clearly: "through a Cyber Asset or Virtual Cyber Asset that converts the communication from a routable protocol to a non-routable protocol that is passed on to a Cyber System not within an ESP." This also consistently applies abbreviations after the first instance of the term is spelled out.

Duke has concerns with the application of the IRA definition to the Management Interfaces of EACMS that enforce ESPs. This may result in reliability impacts when an EACMS Firewall management interface can only be accessed by an IS that is secured in a DMZ behind that firewall, and a failure of the firewall prevents access to the IS. We would suggest that the last bullet be removed from the definition. Proposed requirements in CIP-005 R1 Part 1.2 should provide adequate protection for these interfaces.

Finally, Duke Energy recommends that the SDT either explicitly refer to the defined term "Real-time" or use alternative language to avoid auditor interpretations as seen in the difference between "adverse impact" used in the BCA definition and the defined term "Adverse Reliability Impact".

Request clarification of the second bullet – “Provide lights-out management capabilities; or.” Suggest using the old language instead of a vendor’s term. The old language was “an autonomous subsystem of a Cyber Asset or Shared Cyber Infrastructure that provides management and monitoring capabilities independently of the host system's CPU, firmware, and operating system.”

Request clarification of the term “out-of-band.” What is the out-of-band risk? What is the requirement addressing?

The definition seems to be too specific, i.e. direct reference to SCI, LOM, and ESP. Why not a more generic and simple definition like

A user interface, logical interface, or dedicated physical port that is used to control the processes of initializing, deploying, and configuring a cyber asset, excluding physical user interfaces (e.g., power switch, touch panel, etc.).

Reference

A user interface, logical interface, or dedicated physical port that is used to:

•   Control the processes of initializing, deploying, and configuring Shared Cyber Infrastructure; or

•   Provide lights-out management capabilities; or

•   Configure an Electronic Security Perimeter; excluding physical user interfaces (e.g., power switch, touch panel, etc.).

The revised definition does provide improvement over what was provided in the last draft, however, additional clarity to the intended meaning of Management Interface is still needed. This may be possible through additional enhancements to the definition or through additional explanation/defining what a Management Interface is through the Rationale. EEI offers the following revised definition:

"A user interface, logical interface or dedicated physical port, excluding touch controls (e.g., power switch, touch panel, etc.), that is used to: control the processes of initializing, deploying, and configuring or lights-out management capabilities of Cyber Systems."

Comment

ATC understands the intent of the SDT and the rationale for Management Interface; however, the concepts of Management Plane and Operational Plane were clearer. While ATC appreciates the attempt to consolidate these terms and views Draft 2 as an improvement over Draft 1, 'interface' may be an overly broad term. The words 'user interface' are doing some heavy lifting and while the application interface and physical interface are performing the same "user interface" function, they really are very different things. There may be room for entities to misinterpret the current definition to their own peril.

- Is the overall purpose to protect from lateral movement, or to protect from unauthorized access to a management system?
- Is identity the primary perimeter?
    - Would it help if the SDT considered that concept when reassessing this definition and corresponding requirement language?
- The communication channel from which management is performed must be segregated from the channel with which operational functions are performed.

Southern disagrees with the addition of “Configure an Electronic Security Perimeter” to the Management Interface definition. With the definition of ESP being “a set of configurations or policies”, a Management Interface is something that configures a configuration that controls communications of any type at all. See Q14 for an example of the issues caused by this construct. Southern suggests that requirements be written that apply to BES Cyber Systems and separate requirements that set clear expectations around the use and administration of electronic access controls (and by extension PACS) and begin the process of moving away from an EACMS as a ‘device’ focus.

ACES feels the inclusion of “Configure an Electronic Security Perimeter” does not cover what is intended and leaves a gap. We feel EACMS is a more inclusive term in place of ESP. Use of EACMS instead of ESP would then include Intermediate Systems, which pose a risk if Management Interfaces are not protected. This would then be consistent with the IRA definition.

We agree with the Management Interface definition, but disagree with the language in the definition. In our view, the definition should focus on in CIP scope management interfaces. “Provide lights-out management capabilities” should be removed since this criterion cannot make a management interface to fall within CIP scope. Also, we suggest changing “configure ESP” to “configure EAP” and “configure EACMS” to address the zero-trust mode (See our comments in Q4). Also, the Management Interface definition only covers the Management Interface of a management system such as vCenter that configures and manage SCI while the Hypervisor Management Interface that initializes, deploys and configures VCAs is missing from the definition. Furthermore, the Management Interface should include managing non-ESP model based on our comments in Q4.

Recommendation: We propose the following changes to Management Interface definition and rationale in Q1.

Since the Glossary modifications are the foundation to all Standard changes, NERC should seek approval of the new terms prior to any changes being introduced in the Standards to reduce potential misunderstanding or misinterpretation of both the new definitions and modified Standards. This will also allow NERC, and industry, time to determine additional courses of action, reduce confusion, and reduce additional risk associated with such wholesale changes.

We support NPCC TFIST's comments as found below: Request clarification of the second bullet – "Provide lights-out management capabilities; or." Suggest using the old language instead of a vendor's term. The old language was "an autonomous subsystem of a Cyber Asset or Shared Cyber Infrastructure that provides management and monitoring capabilities independently of the host system's CPU, firmware, and operating system." Request clarification of the term "out-of-band." What is the out-of-band risk? What is the requirement addressing?

Additional clarity is required around the concept of "user interfaces" that are in scope per the new definition vs. the physical user interfaces that are indicated as being out of scope. This is a confusing and contradictory element of the definition. The definition is very broad and would include interface ports such as PS2 mouse/keyboard ports. It is not clear as to how practical considerations of such ports that have connected mice and keyboards for example would need to be protected per the CIP-005-8 proposed standard requirements to permit only needed and controlled communications to and from Management Interfaces and deny all other communications. Alternatively, as an example, it is not clear from a practical sense of how, per CIP-007-7, one would prevent the sharing of the CPU and memory of keyboard/mouse user interface ports. BC Hydro recommends changing the reference per the bullet "Provide lights-out management capabilities' within the definition of Management Interface to a more generic reference such as "out-of-band management capabilities" to meet the security intent instead of limiting to a particular type/brand.

SIGE does not agree with the new Management Interface definition, because it singles out a few Cyber Systems within the definition. The definition should define what a Management Interface is, and the standards/requirements will pinpoint which Cyber Systems should be applied.

SIGE proposes the following:

“A user interface, logical interface or dedicated physical port, excluding touch controls (e.g., power switch, touch panel, etc.), that is used to: control the processes of initializing, deploying, and configuring or lights-out management capabilities of Cyber Systems.”

ACES feels the inclusion of “Configure an Electronic Security Perimeter” does not cover what is intended and leaves a gap. We feel EACMS is a more inclusive term in place of ESP. Use of EACMS instead of ESP would then include Intermediate Systems, which pose a risk if Management Interfaces are not protected. This would then be consistent with the IRA definition. AEPC has signed on to ACES comments.

The proposed definition leaves a great deal of ambiguity about the intent of the ‘user interface, logical interface, or dedicated physical port’. While in most cases, an entity would likely choose to go to the physical or logical (VLAN/sub-interface) port level, there are concerns about an approach where the entity may try to only protect the user interface, leaving other ports (TCP/UDP) on the same physical/logical port unprotected. It is unclear how vCenter would be treated – MRO would interpret it to be a ‘user interface’ included with SCI (per SCI definition, “including the software and Management Interfaces”).

In an all-in scenario, how do the protections apply to a Management Interface that is a different Cyber Asset (CA) from the SCI. For example, if vCenter is a different CA than the SCI its managing, how does the applicability of in CIP-005, CIP-007 and CIP-010 extend to that different CA running vCenter become SCI identified independently or a Cyber Asset?

The SCI definition includes Management Interfaces, if the Management Interface is a separate Cyber Asset how does the applicability extend to the separate Cyber Asset? For example, if a central firewall management system is outside of the ESP, how would this system be protected in the all-in scenario, or will it be required to be inside an ESP?

Duke Energy supports a consolidated definition for the various management components that require protection but suggests the use of “Management System” instead of “Management Interface” for parity with BCS, Cyber System, etc. as the preferred terminology for Applicable Systems. Additionally, Duke requests that the SDT provide thorough implementation guidance to assist in correctly classifying systems that provide management functions but	

are not associated specifically with SCI (e.g. SCOM) as this definition may introduce a confusing break in consistency of classification between SCI management (e.g. vCenter) and other management tools.

The previously proposed term “Management Systems” provided better clarity for identification of systems that support patching, configuration management, anti-malware signature updates, and other management functions. This clarity was lost with the newly proposed term. Specifically, the ‘and’ clause in “Control the processes of initializing, deploying, and configuring Shared Cyber Infrastructure;’ seems to imply only inclusion of systems used for initial provisioning (e.g., installing an operating system & configuring a network card) as opposed to systems that supporting ongoing health and maintenance activities for deployed systems.

BPA agrees that this will reduce the burden of documenting ESPs in a zero trust environment. However, additional language is needed to address whether the drafting committee still intends for standalone networks that have no external connectivity to other networks (”standalone networks”) to have a defined ESP.

Option 1: If standalone networks DO NOT require an ESP, please update the Technical Rationale to address standalone networks (as was traditionally done in the **TR for CIP-005-6 and CIP-005-7**).

Option 2: If standalone networks DO still require an ESP, the proposed definition requires all ESPs to be “enforced by an EACMS;” this will add a high burden for standalone networks. For example, a standalone ESP consisting of a local operator HMI (PCA, used for local review of SCADA alarms) connected to 2 local SCADA RTUs (BCAs) via a switch (PCA) would need to have an EACMS added in order to meet the letter of the requirement, but without gaining any security or protection.

(1) Definition for Electronic Security Perimeter (ESP): A set of configurations or policies that controls communications to or from any part of a BES Cyber System. These configurations or policies group CIP Systems of the same impact rating and their associated PCAs.

Benefit: This would permit the isolated nature – or “configuration” – of the small local network to provide the control of communications to/from the BES Cyber System by simply excluding it.

(2) Add an additional requirement under CIP-005-8 R1.1 [hypothetically referenced here as R “1.1-A” for numbering clarity] for the EACMS portion:

Requirement: 1.1-A

Applicable Systems: BCS with ERC and their associated PCA

Requirements: Utilize an EACMS to enforce the control of communications to or from any part of a BES Cyber System.

(3) Related update is needed to correct the Applicable Systems in R2.1: "EACMS that enforces an ESP for the Applicable Systems in Part 1.1-A."

(4) Update the Technical Rationale (TR) to clarify for standalone networks (as was traditionally done in the TR for CIP-005-6 and CIP-005-7).

While Zero Trust and it’s assumption of assuming no network edge is an excellent security approach, it is necessary to ensure that a discrete boundary defines the edge of the auditable network. The current definitions significantly blur this border introducing uncertainty into what will be audited under the CIP standards and introduces opportunity for significantly different viewpoints between auditors and entities regarding the boundary of what will be subject to NERC compliance standards. We support adopting definitions and standards that support virtualization. However until this is resolved, it will be impossible to support the revised standards. We recommending basing the new definition around the previous definition of an ESP as it has a defined border.

ACES feels no matter how zero trust environments are implemented, the policy (ies) or configurations will be highly complex and exponentially more difficult to prove strict compliance, thus increasing compliance burden. Additionally on the latest webinar, it was discussed each policy enforcement point would be an EACMS. In a Cisco based SDN, each switch port, switch port group, VLAN, or switch has an enforcement policy applied to it from the policy server, increasing the number of EACMS significantly, therefore increasing compliance burden. Another issue will be varying technology compared to firewall rules/ACL as used today. This will make auditing extremely complex and require an auditor to have significant knowledge of varying SDN/zero trust products to be able to accurately audit. AEPC has signed on to ACES comments.

While it may be the SDT's intent to reduce ESP documentation burden for entities employing Zero Trust environments, the language of the standards themselves do not reduce any such documentation burden pertaining to ESPs. In fact, the requirements still require ESPs to be implemented. BC Hydro recommends adding clarifying language around documentation expectations when Zero Trust environments are implemented vs. traditional firewall bounded ESPs.

Comment

Since the Glossary modifications are the foundation to all Standard changes, NERC should seek approval of the new terms prior to any changes being introduced in the Standards to reduce potential misunderstanding or misinterpretation of both the new definitions and modified Standards. This will also allow NERC, and industry, time to determine additional courses of action, reduce confusion, and reduce additional risk associated with such wholesale changes.

In support of NPCC RSC comments.

We agree with the modified ESP definition. We do not agree this change reduces the documentation burden of ESPs in a zero-trust environment.

Looking solely at the definition of ESP, the old definition required to simply produce a list of assets in a boundary, this resulted in a large ESP. Establishing these ESP was easy and there were only one criteria to evaluate (connected using a routable protocol), overall (less burden). The suggested definition permits potentially smaller ESP, so more ESP, but those ESPs come with more controls, i.e., configurations or policies enforced and EACMS. With the new definition, the burden of the demonstration is more.

The ideas behind the new definition are interesting and they could facilitate the instauration of a zero-trust environment, but those ideas don’t lessen the burden of compliance demonstrations.

Reference:

Old Definition: The logical border surrounding a network to which BES Cyber Systems are connected using a routable protocol. Suggested Definition: A set of configurations or policies enforced by an EACMS that controls communications to or from any part of a BES Cyber System. These configurations or policies group CIP Systems of the same impact rating and their associated PCAs.

AEP agrees with EEI's concern that it is unclear how the use of the terms "configuration or policy" reduces the burden of documenting ESPs in a zero trust environment. AEP also supports EEI's recombination on providing additional clarity and examples. In addition, AEP suggests the removal of the second sentence in the proposed ESP definition as noted in response to Question #4 above.

GRE has not seen how the modified ESP definition can reduce the burden of documenting ESPs in a zero-trust environment (see NSRF comments in Q4). Given that a zero-trust environment in virtualization layer is a non-ESP topology and ESP drawings are not needed, there is no compliance burden reduction. Resulting from our comments in Q4, the zero-trust model can be resolved by adding an alternative requirement in CIP-005 R1.1.

Regardless of which direction we go in will always have a burden - and again each entity will still have to show the auditors we are compliant. Depending on the auditor and their intreption of the requirement - can become burdensome. We don’t understand the zero trust environment as defined.

We are concerned that in hybrid environments with traditional firewalls AND zero-trust or host-based firewall applications, the new definitions of ESP and EACMs could create a burden to industry by requiring additional protections (such as encryption and multifactor authentication) on communications between devices that are already protected inside an ESP by a traditional firewall, and actually discourages the use of multi-layered protection.

• The ESP definition enables virtualization and logical boundaries but is not really going to reduce the documentation load. Zero trust will require documentation of where controls are applied including locations. • The IP to serial conversion for ERC and IRA appears to require additional documentation beyond the ESP. Please clarify how Entities are expected to document the logical boundaries beyond the ESP for serial devices.

Comment	
ACES feels no matter how zero trust environments are implemented, the policy (ies) or configurations will be highly complex and exponentially more difficult to prove strict compliance, thus increasing compliance burden. Additionally on the latest webinar, it was discussed each policy enforcement point would be an EACMS. In a Cisco based SDN, each switch port, switch port group, VLAN, or switch has an enforcement policy applied to it from the policy server, increasing the number of EACMS significantly, therefore increasing compliance burden. Another issue will be varying technology compared to firewall rules/ACL as used today. This will make auditing extremely complex and require an auditor to have significant knowledge of varying SDN/zero trust products to be able to accurately audit.

AWS supports the implementation of zero-trust architectures in fulfilling the security objectives of the NERC CIP Standards, but is seeking clarity on the assertion that the use of configurations or policies in the modified ESP definition can reduce the burden of documenting ESPs in a zero-trust environment. In a zero-trust environment the ESPs implemented by a Responsible Entity become more granular increasing the compliance documentation needed to support each policy or set of policies applied.

Pamela Hunter - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - SERC, Group Name Southern Company

Answer	No
Document Name	

Comment

Southern agrees with the focus on network access policies rather than strictly network subnets (while not disallowing it) as things progress towards zero trust. However, as more fully stated in Q4, the phrase “that control communications” is overly broad and the ESP definition has nothing that scopes it to network communications.

It is unclear how the use of the terms "configuration or policy" reduces the overall burden of documenting ESPs in a zero-trust environment. Zero trust is not used under the current definition of ESPs within a substation environment and for those entities that plan to continue using traditional firewalls, their processes for maintaining documentation will remain unchanged. For this reason, EEI requests additional clarity and examples describing how the use of "configuration or policy" language in this definition reduces the current burdens of documenting ESPs.

We agree with the modified ESP definition but are not sure it reduces the burden as entities will have to prove to auditors they are compliant and we don’t know at this point what audit evidence requests will look like. We would also like to point out that because the routable protocol qualifier was eliminated from the ESP definition, and changes to the CIP-005 R1 Part 1.1, serial connectivity in some cases has been brought into the scope of an ESP. Refer to question #10 below.

8. The SDT added new and revised several defined terms to incorporate virtualization and future technologies within the CIP Standards. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

Dan Zollner - Portland General Electric Co. - 3

Answer	No
Document Name	

Comment

Portland General Electric Company supports the comments provided by EEI for this survey question. Additionally, Portland General Electric Company has concerns regarding the Interactive Remote Access (IRA) defintion. In the second bullet of the definition, the clause "to a Cyber System not within an Electronic Security Perimeter" implies that IRA can exist in scenarios where a person has no intent of remotely connecting to a BES Cyber System or PCA. The proposed definition of a Cyber System includes any number of Cyber Assets, Virtual Cyber Assets, or Shared Cyber Infrastructure that may be either CIP or non-CIP. If an individual was remotely communicating through a protocol converter to a device like a PACS, EACMS, or non-CIP Cyber Asset existing outside the ESP, that would be considered IRA under the current definition even if those systems didn't have connectivity to a BES Cyber System. Portland General Electric Company believes changing the clause to "to a BES Cyber System not within an Electronic Security Perimeter" achieves the objective of controlling IRA to BES Cyber Assets that are serially connected to the BES Cyber System.

The IRC SRC requests the SDT clarify ERC for serial – IP communications to ensure backwards compatibility. We understand the proposed definition will not be backwards compatible; e.g. CIP-005, R3.1 and CIP-007, R4.2. Is that correct?

In addition, we request the SDT clarify the definition for BES Cyber System Information (BCSI) to include “SCI identified independently, supporting an Applicable System.”

N&ST recommendations for the definitions of ERC, ESP, and IRA are in our responses to Questions 3, 4 and 5, respectively. N&ST respectfully suggests the following changes to these additional definitions:

> EAP: “A policy enforcement point or a Cyber Asset interface that controls routable communication to and from a BES Cyber System from outside its Electronic Security Perimeter.”

> IS: The statement within the current IS definition, “The Intermediate System must not be located inside the Electronic Security Perimeter,” should be retained.

> EACMS and PACS: N&ST recommends both definitions, which begin with “Cyber Assets, Virtual Cyber Assets, or Shared Cyber Infrastructure (SCI),…” be modified to begin with, “Cyber Assets, Virtual Cyber Assets, Cyber Systems, or Shared Cyber Infrastructure (SCI),…” This would clarify that it’s permissible to group an SCI with the EACMS and/or the PACS it supports.

Request clarification on ERC for serial – IP communications. We understand this will not be backward compatible. Is that correct? Such as CIP-005 R3.1 and CIP-007 R4.2

Request clarification of the updated BCSI definition. We believe this new definition should include “SCI identified independently supporting an Applicable System.”

We suggest some additional work on the definitions (ESP/IRA/CIP System/SCI) and a better alignment with the current CIP language.

Also, some definition includes some requirements on CPU and memory (isolation/shared), those requirements are not future proof. Furthermore, the definitions by focusing on shared CPU and memory trend toward hypervisor-based virtualization and don’t seem to provide a clear framework around other types of virtualizations like containerization technology.

We Suggest that the SDT review the definitions, the need for defining new terms and the nested definitions.

Some additional revisions:

Remove “TCA” from CIP Systems - A Cyber System identified by the Responsible Entity as a BES Cyber System, Electronic Access Control or Monitoring System, Physical Access Control System, or Shared Cyber Infrastructure, or Protected Cyber Asset. [delete - or Transient Cyber Asset.]

Remove “or a PCA” from the Virtual Cyber Asset - A logical instance of an operating system or firmware hosted on Shared Cyber Infrastructure [delete - or a PCA.]

Add “protocol” to EAP - A policy enforcement point or a Cyber Asset interface that allows routable protocol communication to and from the BES Cyber System within an Electronic Security Perimeter.

Cyber Asset – consider not excluding SCI, keeping the original - Programmable electronic devices, including the hardware, software, and data in those devices; [delete - excluding Shared Cyber Infrastructure.]

Cyber System – we suggest reverting back to Cyber Assets where this is used or go with a generic “cyber system” term in the exemptions language. Leave cyber system an undefined term. Simplifying applicability can create increased scope in the requirements.

Shared Cyber Infrastructure – Please provide more information in the technical rationale on what is intended with “including the software.”

Management Interface – In the non-virtualized environments there are applications that manage the policy implementation of firewalls that would be both a Management Interface and an EACMS under the new requirements and definitions. Was this the SDT’s intent?

Regarding ERC, this is a substantial change to the definition of ERC that has a larger impact than in the context of addressing virtualized environments. Several of the terms have been removed from the proposed definitions but are still being used other definitions and standards. For example Management Systems and Management Module have been removed but are still used in the SCI definition and in the CIP-005 R2.1 Measures and through the CIP-005 violation severity levels.

Comment	
Generally, EEI supports most of the new/revised terms, but we have concerns with the following terms:	

External Routable Connectivity (ERC): See our comments to Question 3 above.

Electronic Security Perimeter (ESP): See our comments to Questions 4 and 7 above.

Interactive Remote Access (IRA): See our comments to Question 5 above.

Management Interface: EEI disagrees with the practice of nesting other Glossary Terms within the definition of other Glossary Terms. This practice makes it difficult to support definition that might otherwise be supported. While there are a number of other examples of this practice (see SCI) Management Interface serves as a good example of our concern.

Protected Cyber Asset (PCA): EEI seeks additional clarifications on the qualifier of “excluding Virtual Cyber Assets that are being actively remediated prior to introduction to the ESP.” If the VCA, or physical Cyber Asset, is outside of the ESP, how could it be considered a PCA when the required attribute of a PCA is that it is inside an ESP? Please provide clarification.

Virtual Cyber Asset (VCA) – The current definition is unclear and possibly unnecessary given the intent is to simply provide an equivalent virtualized term for a Cyber Asset, which is not a system but a programmable electronic device. If the SDT believes this term is necessary, we suggest the following:

“A logical instance of a programmable device, including the software and data, hosted on Shared Cyber Infrastructure or a PCA.”

Response

LaTroy Brumfield - American Transmission Company, LLC - 1

Answer	No
Document Name	

Comment

ATC continues to have some questions about ERC and devices wholly inside an ESP.

- Where does the chain end?
- Do Cyber Assets two hops removed from the IRA entry point inside the ESP, or the system to system routable communication path between a system inside and outside the ESP have ERC?

The use of the term asset may make it more difficult to determine where ERC exists. Non-CIP systems inside a Control Center “asset” that are connecting into a CIP System inside the same Control Center “asset” could be at varied trust levels and should be protected via ERC and IRA controls.

Comment	
For “CIP System”, Southern agrees with having defined terms as shorthand, such as in CIP-007 R1.3 with its use of “non-CIP Systems.” However, Southern disagrees with the inclusion and nesting of this broad term within *many other* definitions. Analyzing the resulting scope of nested definitions based on “CIP System” is problematic, and our answers to Q3 and Q4 are specific examples of issues in its inclusion in ERC and ESP definitions.

Maggy Powell - Amazon Web Services - 7

Answer	No
Document Name	

Comment

In addition to the comments regarding the ESP definition provided in response to question 4, AWS offers comments on the terms: CIP System, Cyber System and Transient Cyber Asset.

The terms CIP System and Cyber System are similar and could easily be confused or misunderstood. Please clarify whether the term “System” implies that evidence of compliance can be presented at the system level rather than the device level.

In addition, we oppose and suggest reconsideration to the Transient Cyber Asset (TCA) definition revision that allows virtual machines running on a physical TCA to be treated as software on the device. As written, a Responsible Entity is not be required to apply the appropriate security controls to the virtual machines running on physical TCAs. For security purposes, Responsible Entities should be monitoring the state of the virtual machines running on their physical hardware for security issues. We propose removing the language “Virtual machines hosted on a physical TCA can be treated as software on that physical TCA” from the TCA definition, and modifying the VCA definition to read, “A logical instance of an operating system or firmware hosted on Shared Cyber Infrastructure, a PCA, or a TCA.”

Comment

We believe the definition of ERC is confusing because it is unclear what the term "asset" is referring to when it states "from outside the asset containing the CIP System". Is this referring to a cyber asset, a BES asset, or a Facility? The definition was much clearer when referring to an ESP. The additional concerns with definitions have been addressed above.

Request clarification on ERC for serial – IP communications. We understand this will not be backward compatible. Is that correct? Such as CIP-005 R3.1 and CIP-007 R4.2

Request clarification of the updated BCSI definition. We believe this new definition should include “SCI identified independently supporting an Applicable System.”

We suggest some additional work on the definitions (ESP/IRA/CIP System/SCI) and a better alignment with the current CIP language.

Also, some definition includes some requirements on CPU and memory (isolation/shared), those requirements are not future proof. Furthermore, the definitions by focusing on shared CPU and memory trend toward hypervisor-based virtualization and don’t seem to provide a clear framework around other types of virtualizations like containerization technology.

We Suggest that the SDT review the definitions, the need for defining new terms and the nested definitions.

Response

Jamie Monette - Allete - Minnesota Power, Inc. - 1

Answer	No
Document Name	

Comment

Minnesota Power has concerns about acronyms CSI and SCI being confused. The SDT needs to consider other terms as it is close to an existing one. The SDT should consider *Private Cloud Infrastructure (PCI)* or *Virtual Cloud Infrastructure (VCI)* which could help facilitate a move to Public Cloud Infrastructure should an entity decide to do so. The second term may provide more flexibility in utlizing public cloud resources where an entity decides public cloud is more effective.

Response

JT Kuehne - AEP - 6

Answer	No
Document Name	

Comment

In general, AEP supports most of the new and revised terms, but we have concerns with the following terms:

- **BES Cyber System Information (BCSI)**: There is no need to call out SCI in the BCSI definition when it is already covered in BES Cyber System definition.
- **Cyber Assets**: While the exclusion of Shared Cyber Infrastructure (SCI) in Cyber Assets definition seems okay upfront, it gets very confusing when applying this definition along with other definitions, such as SCI and Virtual Cyber Asset (VCA). VCA definition says it might be hosted on SCI (i.e., “A logical instance of an operating system or firmware hosted on SCI or a PCA”); However, SCI definition says “SCI does not include the supported VCA or CA with which it shares its resources”. Implementation may become chaotic unless all four definitions of CA, VCA, SCI and PCA are all logically explained in a real life context.
- **External Routable Connectivity (ERC)**: See response to Question #3 above
- **Electronic Security Perimeter (ESP)**: See responses to Questions #4 and #7 above.
- **Interactive Remote Access (IRA)**: See response to Question #5 above.
- **Management Interface**: See response to Question #6 above.
- **Protected Cyber Asset (PCA)**: AEP seeks additional clarifications on the qualifier of “excluding VCA that are being actively remediated prior to introduction to the ESP.” If the VCA, or physical Cyber Asset, is outside of the ESP, how could it be considered a PCA when the required attribute of a PCA be that it is inside an ESP? Please provide clarification.
- **Shared Cyber Infrastructure (SCI)**: AEP in general supports the definition of SCI except for “identified independently” and the nested inclusion of the Management Interface term. Please see responses to Questions #2 and #6.
- **Transient Cyber Asset (TCA):** AEP seeks additional clarifications on the significance of "Virtual machines hosted on a physical TCA can be treated as software on that physical TCA". If there were stated outcome(s) of treating as software, it might be more clear (implications of treating as software, that is).

Since the Glossary modifications are the foundation to all Standard changes, NERC should seek approval of the new terms prior to any changes being introduced in the Standards to reduce potential misunderstanding or misinterpretation of both the new definitions and modified Standards. This will also allow NERC, and industry, time to determine additional courses of action, reduce confusion, and reduce additional risk associated with such wholesale changes.

The CIP standards as currently written are sufficient to accommodate virtualization based on security objectives. The proposed changes to the standards are overly prescriptive and difficult to understand. The previous proposed revision of the standards by this Project also adequately expanded the potential use of virtualization without removing backwards compatibility. Such drastic changes will be difficult to comply with and pose a security risk to the grid as time is taken away from practicing security and applied towards implementing overly prescriptive compliance requirements that seem to be a hall of mirrors.

Individually each new or revised term is acceptable. On the whole, however, it makes for a somewhat confusing “alphabet soup” of acronyms which only those with past experience in these technologies are easily able to tell apart or know which term is the appropriate one to use for which compliance tasks. The multiple new terms confuse efforts to comply and thus entail, even if only minor, more compliance risk rather than less. Further, it is not clear why all these terms are needed if we have an acceptable definition for Virtual Cyber Asset and a revised definition of BES Cyber System that includes Virtual Cyber Assets. We recommend the SDT review the definitions again to determine if few terms are needed and, if a new term is needed, to provide further clarity on what it addresses that other definitions do not.

Need to define/clarify “asset” in the definition of ERC,

Need clarification for the IRA definition (second bullet point is not clear)

Need clarification for “identified independently” in the definition of SCI

“CIP System” Definition – Transient Cyber Asset (TCA) should not be seen as a part of any system. A TCA is an asset connected to a system for a limited period of time. If it has to be seen as a part of a system, it is no longer a TCA. Also, this term is, in some ways, redundant compared to BCS. Even if “CIP System” designates any group of assets under CIP requirements, TCA cannot be seen as a “system”. It is an asset.

“Cyber System” Definition – Very confusing regarding “CIP System” and “BCS” definitions. Need more precisions or details about the context and when those definitions are used.

We support adopting definitions and standards that support virtualization. However, it will be impossible to support the revised standards without a clearly defined demarcation of the auditable network infrastructure. We do not have a reasonable recommendation to meet this need using the current approach to the proposed CIP standards. The important items to consider are ensuring defined borders that clearly identify what is in and out of scope of the definitions, ensuring that a company that is implementing currently acceptable virtualization approach with high watermarking does not have extensive changes to their CIP programs, no inadvertent changes to compliance standards, and ensuring definitions that clearly separate hosts and guests within virtualization.

AZPS does not agree with all changes to the NERC Glossary terms. AZPS agrees with the concerns included in EEIs comments filed in this matter regarding Cyber Assets and Virtual Cyber Assets.

Cyber Assets – This term should revert back to its original singular form. While the definition refers to programmable electronic devices, the term remains singular in form and intent. This change would also harmonize with the new definition for Virtual Cyber Asset, which is not pluralized.

Virtual Cyber Asset (VCA) – The current definition is unclear and possibly unnecessary given the intent is to simply provide an equivalent virtualized term for a Cyber Asset, which is not a system but a programmable electronic device. If the SDT believes this term is necessary, we suggest the following:

“A logical instance of a programmable device, including the software and data, hosted on Shared Cyber Infrastructure or a PCA.”

Comment

CIP System – The definition contains an implicit requirement for entities to identify CIP Cyber Systems. The definition should not leave it up to the entity to make this identification, it should be criteria-based to include all of the described types of CAs. Alternate proposal: *A BES Cyber System and* *all associated Electronic Access Control or Monitoring Systems, Physical Access Control Systems, Shared Cyber Infrastructure, Protected Assets, and Transient Cyber Assets.*

Transient Cyber Asset – The use of ‘network within an Electronic Security Perimeter’ no longer works with the new definition of ESP. Alternate proposal: replace ‘network within an Electronic Security Perimeter’ with ‘network protected by an Electronic Security Perimeter’. (Even though the ESP definition no longer includes ‘network’, it is reasonable that a network could be protected by an ESP protecting all BCAs on that network.)

Removeable Media - The use of ‘network within an Electronic Security Perimeter’ no longer works with the new definition of ESP. Alternate proposal: replace ‘network within an Electronic Security Perimeter’ with ‘network protected by an Electronic Security Perimeter’. (Even though the ESP definition no longer includes ‘network’, it is reasonable that a network could be protected by an ESP protecting all BCAs on that network.)

Katie Connor - Duke Energy - 1,3,5,6 - SERC,RF

Answer	No
Document Name	

Comment

Duke has a number of definition concerns that are enumerated in response to the specific questions where the definition is relevant. In addition to those concerns, Duke Energy believes the following definition changes are required for the successful implementation of 2016-02's goals:

CIP System – Duke Energy suggests removal of TCAs from this collection of other device types to ensure that there are no inadvertent changes to scoping that historically excluded TCA devices (e.g. list of Cyber Assets to be included on the ERT CA tab).

PACS/EACMS – definitions do not take advantage of the new Cyber System definition

Cyber System – Duke Energy suggests that the inclusion of the term group here may provide an auditor basis to expect REs to actively group things that otherwise would be passively addressed. Additionally, it would be helpful to clarify that Cyber Systems are not necessarily in CIP scope. Suggested language is as follows: One or more Cyber Assets, Virtual Cyber Assets, or Shared Cyber Infrastructure. Cyber Systems may or may not receive one or more NERC CIP classifications.

ESP – Duke notes that the proposed definition for ESP drops the term "boundary" which was helpful in ensuring that auditors correctly evaluated this term. We propose to add this concept back in a manner that supports future interpretation of how a boundary may be implemented. This helps to ensure that dependent definitions (e.g. PCA use of "within") remain compatible with this iteration of the standards. Duke's proposed definition is repeated from Question 4 here: "A set of configurations enforced by an EACMS that creates a logical boundary where communications to or from any part of a BES Cyber System and any PCA or SCIG associated with a BES Cyber System are controlled. All BCS, PCA, and SCIG included in an ESP have the same impact rating as the highest included device. The EACMS enforcing the ESP may not be part of a BES Cyber System."

The definition of PCA is problematic. The first is the general issue with the CPU/memory affinity requirements. For details on this, see comments in Q14. The PCA definition has a specific problem however. It essentially places a requirement inside a definition. The implicit requirement is that a BES Cyber Asset cannot share CPU/memory with a non-BCS of the same impact rating or a Protected Cyber Asset.. This is similar to the problem the current standards have with the definition of IRA having a requirement in it. If the SDT wishes this to be an auditable requirement, they should place the requirement within the standards and not within the glossary of terms.

Suggest removing 'by a Responsible Entity' from the following definitions as it is implied or already stated in parent requirements.

BCS - One or more BES Cyber Assets logically grouped to perform one or more reliability tasks for a functional entity, including Shared Cyber Infrastructure grouped in the BES Cyber System it supports.

CIP System - A Cyber System identified as a BES Cyber System, Electronic Access Control or Monitoring System, Physical Access Control System, Shared Cyber Infrastructure, Protected Cyber Asset, or Transient Cyber Asset.

PACS - Cyber Assets, Virtual Cyber Assets, or Shared Cyber Infrastructure (SCI) (including SCI grouped in the Physical Access Control Systems it supports) that control, alert, or log access to the Physical Security Perimeter(s), exclusive of locally mounted hardware or devices at the Physical Security Perimeter such as motion sensors, electronic lock control mechanisms, and badge readers.

Answer

Document Name

Comment

Texas RE recommends revising the definition of Shared Cyber Infrastructure (SCI) to indicate that SCI inherit the impact categorizations of all hosted VCAs. For example, the VCA definition states “A logical instance of an operating system or firmware hosted on Shared Cyber Infrastructure or a PCA.” Also, the BCA definition includes “…or Virtual Cyber Asset..” This could lead to interpretations that PCAs can host BCAs.

The proposed definition for Protected Cyber Asset is written in a way where Virtual Cyber Assets may be out of scope for security requirements despite being hosted on SCI that host critical systems, such as high impact BCS. These VCAs will hereafter be referred to as non-CIP VCAs. These non-CIP VCAs would not be required to be protected by an ESP pursuant to CIP-005 R1.1 and as such permitting any and all network traffic to them would be permissible. Additionally, as these non-CIP VCAs would not meet the definition of an applicable system in CIP-005 R1.1 then CIP-005 R1.3 would not apply and communications between the non-CIP VCAs and the SCI hosting them would be also permissible.

Texas RE notes that if there are security concerns related to network communications between CIP VCAs and their hosting SCI then these same concerns should be present for network communications between non-CIP VCAs and their hosting SCI. Texas RE proposes that the portion of the PCA definition “Share CPU or memory with any part of a BES Cyber System,” be revised to “Share CPU or memory with any part of a BES Cyber System or Shared Cyber Infrastructure,”

Texas RE seeks clarity around the description of the definition of Intermediate System in the Definitions and Exemptions technical rationale document. For the definition of Intermediate System, the “Definitions and Exemptions” technical rationale document states that requirement language has been removed from the definition. The specific example of where the Intermediate System must reside was provided, as the current definition of Intermediate System prevents Intermediate Systems from being located within ESPs. The technical rationale then goes on to say that such language has been moved to a mandatory requirement within CIP-005 R2. Texas RE believes this statement is a reference to CIP-005 R2.6.2.

Texas RE seeks clarity around this concept and proposes the following language for CIP-005 R2.6.3: Communications between Intermediate Systems and Applicable Systems of Part 2.1. must go through an EACMS enforcing an ESP.

Comment

As further discussed in response to Questions 1 and 2, Duke Energy disagrees with the complexity added to the CIP-002 requirements. Based on our suggestion of the addition of an SCI Group defined term, simplified language proposed in response to Question 1 can be used.

In Requirement 1.3, the comma following BCS introduces confusion and should be removed to be clear that the SCI clause follows onto the identify clause, and is not a requirement for a separate/additional list of assets that contain SCI supporting low BCS. Alternatively, bulleting the requirement after “asset that contains:” may be clearer.

Changes to the Attachment 2 criteria 2.1 to incorporate the term “discrete” lose the context of the original RFI; if the SDT retains the new “discrete shared” language, a comma should be inserted between these terms, and clarification should be provided in the technical rationale to carry forward the clarification provided in the RFI. Additionally, the SCI bullet appears to exclude the possibility of independently identifying SCI at Generation facilities. If

this was the SDT’s intent, justification should be provided that explains why this option is not available to this facility type under section 2.1. Finally, Section 2.2 generally follows the same format as section 2.1 but was not given the second bullet related to SCI; was this intentional? If so, it would be helpful to provide explanation in an appropriate document.

The first draft contained the weighting to determine if a TOP Control Center met the medium impact criteria from CIP-002-6. The second draft reverted back to CIP-002-5.1a’s criteria 2.12’s language without informing the industry. While there is a new project to “study” the impacts to the BES with this change further delaying smaller entities compliance burden relief, it was not made clear to industry CIP-002’s language was being reverted back under this project and was not shown as a change/redline from the first or redlined in the second draft which is highly misleading. If it is possible to incorporate other projects modifying other CIP standards into this project, why not the approved CIP-002-6 and complete the study at a later time?

CEHE does not agree with the proposed changes to the 4.2.3.2. Exemption because in the “Lessons Learned CIP Version 5 Transition Program CIP-002-5.1: Communications and Networking Cyber Assets” issued by NERC, “study participants [in the Implementation Study] made a distinction between devices facilitating network communication locally for the BES Cyber Systems and those facilitating network communication external to the BES Cyber System or Facility. Entities determined network devices used only for external communication were out of scope in association with the high or medium impact BES Cyber System.” The “Lessons Learned CIP Version 5 Transition Program CIP-002-5.1: Communications and Networking Cyber Assets” was authorized by the Standards Committee on October 29, 2015 and is “ERO Enterprise – Endorsed Implementation Guidance.” However, it is still not in the standards and auditors can only go by the standards and not “Lesson Learned” documents.

The “between discrete ESPs” exemption is too narrow; all Cyber Systems used only for external communication need to be exempt, not just those between discrete ESPs. The reason is that there are instances when the same Cyber Systems can be used between two discrete ESP and between an ESP and non-ESP site. In one instance the Cyber Systems are exempt, in the other they are not, even though it is the same equipment performing the same function.

This narrow exemption has the potential of pulling Cyber Systems used for only external network communications into scope. Entities may have to bring telecommunication sites into compliance, which could mean additional costs, physical and electronic controls that would otherwise not be needed, and possibly more staff to produce and maintain the documentation required for compliance. This could create a situation where an Entity may have to choose a leased network over a private network due to the leased network being exempt even though it performs the same function as a private system.

Private systems are usually more reliable than leased systems, so overall the BES would be less reliable when using a leased system which is directly opposite of the purpose of the NERC standards. Private systems should be encouraged and exempting all Cyber Systems used only for external communications would do that.

CEHE proposes the following:

“4.2.3.2. Cyber Systems used only for external network communication between assets, or one or more geographic locations.”

As noted in the answer to Question #1, Texas RE recommends the language require identification of all BCS, as well as their associated EACMS, PACS, and PCAs. Absent that change, Texas RE recommends the SDT review Requirement R1 for logical flow. The proposed Requirement R1 language instructs registered entities to identify each BCS as either a BCS or as a BCS and independent SCI. Texas RE notes that it is not possible to identify a BCS as an independent SCI. If the system is a BCS then it must be identified as a BCS. The SDT could consider revising the language to:

1.1. Per Attachment 1, Section 1:

1.1.1. Identify each high impact BCS; and

1.1.2. Identify each independent SCI supporting any part of the high impact BCS or its associated EACMS, PACS, or PCAs.

1.2. Per Attachment 1, Section 2:

1.2.1. Identify each medium impact BCS; and;

1.2.2. Identify each independent SCI supporting any part of the medium impact BCS or its associated EACMS, PACS, or PCAs.

Since the Glossary modifications are the foundation to all Standard changes, NERC should seek approval of the new terms prior to any changes being introduced in the Standards to reduce potential misunderstanding or misinterpretation of both the new definitions and modified Standards. This will also allow NERC, and industry, time to determine additional courses of action, reduce confusion, and reduce additional risk associated with such wholesale changes.

"SCI independently identified" is frequently used throughout VSL in CIP-002, and "independent SCI" is used in the requirements. These phrases are not broadly understood and the intent needs to be clarified. In addition, AEP recommends SDT to add clarifying language to allow for the identification of both physical and virtual systems as EACMS, PACS and PCAs under CIP-002 as noted in response to Question #1.

Remove the following phrases: from the second bullet on R1.1: “or its associated Electronic Access Control or Monitoring Systems (EACMS), Physical Access Control Systems (PACS) or Protected Cyber Assets (PCAs)” and from the second bullet on R1.2: “or its associated EACMS, PACS or PCAs.” These are expanding the scope of the CIP-002 identification and CIP Senior Manager approval, and identification of these associated with SCI will create confusion since these do not have to be identified in CIP-002 if they are not associated with SCI. On Attachment 1, under the medium impact rating criteria 2.1, to clarify the second bullet, change it to begin: “Any SCI supporting BCS that could, within 15 minutes, adversely impact….” (Delete “(which must be included in a shared BCS),” “one or more” and “together.”

In support of IRC SRC/SWG. Request clarification of capitalization of “High Impact,” “Medium Impact” and “Low Impact.” Parts 1.1, 1.2 and 1.3 use lower case while other Standards use capitalization. Is there a difference? If so, please explain	

Request clarification on the “OR” in Part 1.3. What is the Entity required to identify? Assets or BCSI/SCI?

Request correction of typo in R2 from the beginning “Each” to “The”

Request clarification on the new (second) bullet in 2.1 in Attachment 1. Does the SDT intend that a series of Low Impact asset could be consolidated into Medium Impact asset due to shared SCI?

The first draft contained the weighting to determine if a TOP Control Center met the medium impact criteria from CIP-002-6. The second draft reverted back to CIP-002-5.1a's criteria 2.12's language without informing the industry. While there is a new project to "study" the impacts to the BES with this change further delaying smaller entities compliance burden relief, it was not made clear to industry CIP-002's language was being reverted back under this project and was not shown as a change/redline from the first or redlined in the second draft which is highly misleading. If it is possible to incorporate other projects modifying other CIP standards into this project, why not the approved CIP-002-6 and complete the study at a later time?

The modifications to CIP-002 are complex and include a number of new terms and concepts. For example, AWS supports the SDT’s addition of requirements for Management Interfaces, but Management Interfaces are not required to be identified in CIP-002. CIP-002 requires the identification of SCI and EACMS, not the associated Management Interface. This situation also occurs with Intermediate Systems under the currently enforceable

Standards and has been problematic. The embedded classifications increase the opportunity for compliance violations and security oversights. AWS suggests including those terms directly in CIP-002 for clarity. It would be helpful if the SDT provided in Implementation Guidance a logic diagram depicting how the device classifications and embedded definitions like Management Interface and CIP System can be applied. Lastly, the SDT has been clear that this project focuses on on-premise virtualization, however, many virtualization concepts could be interpreted as being related to cloud computing technologies. AWS suggests explicitly stating that the Standards do not apply to cloud within the Applicability section of CIP-002. If these updated Standards do not apply to cloud, it should be obvious to the reader.

EEI notes significant improvements to CIP-002 but asks for additional clarity for the following: 1) "SCI independently identified" is frequently used throughout CIP-002. This phrase is not broadly understood and the intent needs to be clarified. 2) In EEI's comments to the previous draft of CIP-002, we expressed concern regarding the proposed removal of communications networks from the Exemption Section of the previous draft, noting that both data communication links and communication networks should remain exempt. Nevertheless, this change remains in Draft 2 and EEI seeks clarification why communications networks remain excluded from the Exemptions section in this proposed draft of CIP-002.	

3) EEI recommends modifying 4.2.3.2 to align with endorsed ERO General Implementation Guidance titled “CIP Version 5 Transition Program, CIP-002-5-1: Communications and Networking Cyber Assets” dated October 6, 2015. EEI suggests the following: 4.2.3.2 Cyber Systems associated with: 4.2.3.2.1 Communication and networking devices between discrete Electronic Security Perimeters (ESP), and Cyber Systems associated with external communication to one or more geographic locations.” or 4.2.3.2.2 Non-routable communication externally directed between an ESP and one or more other geographic locations. or 4.2.3.2.3 Non-routable communication externally directed between BCS and one or more other geographic locations. 4) The inclusion of EACMS, PACS and PCAs seems redundant and possibly unnecessary in both the second bullet of R1.1 and the second bullet of R1.2. If this is an intentional, EEI request clarification within the Technical Rationale explaining the purpose of including of EACMS, PACS and PCAs.

The requirement requires the identification of BCS as either “including any supporting SCI as part of the BCS” or with “independent SCI supporting any part of the high impact BCS or its associated Electronic Access Control or Monitoring Systems (EACMS), Physical Access Control Systems (PACS) or Protected Cyber Assets (PCAs).” This does not allow for the identification of BCS independent of having SCI, and therefore doesn’t account for non-virtualized environments. The requirements and measures of CIP-002 do not sufficiently detail what is required to demonstrate compliance. The requirements are to create a list that identifies “each [BCS] as either” including supporting SCI or having independent SCI. However, the independent SCI details an association to EACMS, PACS, PCA. The requirement expects an identification of “BES Cyber Systems” but the sub-bullets imply an expectation to identify SCI and corresponding asset/system classifications. The measures and technical rationale provide no additional clarity other than creating lists. Is the expectation to simply provide identification that the identified BCS either include SCI or are supported by SCI (e.g. Yes/No or Checkbox), or is the expectation to explicitly identify and categorize SCI that meet this criteria (e.g. “1.) ABC High Impact BCS; 2.) CDE High Impact EACMS SCI”). If the expectation is to classify SCI, what should be the approach for classifying SCI that supports multiple classifications (e.g. EACMS and PACS)? As mentioned in Comment for #2 above, more clarity regarding grouping SCI could be beneficial as well.

N&ST believes the proposed revisions to Medium Impact Criterion 2.1 are confusing, particularly the parenthetical note in the second bullet that SCI “…must be included in a shared BCS” in order to potentially meet this criterion. If N&ST’s understanding of the SDT’s intentions regarding SCI, namely, that a Responsible Entity has the option of either including an SCI in a BCS (or an EACMS or a PACS) or identifying it as “independent” but supporting one or more BCS, EACMS, or PACS is correct, then we believe the second bullet, as written, is unnecessary. However, “independently identified” SCI that support BCS that meet Criterion 2.1 should be accounted for.

N&ST also believes the SDT should address the fact that Criteria 2.1 and 2.2, although ostensibly similar, are not consistent with each other: Criterion 2.2, as proposed, makes no mention of SCI at all.

The draft CIP-002-7 standard now allows the Responsible Entity to identify SCI in the overall BCS or to identify them independently, it also requires the identification of SCI that supports EACMS, PACS, or PCAs. This gives Regional Entity enforcement staff the ability to identify noncompliance in a single requirement for a missed (SCI based) EACM, PACS, or PCA; rather than identifying all applicable requirements for a missed EACMS, PACS, or PCA.

A long standing “error” appears to remain in the High VSL for R1, where it states “For Responsible Entities with a total of 100 or fewer high or medium impact and BCA, more than 10 but less than or equal to 15 identified BCA have not been categorized or have been incorrectly categorized at a lower category” where Medium and Severe mention “BCS” instead of “BCA” This is the only mention of BCA in the VSL. It appears as though the latest modifications only replaced definitions and did not correct this error.

Comment	
Southern generally agrees with the proposed changes to CIP-002 but with these suggestions for improvement. For R1.1 it would be clearer if it said “identify each high impact BCS as either of the following, if any, at each asset.” The same for R1.2, “identify each medium impact BCS as either of the following, if any, at each asset.” Both high and medium impact are clearly identified, and it does not imply that all BCS within an asset are of the same impact level. In addition, we suggest that CIP-002 not imply any process steps as identification methods vary within differing environments. Keep CIP-002 R1 as results-oriented as it has always been. We suggest capturing the options for SCI identification within the relevant definitions (as it currently is in the SCI proposal) and keep CIP-002 as close to the version 5.1a language as possible.

10. The SDT revised CIP-005 based on industry comments. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

Dan Zollner - Portland General Electric Co. - 3

Answer	No
Document Name	

Comment

Portland General Electric Company supports the comments provided by EEI for this survey question. Additionally, Replacing "BES Cyber System" with "CIP System" in the proposed definition of ERC appears to expand the scope of ERC from what was previously in place and now would include remote routable connectivity to PACS or EACMS. PGE wonders if this was the drafting team’s intent. If not, Portland General Electric Company believes the phrase "CIP System" in the proposed definition of ERC could be replaced with "BES Cyber System" to resolve the scope expansion.

Request clarification between Part 1.2 and Part 1.3. Part 1.2 reads “Permit only needed and controlled communications to and from Management Interfaces, and deny all other communications” which seems to include Part 1.3 which reads “Deny network communications from Applicable Systems of Part 1.1 to the Management Interface, per system capability.”

Request clarification on Parts 1.4 and 2.1. Does Applicable System “above” refer to the other items in this Applicable Systems or the above Requirements / Parts?

Request additional language in Part 2.1 to make it obvious this is for IRA where the EACMS is the destination - - - not passing through the EACMS.

Request the SDT correct the typographical error, “Systerms” in Part 2.6.2 Requirements

Request the SDT clarify whether Exemption 4.2.3.3, which reads “Cyber Systems, associated with communication links, between the Cyber Systems providing confidentiality and integrity of an ESP that extends to one or more geographic locations,” exempts any entity including third parties?

N&ST offers the following observations about the proposed changes to CIP-005:

> Regarding the statement in Requirement R1 Part 1.1 (“Host-based firewalls that only protect the host on which they reside are not a sufficient control to meet this requirement.”), N&ST believes it is highly inappropriate to include such an explicit directive in a CIP Standard Requirement statement. Standard Drafting Teams have, in recent years, endeavored to make Requirements non-prescriptive. The should likewise be non-proscriptive. N&ST notes this proposed change seems to have been made in response to a concern about “logical isolation” that was expressed by a single individual, representing one organization, during the previous ballot’s comment period, which ended 3/22/2021. N&ST believes concerns about host-based firewalls may actually be moot, given the fact the SDT has dropped “logical isolation” and restored the better-defined “ESP.” However, if the SDT believes this prohibition should be put in writing, it should by all means be done, but in an implementation guide, not a Standard.

> N&ST believes Requirement R1 Part 1.2 (“Permit only needed and controlled communications to and from Management Interfaces,…”) should apply to SCI identified independently and to SCI that are grouped into BES Cyber Systems.

> N&ST believes Requirement R1 Parts 1.2 and 1.3 are largely redundant and should be combined.

> Regarding Requirement R2, Part 1.2, N&ST believes “Applicable Systems” should include EACMS inside an ESP, if any (there are such devices in practice today).

> N&ST recommends that the SDT “true up” the wording of Requirement R2 Part 2.5 and Requirement R3 Part 3.2, which both address disabling/terminating vendor remote connections, so that they both say the same thing.

Answer	No
Document Name	

Comment

Portland General Electric Company supports the comments provided by EEI for this survey question. Additionally, Replacing "BES Cyber System" with "CIP System" in the proposed definition of ERC appears to expand the scope of ERC from what was previously in place and now would include remote routable connectivity to PACS or EACMS. PGE wonders if this was the drafting team’s intent. If not, Portland General Electric Company believes the phrase "CIP System" in the proposed definition of ERC could be replaced with "BES Cyber System" to resolve the scope expansion.

Request clarification between Part 1.2 and Part 1.3. Part 1.2 reads “Permit only needed and controlled communications to and from Management Interfaces and deny all other communications” which seems to include Part 1.3 which reads “Deny network communications from Applicable Systems of Part 1.1 to the Management Interface, per system capability.”

Request clarification on Parts 1.4 and 2.1. Does Applicable System “above” refer to the other items in this Applicable Systems or the above Requirements / Parts?

Request additional language in Part 2.1 to make it obvious this is for IRA where the EACMS is the destination - - - not passing through the EACMS.

Request correction of the typo “Systerms” in Part 2.6.2’s Requirements

Request clarification on Exemption 4.2.3.3 which reads “Cyber Systems, associated with communication links, between the Cyber Systems providing confidentiality and integrity of an ESP that extends to one or more geographic locations.” Does this exempt any entity including third parties?

Overall comment: We suggest reviewing the word ‘’communications’’, it should be a bi-directional routable protocol or a routable protocol. Communication is too vague. One could imply that serial, layer 2 communication needs to be controlled. If the intent of the SDT is to broaden the scope, why keep the notion of bi-directional routable protocol or routable protocol.

Requirement 1.1 New concept is inserted “between intelligent electronic devices”, what is an intelligent electronic device? We propose the SDT to use Cyber Asset definition.

The note regarding Host-based firewalls, is in sync with the definition of ESP, except we don’t agree on imposing this limitation. Also, the firewall wording is not used in the language of the requirements, controlled communication is the usual wording. We suggest the removal of this note.

The requirement should use the same language that is used for the other requirements. Suggestion

Applicable Systems connected to a network via a routable protocol must be protected by an ESP that Permits only needed and controlled communications and denies all other communications.

Requirement 1.2 We suggest reviewing the measure column. MPLS is mainly a WAN protocol. Also, a network switch enforces the VLAN concept so the network switch would be an SCI and EACMS? We suggest that the SDT review the mechanism permitting the control of communication. Someone could build a complete ecosystem with only a network switch (BCA is on VLAN 2 and the permitted users are on VLAN 2, the denied users are on VLAN 3, all of this is managed and controlled by a network switch, a switch this is virtualized.

Requirement 1.3 introductions of network communication. For some requirement, communication is the only word used (1.1, 1.2), we suggest that the SDT review the usage of the word ‘’network’’ and be uniform within all standards.

Requirement 1.4: No Comments

Requirement 1.5 version 6 of this requirement is only applicable to BCA and PCA, in this version the SDT as added PACS hosted on SCI; and EACMS hosted on SCI, and SCI identified independently supporting an Applicable System above. One could understand why the SCI is part of the applicable systems but why did the SDT target PACS and EACMS. We suggest to the SDT to remove PACS and EACMS. Also the line “SCI identified independently supporting an Applicable System above” should be replaced by the usual language used throughout the requirements, i.e.” SCI identified independently supporting an Applicable System from Part 1.1.” Clarification to that sentence would also be welcome, are they “SCI identified independently” or are they “SCI that is identified to be supporting independently an Applicable System”.

Requirement 1.6, this requirement is valid in the context of the old ESP definition. In the context of the suggested definition, this is an additional requirement resulting in a burden for the entity. The SDT should evaluate the possibility of enforcing the ESP controls (permitted communication and malicious communications) directly on the cyber asset itself, an EACMS wouldn’t be required. The BCA, PCA, EACMS, PACS, SCI could have their own controls (host firewall, host IDS, Host Endpoint controls).

Requirement 2.1 We suggest reviewing the Applicable column

EACMS that enforces an ESP for the Applicable Systems in Part 1.1.

This is an additional requirement resulting in an additional burden for the entity.

SCI identified independently supporting an Applicable System above

We suggest the normal wording (SCI identified independently supporting an Applicable System from Part 1.1.

Increase in the need for Intermediate System (EACMS used for the ESP, SCI).

Requirement 2.2 No Comments

Requirement 2.3 No Comments

Requirement 2.4 We suggest the SDT normalize the wording, ‘’from SCI identified independently supporting an Applicable System above’’ to ‘’SCI identified independently supporting an Applicable System from Part 1.1’’.

Also, SDT proceeded in a change of scope for the Medium Impact BES Cyber Systems. In the previous version, ERC was a criteria. The suggested version doesn’t have this criteria which will increase the scope of the requirements and the burden on the entities.

Requirement 2.5 We suggest the SDT normalize the wording, ‘’from SCI identified independently supporting an Applicable System above’’ to ‘’SCI identified independently supporting an Applicable System from Part 1.1’’.

Also, SDT proceeded in a change of scope for the Medium Impact BES Cyber Systems. In the previous version, ERC was a criteria. The suggested version doesn’t have this criteria which will increase the scope of the requirements and the burden on the entities.

Requirement 2.6. Requirement 2.6.1 is greatly limiting. One objective of virtualization is to optimize the usage of computer resources (CPU power, memory, etc.). Enforcing restriction of those types limits the possible gain of instating virtualization or consolidating services like databases or web applications. We suggest the SDT review their objectives and how to implement them. The reference to Part 2.1 in 2.6 can also be confusing for the requirement, does the restriction in CPU and memory also apply to the SCI in 2.1 or only to the Intermediate Systems.

Requirement 2.6.2 should use the same language that is used for the other requirements. Suggestion

Permit only needed and controlled communications and denies all other communications between Intermediate Systems and Applicable Systems of Part 2.1.

Reference 2.6.1, Restrict VCAs of Intermediate Systems to only share CPU and memory with other Intermediate Systems and their associated SCI

Reference 2.6.2. Permit only needed and controlled communications between Intermediate Systems and Applicable Systems of Part 2.1.

Requirement 3 Is this a new requirement part of the SAR?

Also, requirement 2.4 and Requirement 2.5 doesn’t mention the ERC criteria for the Medium Impact BES Cyber Systems, yet requirements 3.1 and 3.2 mention the ERC criteria. This will increase the burden on the entities. We suggest the SDT review the scope and criteria.

Remove Intermediate Systems from the applicability for 2.1 to permit authorized IRA through an Intermediate System (on the clean version).

R1.1 – The last sentence in the requirement is prescriptive and would be more appropriate in the technical rationale document. Consider removing this and moving it to TR: “Host-based firewalls that only protect the host on which they reside are not a sufficient control to meet this requirement.”

R2.1 – Revise as follows to improve readability - Permit authorized IRA to Applicable Systems only through an Intermediate System.

EEI generally agrees with many of the proposed NERC Glossary terms, but we also identified a number of proposed terms that remain a concern. EEI is specifically concerned with the phrase "SCI identified independently", which is not widely understood and needs to be clarified. For this and the following concerns we cannot support the proposed changes at this time. Requirement R1, subpart 1.4 may not fully cover the requirements set forth in CIP-006, Requirement R1, subpart 1.10. Associated PCAs are not included within subpart 1.4 but were specifically identified in CIP-006, subpart 1.10. This should be addressed or more clearly explained.

Pamela Hunter - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - SERC, Group Name Southern Company

Answer	No
Document Name	

Comment

Southern disagrees with the applicability within R2. In R2.1, each Intermediate System is itself the object of the Intermediate System requirement, creating a hall of mirrors. Each Intermediate System is also an “EACMS that enforces an ESP”; it is an EACMS that enforces “policies or configuration” that “control communications”. See our fuller explanation of EACMS issues in Q14. In addition, there is an applicability difference between the clean and redline posted versions.

In addition, R2.6.2 points to the Applicable Systems of Part 2.1 as its applicability, however Part 2.1 includes the firewall (EACMS enforcing an ESP). We suggest R2.6.2 applicability should actually refer to Part 1.1, where only the BCS and the PCAs are in scope. That firewall (EACMS enforcing an ESP) is where one would implement R2.6.2, not the object of R2.6.2. Additionally, R2.6.2 has a spelling error (Systerms).

The SDT is using the update to the definition as a mechanism to support zero-trust models, but the existing ESP definition does not preclude a Responsible Entity from applying the concept of zero-trust to its environment(s) in addition to its traditional ESP. The proposed modification does not obligate a Responsible Entity to adopt additional security controls.

The statement in the Definitions and Exemptions Technical Rationale, "[i]n these models, the perimeter shrinks to increasingly more granular levels, potentially down to a process or resource level on a BCS and nothing on the network is trusted for unrestricted communications," could be interpreted as meaning that traditional ESP-based perimeter security is not necessary or required. A Responsible Entity may choose to adopt a traditional ESP model, or a zero-trust model, without considering the benefits of a defense-in-depth approach that leverages both traditional perimeter-based security and zero-trust concepts.

AWS proposes the following language, "The logical border surrounding a network to which BES Cyber Systems are connected using a routable protocol that includes a set of configurations or policies enforced by an EACMS that controls communications to or from any part of a BES Cyber System. These configurations or policies group CIP Systems of the same impact rating and their associated PCAs."

Detailed implementation guidance is necessary to support zero-trust and hybrid approaches.

AWS supports the implementation of zero-trust architectures in fulfilling the NERC CIP Standards, but is seeking clarity on the assertion that the use of configurations or policies in the modified ESP definition can reduce the burden of documenting ESPs in a zero-trust environment. As the ESPs implemented by a Responsible Entity become more granular in a zero-trust environment, the documentation needs to support each policy or set of policies applied seeming to increase the compliance documentation.

GSOC generally agrees with the proposed revision to the term ESP, but is concerned that, despite those revisions, the term ESP is used inconsistently in CIP-005-8. As an example, the proposed language in CIP-005-8, R1.2 appears to have an inconsistency between the	

requirement and the measures. Specifically, the requirement language does not explicitly require an ESP while the measure appears to require an ESP. This also calls into question the inconsistent use of ESP between R1.1 and R1.2/1.3 and between these requirements and R1.6.

With the proposed modifications to the ESP definition, to avoid any confusion, it is recommended that specific language providing for traditional ESP protection of Applicable Systems be referenced as an option for meeting these requirements. Finally, if such language is not revised, GSOC requests clarification as to whether R1.6 is or should be applicable to any systems that are protected or are providing protections under R1.2 and R1.3 where those protections are not formally identified as an ESP. Inclusion of language such as “or other system or ESP” in Requirement R 1.6 would eliminate any uncertainty regarding protection of the Applicable Systems.

Comment

We disagree with the changes in CIP-005.

Recommendations:

- For CIP-005 R1.1, we have provided recommendation in Q4.
- For CIP-005 R1.2 and R1.3, resulting from our proposed changes to the definition of SCI, BCA, EACMS, PACS and PCA, the devices containing Management Interface will be identified as BCA, EACMS, PACS or PCA, therefore CIP-005 R1.2 and R1.3 are no longer needed.
- For CIP-005 R1.4, we agree to moving the CIP-006 R1.10 to CIP-005 R1.4 that is the right spot.
- For CIP-005 R1.6, resulting from our proposed changes to the definitions, we suggest changing the Applicable Systems to the following:
- Electronic Access Points for High Impact BES Cyber Systems
- Electronic Access Points for Medium Impact BES Cyber Systems at Control Centers
- EACMS that controls all communications to and from the BCS unless ESP model is used.
- For CIP-005 R2.1, it has a “hall of mirrors” issue since the Intermediate System requires another Intermediate System. Resulting from our proposed changes to the definitions, we suggest changing the Applicable Systems to the following:
- High Impact BES Cyber Systems and their associated PCA
- Medium Impact BES Cyber Systems with External Routable Connectivity and their associated PCA
- EACMS that contains EAP

- EACMS that controls all communications to and from the BCS unless ESP model is used
- For CIP-005 R2.4 and R2.5, resulting from our proposed changes to the definitions, we suggest removing SCI language from the Applicable Systems.
- For CIP-005 R2.6, resulting from our proposed changes to the definition of PCA, this requirement is no longer needed since a non-CIP VCA sharing resources with any CIP Cyber Assets (BCA, EACMS, PACS or PCA) will be identified as a PCA. We haven’t seen any problem for an Intermedium System to share resources with other types of CIP Cyber Assets.
- For CIP-005 R3.1 and R3.2, resulting from our proposed changes to the definitions, we suggest removing SCI language from the Applicable Systems.

We also want to point out that CIP-005-8 R1 Part 1.1 specifically denies ‘*Host-based firewalls that only protect the host on which they reside are not a sufficient control to meet this requirement*’ which does not meet the objective based model that the standards are supposed to now be written to. This very specifically identifies a technology that cannot be used to meet the requirement. This statement appears to be in conflict with the Technical Rationale for the ERC term.

ERC is no longer based on ‘external’ being defined in terms of the ESP as ESPs are changing in light of Zero Trust models. Zero Trust will shrink ESP’s over time to the smallest, most granular object possible including a single device or possibly to process or resource level on a device.

Question #10 begins by asking about the revised CIP-005 but then asks about proposed changes to the NERC Glossary terms. We presume that this is a typo and that the question was about CIP-005.

Please see comments regarding new definitions for ESP and EACMS. We believe the standard should address multi-layered access controls where traditional ESP boundaries are deployed using traditional firewalls, in addition to zero trust or host-based solutions. The IRA requirements should not apply to individual BCAs or PCAs with host-based solutions when they are also inside an ESP controlled by a traditional firewall.

NERC Definition Changes -- Electronic Security Perimeter (ESP) - removed the routable protocol qualifier. Consider the following:

* The new ESP qualifier is an EACMS. The EACMS definition does not have a routable protocol/communication qualifier, and it references ESPs. It seems like a circular definition.

When looking at the definitions only, it appears to require serial connected Cyber Assets have an EACMS to protect their serial communication links, however they are not required to have an Electronic Access Point (EAP) as the EAP definition has a routable communication qualifier.

When assessing CIP-005-8 R1.1 the Requirements section qualifies ESPs are only required for Applicable Systems with routable protocols. It does not have a qualifier of ERC so if there is only ethernet within a system that never leaves an asset, an ESP is required even if you have no EAP. This is the same as V5 of the standards.

If a BCA has both serial and Ethernet communications that leave an asset, auditors could require an EACMS for serial connections because a BCA that has routable protocol leaving an asset is required to have an ESP, and an ESP is required to have an EACMS. The same BCA serial that would leave the asset would require an EACMS because the ESP definition does not exclude serial communication. Not sure what type of device a serial EACMS would be.

The SDT proposed definition creates ambiguity around serial communication configurations and whether they have to be documented as part of an ESP.

We recommend revising CIP-005-X R1 Part 1.1 to read:

Applicable Systems connected to a network via a routable protocol must be protected by an ESP that permits only needed communications and denies all other commuincations. Host-based firewalls that only protect the host on which they reside are not a sufficient control to meet this requirement. Excluding:

* Time sensitive protection or control functions between intelligent electronic devices

* Cyber Asset to Cyber Asset serial communication not meeting the IRA definition

Additionally, question #10 begins by asking about the revised CIP-005 but then asks about proposed changes to the NERC Glossary terms. We presume that this is a typo and that the question was about CIP-005.

Amy Bratkovic - PNM Resources - Public Service Company of New Mexico - 1,3

Answer	No
Document Name	

Comment

Regarding CIP-005 R1.3, PNM Resources disagrees with this requirement. The technical rational is to keep users on SCI from being able to manage the SCI.This can be done via CIP-005 R1.2 where only permitted communication is allowed. It may be possible that an entity has an administrator workstation that is also a BCA that can access both the data plane and management plane. CIP-005 R1.2 can restrict the network traffic to include the administrator workstation. In addition electronic access controls should be in-place on the Management Interface to only allow the appropriate administrators access to it. The prescriptive and broad ban of traffic from the data plan seems excessive. The separation occurs in cloud-based hosting because the hosting service is the administrator and the tenant is not. For on-premise that is not the case and the administrator and tenant are the same entity.

Does the SDT intend that those with on-premise virtualization purchase other physical workstation to manage the SCI? We cannot simply virtualize a PCA on the SCI to manage the SCI as it would be forbidden. The technical rational also is a bit inconsistent with the actual requirement. “The intent is users of a BCS hosted on an SCI that is identified independently and hosting other VCAs of differing impact levels should be prevented from having any access to the Management Interface of the underlying SCI.” The technical rational also doesn’t look at the 2nd and 3rd bullets in the definition of Management Interface, but only the first. The CIP-005 R1.3 requirement eliminates all BCS regardless of hosting status from having access to the Management Interface of the underlying SCI. We believe the controls in CIP-005 R1.2 along with electronic access controls for Management Interfaces is enough to prevent unauthorized users from managing the SCI or the EACMS that enforces the ESP. However CIP-005 R1.2 doesn’t address Management Interfaces on stand alone devices like physical server’s lights-out management port. If the SDT intends to fully protect lights-out management ports on stand-alone physical devices then it needs to be placed in scope in CIP-005 R1.2.

Request clarification on Exemption 4.2.3.3 which reads “Cyber Systems, associated with communication links, between the Cyber Systems providing confidentiality and integrity of an ESP that extends to one or more geographic locations.” Does this exempt any entity including third parties?

Overall comment: We suggest reviewing the word ‘’communications’’, it should be a bi-directional routable protocol or a routable protocol. Communication is too vague. One could imply that serial, layer 2 communication needs to be controlled. If the intent of the SDT is to broaden the scope, why keep the notion of bi-directional routable protocol or routable protocol.

Requirement 1.1 New concept is inserted “between intelligent electronic devices”, what is an intelligent electronic device? We propose the SDT to use Cyber Asset definition.

The note regarding Host-based firewalls, is in sync with the definition of ESP, except we don’t agree on imposing this limitation. Also, the firewall wording is not used in the language of the requirements, controlled communication is the usual wording. We suggest the removal of this note.

The requirement should use the same language that is used for the other requirements. Suggestion

Applicable Systems connected to a network via a routable protocol must be protected by an ESP that Permits only needed and controlled communications and denies all other communications.

Requirement 1.2 We suggest reviewing the measure column. MPLS is mainly a WAN protocol. Also, a network switch enforces the VLAN concept so the network switch would be an SCI and EACMS? We suggest that the SDT review the mechanism permitting the control of communication. Someone could build a complete ecosystem with only a network switch (BCA is on VLAN 2 and the permitted users are on VLAN 2, the denied users are on VLAN 3, all of this is managed and controlled by a network switch, a switch this is virtualized.

Requirement 1.3 introductions of network communication. For some requirement, communication is the only word used (1.1, 1.2), we suggest that the SDT review the usage of the word ‘’network’’ and be uniform within all standards.

Requirement 1.4: No Comments

Requirement 1.5 version 6 of this requirement is only applicable to BCA and PCA, in this version the SDT as added PACS hosted on SCI; and EACMS hosted on SCI, and SCI identified independently supporting an Applicable System above. One could understand why the SCI is part of the applicable systems but why did the SDT target PACS and EACMS. We suggest to the SDT to remove PACS and EACMS. Also the line “SCI identified independently supporting an Applicable System above” should be replaced by the usual language used throughout the requirements, i.e.” SCI identified independently supporting an Applicable System from Part 1.1.” Clarification to that sentence would also be welcome, are they “SCI identified independently” or are they “SCI that is identified to be supporting independently an Applicable System”.

Requirement 1.6, this requirement is valid in the context of the old ESP definition. In the context of the suggested definition, this is an additional requirement resulting in a burden for the entity. The SDT should evaluate the possibility of enforcing the ESP controls (permitted communication and malicious communications) directly on the cyber asset itself, an EACMS wouldn’t be required. The BCA, PCA, EACMS, PACS, SCI could have their own controls (host firewall, host IDS, Host Endpoint controls).

Requirement 2.1 We suggest reviewing the Applicable column

EACMS that enforces an ESP for the Applicable Systems in Part 1.1.

This is an additional requirement resulting in an additional burden for the entity.

SCI identified independently supporting an Applicable System above

We suggest the normal wording (SCI identified independently supporting an Applicable System from Part 1.1.

Increase in the need for Intermediate System (EACMS used for the ESP, SCI).

Requirement 2.2 No Comments

Requirement 2.3 No Comments

Requirement 2.4 We suggest the SDT normalize the wording, ‘’from SCI identified independently supporting an Applicable System above’’ to ‘’SCI identified independently supporting an Applicable System from Part 1.1’’.

Also, SDT proceeded in a change of scope for the Medium Impact BES Cyber Systems. In the previous version, ERC was a criteria. The suggested version doesn’t have this criteria which will increase the scope of the requirements and the burden on the entities.

Requirement 2.5 We suggest the SDT normalize the wording, ‘’from SCI identified independently supporting an Applicable System above’’ to ‘’SCI identified independently supporting an Applicable System from Part 1.1’’.

Also, SDT proceeded in a change of scope for the Medium Impact BES Cyber Systems. In the previous version, ERC was a criteria. The suggested version doesn’t have this criteria which will increase the scope of the requirements and the burden on the entities.

Requirement 2.6. Requirement 2.6.1 is greatly limiting. One objective of virtualization is to optimize the usage of computer resources (CPU power, memory, etc.). Enforcing restriction of those types limits the possible gain of instating virtualization or consolidating services like databases or web applications. We suggest the SDT review their objectives and how to implement them. The reference to Part 2.1 in 2.6 can also be confusing for the requirement, does the restriction in CPU and memory also apply to the SCI in 2.1 or only to the Intermediate Systems.

Requirement 2.6.2 should use the same language that is used for the other requirements. Suggestion

Permit only needed and controlled communications and denies all other communications between Intermediate Systems and Applicable Systems of Part 2.1.

Reference 2.6.1, Restrict VCAs of Intermediate Systems to only share CPU and memory with other Intermediate Systems and their associated SCI

Reference 2.6.2. Permit only needed and controlled communications between Intermediate Systems and Applicable Systems of Part 2.1.

Requirement 3 Is this a new requirement part of the SAR?

Also, requirement 2.4 and Requirement 2.5 doesn’t mention the ERC criteria for the Medium Impact BES Cyber Systems, yet requirements 3.1 and 3.2 mention the ERC criteria. This will increase the burden on the entities. We suggest the SDT review the scope and criteria.

We disagree with the changes in CIP-005.

Recommendations:

- For CIP-005 R1.1, we have provided recommendation in Q4.
- For CIP-005 R1.2 and R1.3, resulting from our proposed changes to the definition of SCI, BCA, EACMS, PACS and PCA, the devices containing Management Interface will be identified as BCA, EACMS, PACS or PCA, therefore CIP-005 R1.2 and R1.3 are no longer needed.
- For CIP-005 R1.4, we agree to moving the CIP-006 R1.10 to CIP-005 R1.4 that is the right spot.
- For CIP-005 R1.6, resulting from our proposed changes to the definitions, we suggest changing the Applicable Systems to the following:
    - Electronic Access Points for High Impact BES Cyber Systems
    - Electronic Access Points for Medium Impact BES Cyber Systems at Control Centers
    - EACMS that controls all communications to and from the BCS unless ESP model is used.
- For CIP-005 R2.1, it has a “hall of mirrors” issue since the Intermediate System requires another Intermediate System. Resulting from our proposed changes to the definitions, we suggest changing the Applicable Systems to the following:
    - High Impact BES Cyber Systems and their associated PCA
    - Medium Impact BES Cyber Systems with External Routable Connectivity and their associated PCA
    - EACMS that contains EAP
    - EACMS that controls all communications to and from the BCS unless ESP model is used
- For CIP-005 R2.4 and R2.5, resulting from our proposed changes to the definitions, we suggest removing SCI language from the Applicable Systems.
- For CIP-005 R2.6, resulting from our proposed changes to the definition of PCA, this requirement is no longer needed since a non-CIP VCA sharing resources with any CIP Cyber Assets (BCA, EACMS, PACS or PCA) will be identified as a PCA. We haven’t seen any problem for an Intermedium System to share resources with other types of CIP Cyber Assets.
- For CIP-005 R3.1 and R3.2, resulting from our proposed changes to the definitions, we suggest removing SCI language from the Applicable Systems.

NERC Definition Changes -- Electronic Security Perimeter (ESP) - removed the routable protocol qualifier. Consider the following:

- The new ESP qualifier is an EACMS. The EACMS definition does not have a routable protocol/communication qualifier, and it references ESPs. It seems like a circular definition.
- When looking at the definitions only, it appears to require serial connected Cyber Assets have an EACMS to protect their serial communication links, however they are not required to have an Electronic Access Point (EAP) as the EAP definition has a routable communication qualifier.

o When assessing CIP-005-8 R1.1 the Requirements section qualifies ESPs are only required for Applicable Systems with routable protocols. It does not have a qualifier of ERC so if there is only ethernet within a system that never leaves an asset, an ESP is required even if you have no EAP. This is the same as V5 of the standards.

o If a BCA has both serial and Ethernet communications that leave an asset, auditors could require an EACMS for serial connections because a BCA that has routable protocol leaving an asset is required to have an ESP, and an ESP is required to have an EACMS. The same BCA serial that would leave the asset would require an EACMS because the ESP definition does not exclude serial communication. Not sure what type of device a serial EACMS would be.

o The SDT proposed definition creates ambiguity around serial communication configurations and whether they have to be documented as part of an ESP.

We recommend revising CIP-005-X R1 Part 1.1 to read:

Applicable Systems connected to a network via a routable protocol must be protected by an ESP that permits only needed communications and denies all other communications. Host-based firewalls that only protect the host on which they reside are not a sufficient control to meet this requirement. Excluding:

- Time sensitive protection or control functions between intelligent electronic devices
- Cyber Asset to Cyber Asset serial communication not meeting the IRA definition

We also want to point out that CIP-005-8 R1 Part 1.1 specifically denies '*Host-based firewalls that only protect the host on which they reside are not a sufficient control to meet this requirement*' which does not meet the objective based model that the standards are supposed to now be written to. This very specifically identifies a technology that cannot be used to meet the requirement. This statement appears to be in conflict with the Technical Rationale for the ERC term.

ERC is no longer based on 'external' being defined in terms of the ESP as ESPs are changing in light of Zero Trust models. Zero Trust will shrink ESP's over time to the smallest, most granular object possible including a single device or possibly to process or resource level on a device.

Additionally, question #10 begins by asking about the revised CIP-005 but then asks about proposed changes to the NERC Glossary terms. We presume that this is a typo and that the question was about CIP-005.

Comment

•   R1.6 – Minnesota Power believes that the requirement is ambiguous and could be interpreted as traffic is only required to be monitored entering or leaving an ESP, but it could also be interpreted as traffic must be monitored both entering and leaving an ESP.

•   R2.1 - Minnesota Power believes the inclusion of "Intermediate Systems used to access Applicable Systems of Part 2.1" in the Applicable Systems section of Part 2.1 creates a recursive reference that will never resolve as it would require an Intermediate System be used to access another Intermediate System.

In support of NPCC RSC comments.

Request clarification between Part 1.2 and Part 1.3. Part 1.2 reads “Permit only needed and controlled communications to and from Management Interfaces and deny all other communications” which seems to include Part 1.3 which reads “Deny network communications from Applicable Systems of Part 1.1 to the Management Interface, per system capability.”

Request clarification on Parts 1.4 and 2.1. Does Applicable System “above” refer to the other items in this Applicable Systems or the above Requirements / Parts?

Request additional language in Part 2.1 to make it obvious this is for IRA where the EACMS is the destination - - - not passing through the EACMS.

Request correction of the typo “Systerms” in Part 2.6.2’s Requirements

Request clarification on Exemption 4.2.3.3 which reads “Cyber Systems, associated with communication links, between the Cyber Systems providing confidentiality and integrity of an ESP that extends to one or more geographic locations.” Does this exempt any entity including third parties?

Overall comment: We suggest reviewing the word ‘’communications’’, it should be a bi-directional routable protocol or a routable protocol. Communication is too vague. One could imply that serial, layer 2 communication needs to be controlled. If the intent of the SDT is to broaden the scope, why keep the notion of bi-directional routable protocol or routable protocol.

Requirement 1.1 New concept is inserted “between intelligent electronic devices”, what is an intelligent electronic device? We propose the SDT to use Cyber Asset definition.

The note regarding Host-based firewalls, is in sync with the definition of ESP, except we don’t agree on imposing this limitation. Also, the firewall wording is not used in the language of the requirements, controlled communication is the usual wording. We suggest the removal of this note.

The requirement should use the same language that is used for the other requirements. Suggestion

Applicable Systems connected to a network via a routable protocol must be protected by an ESP that Permits only needed and controlled communications and denies all other communications.

Requirement 1.2 We suggest reviewing the measure column. MPLS is mainly a WAN protocol. Also, a network switch enforces the VLAN concept so the network switch would be an SCI and EACMS? We suggest that the SDT review the mechanism permitting the control of communication. Someone could build a complete ecosystem with only a network switch (BCA is on VLAN 2 and the permitted users are on VLAN 2, the denied users are on VLAN 3, all of this is managed and controlled by a network switch, a switch this is virtualized.

Requirement 1.3 introductions of network communication. For some requirement, communication is the only word used (1.1, 1.2), we suggest that the SDT review the usage of the word ‘’network’’ and be uniform within all standards.

Requirement 1.4: No Comments

Requirement 1.5 version 6 of this requirement is only applicable to BCA and PCA, in this version the SDT as added PACS hosted on SCI; and EACMS hosted on SCI, and SCI identified independently supporting an Applicable System above. One could understand why the SCI is part of the applicable systems but why did the SDT target PACS and EACMS. We suggest to the SDT to remove PACS and EACMS. Also the line “SCI identified independently supporting an Applicable System above” should be replaced by the usual language used throughout the requirements, i.e.” SCI identified independently supporting an Applicable System from Part 1.1.” Clarification to that sentence would also be welcome, are they “SCI identified independently” or are they “SCI that is identified to be supporting independently an Applicable System”.

Requirement 1.6, this requirement is valid in the context of the old ESP definition. In the context of the suggested definition, this is an additional requirement resulting in a burden for the entity. The SDT should evaluate the possibility of enforcing the ESP controls (permitted communication and malicious communications) directly on the cyber asset itself, an EACMS wouldn't be required. The BCA, PCA, EACMS, PACS, SCI could have their own controls (host firewall, host IDS, Host Endpoint controls).

Requirement 2.1 We suggest reviewing the Applicable column

EACMS that enforces an ESP for the Applicable Systems in Part 1.1.

This is an additional requirement resulting in an additional burden for the entity.

SCI identified independently supporting an Applicable System above

We suggest the normal wording (SCI identified independently supporting an Applicable System from Part 1.1.

Increase in the need for Intermediate System (EACMS used for the ESP, SCI).

Requirement 2.2 No Comments

Requirement 2.3 No Comments

Requirement 2.4 We suggest the SDT normalize the wording, ''from SCI identified independently supporting an Applicable System above'' to ''SCI identified independently supporting an Applicable System from Part 1.1''.

Also, SDT proceeded in a change of scope for the Medium Impact BES Cyber Systems. In the previous version, ERC was a criteria. The suggested version doesn't have this criteria which will increase the scope of the requirements and the burden on the entities.

Requirement 2.5 We suggest the SDT normalize the wording, ''from SCI identified independently supporting an Applicable System above'' to ''SCI identified independently supporting an Applicable System from Part 1.1''.

Also, SDT proceeded in a change of scope for the Medium Impact BES Cyber Systems. In the previous version, ERC was a criteria. The suggested version doesn't have this criteria which will increase the scope of the requirements and the burden on the entities.

Requirement 2.6. Requirement 2.6.1 is greatly limiting. One objective of virtualization is to optimize the usage of computer resources (CPU power, memory, etc.). Enforcing restriction of those types limits the possible gain of instating virtualization or consolidating services like databases or web applications. We suggest the SDT review their objectives and how to implement them. The reference to Part 2.1 in 2.6 can also be confusing for the requirement, does the restriction in CPU and memory also apply to the SCI in 2.1 or only to the Intermediate Systems.

Requirement 2.6.2 should use the same language that is used for the other requirements. Suggestion

Permit only needed and controlled communications and denies all other communications between Intermediate Systems and Applicable Systems of Part 2.1.

Reference 2.6.1, Restrict VCAs of Intermediate Systems to only share CPU and memory with other Intermediate Systems and their associated SCI

Reference 2.6.2. Permit only needed and controlled communications between Intermediate Systems and Applicable Systems of Part 2.1.

Requirement 3 Is this a new requirement part of the SAR?

Also, requirement 2.4 and Requirement 2.5 doesn't mention the ERC criteria for the Medium Impact BES Cyber Systems, yet requirements 3.1 and 3.2 mention the ERC criteria. This will increase the burden on the entities. We suggest the SDT review the scope and criteria.

Remove Intermediate Systems from the applicability for 2.1 to permit authorized IRA through an Intermediate System (on the clean version). R1.1 – The last sentence in the requirement is prescriptive and would be more appropriate in the technical rationale document. Consider removing this and moving it to TR: “Host-based firewalls that only protect the host on which they reside are not a sufficient control to meet this requirement.” R2.1 – Revise as follows to improve readability - Permit authorized IRA to Applicable Systems only through an Intermediate System.

There is still there is a gap between what is system-to-system and what is Interactive Remote Access (IRA) with the new IRA definition. Entities often rely on IRA ports for system-to-system communication, but have not adequately enforced protections to ensure that the ports are not used by malicious actors – regardless of whether a remote access client is available or used. Additional technical measures or controls should be added to ensure validity of communications to Applicable Systems. CIP-005 Requirement R1 Part1.3 to protect the confidentiality and integrity of data traversing communication links that span multiple Physical Security Perimeters but no minimum level of encryption is required which could result in older less secure methods being used leaving the data at risk. CIP-005-8 depends upon approved SCI terminology and other definitions associated with virtualization as a whole. Approval of CIP-005-8 would be conditional, based upon approval of the entire suite of new standards associated with virtualization.

Texas RE recommends that the SDT consider an approach by which SCI is “high watermarked” to whatever applicable systems they are hosting.

Texas RE is concerned that not requiring SCI hosting BCS to be categorized as BCS themselves will result in a reduced security posture for those SCI. A previous version of the Technical Rationale indicated that SCI would be sufficiently protected, stating “The SDT recognizes that SCI indeed has the same impact as a virtual BES Cyber Asset and even more so if hosting numerous BES Cyber Assets. For the first formal posting of all affected standards, the requirements for SCI will be equal to BCA and in fact be subjected to additional requirements due to its impact (e.g. CIP-005 R1 Part 1.6).” In this current posting, however, Texas RE noticed CIP-005 R1.1 and CIP-005 R1.4 do not include SCI within scope as applicable systems, which means SCI arguably may not fall within the full scope of the CIP standards.

Texas RE also notes that “Intermediate Systems use to access Applicable Systems of Part 2.1” are an applicable system of Part 2.1. CIP-005 R2.1 requires that IRA must go through an Intermediate System. This appears to require Registered Entities to use an Intermediate System (IS1) prior to accessing a separate Intermediate System (IS2) that will then be used to access other applicable systems, such as high or medium impact BCS. Texas RE inquires as to whether or not this is the SDT’s intent.

The proposed revised definition of IRA as written, Management Interfaces of SCI would appear to need to reside within an ESP and Management Interfaces of EACMS that enforce the ESP would also need to reside within an ESP. As a whole it is very difficult to understand the security objective. This seems very prescriptive, trying to introduce security that is perhaps outside the scope of virtualization.

SCI identified independently supporting an Applicable System. 1.1 - is communication protected both inbound and outbound or only inbound? 1.3 - isn't this the same as 1.2; if an entity is only permitting needed communications then wouldn't one be denying communications from high impact BCS and PCA?

In CIP-005 R1.2 it is not clear with “only needed and controlled communications.” Only needed communications seems clear but controlled communications does not seem clear. Is this referencing not routed traffic such as broadcast traffic?

For 1.4 SMUD would like to see "mitigate the risk to data traversing" instead of "Protect the data." This would allow for entities to use their own transport media rather than a third parties transport networks. Encryption should not be a required control in this environment where availability is the top priority. For CIP-005 R2.1 – An RE would need an intermediate system to access an intermediate system and also need an intermediate system to get to an EACMS that enforces and ESP?

It is unclear what a bi-directional routable protocol is. It seems that the definition itself would exclude serial devices that are being communicated to since technically the communication is uni-directional. A serial connection cannot have bi-directional routable communication using a routable protocol, this is wrong. There can be IRA, but there is no bi-directional communication using a routable protocol. Entities are forced to overlook the fact that this is technically not correct but continues to be misinterpreted to ensure that serial communication is kept in scope. SMUD does agree that this serial communication should be in scope, but changing the meaning of bi-directional routable protocol make it very difficult to understand from a networking perspective.

While mostly in agreement with the proposed changes, we note a possibility that with the revised ESP definition and revised verbiage of R1.1 that an interpretation could be made that an ESP is required around serial-only connections. Please revise requirement part verbiage accordingly to prevent this possible interpretation.

Additionally, question #10 begins by asking about the revised CIP-005 but then asks about proposed changes to the NERC Glossary terms. We presume that this is a typo and that the question was about CIP-005.

Consider adding ‘Virtual Cyber Asset’ context to the EAP definition, just as has been added to the EACMS definition. This would allow for Virtual Cyber Asset based firewalls and virtual firewall appliances to have an identified EAP as well. The inclusion of ‘Host-based firewalls that only protect the host on which they reside are not a sufficient control to meet this requirement’ is not consistent with the proposed ESP definition. Consider the following - **EAP -** A policy enforcement point or a Cyber Asset, Virtual Cyber Asset interface that allows routable communication to and from the BES Cyber System within an Electronic Security Perimeter. The language ‘must be protected by an ESP that permits only…’ used in Part 1.1 appears to be out of context for an ESP, as defined. Wouldn’t it be an EACMS that is performing the electronic access control? This would be more consistent with the language use in the Applicable Systems of Part 1.6. Consider the following language -	

Applicable Systems connected to a network via a routable protocol must be (within an ESP and protected by an EACMS) ADD WORDS IN () that permits only needed communications and denies all other communications, excluding time-sensitive protection or control functions between intelligent electronic devices.

Specific to Part 1.2, the use of ‘controlled’ may create more ambiguity in meeting the security objective than intended. Also noting the use of ‘needed communications’ in Part 1.1, ‘controlled communications’ in Part 1.2 and ‘network communications’ in Part 1.3. Consider the following language –

Permit only needed and controlled communications to and from Management Interfaces, and deny all other communications.

Part 1.4, consider the use of ‘electronic controls’ to be consistent with the second bullet.

‘Electronic controls that ensure confidentiality and integrity (such as encryption), or…’

Part 2.1, the use of ‘Intermediate Systems used to access Applicable Systems of Part 2.1’ as an Applicable Systems does not appear to be consistent with the ESP definition as IRA to an IS does not include an IS.

Part 2.2, consider changing ‘client’ to ‘remote Cyber Asset’ or ‘remote client’ to the requirement –

Protect the confidentiality and integrity (e.g., encryption) of IRA between the (remote) ADD WORK IN () Cyber Asset and the Intermediate System.

Part 2.6, the inclusion ‘Intermediate Systems used to access Applicable Systems of Part 2.1’ appears to create a hall of mirrors, meaning an Intermediate System used to access an Intermediate System.

Part 2.6.2, suggest removing ‘controlled’ and only using ‘needed communications’ as has been used in other parts.

Permit only needed (and controlled) DELETE WORDS IN () communications between Intermediate Systems and Applicable Systems of Part 2.1.

We agree with the changes to the standard, however, the potential clarity issues that arise from the definition changes of ESP (and subsequently an EACMS) may cause unintended scoping regarding Registered Entities BCS in the field. See question 4 for further explanation and alternative proposal.

Answer No

Document Name	

Comment

NERC Definition Changes -- Electronic Security Perimeter (ESP) - removed the routable protocol qualifier. Consider the following:

- The new ESP qualifier is an EACMS. The EACMS definition does not have a routable protocol/communication qualifier, and it references ESPs. It seems like a circular definition.
- When looking at the definitions only, it appears to require serial connected Cyber Assets have an EACMS to protect their serial communication links, however they are not required to have an Electronic Access Point (EAP) as the EAP definition has a routable communication qualifier.
- When assessing CIP-005-8 R1.1 the Requirements section qualifies ESPs are only required for Applicable Systems with routable protocols. It does not have a qualifier of ERC so if there is only ethernet within a system that never leaves an asset, an ESP is required even if you have no EAP. This is the same as V5 of the standards.
- If a BCA has both serial and Ethernet communications that leave an asset, auditors could require an EACMS for serial connections because a BCA that has routable protocol leaving an asset is required to have an ESP, and an ESP is required to have an EACMS. The same BCA serial that would leave the asset would require an EACMS because the ESP definition does not exclude serial communication. Not sure what type of device a serial EACMS would be.
- The SDT proposed definition creates ambiguity around serial communication configurations and whether they have to be documented as part of an ESP.

We recommend revising CIP-005-X R1 Part 1.1 to read:

Applicable Systems connected to a network via a routable protocol must be protected by an ESP that permits only needed communications and denies all other commuincations. Host-based firewalls that only protect the host on which they reside are not a sufficient control to meet this requirement. Excluding:

- Time sensitive protection or control functions between intelligent electronic devices
- Cyber Asset to Cyber Asset serial communication not meeting the IRA definition

We also want to point out that CIP-005-8 R1 Part 1.1 specifically denies '*Host-based firewalls that only protect the host on which they reside are not a sufficient control to meet this requirement*' which does not meet the objective based model that the standards are supposed to now be written to. This very specifically identifies a technology that cannot be used to meet the requirement. This statement appears to be in conflict with the Technical Rationale for the ERC term.

ERC is no longer based on 'external' being defined in terms of the ESP as ESPs are changing in light of Zero Trust models. Zero Trust will shrink ESP's over time to the smallest, most granular object possible including a single device or possibly to process or resource level on a device.

Additionally, question #10 begins by asking about the revised CIP-005 but then asks about proposed changes to the NERC Glossary terms. We presume that this is a typo and that the question was about CIP-005.

For Part 1.1, we suggest including the word “directly” in this phrase “connected directly to a network” for absolute clarity that serial devices do not require an ESP, regardless of any upstream protections afforded by the newly proposed IRA definition.

We also suggest that Part 1.1 be modified to remove the host-based language due to proposed inclusion in glossary term as described in response to Question 4.

We suggest aligning the Applicable Systems language in (current) Part 1.4 and (current) Part 1.6 using reference back to Part 1.1 with additional “at Control Centers” qualifier.

We suggest placing the “ESP outside PSP” requirement as the new Part 1.6 so that dial-up and malicious communications requirements maintain their current part numbers. This minor change would allow for continuity of evidence references that would otherwise be confusing and burdensome.

Inclusion of the ESP reference in the malicious communication requirement may present challenges for Zero Trust environments where an application layer firewall or IDS cannot be applied between each ESP. Language such as the following would allow for more flexible implementations that still meet the security objective of this requirement: “Detect known or suspected malicious Internet Protocol (IP) communications entering or leaving an ESP. Detection may occur at the boundary or as part of EACMS monitoring capabilities.”

Meaghan Connell - Public Utility District No. 1 of Chelan County - 5, Group Name CHPD

Answer	No
Document Name	

Comment

Chelan agrees in principle with CIP-005, but there is a major flaw in CIP-005 R2. CIP-005-8 R2.1 includes "Intermediate Systems used to access Applicable Systems of Part 2.1" as part of the Applicable Systems. This language indicates that an Intermediate System is required to access an Intermediate System. Is this a typo? If not, additional clarification is requested. This appears to create a hall of mirrors.

Sean Bodkin - Dominion - Dominion Resources, Inc. - 6, Group Name Dominion

Answer	No
Document Name	

Comment

CIP-005-8 R1 Part 1.6 proposes the following:

Detect known or suspected malicious Internet Protocol (IP) communications entering or leaving an ESP.

In light of the new ESP definition, perhaps this requirement should state: Detect known or suspected malicious Internet Protocol (IP) communications entering or leaving an applicable system.

In the alternative, the new definition of ESP would need further refinement. CIP-005-8 R1 Part 1.4 is another example where the language of the requirement appears to be using the approved ESP definition from CIP V5.

Answer	Yes
Document Name	

Comment

Tacoma Power agrees with the proposed changes to the NERC Glossary terms. However, we identified the following improvements and minor corrections to the CIP-005 documentation:

- Suggest simplifying the measures in CIP-005 R1 Part R1.1 by moving the following sentence into the opening statement: “that enforces an ESP electronic access control and logical isolation and documents the business need.”
- In CIP-005 R2 Part 2.1, a space is needed between “onlythrough”.
- In the clean version of CIP-005 R2 Part 2.1, the last statement in the Applicable Systems column, “Intermediate Systems used to access Applicable Systems of Part 2.1,” should be removed.
- Correct typo in CIP-005 R2 Part 2.6.2: “Systerms” should be “Systems”.

The modification to the definition to ERC brings serially connected OT Devices using a protocol-converter into scope for multiple CIP-007 requirements. In some instances, compliance with all the CIP-007 requirements would be impossible. The use of a protocol converter does not facilitate centralized logging, review, and alarming (based on events). It simply facilitates data acquisition and IRA to these devices. We suggest not revising the definition of ERC, leaving the concept of a protocol break in place and require the protocol converter to either be categorized as a BCA, PCA or EACMS (depending on the circumstance). The serial OT device could still utilize the proposed definition for IRA to be in scope for CIP-005.

In support of NPCC RSC comments.

Request clarification on CIP-007 Part 1.1. Why is this Requirement so technology specific? We refer to “Internet Protocol ports” instead of “ports.”

Request clarification on the inconsistency between CIP-007 Parts 1.1 and 1.2. 1.1 uses “Internet Protocol ports” while 1.2 uses “physical input/output ports” and “network connectivity.” We expected consistency

Request explicit language in CIP-007 R2 that these patching Requirement do not include patching in the cloud. We understand that the SAR does not include cloud connectivity.

Requirement 1.1 We suggest that SDT normalize the wording, from SCI identified independently supporting an Applicable System above To SCI identified independently supporting a High Impact BC, Medium Impact BCS with ERC and their associated: 1. EACMS; 2. PACS; and 3. PCA

We do not understand the change from Where technically feasible, enable only logical network accessible ports (previous version) to Enable only network-accessible Internet Protocol (IP) ports (suggested version). The introduction of IP is limiting. SDT should try to use routable protocol, Enable only network-accessible routable protocol ports.

Requirement 1.2 This new criteria for the applicable system, Non-programmable communication components located inside both a PSP and ESP is difficult to understand because the NERC CIP always treated cyber assets, the non-programmable were always excluded from the CIP standards. This is an increase in scope and doesn’t seem related to the virtualization project.

We suggest that SDT normalize the wording, from SCI identified independently supporting an Applicable System above.

Requirement 1.3 This requirement is greatly limiting. One objective of virtualization is to optimize the usage of computer resources (CPU power, memory, etc.). Enforcing restriction of those types limits the possible gain of instating virtualization. Thus, avoiding the sharing resources between non-CIP VCAs and CIP VCA doesn’t offer any benefits versus the current version. We suggest that the SDT review their objectives and how to implement them.

Requirements 2, 3, 4, 5 We suggest that SDT normalize the wording, from SCI identified independently supporting an Applicable System above To SCI identified independently supporting a High Impact BC, Medium Impact BCS with ERC and their associated: 1. EACMS; 2. PACS; and 3. PCA

We disagree with the changes in CIP-007.

Recommendations:

- For CIP-007 R1.1 and R1.2, resulting from our proposed changes to the definitions, we suggest removing SCI language from the Applicable Systems.

- For CIP-007 R1.3, resulting from our proposed changes to the definition of PCA, this requirement is no longer needed since a non-CIP VCA sharing resources with any CIP Cyber Assets (BCA, EACMS, PACS or PCA) will be identified as a PCA.

- For CIP-007 R2.1, R2.2, R2.3 and R2.4, resulting from our proposed changes to the definitions, we suggest removing SCI language from the Applicable Systems.

· For CIP-007 R3, R4, R5 and their Parts, resulting from our proposed changes to the definitions, we suggest removing SCI language from the Applicable Systems.

The phrase “SCI identified independently supporting an Applicable System” is confusing and not entirely clear if needed rather than just revise existing definition of BES Cyber System. It is unclear why R1.2 Applicable Systems now include “Non-programmable communications components located inside both a PSP and ESP” for both high and medium impact.

R1.4 Applicablity is missing SCI that may be part of a BCS. As written, it implies that SCI as part of a BCS aren't subject to this requirement. Or is this an issue with clarity around CIP-002 or the actual definition? Is the idea the independently identified SCI is the only SCI with non-CIP Systems hosted on them. If so that needs to be made clear in CIP-002 or the definition. If not then the scope of R1.4 needs to include "SCI identified as part of a BES Cyber System, EACMS, or PACS" or possibly strike "identified independenty" so we get "SCI supporting:…"

The change to specification of "Internet Protocol ports" in proposed CIP-007-7 R1.1 supports technical restriction of protection to only a particular network technology. The prior language for CIP-007 R1.1 did not involve "Internet Protocol" ports and allowed for service identification to include one/more ports. ISO-NE requests either clarification of the intent regarding technical specification of networking technology for this case or reversion of the requirement language to support backward compatibility.

We disagree with the changes in CIP-007.

Recommendations:

- For CIP-007 R1.1 and R1.2, resulting from our proposed changes to the definitions, we suggest removing SCI language from the Applicable Systems.
- For CIP-007 R1.3, resulting from our proposed changes to the definition of PCA, this requirement is no longer needed since a non-CIP VCA sharing resources with any CIP Cyber Assets (BCA, EACMS, PACS or PCA) will be identified as a PCA.

- For CIP-007 R2.1, R2.2, R2.3 and R2.4, resulting from our proposed changes to the definitions, we suggest removing SCI language from the Applicable Systems.
- For CIP-007 R3, R4, R5 and their Parts, resulting from our proposed changes to the definitions, we suggest removing SCI language from the Applicable Systems.

o CIP-007 R1 – Please confirm the P1.1 Logical ports justification and details for serially connected CIP Systems are excluded but expectation of the physical wiring will be required for P1.2?

  o CIP-007 R4.2 – Please clarify the serial CIP System must now alert for failure of event logging.

o CIP-007 R5.6 – Please clarify a serial CIP System such as an RTU or Relay that was a BCA or PCA without ERC now with the proposed change requires the password change every 15 months?

Request clarification on CIP-007 Part 1.1. Why is this Requirement so technology specific? We refer to “Internet Protocol ports” instead of “ports.”

Request clarification on the inconsistency between CIP-007 Parts 1.1 and 1.2. 1.1 uses “Internet Protocol ports” while 1.2 uses “physical input/output ports” and “network connectivity.” We expected consistency

Request explicit language in CIP-007 R2 that these patching Requirement do not include patching in the cloud. We understand that the SAR does not include cloud connectivity.

Requirement 1.1 We suggest that SDT normalize the wording, from SCI identified independently supporting an Applicable System above To SCI identified independently supporting a High Impact BC, Medium Impact BCS with ERC and their associated: 1. EACMS; 2. PACS; and 3. PCA

We do not understand the change from Where technically feasible, enable only logical network accessible ports (previous version) to Enable only network-accessible Internet Protocol (IP) ports (suggested version). The introduction of IP is limiting. SDT should try to use routable protocol, Enable only network-accessible routable protocol ports.

Requirement 1.2 This new criteria for the applicable system, Non-programmable communication components located inside both a PSP and ESP is difficult to understand because the NERC CIP always treated cyber assets, the non-programmable were always excluded from the CIP standards. This is an increase in scope and doesn’t seem related to the virtualization project.

We suggest that SDT normalize the wording, from SCI identified independently supporting an Applicable System above.

Requirement 1.3 This requirement is greatly limiting. One objective of virtualization is to optimize the usage of computer resources (CPU power, memory, etc.). Enforcing restriction of those types limits the possible gain of instating virtualization. Thus, avoiding the sharing resources between non-CIP VCAs and CIP VCA doesn’t offer any benefits versus the current version. We suggest that the SDT review their objectives and how to implement them.

Requirements 2, 3, 4, 5 We suggest that SDT normalize the wording, from SCI identified independently supporting an Applicable System above To SCI identified independently supporting a High Impact BC, Medium Impact BCS with ERC and their associated: 1. EACMS; 2. PACS; and 3. PCA

N&ST believes Requirement R1 Part 1.3 (“Prevent the sharing of the CPU and memory,…”) should apply to SCI identified independently and to SCI that are grouped into BES Cyber Systems.

N&ST also believes Requirement R1 Part 1.3 should be slightly revised for better clarity. We suggest, “Prevent the sharing of the CPU, memory, and Management Interfaces of SCI with non-CIP Systems.”

ACES agrees with the changes made based on industry comments, but regarding R2, based on webinar and technical rationale documentation, dormant VCAs are not considered Applicable Systems until they become “active” instances again. How is this going to be handled if an entity’s SCI automatically spins up dormant VCA’s when needed, how would an entity track and document the controls necessary prior to being an active VCA? Allowing automatic remediation of non-responsive VCAs is a benefit to utilizing virtualization and could cause an entity to be out of strict compliance. Also, wouldn’t a dormant instance previously a VCA, which could be a VCA in the future that has not been “connected” to the BCS for 30 consecutive days be considered a TCA? ACES feels like there needs to be VERY clear guidance on how to keep dormant VCAs compliant, that aren’t actually in scope when dormant and if dormant for greater than 30 days constitutes a VCA as a TCA. In our opinion an in scope VCA, dormant or not, should always remain in scope until retired. Virtualized environments are highly dynamic, thus the standards should have considerations for such capabilities. AEPC has signed on to ACES comments.

Although we agree with returning back to looking at ports and not just services the updated language uses the term “Internet Protocol (IP) Ports”. Under Internet Protocol (IP), the transport layers (e.g. TCP, UDP) create and maintain the ports for the underlying services. The Internet Protocol is the network layer, which uses the host address to communicate. Consider alternate verbiage.

12. The SDT revised CIP-010 based on industry comments. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

Dan Zollner - Portland General Electric Co. - 3

Answer	No
Document Name	

Comment

Portland General Electric Company supports most changes, but has concerns regarding changes to the TCA definition and applicability language in R4. In the current CIP-010-2 Standard, R4 clearly limits scope to High Impact and Medium Impact BES Cyber Systems and their associated PCAs. The proposed modification to the Standard appears to only exclude Low Impact BES Cyber Systems and supporting SCI. This implies that EACMS and PACS may now also be in scope. Based on the proposed definition of TCA, any Cyber Asset or VCA that meets the first three qualifiers and is connected for 30 consecutive calendar days or less to any Shared Cyber Infrastructure (including SCI that is only supporting a PACS or EACMS) is in scope for R4. This appears to be a fairly significant change in scope. Portland General Electric Company wonders if this was the drafting team's intent. If not, changing "Shared Cyber Infrastructure" to "Shared Cyber Infrastructure supporting a BES Cyber System" may resolve this. Additionally, clearly identifying scope within the R4 language (i.e. high impact and medium impact BES Cyber Systems, associated Protected Cyber Assets, and supporting SCI) may reduce confusion about the applicability of R4.

Suggest this Applicable Systems language can be misinterpreted – “SCI identified independently supporting an Applicable System.” Recommend clarification. Suggest adding a comma to distinguish between “identified independently” and “supporting.” Resulting in “SCI identified independently, supporting an Applicable System”

Request clarification of Requirement 1.1.1. Why is the lack of operating system relevant to patching?

We believe 1.1.4 will be hard to manage dynamic ports. We suggest managing (authorizing) by port (service) ranges is more manageable.

Request clarification of 3.3. The existing language allows for a noticeable time gap between the vulnerability assessment and becoming an Applicable System. If there is an expectation of the scan and the deployed state, we request an explicit expectation.

Request clarification of 3.3. What is the expectation of the timeline for devices that are in production and become in scope?

Since CIP-010 no longer includes a baseline, Part 3.3 Requirement of “like” and “type” seems loose. Request clarification. Does the entity define like, type and/or configuration?

Request three clarification on R4. 1) request clarification that this scoping applies to both TCAs and Removeable Media instead of TCAs and/or Removeable Media; 2) Request clarification on the applicable systems since this Requirement is different than others. Other Requirements identify applicable systems in scope. This Requirement identifies what is not in scope; 3) Request confirmation that this Requirement’s scoping is in the definitions

Request removal of the second bullet in 1.3 of Attachment 1 since freezing an OS does not protect against a vulnerability. This bullet does not belong in 1.3 (vulnerability). The intent seems to be preventing malicious code which is 1.4.

N&ST believes proposed changes beyond those needed for conformance:
Have little or nothing to do with virtualization,
Are unlikely to improve anyone’s cyber security posture,
Are outside the scope of the original 2016 SAR,
Are not addressed in any relevant FERC Order, and
Would be an unnecessary and unwelcome distraction for entities trying to adjust their CIP programs and documentation to accommodate new virtualization-related requirements.

Request removal of the second bullet in 1.3 of Attachment 1 since freezing an OS does not protect against a vulnerability. This bullet does not belong in 1.3 (vulnerability). The intent seems to be preventing malicious code which is 1.4.

Requirements 1.1 We suggest that SDT normalize the wording, from SCI identified independently supporting an Applicable System above, SDT should be more precise. Requirement 1.1.5 (.1.5. Any security patches applied.) was removed, yet the measure “Documentation of authorization for cybersecurity patches implementation” was added as evidence of change authorization for security patches. Need for clarification as the change seems contradictory.

We suggest that the SDT review the wording of requirement 1.1.1. Operating system(s) (OS); or firmware where no independent OS exists; or images used to derive operating systems; or firmware; This requirement mention ‘’images’’, why not use the word ‘’container’’?

Requirement 1.2 The overall requirement is questionable. Enforcing restrictions on the sharing of CPU or memory between systems limits the possible gain of instating virtualization. Also following the new definition of ESP, the latter is enforced by an EACMS and not by the SCI. We suggest that the SDT reviews their objectives and how to implement them.

Requirement 1.3 To be coherent shouldn't this requirement refer also to 1.2. After all, the CPU and memory controls are CIP-007 and the ESP is CIP-005. Follow the same logic as 1.4, i.e. ‘’for each change to the items listed in Part 1.1 or Part 1.2’’.

Requirement 1.4 no comments

Requirement 1.5 Our understanding is that we don’t need to verify the source nor the integrity of the security patches any longer. Since CIP-007 Patch management does not include those checks, wouldn’t this be considered as neglecting a compliance sound practice? (To validate the security patches)? Is this the real intent of the SDT?

Requirement 2.1 no comments

Requirement 3.3 What does ‘’Prior to becoming a new Applicable System” means?

We suggest that the SDT defines ‘’becoming’’. Is the intent of the SDT to permit the creation of a virtual cyber asset on an SCI, this SCI being in a production environment? We suggest that the SDT review the usage of ‘’production environment’’ versus ‘’becoming’’.

There is a need for additional clarification for “same type” in “like replacements of the same type of Cyber System”. Is ‘’type’’ associated with the Cyber System definition?

Since the baseline configuration doesn’t exist anymore, what is the intent of the SDT with the usage of the word ‘’configuration’’? How does one entity define configuration?

Gail Golden - Entergy - Entergy Services, Inc. - 5	
Answer	No
Document Name	
Comment	

The requirement to “Authorize changes to 1.1.5 Security patches applied” was removed per the Technical Rationale that these changes would be included to changes to OS/Firmware or software, which Entergy agrees. However, the measures were explicitly updated to include “Documentation of authorization for cyber security patch implementation.” Calling out cyber security patches under this measure of authorization outside of a “change request record” as opposed to applying it to the other items may cause confusion regarding differing expectations for cyber security patches. This statement should be more generalized for the other CIP-010 R1.1 items as well.

Agree with change to CIP-010. Do not agree with Glossary of Terms

Response

Mark Gray - Edison Electric Institute - NA - Not Applicable - NA - Not Applicable

Answer	No
Document Name	

Comment

EEI supports many of the proposed NERC Glossary terms, however, concerns remain with those terms identified in our comments above. EEI also notes that the phrase “SCI identified independently” is unclear in its intent and needs to be clarified before EEI can support the revisions to CIP-010. For this and the following concerns we cannot support the proposed changes at this time

1) Subpart 1.2.2 could be interpreted to allow mixed trust. The language does not provide sufficient clarity to ensure mixed trust is not allowed.

2) There is a typo in the Applicable Systems part of Requirement 2, Part 2.1, Table R2. SCI is incorrectly identified as CI.

3) Attachment 1 – Section 3; Removable Media; Part 3.2: the removal of language identifying high impact or medium impact BES Cyber Systems appears to expand this obligation beyond its original intent. EEI recommends that the original language be restored.

ERCOT supports the IRC SRC comments and offers these additional comments:

- ERCOT appreciates the removal of part 1.1.5 from the requirement language since patches would be covered under parts 1.1.1 and 1.1.2. However, the measure should be updated to be consistent with the requirement language.

- For Part 3.3, the requirement to build outside of the production environment and perform the vulnerability scan has been removed.

Pamela Hunter - Southern Company - Southern Company Services, Inc. - 1,3,5,6 - SERC, Group Name Southern Company

Answer	No
Document Name	

Comment

Southern agrees with the overall concepts but has several specific issues with the language.

In R1.1.1 the last "or firmware;" seems to be in error as firmware has already been covered in the list. The measures for this requirement could also use examples of evidence in regards to parent/child images such as VDI.

In R1.1.3 'including-applications containers' should be 'including application containers'

In R1.1.4 by including SCI in applicability, is the intent to know and authorize change to the SCI underlay communications at the IP port level? Typically the SCI underlay is service level due to the proprietary nature of the communication protocols, but 1.1.4 only allows services if one is unable to determine ports. Since you can always determine port numbers in use, this requires authorizing changes to port numbers within the underlay and not services, which may not be possible or of no value.

Also R1.1.4 could be improved by clarifying that the authorization is for a change to the OS, software, or configuration that subsequently will change ports or port ranges. Port numbers may be dynamically changing in real-time during process execution and further clarity around the level of change authorization intended is needed. As currently worded, a change authorization could be required every time a logical port is opened or closed by an executing process.

In R3.3, it would be clearer to state "Perform an active vulnerability assessment of a new Applicable System prior to it becoming a new Applicable System…" We suggest it helps with clarity to lead with the main required action and then follow it with the timing aspect of the 'prior to' phrasing rather than leading with it.

In R4, the scoping is set to “not lows”, which includes everything outside of CIP scope. The scoping has been removed from Attachment 1 as well, leaving the scoping for this requirement within the glossary definitions of TCA and RM. While this works, we’d prefer the scoping to be in the requirements within the standard.

Comment

AWS agrees with changes to CIP-010 R1, R2, and R3. CIP-010 R4 has been updated to accommodate Virtual Cyber Assets and virtual machines hosted on physical Transient Cyber Assets, but because the standard language allows a Responsible Entity to choose one or a combination of security controls there may be security control gaps.

Since the TCA definition explicitly states that a VM running on a physical TCA can be treated as software running on the physical TCA, the VMs could be vulnerable to security threats undetected by the physical host. The Standard does not require additional security controls to be applied to the VMs running on physical TCAs.

We propose removing the language “Virtual machines hosted on a physical TCA can be treated as software on that physical TCA” from the TCA definition, and modifying the VCA definition to read, “A logical instance of an operating system or firmware hosted on Shared Cyber Infrastructure, a PCA, or a TCA.”

Suggest this Applicable Systems language can be misinterpreted – “SCI identified independently supporting an Applicable System.” Recommend clarification. Suggest adding a comma to distinguish between “identified independently” and “supporting.” Resulting in “SCI identified independently, supporting an Applicable System”

Request clarification of Requirement 1.1.1. Why is the lack of operating system relevant to patching?

We believe 1.1.4 will be hard to manage dynamic ports. We suggest managing (authorizing) by port (service) ranges is more manageable.

Request clarification of 3.3. The existing language allows for a noticeable time gap between the vulnerability assessment and becoming an Applicable System. If there is an expectation of the scan and the deployed state, we request an explicit expectation.

Request clarification of 3.3. What is the expectation of the timeline for devices that are in production and become in scope?

Since CIP-010 no longer includes a baseline, Part 3.3 Requirement of “like” and “type” seems loose. Request clarification. Does the entity define like, type and/or configuration?

Request three clarification on R4. 1) request clarification that this scoping applies to both TCAs and Removeable Media instead of TCAs and/or Removeable Media; 2) Request clarification on the applicable systems since this Requirement is different than others. Other Requirements identify applicable systems in scope. This Requirement identifies what is not in scope; 3) Request confirmation that this Requirement’s scoping is in the definitions

Request removal of the second bullet in 1.3 of Attachment 1 since freezing an OS does not protect against a vulnerability. This bullet does not belong in 1.3 (vulnerability). The intent seems to be preventing malicious code which is 1.4.

Request removal of the second bullet in 1.3 of Attachment 1 since freezing an OS does not protect against a vulnerability. This bullet does not belong in 1.3 (vulnerability). The intent seems to be preventing malicious code which is 1.4.

Requirements 1.1 We suggest that SDT normalize the wording, from SCI identified independently supporting an Applicable System above, SDT should be more precise. Requirement 1.1.5 (.1.5. Any security patches applied.) was removed, yet the measure “Documentation of authorization for cybersecurity patches implementation” was added as evidence of change authorization for security patches. Need for clarification as the change seems contradictory.

We suggest that the SDT review the wording of requirement 1.1.1. Operating system(s) (OS); or firmware where no independent OS exists; or images used to derive operating systems; or firmware; This requirement mention ‘’images’’, why not use the word ‘’container’’?

Requirement 1.2 The overall requirement is questionable. Enforcing restrictions on the sharing of CPU or memory between systems limits the possible gain of instating virtualization. Also following the new definition of ESP, the latter is enforced by an EACMS and not by the SCI. We suggest that the SDT reviews their objectives and how to implement them.

Requirement 1.3 To be coherent shouldn't this requirement refer also to 1.2. After all, the CPU and memory controls are CIP-007 and the ESP is CIP-005. Follow the same logic as 1.4, i.e. ‘’for each change to the items listed in Part 1.1 or Part 1.2’’.

Requirement 1.4 no comments

Requirement 1.5 Our understanding is that we don’t need to verify the source nor the integrity of the security patches any longer. Since CIP-007 Patch management does not include those checks, wouldn’t this be considered as neglecting a compliance sound practice? (To validate the security patches)? Is this the real intent of the SDT?

Requirement 2.1 no comments

Requirement 3.3 What does ‘’Prior to becoming a new Applicable System” means?

We suggest that the SDT defines ‘’becoming’’. Is the intent of the SDT to permit the creation of a virtual cyber asset on an SCI, this SCI being in a production environment? We suggest that the SDT review the usage of ‘’production environment’’ versus ‘’becoming’’.

There is a need for additional clarification for “same type” in “like replacements of the same type of Cyber System”. Is ‘’type’’ associated with the Cyber System definition?

Since the baseline configuration doesn’t exist anymore, what is the intent of the SDT with the usage of the word ‘’configuration’’? How does one entity define configuration?

R1-Removing baseline configuration does not change what needs to be done in practice. Entities will still need to retain a baseline configuration as evidence from which to establish the changes that were authorized.

- For Part 1.4 an entity will still need to show the baseline configuration prior to the change to show required cyber security controls in CIP-005 and CIP-007 are not adversely affected.

- For Part 2.1 an entity will still need to provide baseline configurations for evidence that they monitor at least once every 35 calendar days for unauthorized changes to the items listed Parts 1.1 and 1.2.

R3- The concern is that Remediation VLANs should be properly defined in the technical rational or Glossary as it may introduce situations where an entity could inadvertently place production Cyber Assets in this VLAN.

Comment

Per CIP-010 R1, Part 1.1, the requirement to authorize all changes is very broad in terms of reference to OS, software applications, logical network accessible ports, etc. Per the strict language of the proposed standard, it is not clear what constitutes a change. Does the modification of a desktop background constitute an OS change? While it is expected the SDT intended to limit the nature of changes to versions or upgrades of OS and software and patches for example, the chosen language leaves this open to interpretation.

BC Hydro recommends adding more clarity here with the language of the standard. The Technical Rationale is not used as actual compliance guidance as indicated by NERC and without explicit language in the standard or without an endorsed compliance guidance document to supplement, the SDT's intent will be subject to the interpretation of audit entities. Also, it is not clear if these changes to be authorized are restricted only to changes to pre-existing CIP Systems or as part of the commissioning of a new CIP System.

While the new and revised defined terms are seen by BC Hydro to accommodate virtualization and future technologies, BC Hydro does not agree with the 'as is' state of the SCI definition proposed in this project comment/ballot submission.

Attachment 1 to CIP-010 covering TCA and RM requirements have removed any context of what RM is expected to be connected to. It is not clear if the SDT intended for this removal to imply connection to any CIP System or to any non-CIP System? Recommend restoring the deleted text which referenced high and medium impact BES Cyber Systems, PCAs, and associated networks but to also include applicable SCIs, etc.to provide context.

Comments:

R1.1:

Could the SDT explain why the security patches were removed?

What measures are in place to include alternate changes?

R1.2:

Is the SDT not including non CIP Assests to bring in all assets into the program by default?

Definitions:

Recommend the SDT provide an interpretation of the definition for Self-Contained Application. As written, the definition seems confusing, and could have the potential to be misinterpreted.

Recommend the SDT define and provide an interpretation in the scope of what it means by “Authorized Changes”.

R1.4 and R1.5:

Is the SDT asking for entities to include both firmware and OS? In the past, entities could not show firmware if an OS was present. This has the potential to broaden the scope, and includes authorized changes to the OS. Any changes to the OS would be included in scope and would have to be tested as part of 1.4 and 1.5. In the past, if the baseline was not changed, then the entity would not have concern about R1.4 and 1.5. This new standard will change that, and potentially add additional work for entities when a change is made. This could open entities to an investment in new tools because baseline is being removed.

R2.1:

Recommend defining in each subpart what is the change.

These changes seem broader than virtualization, is this in line with scope of the SAR?

Comment

The phrase “SCI identified independently supporting an Applicable System” is confusing and not entirely clear if needed rather than just revise existing definition of BES Cyber System. Additionally, question #12 begins by asking about the revised CIP-010 but then asks about proposed changes to the NERC Glossary terms. We presume that this is a typo and that the question was about CIP-010.

We are concerned about revising the existing CIP standards to address virtual technologies. We recommend any necessary requirements pertaining to change management of virtual cyber assets used for a CIP function be encoded in a new Reliability Standard. Please see our comment on this in response to question #14.

Comment
In R1.1.1, need for clarification as to the meaning of "…images used to derive operating systems". In Measures of R1.1, "Documentation of authorization for cyber security patches implementation" was added as evidence of change authorization for security patches, but the requirement for authorize change to security patches (formerly 1.1.5) was removed. Need for clarification as the change seems contradictory. In R1.5, need for clarification as to why prior to a change associated with security patches (formerly 1.1.5) was removed. In R1.3, since changes to SCI Configuration mentioned in R1.2 may impact CIP-005 controls, R1.2 should also be included similarly to R1.4 "For each change to the items listed in Part 1.1 or Part 1.2". In R3.3, need for clarification for "same type" in "…like replacements of the same type of Cyber System…"

AZPS agrees with EEI's comments on the repeated use of the undefined term "application container" causing confusion, as well as Attachment 1 – Section 3; Removable Media; Part 3.2: the removal of language identifying high impact or medium impact BES Cyber Systems appears to expand this obligation beyond its original intent. AZPS recommends that the original language be restored.

Katie Connor - Duke Energy - 1,3,5,6 - SERC,RF

Answer	No
Document Name	

Comment

Duke Energy generally agrees with the approach enumerated by the SDT but notes that the inclusion of “application containers” must be addressed in the Technical Rationale document if it remains an undefined term. There is currently no explanation for this inclusion, leaving RE’s subject to auditor interpretation. Additionally, subpart 1.2.2 seems unnecessarily constrained and should likely include all changes to configuration that enforces an ESP.

Comment

GSOC recommends that CIP-010 be reviewed to ensure consistent usage of he acronym “BCS” versus BES Cyber System. Additionally, the proposed language in CIP-010 R 1.1.2 to include and address ‘application containers’ is confusing and unlikely to lead to the expected protections. Neither CIP-010 nor the proposed definitions address the definition of or criteria determinative of an “application container.” Additionally, the technical rationale also does not address what such ‘application containers’ consist of or provide language or criteria defining them. Accordingly, GSOC recommends providing additional defining language around the nature and scope of such ‘application containers.’

Answer	Yes
Document Name	

Comment

Tacoma Power supports the proposed language, and has the following recommended edits:

- For CIP-010 R1.2, change language in the Applicable Systems column to match the Applicable Systems language used in CIP-007 R1.3
- Consider using a clearer or more commonly referenced word other than “instantiation” in CIP-010 R3.4 measures
- Correct typo in the second bullet in CIP-010 R3.4 measures: “Documention” should be “Documentation”
- For CIP-010 Attachment 1, Section 1.3 and 1.4, re-word the second bullet to state “Controls that maintain the last known good state of...”
- For CIP-010 Attachment 1, Section 2.2, re-word the fourth bullet to state “Review of controls that maintain the last known good state of...”
- Remove the “;” at the end of R1 Part 1.1.1 “; or firmware;” The reference here is back to the disk image used to derive, not stand alone firmware. So 1.1.1 should read: “1.1.1. Operating system(s) (OS); or firmware where no independent OS exists; or images used to derive operating systems or firmware;”

JT Kuehne - AEP - 6	
Answer	Yes
Document Name	
Comment	

AEP supports the changes but has identified the following concerns:

- The repeated use of the undefined term “application container” could cause confusion. Given this term is an important part of CIP-007 Requirements, it should be defined.
- AEP does not support the need for the note in requirement 1.5 under Applicable Systems. We were not able to rationalize the note in Requirement 1.5 to contracts and thereby suggest removal of this note.
- There is a typo in the Applicable Systems part of Requirement 2, Part 2.1, Table R2. SCI is incorrectly identified as CI.

Texas RE noticed that proposed CIP-010 R4 language references the definitions of Transient Cyber Assets (TCA) and Removeable Media to define in scope devices for the requirement R4. For purposes of clarity, Texas RE recommends revising the requirement language to indicate which devices are in scope within the requirement language itself. Texas RE proposes the following language:

Each Responsible Entity shall implement, except under CIP Exceptional Circumstances, one or more documented processes that include each of the applicable requirement parts in Table CIP-010-x Table R4:

Applicable Systems

High Impact BCS and their associated:

1. SCI; and

2. PCA

Medium Impact BCS and their associated:

1. SCI; and

2. PCA

Requirement 4 Part 1

One or more documented plan(s) for Transient Cyber Assets (TCA) and Removable Media that include the sections in Attachment 1, except for use on low impact BCS or SCI supporting only low impact BCS(s).

Additionally, Texas RE continues to be concerned that security obligations will be reduced by removing the reference to baseline configurations. Establishing and maintaining baseline configurations represent best practices for system hardening. Texas RE recommends adhering to NIST Special Publication 800-53 (Rev. 5), CM-2 Baseline Configuration, which states, "*Baseline configurations for systems and system components include connectivity, operational, and communications aspects of systems. Baseline configurations are documented, formally reviewed, and agreed-*

upon specifications for systems or configuration items within those systems. Baseline configurations serve as a basis for future builds, releases, or changes to systems and include security and privacy control implementations, operational procedures, information about system components, network topology, and logical placement of components in the system architecture. Maintaining baseline configurations requires creating new baselines as organizational systems change over time. Baseline configurations of systems reflect the current enterprise architecture.”

Comment

We do not agree with the proposed changes to these Reliability Standards and do not believe these specific standards need revising.

The requirements in CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013 are more policy and process focused than the more technical requirements of CIP-005, CIP-007, and CIP-010. Thus, the requirements among the larger population of CIP standards should apply regardless of the technologies in use (ex. you are required to have a process for PRA, to have an Incident Response Plan, to have one or more recovery plans, etc.). Virtual assets or mixed-trust environments should not impact the requirements in these standards.

Second, the proposed change is only to include the phrase “SCI identified independently supporting an Applicable System.” As noted above this is a confusing phrase and not at all clear how an SCI could be both independent and supporting. These terms are incongruous when used together in the same phrase.

If there is concern that going forward some virtual assets may improperly be left out of the scope of CIP requirements, we note that the proposed revised definition of BES Cyber System would include “Shared Cyber Infrastructure grouped, by the Responsible Entity, in the BES Cyber System it supports.” This should be sufficient to allow each Responsible Entity to identify its BES Cyber Systems including virtual technologies under CIP-002 and then comply with the requirements of CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013 without the need for changing the Applicability Section of each Standard. [We also note the possibility that by including the phrase about Shared Cyber Infrastructure separate from BES Cyber System we are opening the door to compliance at the asset level instead of the system level, and thus undoing one of the improvements from the CIP v5/6 revisions.]

We recommend retracting the revisions for CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013, and only moving forward with revisions to CIP-002, CIP-005, CIP-007, and CIP-010 to address virtual assets and mixed-trust environments.

Comment	
All of the standards (CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013) referred in this question are proposed with a change the phrase "SCI identified independently supporting an Applicable System." This phrase requires more clarity from the SDT team as to what is meant by an SCI being independent and as well as supporting an applicable system. The terms used here have some level of ambiguity specifically when used in conjunction with each other. SDT is requested to provide examples and better clarity on this phrase as it pertains and becomes applicable as a proposed change to all of the above listed standards. Secondly as advised in the comments above while the new and revised defined terms are seen by BC Hydro to accommodate virtualization and future technologies, BC Hydro does not agree with the 'as is' state of the SCI definition proposed in this project comment/ballot submission. As explained in the comments of Questions 10 related to CIP-005, Question 11 related to CIP-007 and Question 11 related to CIP-010 above BC Hydro does not agree with the changes in the NERC glossary of terms introduced in Draft 2 of Project 2016-02.

We support NPCC TFIST's comments as found below: For CIP-003 Attachment 1 Section 5, see Q12 comments on TCAs For CIP-011, see BCSI comment in Q8	

Suggest moving CIP-011 R2 to CIP-002 so the entire BCS lifecycle question is one Standard. Also suggest expanding this disposal and reuse language beyond BCSI. We believe the BCSI SDT could not recommend this change because it was not in their SAR. There is potential double jeopardy between the proposed CIP-011 R2 and CIP-011 R1.2.

Request clarification on CIP-013's use of high and medium impact. This Standard uses upper and lower case. Other Standards use capitalization. Is there a difference? If so, please explain

Request clarification on CIP-013 before the Requirements section. Were the conforming changes in the other CIP Standards made in this earlier part of CIP-013?

Request clarification on CIP-013 R1. Are these updates conforming changes OR expansion of scope? It is hard to tell without a redline to the last approved version.

Request correction of typo in CIP-006 R2.2 Applicability – "EERC"

Request clarification of SCI supporting multiple Impact Ratings. Is this scenario double or triple jeopardy?

While AEP supports conforming formatting changes and removal of Background and Technical Rationale, we do still have concerns regarding some of the terms proposed to be added to Applicable Systems (as stated in the responses to Questions #1 through #8 above). We recommends adding clarification on “SCI identified independently”, as this phrase has been added to Applicable Systems column for many of the CIP standards. AEP recommends that the terms and definitions should be clarified before included in the standard revisions.

Comments 1:

We disagree with the changes in CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013.

Recommendations:

- Resulting from our proposed changes to the definitions (See our comments in Q1), we suggest removing SCI language from all Applicable Systems.

Comments 2:

We do not agree with the proposed changes to these Reliability Standards and do not believe these specific standards need revising.

The requirements in CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013 are more policy and process focused than the more technical requirements of CIP-005, CIP-007, and CIP-010. Thus, the requirements among the larger population of CIP standards should apply regardless of the technologies in use (ex. you are required to have a process for PRA, to have an Incident Response Plan, to have one or more recovery plans, etc.). Virtual assets or mixed-trust environments should not impact the requirements in these standards.

Second, the proposed change is only to include the phrase “SCI identified independently supporting an Applicable System.” As noted above this is a confusing phrase and not at all clear how an SCI could be both independent and supporting. These terms are incongruous when used together in the same phrase.

If there is concern that going forward some virtual assets may improperly be left out of the scope of CIP requirements, we note that the proposed revised definition of BES Cyber System would include “Shared Cyber Infrastructure grouped, by the Responsible Entity, in the BES Cyber System it supports.” This should be sufficient to allow each Responsible Entity to identify its BES Cyber Systems including virtual technologies under CIP-002 and then comply with the requirements of CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013 without the need for changing the Applicability Section of each Standard. [We also note the possibility that by including the phrase about Shared Cyber Infrastructure separate from BES Cyber System we are opening the door to compliance at the asset level instead of the system level, and thus undoing one of the improvements from the CIP v5/6 revisions.]

We recommend retracting the revisions for CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013, and only moving forward with revisions to CIP-002, CIP-005, CIP-007, and CIP-010 to address virtual assets and mixed-trust environments.

Comment

The proposed changes to the above requirements (CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013), should not be revised, but be left as is.

Since these requirements are policy and process focused than the technical requirements of CIP-005, CIP-007 and CIP-010. In saying this (CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013) should apply regardless of technology.

Again the phrase “SCI identified independently supporting an Applicable System” The phrase is confusing and up to interparation.

We do not agree with the proposed changes to these Reliability Standards and do not believe these specific standards need revising.

The requirements in CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013 are more policy and process focused than the more technical requirements of CIP-005, CIP-007, and CIP-010. Thus, the requirements among the larger population of CIP standards should apply regardless of the technologies in use (ex. you are required to have a process for PRA, to have an Incident Response Plan, to have one or more recovery plans, etc.). Virtual assets or mixed-trust environments should not impact the requirements in these standards.

Second, the proposed change is only to include the phrase “SCI identified independently supporting an Applicable System.” As noted above this is a confusing phrase and not at all clear how an SCI could be both independent and supporting. These terms are incongruous when used together in the same phrase.

If there is concern that going forward some virtual assets may improperly be left out of the scope of CIP requirements, we note that the proposed revised definition of BES Cyber System would include “Shared Cyber Infrastructure grouped, by the Responsible Entity, in the BES Cyber System it supports.” This should be sufficient to allow each Responsible Entity to identify its BES Cyber Systems including virtual technologies under CIP-002 and then comply with the requirements of CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013 without the need for changing the Applicability Section of each Standard. [We also note the possibility that by including the phrase about Shared Cyber Infrastructure separate from BES Cyber System we are opening the door to compliance at the asset level instead of the system level, and thus undoing one of the improvements from the CIP v5/6 revisions.]

We recommend retracting the revisions for CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013, and only moving forward with revisions to CIP-002, CIP-005, CIP-007, and CIP-010 to address virtual assets and mixed-trust environments.

CIP-003 Requirement 2/Attachment 1 appear to either be in conflict or redundant to CIP-010 R4 where the language "except for use on low impact BCS or SCI supporting only low impact BCS(s)". The actual requirements for TCA for Low BCS are ambiguous given this redundancy or conflict.

EEI supports the changes made to CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011 and CIP-013 except as described below:

- CIP-003: EEI supports the proposed conforming changes but proposes the following for Attachment 1 Section 5, 5.1 and 5.2.

  “Controls that maintain the state of the operating system and software such that it is in a known state prior to use;”.

- CIP-004: The phrase “SCI identified independently” is frequently used throughout CIP-004 but is unclear in its intent and needs to be clarified before EEI can support the revisions to this Reliability Standard.
- CIP-006: The phrase “SCI identified independently” is frequently used throughout CIP-006 but is unclear in its intent and needs to be clarified before EEI can support the revisions to this Reliability Standard. The following concerns should also be addressed:

1) *Requirement R1, Subpart R1.10 was removed and the technical rationale states that the requirements were fully moved to CIP-005, Subpart 1.4 but their associated PCAs were not included, which represents an unintentional reliability gap.*

2) EEI notes that within the Applicable Systems column of Part 1.1, the term “hosting” is used in “SCI without ERC hosting Medium Impact BCS”, but “hosting” has been changed to “supporting” in other places.

- CIP-008: The phrase “SCI identified independently” is frequently used throughout CIP-008 but is unclear in its intent and needs to be clarified before EEI can support the revisions to this Reliability Standard.
- CIP-009: The phrase “SCI identified independently” is unclear. Additionally, restoration plans as currently described are too prescriptive and should not be tied to the restoration of SCI even if an entity intends to utilize virtualization. The focus should be the restoration of critical systems necessary for restoration and not predefine how entities define their restoration plans. For example, an entity may decide to incorporate into their restoration plan a more barebones approach that restores an image to a dedicated server without the restoration of SCI. While this may not restore their systems in an identical fashion to what they were operating prior to the failure, it would allow them to quickly and efficiently restore their critical systems. The objective of a recovery plan should focus on the recovery of those critical systems (i.e., BCS, EACMS and PACS functionality). For those entities who chose to take another approach such as restore their SCI as a part of their recovery plan, they too would not be limited by this Reliability Standard. Such an approach would provide flexibility and promote a results-based approach.

Applicable Systems column of Parts 2.1 and 2.2, the term “hosting” is used in “SCI hosting Medium Impact BCS at Control Centers or their …”, but “hosting” has been changed to “supporting” in other places. This difference should either be explained or corrected if it was an unintentional error.

- CIP-011: The phrase “SCI identified independently” is used throughout CIP-011 but is unclear in its intent and needs to be clarified before EEI can support the revisions to this Reliability Standard. .
- CIP-013: The phrase “SCI identified independently” is used in Requirement R1 of CIP-013 but is unclear in its intent and needs to be clarified before EEI can support the revisions to this Reliability Standard.

CIP-003:

Section 3.1 - suggest removing ‘as determined by the Responsible Entity’ as it is already stated in Attachment 1.

Section 3.1, second bullet – Change ‘an SCI’ to just SCI

Section 3.1, Should ‘and a system(s) outside:’ be changed to ‘and a Cyber System outside:’

CIP-004, Part 2.1.9 – Would the intended scope be more accurate by changing Cyber Systems to CIP Systems?

Cyber security risks associated with electronic interconnectivity and interoperability with other CIP Systems, including Transient Cyber Assets, and with Removable Media.

CIP-013, R1.1 and R1.2 – Would the scope more accurately be identified by changing ‘system’ to ‘CIP Systems?’

Since the Glossary modifications are the foundation to all Standard changes, NERC should seek approval of the new terms prior to any changes being introduced in the Standards to reduce potential misunderstanding or misinterpretation of both the new definitions and modified Standards. This will also allow NERC, and industry, time to determine additional courses of action, reduce confusion, and reduce additional risk associated with such wholesale changes.

Tacoma Power agrees with the proposed changes to the NERC Glossary terms. However, we identified the following improvements and minor corrections to the CIP-003 and CIP-006 documentation:

- CIP-003 Attachment 1 Section 1 has inconsistent language for the inclusion of SCI. Suggest modifying to “...SCI that supports any part of a low impact BCS...”
- CIP-009 R2.1 and R2.2, the redline should delete the following item from the Applicable System column: “SCI hosting High or Medium Impact BCS at Control Centers or their associated: • PACS; or • EACMS”

Comment

Relative to CIP-003, the inclusion of a reference to SCI in R2, which addresses low impact assets, would seem to suport the inclusion of SCI where SCI is independently identified, but supporting a high or medium impact BCS. However, this language was struck from the requirement despite the fact that independently identified BCS supporting an applicable system is subject to several requirements and standards addressed within the policies required under R1. Further, this raises a question as to whether SCI grouped with BCS would be subject to CIP-003 by virtue of their grouping while independently identified SCI would not. For this reason, GSOC requests clarification regarding whether SCI that is identified independent of BCS, but is supporting such systems should be addressed in the policies required under CIP-003, R1.

Relative to CIP-005, GSOC recommends revising the following language

Real-time Assessment and Realtime monitoring data while being transmitted between Control Centers subject to CIP012; and

as follows:

Real-time Assessment and Realtime monitoring data subject to CIP012; and.

Document Name	
Comment	
For CIP-006 R1.1, Southern believes the first "SCI without ERC hosting Medium Impact BCS" is unnecessary and we suggest deletion. For CIP-009, we suggest deleting "SCI identified independently" throughout the standard. The goal of CIP-009 according to R1.3 and the GTB is to recover the functionality of the BCS. In the "all-in" scenario, the SCI underlay isn't called out as a specific component of a recovery plan. To recover the functionality of a system, such as a virtualized EACMS, the entity may restore an image to a dedicated server HW without SCI. The SCI should not be a specific object of recovery plans - the object is to recover the BCS, EACMS, or PACS functionality. If recovery of the SCI is required by the entity to recover the BCS functionality, that would be required as part of the plan but not a distinct object of the requirement. If SCI applicability is left in CIP-009, it seems duplicated throughout most of R2's requirement parts. The edits made in R1 and R3 to applicable systems were not made in R2. The 'applicable system' in R2.2 should be capitalized. R2.2 and in particular its measures need to be updated for virtualization scenarios. It maintains a sense of tape backups of static files.

14. Please provide any additional comments for the SAR drafting team to consider, if desired.

Daniel Mason - Portland General Electric Co. - 6, Group Name PGE FCD

Answer

Document Name

Comment

Portland General Electric Company is providing the following comments for the drafting team's consideration:

CIP-005-8 R2.6.2 – “Applicable Systerms” is used instead of “Applicable Systems”

CIP-005-8 R2.1 - In the Applicable Systems column, the phrase "Intermediate Systems used to access Applicable Systems of Part 2.1" is included. However, the requirement states that Responsible Entities must "Permit authorized IRA, if any, only through an Intermediate System." Portland General Electric Company believes this implies that an Intermediate System would need to broker access to the Intermediate System that is brokering access to the other Applicable Systems in R2.1. Portland General Electric Company wonders if it was the drafting team’s intent to include "Intermediate Systems used to access Applicable Systems of Part 2.1."

Portland General Electric Company is providing the following comments for the drafting team's consideration:

CIP-005-8 R2.6.2 – “Applicable Systerms” is used instead of “Applicable Systems”

CIP-005-8 R2.1 - In the Applicable Systems column, the phrase "Intermediate Systems used to access Applicable Systems of Part 2.1" is included. However, the requirement states that Responsible Entities must "Permit authorized IRA, if any, only through an Intermediate System." Portland General Electric Company believes this implies that an Intermediate System would need to broker access to the Intermediate System that is brokering access to the other Applicable Systems in R2.1. Portland General Electric Company wonders if it was the drafting team’s intent to include "Intermediate Systems used to access Applicable Systems of Part 2.1."

CIP-006-7 R1.6 - In the Applicable Systems column, there should be a bullet next to "Medium Impact BCS with ERC" so that the Applicable Systems column reads "Physical Access Control Systems (PACS) associated with: • High Impact BCS, or • Medium Impact BCS with ERC"

CIP-006-7 R1.6 - The requirement language says, "Monitor each Physical Access Control System for unauthorized physical access to a Physical Access Control System." However, SCI identified independently is only supporting PACS, not categorized as part of the PACS itself. For clarity, Portland General Electric Company suggest rephrasing the requirement language to say, "Monitor Applicable Systems for unauthorized physical access."

CIP-006-7 R1.7 - The requirement language says, "Issue an alarm or alert in response to detected unauthorized physical access to a Physical Access Control System to the personnel identified in the Cyber Security Incident response plan within 15 minutes of the detection." However, SCI identified independently is only supporting PACS, not categorized as part of the PACS itself. For clarity, Portland General Electric Company suggest rephrasing the requirement language to say, "Issue an alarm or alert in response to detected unauthorized physical access to an Applicable System to the personnel identified in the Cyber Security Incident response plan within 15 minutes of the detection."

Bobbi Welch - Midcontinent ISO, Inc. - 2, Group Name ISO/RTO Council Standards Review Committee 2016-02 Virtualization (Draft 2)

Answer	
Document Name	

Comment

Overall, the ISO/RTO Council (IRC) Standards Review Committee (SRC)[1] recommends a separate virtualization standard be adopted to reduce the amount of change, additional work and confusion that will be required by a more holistic change as noted by the SDT. The new standard should be limited to only the requirements that directly relate to virtualization technology (e.g. dedicated infrastructure, shared infrastructure and management systems). In the event the SDT declines to pursue a separate virtualization standard, the SRC offers these comments in Questions 1-14 on the draft standards as presented.

Are these comments for the SAR drafting team or the Standards drafting team per the question’s text?

Request clarification on cloud connectivity. The SAR explicitly excludes cloud connectivity. However, entities may use cloud connectivity. Does this divergence create a perverse incentive for entities to move to the cloud so assets/systems in the cloud are out of audit scope? See CIP-007 R2 – does not include patching in the cloud. And requirements that deal with physical boundaries.

Request that the SDT post the draft revisions as “red-line to last approved” rather than “to last posted.” This expectation is consistent with posting of other NERC Standards and earlier postings of CIP updates.

Since CIP-013 is part of this update, is there a reason why CIP-014 is not part of this update?

[1] For purposes of these comments, the IRC SRC includes the following entities: CAISO, ERCOT, IESO, ISO-NE, MISO, NYISO, SPP and PJM (with the exception of our response to question 14, paragraph 1).

Roger Fradenburgh - Roger Fradenburgh On Behalf of: Nicholas Lauriat, Network and Security Technologies, 1; - Roger Fradenburgh

Answer

Document Name

Comment

N&ST believes the proposed “Exemption” statement in every CIP Standard, 4.2.3.3, “Cyber Systems, associated with communication links, between the Cyber Systems providing confidentiality and integrity of an Electronic Security Perimeter (ESP) that extends to one or more geographic locations” is both confusing and inaccurate. One provides for the confidentiality and integrity of data, not ESPs. N&ST suggests rewording that’s consistent with the language of proposed CIP-005 Requirement R1 Part 1.4, such as “Cyber Systems associated with communication links used to span a single ESP among two or more geographic locations.”

N&ST reviewed proposed VSL revisions only briefly, but noticed the High and Severe VSLs for CIP-005 Requirement R1 still refer to Requirement Parts (1.2.1 through 1.2.3) that the SDT has deleted. N&ST recommends a thorough proofreading of all VSLs to ensure they reflect the latest proposed Requirement changes.

Elizabeth Davis - Elizabeth Davis On Behalf of: Tom Foster, PJM Interconnection, L.L.C., 2; - Elizabeth Davis

Answer	
Document Name	

Comment

PJM appreciates and supports the continued work of the Standards Drafting Team (SDT) to transition the framework of the NERC CIP standards to one that more readily supports the use of virtualization technology. While PJM recognizes the significant challenges associated with developing revisions and building consensus within the industry, we believe it is critical to sustain the current momentum and finalize these changes. These changes are important not only to better enable the use of virtualization technology to support the reliability of BES Cyber Systems, but also – and more importantly - to better enable the industry’s use of emerging technologies in the future. PJM believes the SDT’s work to update the standards framework will position the industry to take earlier advantage of new technologies to increase reliability as the revised standards will be based more on controls rather than technology type. While there is the possibility that changes to the standards could still result from the introduction of new technologies, these changes should be minimal if the framework of the standards is based on controls.

1) Planned and Unplanned changes language is missing in this version’s implementation plan, and this should be included.

2) Although EEI is not permitted to ballot on these proposed changes to the CIP Reliability Standards, we note that Industry was not afforded an opportunity to vote on the proposed changes to the New, Modified and Retired NERC Glossary of Terms. Section 5.0 of the Standard Processes Manual states that “Glossary of Terms includes terms that have been through the **formal approval process**”, which EEI understands to mean that new terms are to be balloted. Therefore, the proposed terms that have been modified, added, or retired will need to be balloted prior to the final approval of the proposed CIP Reliability Standards.

3) EEI notes that acronym for Shared Cyber Infrastructure (SCI) is used prominently in many of the proposed new NERC CIP Standards but is often not identified in its first use in the following Reliability Standards. (See below)

CIP-002-7 – SCI used 27 times but never identified as Shared Cyber Infrastructure
CIP-004-Y - SCI is used 23 times but never identified as Shared Cyber Infrastructure
CIP-005-8 – SCI is used 30 times but never identified as Shared Cyber Infrastructure
CIP-006-7 - SCI is used 17 times but never identified as Shared Cyber Infrastructure
CIP-007-7 – SCI is used 23 times but never identified as Shared Cyber Infrastructure
CIP-008-7 – SCI is used 12 times but never identified as Shared Cyber Infrastructure

CIP-009-7 – SCI is used 12 times but never identified as Shared Cyber infrastructure
CIP-010-5 – SCI is used 15 times but never identified as Shared Cyber infrastructure
CIP-011-Y – SCI is used 3 times but never identified as Shared Cyber infrastructure
CIP-013-3 – SCI is used 17 times but never identified as Shared Cyber infrastructure

Response

Brandon Gleason - Electric Reliability Council of Texas, Inc. - 2

Answer	
Document Name	

Comment

ERCOT supports the IRC SRC comments and offers these additional comments:

- Redlines to the current approved standard would be appreciated to understand the changes between current obligations and the proposed changes.
- Due to the differences in traditional and virtual technologies, the SDT should consider moving the virtual requirements to a separate standard or standards. This will reduce confusion when applying the requirements and allow those who do not plan to use virtualization to focus on the requirements relevant to them and not be distracted by terminology and requirements that do not apply to them.
- BES Cyber System definition: The proposed definition appears to require two separate groupings if SCI is in use, one for the BES Cyber Assets, and one for the Shared Cyber Infrastructure. Recommend a simplification, "One or more BES Cyber Assets logically grouped by a Responsible Entity to perform one or more reliability tasks for a functional entity, and the Shared Cyber Infrastructure supporting the BES Cyber Assets supported."

Comment

As pertaining to EACMS and with the broadening and nesting of definitions, the need for the EACS/EAMS split becomes more evident, and possibly even different types of EACS (or no type at all) as it appears the requirements are trying to specify requirements for firewalls as opposed to domain controllers as one example. As Zero Trust, policy enforcement within hypervisors, virtual FW's, etc. proliferate, the broad definition of EACMS as a “thing” is becoming more of an issue with virtualization. Electronic Access Control is a function and not a type of CA or VCA and virtualization and zero trust are making this ever more evident. Including logging systems that only monitor access in the same definition adds to the issue. The standards appear to begin to split this broad category with phrases like "EACMS that enforce an ESP", but that is also problematic. Domain Controllers (DC) 'enforce a policy' that can 'control communications', yet some of the requirements that use this scope can’t be applied to a DC. (CIP-005 R1.2 and R1.3 for example. R1.3 would break most systems as it could require that a virtual BCS can't talk to a DC. Although we understand the intent is to prevent virtual tenant access to the SCI management plane, it says far more due to the intertwining of definitions. This requirement says a virtual BCS on independent SCI must be prevented from communications to the Management Interface, which is defined as "a user interface that is…used to configure an ESP" which is defined as "…policies enforced by an EACMS that controls communications". The virtual BCS cannot communicate to the Domain Controller (breaking the BCS) because the DC may enforce group policy that may control communications (what ports or services are enabled/disabled on servers). Attempting to do electronic access control to an EACMS management plane is perilous with these broad constructs. "Electronic access control" is a broad function with no differentiation between IP network type access control (firewalls) and user/process authentication (domain controllers) or IRA access control (Intermediate Systems) or merely logging systems attempting to correlate events for detection. With the philosophy that every Cyber Asset or VCA is every definition it meets, this is an issue that needs simplification.

Regarding the Implementation Plan, it is missing the "Planned or Unplanned Changes Resulting in a Higher Categorization" section that should be included in order to carry that forward to the new version of CIP-002. The list of definitions in the Implementation Plan needs to be updated as well.

The SDT has been clear that this project focuses on on-premise virtualization, however, many virtualization concepts could be interpreted as being related to cloud computing technologies. AWS suggests explicitly stating that the Standards do not apply to cloud within the Applicability section of CIP-002. If these updated Standards do not apply to cloud, it should be obvious to the reader. Thank you to the drafting team for all your work.

Although ACES answered no to question #7, an ACES member agrees with the SDT in question #7, stating they see advantages to leveraging policies in zero trust environments to reduce overall burden of documenting ESPs. Further, they feel the differences in technology between traditional perimeter controls and zero trust would not hinder the audit process.	

We would like to thank the SDT for their hard work on this project and addressing industry comments. This draft is significantly closer to the existing standards while allowing the flexibility to incorporate newer and future technologies to protect the BES.

While GSOC understands the need for the standards and supporting technical rationale to comport to the new style and standards instituted by NERC and the contraints of format revisions, the loss of context in moving historical technical rationale supporting the standards to	

'retired' status creates ambiguity. Specifically, the movement of this substantive guidance to a retired section raises questions regarding whether portions of the guidance that remain applicable and are not clearly superseded can be relied upon by industry. For theses reasons, GSOC recommends that clarification be provided regarding whether substantive guidance provided in previous versions of the technical rationale that were moved to the 'retired' section in the latest version of the technical rationale and are not clearly superseded in the substantive portions of the new/revised technical rationale remain in effect and can be relied upon and utilized by industry in their compliance efforts. This clarification is critical because the movement of substantive guidance without replacement or clear superseding information reduces the overall guidance available to entities trying to adhere to a complex set of obligations.

GSOC appreciates the SDT's efforts on these changes. The proposed revisions are a substantive improvement and should address the majority of concerns previously expressed. Overall, GSOC supports the concepts proposed in the draft revisions.

We understand the SDT desires to allow flexibility for entity's to address a mixed trust environment, however the mixed trust environment may not be allowable based on our comments in Q1. In SDT proposed "independently Identified SCI" scenario (see the diagram in Q1), if the right side SCI containing a CIP Management Interface can remove a CIP cyber asset, the SCI should be identified as a CIP cyber asset (see our comments in Q1) resulting in all non-CIP VCAs it host becoming at least PCAs based on the affinity rule, therefore the proposed mixed trust model is broken and cannot provide flexibility for entities to achieve CIP compliance. To make the right side SCI out of CIP scope, the only way to do so is that the right side SCI cannot have a CIP Management Interface and its hosted VCAs cannot be CIP cyber assets. The only mixed trust environment can be done is the storage array. In our proposed changes, the storage array should be identified as part of the CIP cyber asset only if it contains the information for the real-time operation of a CIP cyber asset like a local hard drive and the rest of the storage array for storing historical information and non-real time information may be identified as a BCSI repository.

Entity's who choose to host both CIP and non-CIP cyber assets on SCI must understand the high security risk to the reliable operation of BES as changes to this complex environment could cause a misconfiguration, loss of service, security vulnerability or other issue which can impact the entire SCI virtual hardware platform and the hosts, VMs and their configurations. Also, resulting from our comments above, the non-CIP cyber assets on the mixed trust SCI becomes PCAs if the SCI contains CIP Management Interface in which it would bring additional compliance obligations to the Entity's who choose to do so.

Resulting from our proposed changes, the We believe the existing standard requirements and definitions could be revised more efficiently to meet the SAR requirements, ensure the virtualization security objectives are met, and reduce the impact to entity's existing CIP programs.

that affect the reliable operation of BES and provide greater clarity to auditors.

We concur with the SDT’s goal of revising the CIP standards to address virtualization, provide more options for Responsible Entities to remain compliant and ensure reliability while utilizing new and different technologies, and be objective-focused. To that end, we applaud the SDT’s continued work and effort on this project. While there are several negative comments listed above, we also feel that CIP-002, 005, 007, and 010 are also close to an acceptable revised state.

While the proposed revisions are made with the intent of allowing Responsible Entities more options to achieve compliance, the inclusion of multiple new and revised terms and requirement language across all CIP requirements gives the appearance of more complexity and thus more difficulty in achieving compliance. This may (or may not) only be an issue of optics but optics are important. The goal of providing Responsible Entities more options for compliance must not also detract from the goal of ensuring that the requirements are understandable and explainable to a wide audience.

The biggest concerns with all of these changes are:

CIP-002 – How will we identify if assets are in scope with the changes made to attachment 1

CIP-010 – How the removal of baseline configurations will affect SRP-PAC

We thank the SDT for this opportunity to provide comment and feedback.

In support of IRC SRC/SWG.

Overall, the SRC recommends a separate virtualization standard be adopted to reduce the amount of change, additional work and confusion that will be required by a more holistic change as noted by the SDT. The new standard should be limited to only the requirements that directly relate to virtualization technology (e.g. dedicated infrastructure, shared infrastructure and management systems). In the event the SDT declines to pursue a separate virtualization standard, the SRC offers these comments in Questions 1-14 on the draft standards as presented.

Are these comments for the SAR drafting team or the Standards drafting team per the question’s text?

Request clarification on cloud connectivity. The SAR explicitly excludes cloud connectivity. However, entities may use cloud connectivity. Does this divergence create a perverse incentive for entities to move to the cloud so assets/systems in the cloud are out of audit scope? See CIP-007 R2 – does not include patching in the cloud. And requirements that deal with physical boundaries request that the SDT post the draft revisions as “red-line to last approved” rather than “to last posted.” This expectation is consistent with posting of other NERC Standards and earlier postings of CIP updates.

Since CIP-013 is part of this update, is there a reason why CIP-014 is not part of this update?

JT Kuehne - AEP - 6

Answer	
Document Name	

Comment

While AEP has provided specific commentary on Questions 1 through 13, we would like to provide the following general thoughts as revisions are incorporated.

We ask the SDT to avoid, wherever possible, the nesting of defined terms within the definition of other defined terms. The current practice of nesting has made it difficult to support some of the great work that has already been put in by the SDT.

AEP recommends clarifying the definitions first, then firming up CIP-002 asset classification requirements in relation to the new definitions, so that the Standards conforming to these changes can be effectively implemented.

AEP anticipates that the outcome of this revision to the CIP standards to have significant impact on the manner by which Access Management and other tasks are performed. For example, this will require the development of controls in the areas of electronic access authorizations, reviews, revocations etc., related to BCSInfo on SCI. As such, we suggest SDT provides clarifications on the new and revised definitions as requested.

We concur with the SDT’s goal of revising the CIP standards to address virtualization, provide more options for Responsible Entities to remain compliant and ensure reliability while utilizing new and different technologies, and be objective-focused. To that end, we applaud the SDT’s continued work and effort on this project.

With that said, after considerable time reviewing the proposed revisions and additions, and much time consulting with and debating peers over the changes, we have arrived at the conclusion that it might be a mistake to attempt virtualization solely through revision of the existing CIP requirements. Currently the revisions are focused on setting the requirements at a level high enough to be technology agnostic, where they can be applied regardless of whether a mixed-trust approach is used. While laudable in theory, the result so far seems to be extensive revisions requiring multiple new definitions, all of which are somewhat confusing in their entirety and potentially difficult to implement properly due to the confusion. Further the extent of the changes presents opportunities for auditors in future to arrive at undesired intepretations. Compounding the issue is that these changes are being made to allow for options which not all Responsible Entities will avail themselves of – and in fact possibly very few will, at least in the near future. Again, we support the SDT’s goal of allowing Responsible Entities more options for maintaining reliability and compliance. But we question how worthwhile it is to enact a raft of changes on existing requirements where only a minority of companies will be seeking to use them.

Accordingly, instead of revising every existing CIP requirement, we believe that a new CIP standard should be enacted, along with any necessary changes to CIP-002 R1 for scope and CIP-005 R1 for ESP, to address virtualization requirements. This can meet all the goals of the SDT while minimizing impact to existing CIP requirements and compliance programs.

We thank the SDT for this opportunity to provide comment and feedback.

This approach is highly based on a Zero Trust Model. While Zero Trust and it’s assumption of assuming no network edge is an excellent security approach, it is necessary to ensure that a discrete boundary defines the edge of the auditable network. The current definitions significantly blur this border introducing uncertainty into what will be audited under the CIP standards and introduces opportunity for significantly different viewpoints between auditors and entities regarding the boundary of what will be subject to NERC compliance standards. The definitions are also too dependent on interpretation that is not enforceable as the appropriate guidelines are no longer a part of the standard. We do support adopting definitions and standards that support virtualization.

‘Where technically feasible’ -> ‘Per system capability’

MRO Comment: There are instances of ‘per system capability’ replacing ‘where technically feasible’ that could allow for fewer protections for those BCS. The ROP requires that TFEs require “Compensating and mitigating measures” (NERC ROP Appendix 4D). This is no longer required and limits compliance monitoring. (Consider an EACMS or PACS, which do not require logical isolation, not requiring authentication [Part 5.1] or limiting authentication attempts [Part 5.7]. This poses an increased risk.)

Recommendation: Modify the language of the requirements beyond just replacing ‘where technical feasible’ with ‘per system capability’ to better address risk posed by the lack of the required controls.

Additional minor and conforming recommendations:

CIP-006 Table R2 part 2.2 - Under Applicable Systems, typo, "EERC" meant to be read as ERC.

CIP-006 Table R3 part 3.1 - Under Applicable Systems, consider removing bulleted SCI applicability and include as a single statement at the bottom of the column for consistency.

CIP-007 Table R1 part 1.3 & Table R4 part 4.2 - Under Applicable Systems, the second bullet "External Routable Connectivity" can be changed to ERC for consistency.

CIP-009 Table R2 part 2.1 & 2.2 - Under Applicable Systems, to improve clarity consider removing 'SCI hosting High or Medium Impact BCS at Control Centers or their associated EACMS/PACS' as these would be included in High and Medium impact BCS in an All-In scenario while 'SCI identified independently supporting an Applicable System Above' covers the independently identified scenario.

The trend with the CIP standards has been to change from requiring a specific control to address a cyber security objective to requiring the RE to achieve a cyber security objective. For example, in CIP-007-3, the RE was required to implement antivirus on in-scope CAs to mitigate the threat of malicious software. CIP-007-5 changed this to require the RE to deploy methods to deter, detect or prevent malicious code. This gave the RE the ability to choose the best control for the actual objective (malicious code protection) as opposed to requiring the entity to implement specific control (antivirus) that may not be suitable in all cases. The same can be said for the proposed revisions to ESPs, rather than requiring the specific control of firewalls to act as EAPs for an ESP, the SDT is revising the requirement to grant the RE the ability to select the control best suited to their environment to achieve the cyber security objective (logical isolation). The SDT should use the same objectives based approach with side-channel threats and create requirements that require the RE to design and implement controls that mitigate the threat of side-channel attacks, rather than force entities to implement the specific control of CPU/memory isolation, which is certainly one option, but not the only one. Other controls that would be effective is network isolation of the SCI and its VCAs, whitelisting, or more organizational control to prevent information disclosure (such as randomizing data in memory). Additionally, the CIP standards already address several of the most important controls to prevent side-channel attacks, namely, regular security patching, ports and services hardening, and restricting user access based on need.

Comments Submitted by Lakeland Electric (JEA was originally expected to submit these comments)

1. Are the two options for identification of SCI within CIP-002 clear and is it understood that when SCI is included in the CIP Systems that it is treated like the CIP System, it is a part of for CIP Requirement Applicability?

☒ Yes
☐ No

Comments: **look at applicability

2. The Applicable Systems column may include “SCI identified independently…” Is this clear or is additional clarification (such as “SCI identified as supporting, but not part of…”) needed?

☐ Yes
☒ No

Comments: Need to combine and include both (because ‘independently’ is listed throughout standards and needs to be defined). Example: “SCI identified IDENPENDENTLY as supporting, but not part of….”

3. The SDT modified the ERC definition to reference “outside the asset containing”. This is to allow scoping based on connectivity of the logging systems as required by CIP-007 Requirement R4 as well as the scoping of requirement parts in CIP-004 and CIP-006 based on risk. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

☐ Yes
☒ No

Comments: This definition of ERC (by including the new definition of CIP System) extends ERC requiremetns to EACMs and PACs and transient cyber assets. Should be limited to environments that control and monitor BES.

4. The SDT proposes that the modified ESP definition can be used for both traditional firewall based networks, as well as future networks such as zero trust. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

☐ Yes
☒ No

Comments: As the proposed change extends ESP application to CIP Systems (which include EACMs and PACs and transient cyber assets). This application of ESP must be limited to assets impacting BES Control and Monitoring Operations.

5. The SDT modified the IRA definition based on industry comments. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

☐ Yes
☒ No

Comments: IRA definition is applied to CIP Systems which requires application of IIRA to TCA, EACMS, and PACS

6. The SDT modified the Management Interface definition based on industry comments. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

☐ Yes
☒ No

Comments: Is Management interface the Virtual Management Consoles or ILO.

7. As discussed in the CIP Definitions and Exemptions Technical Rationale (TR), the SDT believes that the use of configurations or policy in the modified ESP definition can reduce the burden of documenting ESPs in a zero trust environment. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

☐ Yes
☒ No

Comments:

8. The SDT added new and revised several defined terms to incorporate virtualization and future technologies within the CIP Standards. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

☐ Yes
☒ No

Comments: Deviates from industry standard terms such as used in NIST.

9. The SDT revised CIP-002 based on industry comments. Do you agree with the proposed changes to the CIP-002 Reliability Standard? If not, please provide the basis for your disagreement and an alternate proposal.

☐ Yes
☒ No

Comments: No value addition to current CIP process and adds confusion to CIP asset identification process. If the intent is just clarify VCA, then adding the definition should be more than sufficient.

10. The SDT revised CIP-005 based on industry comments. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

☐ Yes
☒ No

Comments: No value addition to current CIP process and adds confusion to CIP asset identification process. If the intent is just clarify VCA, then adding the definition should be more than sufficient.

11. The SDT revised CIP-007 based on industry comments. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

☐ Yes
☒ No

Comments: How does it improve current CIP-007 requirements and improve to risk based compliance.

12. The SDT revised CIP-010 based on industry comments. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

☐ Yes
☒ No

Comments: How does it improve current CIP-010 requirements and improve to risk based compliance.

13. The SDT revised CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013 (conforming changes) based on industry comments. Do you agree with the proposed changes to these Reliability Standards? If not, please provide the basis for your disagreement and an alternate proposal.

☐ Yes
☒ No

Comments: How does it improve current CIP requirements and improve to risk based compliance.

14. Please provide any additional comments for the SAR drafting team to consider, if desired.

Objective of this SAR was to improve CIP standards to allow use of new technologies such as Cloud where appropriate and improve CIP compliance. Unfortunately, this standard stifles any innovation and forces the industry to use obselence.

- SDT classifies all CIP standards as same risk, which defeats the objective of creating a risk based compliance program.
- Adds a level of complexity and a lack of clarity that would make implementation difficult and result in increased violations without an increase in security.
- Move away from risk-based standards by not segregating assets (such as EACMS, PACS, and TCA) in definitions such as those for CIP System and ERC.
- Do not accomplish the goal and deviate from the original purpose of the SAR: to eliminate the language inherent in V5 that has made it difficult to go virtual. In fact, they may limit or handicap an entity’s ability to go virtual.
- This standard does not add any value to CIP standards as all what is being accomplished by these changes can easily be accomplished by current standards. If the intent is to clarify the application of Virtual systems, then SDT or ERO should release an application white paper.

Comments Submitted by Orlando Utilities Commission (JEA was originally expected to submit these comments)

1. Are the two options for identification of SCI within CIP-002 clear and is it understood that when SCI is included in the CIP Systems that it is treated like the CIP System, it is a part of for CIP Requirement Applicability?

☒ Yes
☐ No

☐ Yes
☒ No

Comments: How does it improve current CIP requirements and improve to risk based compliance.

14. Please provide any additional comments for the SAR drafting team to consider, if desired.

Objective of this SAR was to improve CIP standards to allow use of new technologies such as Cloud where appropriate and improve CIP compliance. Unfortunately, this standard stifles any innovation and forces the industry to use obselence.

- SDT classifies all CIP standards as same risk, which defeats the objective of creating a risk based compliance program.
- Adds a level of complexity and a lack of clarity that would make implementation difficult and result in increased violations without an increase in security.
- Move away from risk-based standards by not segregating assets (such as EACMS, PACS, and TCA) in definitions such as those for CIP System and ERC.
- Do not accomplish the goal and deviate from the original purpose of the SAR: to eliminate the language inherent in V5 that has made it difficult to go virtual. In fact, they may limit or handicap an entity's ability to go virtual.
- This standard does not add any value to CIP standards as all what is being accomplished by these changes can easily be accomplished by current standards. If the intent is to clarify the application of Virtual systems, then SDT or ERO should release an application white paper.

Overall Comments:

The June 2021 redlines are an improvement over the previous version; however, the modifications:

- Add a level of complexity and a lack of clarity that would make implementation difficult and result in increased violations without an increase in security.
- Move away from risk-based standards by not segregating assets (such as EACMS, PACS, and TCA) in definitions such as those for CIP System and ERC.
- Do not accomplish the goal and deviate from the original purpose of the SAR: to eliminate the language inherent in V5 that has made it difficult to go virtual. In fact, they may limit or handicap an entity's ability to go virtual.
- This standard does not add any value to CIP standards as all what is being accomplished by these changes can easily be accomplished by current standards. If the intent is to clarify the application of Virtual systems, then SDT or ERO should release an application white paper.

- Definitions
- **CIP System** - this extends the definition to include EACMS, PACS, and TCA. When applied in standards or other definitions, it expands the scope significantly. Systems such as SIEM and PACS are supposed to control and Monitor an enterprise and separate instances limit the ability of security operations to respond to active incidents. Applying CIP System definitions will expand scope to environments where impact will limit security and will be detrimental.
- We recommend this definition be removed and appropriate devices groups such as EACMs, PACS be directly used in order to avoid any confusion.
- **ERC** – by including "ability to connect to a CIP System," in the definition of ERC, this extends ERC requirement to EACMS, PACS, and TCA. Should be limited to environments that control and monitor BES as was the scope of the SAR. Also, the statement "outside the asset containing the CIP system" may need clarity – where does this draw the line? **ESP** – as proposed, it appears this may extend the definition of ESP to CIP Systems (including EACMS, PACS, and TCA), but application of ESP must be limited to assets impacting BES control & monitoring operations. EACM, PACS and TCA should not be required to maintain an ESP as they are support assets and exists in homogeneous corporate environment. This change assumes the same risks for all assets/environments and fails to deliver a Risk based application.
- **Intermediate Systems** – should not be on the same network for which it restricts the access or any of the devices it protects. This definition is understood.
- **IRA** – Does this now apply to all within ESP and IRA applies to any of the CIP Systems? Why does the last bullet so specific and not make reference to "asset point?" Overall, definition is understood, but complicated.
- **Management Interface** – we need more clarity, for example does this include ILO as management interface? Is it a vector or device (ESXI console)?

  - **TCA** – this definition/inclusion of the virtual environment is confusing. If the TCA is on the same network, then it will bea PCA or if separate then it will have to use a jump host. How will this apply to Entity's virtual workstations? Would we have to prove the virtual system has ESP and ERC compliance? Need clarity.

- CIP-002
  - It is clear that we are given two options: (1) SCI included in CIP Systems and treated as the[MDD-DCC1] CIP System; and (2) SCI identified independently; just to be clear, based on "each asset", are we also able to do a hybrid model in which some SCI is include and some SCI is identified as independent? It appears to be the case.
  - New standard allows for either zero trust method (protect close to asset) or former edge-based method (ESP and firewalls); however if we want to continue with the edge-based method, we don't want to high water mark everything
    - i.e. Does this mean the corporate host may become SCI for CIP?
    - That CIP System is really giving us a problem in terms of ERC
  - We have concern that corporate host may become SCI; Will the SIEM systems (EACM) not allowed to share Processor and Memeory, that would require them to maintain separate SCI and hence critical requirements such as SIEM can never be migrated to Cloud instance and can never take advantage of any new technology. Furthermore, such a standard assumes that Risks for the EACM and BES assets is exactly the same, and fails to deliver a Risk based application which was the FERC manadate. SDT can specify the security requirements for Shared SCI in a manner that addresses the risk and hence allowing Entities to benefits from transitioning to more advanced technology for EACMs and Data storage, which will significantly improve security.

- CIP-005
  - Allows us to keep firewall or take protection closer to the asset
  - Part 1.2 – only applies to firewall because "identified independently"
  - Part 1.4 – addresses ability to have a "super ESP" between 2 control centers and protect communication between the two
  - Part 2 – ok with requirement; but is there any other way for vendors to access that doesn't involve intermediate host?

- CIP-007
  - Part 1.1 – if this requires EACMS connect to TCA, we may have a problem – includes EACMS, PACS, & PCA except we've high water marked our PACS as high
    - What is meant by "or services if unable to determine ports" – is this for dynamic port ranges or for cloud services to randomly change ports?
  - Part 1.2 – "non-programmable communications components inside PSP & ES," what is this? Is this encouraging USB port locks?
  - Part 1.4 – If you choose independent SCI, can't run ES Cyber systems along with non-CIP
    - NOTE: JEA does not agree the requirements are risk-based.; should be differentiated because this limits our availability to use virtual technology
    - How can we verify that memory is not shared?

- CIP-010
  - Need to review

- CIP-011
  - Ok for the most part

Response to Comments

Project 2016-02 Modifications to CIP Standards
Draft 2 Posting ending September 1, 2021

Additional information is available on the project page. If you have questions, contact Senior Standards Developer, Jordan Mallory (404-446-2589).

Background Information

Project 2016-02 (1) addresses the Federal Energy Regulatory Commission (Commission) directives contained in Order No. 822 and (2) considers the Version 5 Transition Advisory Group (V5TAG) issues identified in the CIP V5 Issues for Standard Drafting Team Consideration (V5TAG Transfer Document).

The V5TAG, which consisted of representatives from NERC, Regional Entities, and industry stakeholders, was formed to issue guidance regarding possible methods to achieve compliance with the CIP Version 5 standards and to support industry's implementation activities. During the V5TAG's activities, it identified certain issues with the CIP Reliability Standards that would be better addressed by a standard drafting team (SDT) for the CIP Reliability Standards. The V5TAG developed the CIP Version 5 Transition Advisory Group Issues for Consideration document to formally recommend that the SDT address these issues and consider modifications to the standard language during the standards development process. Among other issues, the V5TAG stated "The CIP Version 5 standards comments.

There were 93 sets of responses, including comments from approximately 218 different people from approximately 137 companies representing 10 of the Industry Segments as shown in the table on the following pages.

Question 1.

Are the two options for identification of SCI within CIP-002 clear and is it understood that when SCI is included in the CIP Systems that it is treated like the CIP System, it is a part of for CIP Requirement Applicability?

Q1 Comment Themes

- **The options are mostly clear and acceptable with the exception of the phrase "independent SCI supporting"**
- **The term 'SCI' is still unclear and ambiguous**
- **Does not agree that the two options for identification of SCI are clear. The distinction between SCI included in a BES Cyber System (BCS) and SCI operating independently adds an unnecessary level of complexity to the standards**

SDT Response: Thank you for your comments. The SDT agrees with this theme that much more clarity around SCI is needed and has taken a different and simplified approach for the next draft. The two options remain for entities to either:

1) dedicate a virtualized infrastructure to hosting Virtual Cyber Assets (VCA) of the same CIP impact rating or 'associated with' the same impact rating (i.e., "all-in") or,
2) share the virtualized infrastructure hosting Virtual Cyber Assets (VCA) of different CIP impact ratings or non-CIP impact rated (previously known as "SCI Identified independently").

The terminology of this latter case ("identified independently") will no longer be used. In order to simplify these options, the term SCI will be redefined to ONLY refer to the second option.

For the "all-in" scenario, the virtualized infrastructure hardware components are now simply Cyber Assets that are a part of the systems they are hosting, such as BCAs in a BCS, or as Cyber Assets in an virtual EACMS, PACS, or PCA. In this scenario, every VCA hosted on the Cyber Assets, and the Cyber Assets themselves, are of the same impact rating. *There is no SCI in this option*. The SDT believes this is the way most entities with existing virtual systems have identified and categorized their virtual infrastructures to date and this will allow that to remain unchanged.

The SDT in response to this comment theme has modified the SCI definition so that it ONLY applies to the second scenario, where the "S" in "SCI" means the underlying hardware *is shared among VCAs of differing impact levels* (i.e., 'mixed mode'). This simplification allows for distinct scoping of new additional requirements for the proper isolation required as well as restricting access to the management plane where the isolation is configured.

To recap:

- If the entity implements BCS and any associated EACMS or PACS or PCAs as VCAs on an underlying hardware infrastructure, and all is treated as or 'associated with' the same (highest) impact rating, this is "all-in" and the underlying hardware is identified as Cyber Assets that may also be BCAs in a BCS or part of the EACMS or PACS they host. There is no SCI in this scenario. No CIP-002 recategorization is required.
- If the entity hosts VCAs of varying impact levels and wishes to use the security controls to keep each impact level environment isolated from each other, then the underlying hardware is identified as SCI and additional requirements for such isolation are required for this environment.

Question 2.

The Applicable Systems column may include “SCI identified independently…” Is this clear or is additional clarification (such as “SCI identified as supporting, but not part of…”) needed?

SDT Response:

Thank you for your comments. Most entities answered this question, which is closely related to Q1 with shared themes from Q1. Please see Q1 responses for the SDT response to those themes.

Question 3.

The SDT modified the ERC definition to reference “outside the asset containing”. This is to allow scoping based on connectivity of the logging systems as required by CIP-007 Requirement R4 as well as the scoping of requirement parts in CIP-004 and CIP-006 based on risk. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

Q3 Comment Theme:

- **Use of "asset" for scoping is unclear**

SDT Response: Thank you for your comments. The SDT agrees with comments that the “asset containing” is not defined precisely enough for use in this foundational scoping term of ERC. While the intent of ERC is to restrict the scope of certain requirements for assets/sites that do not have the requisite type of communications, this has traditionally been accomplished by using the ESP as the demarcation point of ERC, not the “asset containing”. The SDT will return ERC to being ESP-based. In addition, the ERC definition essentially mirrors the currently approved definition with one change of replacing concepts of “inside or outside” an ESP to “through its ESP” to better position it for Zero Trust architectures that are not strictly network perimeter based.

Q3 Comment Theme:

- **Expands the existing definition by changing from “BES Cyber System” to “CIP System” and by changing from “to access” to “to communicate”.**

SDT Response: Thank you for your comments. The SDT agrees and has reinstated the BES Cyber System as the subject of ERC definition and reverted to the currently approved “access” language. The ERC definition now essentially mirrors the currently approved definition with one change of replacing the concepts of “inside or outside” an ESP to “through its ESP” to better position it for Zero Trust architectures that are not strictly network perimeter based.

Question 4.

The SDT proposes that the modified ESP definition can be used for both traditional firewall based networks, as well as future networks such as zero trust. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

Q4 Comment Theme:

- **EACMS appears to be required**

SDT Response: Thank you for your comments. The SDT agrees with the commentors. The “enforced by an EACMS” phrase, while meant to help define the extent of the ESP especially in Zero Trust architectures, did require an EACMS in order for an ESP to exist. As commenters rightly pointed out, this negated being able to define ESPs for isolated networks. The SDT addressed this concern by reinstating the current ESP definition and added a second component , "; or a logical boundary defined by one or more EAPs" to address zero trust.

Q4 Comment Theme:

- **ESP does not include routable scoping**

SDT Response: Thank you for your comments. The SDT agrees and worked routable protocol scoping back into the definition.

Q4 Comment Theme:

- **PCA may be redundant in ESP definition**
- **ESP no longer includes boundary**

SDT Response:Thank you for your comments. The SDT agrees with the various comments in this theme, which revolved around being able to define an ESP around isolated networks that do not have ERC but still need an ESP for defining PCAs, knowing the extent of TCA connections, etc. While the SDT's draft 2 proposed definition was more objective in order to incorporate rather different security models (traditional 'castle/moat' perimeter vs. Zero Trust), the SDT agrees the definition needs more specificity in order to not lose its other boundary-like functions that it fulfills even in isolated networks that do not have external connectivity. The SDT also agrees that the PCA definition adequately defines those Cyber Assets, therefore the ESP definition doesn't need to specifiy it includes or groups PCAs.

Q4 Comment Theme:

- **The word "policy" is not well understood**

SDT Response: Thank you for your comments. The SDT agrees that 'policy' needs more context in order to be well understood whether it is a business or administrative policy document or a technical configuration of a firewall policy. The SDT addressed these comments by removing the term 'policy' where it was intended to reflect technical controls, (e.g. software designed networks, instruction detection policies, or firewall rules/policies, etc.) and replaced it with 'configuration or settings'.

Q4 Comment Theme:

- **The use of 'CIP Systems' in the definition is too broad**

SDT Response: Thank you for your comments. The SDT agrees as all types of 'CIP Systems' are not required to be within an ESP. While not a requirement in CIP-005, it is an implication of the definition. The SDT eliminated this new definition and its reference from the ESP definition.

Question 5.

The SDT modified the IRA definition based on industry comments. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

Q5 Comment Theme:

- **The protocol conversion bullet could expand scope beyond the intent (Control Center operator to field device as IRA). The second bullet point is unclear and ambiguous.**

SDT Response: Thank you for your comments. The SDT asserts that the 2nd bullet was correct but agrees it was complex and has made modifications to simplify it. The intent is to cover the situation where an interactive user is using a routable protocol (i.e., an IP address) and is able to access a BES Cyber System and operate or configure it, often called terms such as "engineering access", even if the BES Cyber System itself uses only non-routable communications, such as a serial cable to a console port. In this case, the CIP-005 R2 controls should apply to the routable portion of the communications, and this bullet in the IRA definition is designed to capture that scenario, but with simplified language in our next draft.

Q5 Comment Theme:

- **"real-time" needs deletion/clarification/capitalization.**

SDT Response:

Thank you for your comments. The SDT agrees. The intent was to further define that 'interactive' access was in 'real-time', not access a user has programmed for a future time such as a scheduled batch job that runs when the user is no longer logged in. While this is a risk, its is not the subject of CIP-005 R2's security controls, which are designed for a real-time, interactive user. Batch jobs can't execute through a "pane of glass" interface of a typical Intermediate System, or enter a user's current code from a physical token, or receive a text with a one-time-password from the user's phone. Therefore, IRA is not all-inclusive but is designed around this high risk area of interactive, 'real-time' interaction with a BES Cyber System and isolating the remote user's machine (through an Intermediate System), strongly authenticating the user (through multi-factor authentication), and protecting the session's traffic over less trusted networks (encryption from the Intermediate System to the client). However, as commenters pointed out, the term 'real-time' was confusing or unnecessary, so the SDT deleted it from the definition.

Q5 Comment Theme:

- **Add "IRA does not include system-to-system process communications" back to the definition.**

SDT Response: Thank you for your comments. The SDT believes this comment was made related to the above comment concerning the term 'real-time' in the definition. There was a sense of if the term 'real-time' stayed in, this phrase needed to be added back to state 'real-time' communications did not include system-to-system communications (e.g., a system polling an RTU). The SDT removed the term 'real-time' to respond to these comments and asserts that the first phrases of the definition precludes system-to-system communications without an explicit negative phrase in the definition.

Question 6.

The SDT modified the Management Interface definition based on industry comments. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

Q6 Comment Theme:

- **The second bullet concerning "lights out" needs clarification/is unclear/is vendor specific.**

SDT Response: Thank you for your comments. The SDT does not assert that "lights out management" is a vendor-specific term, but due to the number of comments the SDT changed this second bullet back to the language that had been proposed in the SDT's draft 1 definition of 'Management Module' as suggested by many in the comments.

Q6 Comment Theme:

- **Ambiguity about the intent of the 'user interface, logical interface, or dedicated physical port**

SDT Response: Thank you for your comments. The SDT agrees and replaced this phrasing with "An administrative interface on a Shared Cyber Infrastructure or Electronic Access Control or Monitoring System that…" which is clearer as to the intent of a Management Interface rather than a description of the several forms it may take.

Question 7.

As discussed in the CIP Definitions and Exemptions Technical Rationale (TR), the SDT believes that the use of configurations or policy in the modified ESP definition can reduce the burden of documenting ESPs in a zero trust environment. Do you agree with the proposed change? If not, please provide the basis for your disagreement and an alternate proposal.

Q7 Comment Theme:

- **Agreement/Disagreement with reduced documentation burden**

SDT Response: Thank you for your comments. Most of the comment themes for Q7 were either agreement or disagreement with the reduction in documentation burden based on the overall ESP themes reported in Q4. See Q4 responses to those specific themes. The SDT would like to take this opportunity to clarify the question and its position, which is in agreement with many points commenters made.

The goal of CIP-005 R1 has, from the beginning of CIP-005, been to establish a "policy or configuration" of who/what can communicate with a BCS or its associated PCA's inside a protected network (ESP) and ensure that each element of that policy/configuration allowing communication is necessary; that it implements the security principle of least privilege. This is accomplished in today's more prescriptive perimeter-based architecture by having a documented list of ESPs, which leads to a documented list of EAPs, which then leads to documentation of the policy/configuration within each EAP which is the basis for determining whether the ESP is compliant with the intent of the requirement. So today, ESPs and EAPs are mechanisms for getting to the actual policy/configuration of what is allowed to communicate across the boundary. That intent does not change; the SDT's approach states the eventual policy/configuration as the direct object of the requirement rather than indirectly through documented lists of ESPs and EAPs.

However, the SDT is attempting to change the standards so that other models such as Zero Trust (ZT) are not prohibited or discouraged by overly prescriptive language. As several commenters pointed out, in ZT the number of ESP/EAPs will increase as ESPs "shrink" from protecting a network segment down to protecting a single resource or service, so in that sense going directly to the policy/configuration reduces the burden of the intermediate step of documenting ESPs as the number of those may increase exponentially in full ZT implementations. As other commenters pointed out, ZT with its more granular access control will potentially greatly increase the number of policy/configuration statements of "what can talk to what", so it does not reduce documentation in that regard. The SDT agrees.

Question 8.

The SDT added new and revised several defined terms to incorporate virtualization and future technologies within the CIP Standards. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

NOTE: Many comments for Q8 referred back to issues with the specific questions on specific definitions in Q1-6. Please see responses to those issues in the appropriate question above.

Q8 Comment Theme:

- **Intermediate System: The statement "The Intermediate System must not be located inside the Electronic Security Perimeter" should be retained**

SDT Response: Thank you for your comments. The SDT disagrees and asserts that the "where" of the Intermediate System is a requirement that is embedded within the current definition. If an entity places the Intermediate System inside an ESP such that "public" encrypted traffic is allowed in from yet-to-be authenticated users, that should be a violation of a requirement, not simply not meeting a definition. The SDT removed this phrase from the definition and authored a requirement in CIP-005 R2.6 to address this situation.

Q8 Comment Theme:

- **CIP Systems: Remove "TCA" from "CIP Systems". TCAs are included in the CIP System definition. However, CIP System is used in the definition of ESP.**

SDT Response: Thank you for your comments. The SDT, in response to comments, removed the nested use of "CIP Systems" in other definitions. Upon further analysis, it was then only used in a non-essential clarification in CIP-010 R1.2 that has been removed. The SDT has deleted the proposed term "CIP Systems".

Q8 Comment Theme:

- **Cyber System: Revert back to Cyber Assets or go with generic "cyber system" term, leaving it undefined**
- **Cyber Asset: Consider not excluding SCI, keeping the original**

SDT Response: Thank you for your comments. After mindful consideration of comments, the SDT disagrees that Cyber Asset is now one form an object, with applicable CIP requirements, can take; an inclusive hardware-based electronic device with all the software and data in the device. Virtualization fundamentally breaks the 1:1 tie between hardware resources and the varied and dynamic VCA that may happen to execute on it (be "in the device"). The SDT intent is that the objects of CIP requirements can now take one of three forms: Cyber Assets, Virtual Cyber Assets, or SCI. This term ("Cyber System") was created as an attempt to reduce admistrative burden on Registered Entities by establishing this as shorthand for those three forms so all three do not have to be repeated to update every occurrence of 'Cyber Asset' within all CIP documentation. In addition, in Draft 1, the SDT attempted using the generic words ‘cyber system’ as an undefined term in the exemptions and stakeholder comments were numerous that this term must be a defined glossary term.

The SDT analyzed the comments regarding removal of the exclusion for SCI from the Cyber Asset definition, and after consideration has chosen to retain this exclusion in the Cyber Asset definition for sound cause. If the underlying hardware resource pool of SCI is a “Cyber Asset” then that definition consumes ALL software (VCA) on the SCI. The all-inclusive nature of the Cyber Asset definition is a core issue with SCI scenarios, and the exclusion is necessary to prevent this condition.

Q8 Comment Theme:

- **Protected Cyber Asset (PCA): Additional clarifications on the qualifier of “excluding Virtual Cyber Assets that are being actively remediated prior to introduction to the ESP.”**

SDT Response: Thank you for your comments. The SDT’s intent is this is part of a set of changes to ensure the CIP requirements and definitions do not prohibit or discourage automated means of vulnerability assessment and remediation in virtualized environments (a.k.a “Remediation VLANs”). In these instances, a VCA already resides “in a production environment” but whenever it is instantiated, it is placed on an isolated network where it is assessed against the security policy and remediated as needed to meet the expected security hygiene level before being placed on a production network, all in an automated fashion. However, although during this assessment/remediation process it is isolated from a network perspective, it may for a very brief period of time meet the 2nd part of the proposed PCA definition in that it may be executing on the same hypervisor as a BCS. The SDT asserts that since it is isolated from a network perspective while it is being remediated in an automated fashion, it should not require separate and distinct hypervisor infrastructure for this brief period of time. This is the reason for this exclusionary qualifier in the PCA definition.

Q8 Comment Theme:

- **Overall: Some definitions include requirements on CPU and memory (isolation/shared) and are not future proof**

SDT Response: Thank you for your comments. The SDT intent in these definitions and related requirements is to mitigate the risk unique to virtualization of hardware based ‘side channel’ attacks from other VCAs executing on the same hardware (CPU/Memory). Attacks such as Rowhammer where one process can potentially change code or data in physically adjacent memory belonging to another process, or Spectre/Meltdown where a hardware CPU vulnerability could allow access to other processes are the risk, as a couple examples. The SDT has considered higher level objective language such as “mitigate the risks of side-channel attacks” as suggested by other commenters but finds that to be overly broad. This sharing of physical CPU and memory is a virtualization specific risk that is being mitigated and is specific enough that entities can show affinity rule configurations as evidence of compliance when hosted on SCI. Using such terms may not be ultimately future-proof, but the SDT is having to balance the security objectives with enough specificity that entities know how to comply and how to provide evidence of compliance.

Q8 Comment Theme:

- **PCA: The CPU/memory affinity requirements are problematic in that it essentially places a requirement inside a definition. The implicit requirement is that a BES Cyber Asset cannot share CPU/memory with a non-BCS of the same impact rating or a Protected Cyber Asset.**

SDT Response: Thank you for your comments. After mindful consideration of comments, the SDT disagrees that this is a requirement within a definition. The SDT intent is for it to be each entity's choice whether to 1) employ affinity rules or, 2) separate VCA's of differing impact levels onto separate hypervisors. However, should an entity choose to not employ methods to keep VCAs of different impact levels from executing on the same CPU/memory subjecting those VCAs to hardware-based side-channel attacks, then those VCAs that are not BCAs are properly defined as an associated PCA; creating the need for this language within the PCA definition. If the entity chooses to employ methods to separate VCAs onto different hypervisors or server blades so they do not execute on the same CPU/memory simultaneously, then the risk is mitigated and they no longer meet the definition of a PCA from that perspective. There is no requirement to employ such methods, just the consequence of becoming a PCA if the entity chooses not to.

Q8 Comment Theme:

- **Overall: Since the Glossary modifications are the foundation to all Standard changes, NERC should seek approval of the new terms prior to any changes being introduced in the Standards to reduce potential misunderstanding or misinterpretation**

SDT Response: Thank you for your comments. The SDT suggests that posting definitions alone would not give stakeholders the necessary context of how a definition is used within the standards and would hamper stakeholder acceptance. The SDT asserts that posting these together with the applicable Standard changes is a necessary part for gaining stakeholder acceptance, especially for the very context-sensitive technical terms in CIP, is dependent upon having the context of its use within requirements.

Question 9.

The SDT revised CIP-002 based on industry comments. Do you agree with the proposed changes to the CIP-002 Reliability Standard? If not, please provide the basis for your disagreement and an alternate proposal.

NOTE: Several commenters reported they cannot support CIP-002 changes due to concerns with the definition of SCI expressed in Q1. Please see responses to Q1 above.

Q9 Comment Theme:

- **CIP-002 R1 requirements should be restored and all other SCI language in CIP-002 Attachment 1 should be removed**

SDT Response: Thank you for your comments. After the latested modification of the SCI definition (See Q1 above), the SDT agrees and has reverted the CIP-002 requirements to currently approved language. As our scope was virtualization, we only covered the identification of SCI. However, the identification of "all other" types of Cyber Systems other than the BES Cyber Systems (EACMS, PACS, PCAs, SCI, etc.) is a larger issue that should be considered holistically.

Q9 Comment Theme:

- **Concern that in the Exemptions both data communication links and communication networks should be exempt as in currently approved language.**

SDT Response: Thank you for your comments. The SDT's intent was that shortening to the phrase "communication links" included both, but in response to comments the SDT has reincorporating the full language back into the exemptions.

Q9 Comment Theme:

- **Request clarification of capitalization of "High Impact," "Medium Impact" and "Low Impact."**

SDT Response:

Thank you for your comments. The SDT agrees and the capitalization of these terms was reviewed and corrected.

Question 10.

The SDT revised CIP-005 based on industry comments. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

NOTE: Many comment themes in CIP-005 are based on issues with individual definitions (ESP, EAP, IRA, SCI, etc.). For responses to those themes, please see the appropriate question above.

Q10 Comment Theme:

- **Request clarification between Part 1.2 and Part 1.3. Part 1.2 reads "Permit only needed and controlled communications to and from Management Interfaces, and deny all other communications" which seems to include Part 1.3 which reads "Deny network communications from Applicable Systems of Part 1.1 to the Management Interface, per system capability."**
- **In addition electronic access controls should be in-place on the Management Interface to only allow the appropriate administrators access to it. The prescriptive and broad ban of traffic from the data plane seems excessive. The separation occurs in cloud-based hosting because the hosting service is the administrator and the tenant is not. For on-premise that is not the case and the administrator and tenant are the same entity.**

SDT Response:

Thank you for your comments. The SDT asserts that having the VCAs, on SCI, not have access to the management plane is a best practice, but agrees with the issues brought up by the commenters. Since a person using IRA to a Management Interface will have the controls of CIP-005 R2 applied, and the overarching R1.2 (now 1.3 due to the reinstatement of 1.1 and the renumbering) permits only needed communications to and from the Management Interfaces with justification, the SDT agrees, and deleted the Draft 2 Part 1.3 language.

Q10 Comment Theme:

- **The host-based firewall exclusion in R1 is not appropriate for objective-based model/needs clarification/may be needed for Zero Trust implementation/should be in Implementation Guidance.**

SDT Response: Thank you for your comments. The SDT agrees. The intent of the exclusion was to avoid the scenario of a BCS being plugged into the Internet with only the internal OS firewall turned on. A compromise of the host through any OS vulnerability was then also a compromise of the firewall itself. It met the higher level objective, but with an insufficient separation of the security control from the object protected. The SDT has deleted the exclusion language and reinstated R1.1 in order to address the issue.

Q10 Comment Theme:

- **Requirement 1.1 includes a new insertion "between intelligent electronic devices", what is an intelligent electronic device?**

SDT Response:

Thank you for your comments. The SDT's intent was to bring forward the exclusion from the low impact scenario where ESPs and firewalls are excluded in very time sensitive applications such as relays communicating with each other for asset protection functions. The term "intelligent electronic devices" is a term of art, but remains undefined and the SDT agrees is an overly generic term. The SDT is proposing to use the NERC Glossary defined term of "Protection System" in its place, and moved the exclusion to Part 1.2 after the reinstatment of Part 1.1.

Q10 Comment Theme:

- **Hall of mirrors is created in R2.1 where an Intermediate System is needed for an Intermediate System**

SDT Response:

Thank you for your comments. The SDT agrees. This was a document error that was only in the clean but not the redline versions of the standard. This has been corrected.

Q10 Comment Theme:

- **R1.6 on detecting malicious communications needs consideration of the "where" in light of Zero Trust and changes to the ESP.**

SDT Response:

Thank you for your comments. The SDT has changed the requirement in response so that it refers to the communications that are entering or leaving an ESP and changed the Applicable Systems column to describe which ESPs – it applies to high impact BCS and medium impact BCS at Control Centers. This should make the requirement focus on specifically what communications need to be detected, but avoids implication of where the technology must reside to do so.

Question 11.

The SDT revised CIP-007 based on industry comments. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

Q11 Comment Theme:

- **Requirement 1.2 need clarification on what "non-programmable communications components located inside both a PSP and ESP" includes.**

SDT Response: Thank you for your comments. The SDT asserts that this is a redline error and is from currently approved CIP-007-6 and is not a change made by this SDT. We apologize that it showed as a change in the redline. It covers, for example, "non-programmable" communication components such as a unmanaged network switch that may not meet the definition of "Cyber Asset" but are still the object of this existing requirement.

Q11 Comment Theme:

- **Request clarification on CIP-007 Part 1.1. Why is this Requirement so technology specific? We refer to "Internet Protocol ports" instead of "ports." There is inconsistency between CIP-007 Parts 1.1 and 1.2 where 1.1 uses "Internet Protocol ports" while 1.2 uses "physical input/output ports" and "network connectivity." We expected consistency.**
- **Under Internet Protocol (IP), the transport layers (e.g. TCP, UDP) create and maintain the ports for the underlying services.**

SDT Response: Thank you for your comments. The SDT agrees that logical ports are at the TCP/UDP level and not IP (per RFC 791). Based on the feedback, the SDT has taken a simplified approach to this requirement by stating it as a clearer objective of system hardening – disable or prevent unneeded routable protocol network accessibility on each Applicable System. This intent is that in the virtualization underlay, the hardware resource pools being managed by hypervisors communicating with each other, the entity can manage unneeded network accessibility by disabling underlay services that are not needed. This also allows entities to achieve the objective at either a port or service level; some unneeded accessibility may be disabled/prevented at a TCP/UDP port level, others by disabling a service in the OS. The objective is to reduce the network attack surface of the Applicable System and no longer prescribes that this be accomplished at either a port or a service level.

The intent of the different 1.1 and 1.2 requirement parts remains in that 1.1 is concerned with operating system (OS) level ports and services, while 1.2 is concerned with physical hardware ports, for example, RJ45 ethernet, USB ports, and DB9 serial ports.

Q11 Comment Theme:

- **Requirement 1.3 is greatly limiting. One objective of virtualization is to optimize the usage of computer resources (CPU, memory, etc.) and this limits the possible gain of using virtualization.**

SDT Response:

Thank you for your comments. The SDT is allowing entity choice on the treatment of computer resources by either considering the computing resources and all the hosted VCAs as the same impact level (high watermarked) through the PCA definition (everything that can execute simultaneously on the same CPU/memory becomes an 'associated PCA'). If the entity chooses this path, the computing resources are not SCI and this requirement no longer applies. This requirement only applies if the entity chooses to retain differing impact levels of hosted VCAs and isolates them from each other by configuring affinity rules to keep VCAs of differing impact levels from executing on the same underlying hardware resources.

Q11 Comment Theme:

- **Clarity on Requirement 2 and patching cadence for dormant VCAs.**

SDT Response:

Thank you for your comments. The SDT has added more qualifications to the definition of VCA to clarify that a dormant, non-instantiated VM image is not a VCA, and thus not an Applicable System of R2. Other clarifications have been made in CIP-010 to clearly allow for automated vulnerability assessment and remediation of a VCA upon instantiation in a remediation VLAN.

Q11 Comment Theme:

- **Request explicit language in CIP-007 R2 that these patching Requirements do not include patching in the cloud.**

SDT Response: Thank you for your comments. The SDT does not have authorization in its SAR to address the aspects of off-premise cloud computing, of which this is one of numerous issues that would need to be addressed.

Question 12.

The SDT revised CIP-010 based on industry comments. Do you agree with the proposed changes to the NERC Glossary terms? If not, please provide the basis for your disagreement and an alternate proposal.

Q12 Comment Theme:

- **Overall: Changes are not needed/aren't related to virtualization**

SDT Response:

Thank you for your comments. The SDT asserts changes are needed to CIP-010 for virtualization issues. The SDT is making CIP-010 R1 a requirement with a clear change management security objective to alleviate several virtualization-related issues such as how to treat parent/child images (such as in VDI), application containers, clarifying the use of automated vulnerability assessment capability for VMs with remediation VLANs, and inclusion of authorization of change to the security controls affecting VM affinity and network isolation between VMs of differing impact levels.

Previously, CIP-010 R1 was concerned with five prescriptive attributes of a system, several of which caused issues with the virtualization concepts noted above. Rather than continuing to expand a list of prescriptive attributes in R1.1 with a backwards-looking requirement to update a baseline within 30 calendar days after a change is made and in addition determining affected CIP-005 and CIP-007 security controls, the core of the requirement is now the identification and testing of those CIP-005 and CIP-007 security controls and authorization of changes. It now focuses on the security objective of authorizing changes and allows entities to define those changes, taking into account the virtualization issues, that can affect the CIP-005 and CIP-007 security controls.

As an example of a virtualization issue, the SDT considered VDI scenarios where dozens or hundreds of VCAs may be dynamically instantiated from parent images. The SDT's intent is that the goal of R1 is not to maintain perfect baseline configuration of a hundred individual dynamically created VCAs but to focus on the much higher risk of authorizing and thus controlling change to the parent image from which a hundred dynamic images will be created. A forward looking requirement to authorize a change is of more value to reliability than a requirement to update baseline documentation in a certain timeframe after making a change. Another example is dormant VMs that may rarely instantiate. With automated vulnerability assessment and remediation of patches, AV updates, etc. at instantiation, the goal of R1 is not to have the entity somehow track when this automated process happens to each image file and then prove the update of baseline documentation within 30 calendar days. These are two examples of virtualization enabled scenarios where the SDT asserts CIP-010 needs to change to accommodate these advances in technology in a much more dynamic and automated environment. The SDT will incorporate example measures that include baseline configurations as one tool an entity may choose for this requirement.

Q12 Comment Theme:

- **R1/ Part 1.1.1: Add baselines and parent/child (VDI) examples to the measures as clarifying examples**
- **What level of OS change must be authorized?**
- **Why is lack of OS relevant to patching?**
- **The Measure mentions patch 'implementation' vs the requirement for change authorization**

SDT Response: Thank you for your comments. In response to these and numerous other comments on CIP-010 R1 and to allow for scenarios brought about by virtualization, the SDT has chosen to go with an objective level requirement rather than continue to maintain a prescriptive list of system attributes subject to change management processes. This requirement now requires entities to define the types of changes that will be in the change mgt process that includes changes that may impact CIP-005 and CIP-007 controls. Then, for those changes, the requirement focuses on authorizing those changes and the verification that changes do not adversely impact those security controls. This was the core of the previous version's requirement as well, but is now more future-proof and objective oriented.

Q12 Comment Theme:

- **R1/Part 1.1.2: Clarify "application containers"**

SDT Response: Thank you for your comments. The SDT in our draft 1 posting proposed a new glossary term for "Self-Contained Application (SCA)". Most stakeholder comments said that term is unnecessary and to use the IT industry "application container" term instead of proposing a NERC specific definition. The SDT intent for including this phrase is not to create something new but to simply help clarify that "application containers" as understood in the IT industry are to be treated like other application software and not as some unique form of VCA.

Q12 Comment Theme:

- **R1/Part 1.1.4: Ports and services/clarity on dynamic port ranges/tracking ports in the virtualization underlay rather than services/Clarify the authorization for change is to the OS/SW/Config that affects open ports, not every time a port opens/closes.**

SDT Response: Thank you for your comments. The SDT agrees with many of these comments and based on these and others has, in conjunction with changes to CIP-007 R1, made both of these requirements more objective-oriented. This allows these requirements to incorporate virtualization-specific scenarios and modifies the language in such a way that as technology continues to change, these requirements will not require continual update due to maintaining prescriptive lists of system attributes and baseline config documentation of such attributes – including ports and services. As the network accessibility of a system and reducing the network 'attack surface' remains a CIP-007 R1 security objective, then changes to Applicable Systems that can affect this remain the subject of CIP-010 R1 as well.

Q12 Comment Theme:

- **R3/Part 3.3: the requirement to build outside of the production environment and perform the vulnerability scan has been removed**
- **Clarify timeline between the VA and production**
- **Clarify "prior to becoming an Applicable System"**

SDT Response: Thank you for your comments. The SDT asserts the objective to perform a vulnerability assessment of a new Applicable System before it can have an impact in production remains, but has been reworded to allow for virtualization scenarios and automated means of implementing this requirement. The currently approved language states "Prior to adding a new applicable Cyber Asset to a production environment…" which has worked well with the traditional Cyber Asset such as Cyber Assets that arrive on a loading dock. However, it does not work well with a VCA that is created in an isolated environment WITHIN a virtualized infrastructure. It does not arrive from 'outside', it is created in the environment. The SDT changed the language for clarification. The changes should also clarify that automated tools that implement this functionality, such as remediation VLANs, are a good and allowable practice even though it occurs in a production "environment", but not with production network connectivity and the ability to impact other production VCAs.

The SDT's intent is that "prior to becoming an Applicable System" means that prior to the object in question fulfilling the role of one of the Applicable Systems and their definitions. For example, before it can have the 15 minute impact of the BCA definition, or perform the electronic access control function of an ESP or BCS. At the time the object fulfills those roles and thus meets the corresponding definition, that's when it "becomes an Applicable System" of this requirement, and prior to that point in time the vulnerability assessment must have been performed.
The SDT notes that the maximum allowable timeframe between the vulnerability assessment and the production use of the system has not been prescribed to date and is not a virtualization related issue. The SDT is changing the language to clearly allow for automated tools that will perform this task faster and every time a VCA is booted, not just its initial introduction to the environment.

Q12 Comment Theme:

- **R4: TCA scope changes from High/Med and PCAs to "everything but lows" and includes all non-CIP and thus the scoping is entirely in the definitions of TCA/RM**

SDT Response: Thank you for your comments. The SDT agrees and has reinstated updated applicability statements within the CIP-010 R4 requirement language and removed the applicability statements from the previous draft that were in Attachment 1.

Question 13.

The SDT revised CIP-003, CIP-004, CIP-006, CIP-008, CIP-009, CIP-011, and CIP-013 (conforming changes) based on industry comments. Do you agree with the proposed changes to these Reliability Standards? If not, please provide the basis for your disagreement and an alternate proposal.

Q13 Comment Theme:

- **CIP-006 R1.10 was moved to CIP-005 R1.4 but the associated PCAs aren't included**

SDT Response: Thank you for your comments. The SDT agrees and has included associated PCA's in the scope of the requirement.

Q13 Comment Theme:

- **CIP-009 should not include SCI in applicability. Recovery of the functionality may occur outside of recovering underlying SCI.**

SDT Response: Thank you for your comments. The SDT agrees that the SCI itself does not always require its own recovery plan. The objective of this requirement is not to recover SCI simply as SCI, but to recover the functionality of the systems it supports that remain in scope. Entities could have recovery plans that recover the functionality in other ways if underlying SCI is the issue. However, entities should be aware that if their plan to recover an Applicable System is dependent upon recovery of the SCI, the SCI should be a part of the documented plan. With the exception of Part 1.5, the SDT removed SCI from the Applicable Systems where it had been included before in Draft 2.

Question 14.

Please provide any additional comments for the SAR drafting team to consider, if desired.

Q14 Comment Theme:

- **Associated Data Center (as required by the latest ERT v5 spreadsheet) is not listed in the draft standard**

SDT Response: Thank you for your comments. The 'associated Data Center' is an included component of the currently approved Control Center definition in the NERC glossary. It is not the subject of any changes by this SDT.

Q14 Comment Theme:

- **Planned and Unplanned changes language should be added to the Implementation Plan, similar to the language included in previous CIP implementation plans.**

SDT Response: Thank you for your comments. The SDT agrees and has copied those sections into the proposed Implementation Plan so those provisions remain with this version.

Q14 Comment Theme:

- **CIP-013 is part of this update, is there a reason why CIP-014 is not part of this update?**

SDT Response: Thank you for your comments. CIP-014 is a physical security standard and is not in the suite of cyber security standards, unlike CIP-006 that is specifically related to the physical security of BES Cyber Systems. While CIP-014 has a few similarities with CIP-002, it is not affected by virtualization technology. CIP-013 on the other hand, is in the suite of Cyber Security standards and is affected by virtualization – such as the procurement of SCI.

REMINDER

Standards Announcement

Project 2016-02 Modifications to CIP Standards

Additional Ballots and Non-binding Polls Open through September 1, 2021

Now Available

The additional ballots and associated Violation Risk Factors and Violation Severity Level non-binding polls for the **CIP Virtualization suite of standards (outlined below)** are open through **8 p.m. Eastern, Wednesday, September 1, 2021**.

The standard drafting team's considerations of the responses received from the previous comment period are reflected in these drafts of the standards.

- CIP-002-7 - Cyber Security – BES Cyber System Categorization
- CIP-003-Y - Cyber Security – Security Management Controls
- CIP-004-Y - Cyber Security – Personnel & Training
- CIP-005-8 - Cyber Security – BES Cyber System Logical Isolation
- CIP-006-7 - Cyber Security – Physical Security of BES Cyber Systems
- CIP-007-7 - Cyber Security – Systems Security Management
- CIP-008-7 - Cyber Security – Incident Reporting and Response Planning
- CIP-009-7 - Cyber Security – Recovery Plans for BES Cyber Systems
- CIP-010-5 - Cyber Security – Configuration Change Management and Vulnerability Assessments
- CIP-011-Y - Cyber Security – Information Protection
- CIP-013-3 - Cyber Security – Supply Chain Risk Management

Balloting
Use the Standards Balloting and Commenting System (SBS) to submit votes.

- *Contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern) for problems regarding accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out.*
- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*

- *Please be mindful of ballot and comment period closing dates. We ask to **allow at least 48 hours** for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts **prior to the last day** of a comment/ballot period.*

Next Steps

The ballot results will be announced and posted on the project page. The drafting team will review all responses received during the comment period and determine the next steps of the project.

For information on the Standards Development Process, refer to the Standard Processes Manual**.**

For more information or assistance, Jordan Mallory (via email) or at (404) 446-2589. Subscribe to this project's observer mailing list by selecting "NERC Email Distribution Lists" from the "Applications" drop-down menu and specify “Project 2016-02 Modifications to CIP Standards Observer List” in the Description Box.

UPDATED

Standards Announcement

Project 2016-02 Modifications to CIP Standards | Virtualization

Formal Comment Period Extended, Now Open through September 1, 2021

Now Available

Due to numerous requests received from industry, the 45-day formal comment period for the **CIP Virtualization suite of standards (outlined below)** has been extended and is now open through **8 p.m. Eastern, Wednesday, September 1, 2021**.

The standard drafting team's considerations of the responses received from the previous comment period are reflected in these drafts of the standards.

- CIP-002-7 - Cyber Security – BES Cyber System Categorization
- CIP-003-Y - Cyber Security – Security Management Controls
- CIP-004-Y - Cyber Security – Personnel & Training
- CIP-005-8 - Cyber Security – BES Cyber System Logical Isolation
- CIP-006-7 - Cyber Security – Physical Security of BES Cyber Systems
- CIP-007-7 - Cyber Security – Systems Security Management
- CIP-008-7 - Cyber Security – Incident Reporting and Response Planning
- CIP-009-7 - Cyber Security – Recovery Plans for BES Cyber Systems
- CIP-010-5 - Cyber Security – Configuration Change Management and Vulnerability Assessments
- CIP-011-Y - Cyber Security – Information Protection
- CIP-013-3 - Cyber Security – Supply Chain Risk Management

Commenting

Use the Standards Balloting and Commenting System (SBS) to submit comments. An unofficial Word version of the comment form is posted on the project page**.**

- *Contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern) for problems regarding accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out.*
- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*

- *Please be mindful of ballot and comment period closing dates. We ask to* ***allow at least 48 hours*** *for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts* ***prior to the last day*** *of a comment/ballot period.*

Next Steps

Additional ballots for the standards and non-binding polls of the associated Violation Risk Factors and Violation Severity Levels will be conducted **August 23 – September 1, 2021**.

For information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Senior Standards Developer, Jordan Mallory (via email) or at (404) 446-2589. Subscribe to this project's observer mailing list by selecting "NERC Email Distribution Lists" from the "Service" drop-down menu and specify “Project 2016-02 Modifications to CIP Standards Observer List” in the Description Box.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

This is the third draft of the proposed standard.

Completed Actions	Date
Standards Committee (SC) approved Standard Authorization Request (SAR) for posting	March 9, 2016
SAR posted for comment	March 23–April 21, 2016
SAR posted for comment	June 1–June 30, 2016
SC Accepted the SAR	July 20, 2016
60-day formal comment period with ballot	January 21–March 22, 2021
63-day formal comment period with ballot	June 30 –September 1, 2021
45-day formal comment period with ballot	February 18 – April 4, 2022

Anticipated Actions	Date
Final Ballot	April 2022
Board adoption	May 2022

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s): See Separate document containing all proposed or modified terms titled “Project 2016-02 Draft 3 Definitions”

A. Introduction

1. **Title:** Cyber Security — BES Cyber System Categorization

2. **Number:** CIP-002-7

3. **Purpose:** To identify and categorize BES Cyber Systems (BCS) and their associated BES Cyber Assets (BCA) for the application of cyber security requirements commensurate with the adverse impact that loss, compromise, or misuse of those BCS could have on the reliable operation of the Bulk Electric System (BES). Identification and categorization of BCS support appropriate protection against compromises that could lead to misoperation or instability in the BES.

4. **Applicability:**

4.1. Functional Entities: For the purpose of the requirements contained herein, the following list of functional entities will be collectively referred to as "Responsible Entities." For requirements in this standard where a specific functional entity or subset of functional entities are the applicable entity or entities, the functional entity or entities are specified explicitly.

4.1.1. Balancing Authority

4.1.2. Distribution Provider that owns one or more of the following Facilities, systems, and equipment for the protection or restoration of the BES:

4.1.2.1. Each underfrequency load shedding (UFLS) or undervoltage load shedding (UVLS) system that:

4.1.2.1.1. is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.1.2.1.2. performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.1.2.2. Each Remedial Action Scheme (RAS) where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.1.2.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.1.3. Generator Operator

4.1.4. Generator Owner

4.1.5. Reliability Coordinator

4.1.6. Transmission Operator

4.1.7. Transmission Owner

4.2. **Facilities:** For the purpose of the requirements contained herein, the following Facilities, systems, and equipment owned by each Responsible Entity in 4.1 above are those to which these requirements are applicable. For requirements in this standard where a specific type of Facilities, system, or equipment or subset of Facilities, systems, and equipment are applicable, these are specified explicitly.

4.2.1. **Distribution Provider**: One or more of the following Facilities, systems and equipment owned by the Distribution Provider for the protection or restoration of the BES:

4.2.1.1. Each UFLS or UVLS System that:

4.2.1.1.1. is part of a Load shedding program that is subject to one or more requirements in a NERC or Regional Reliability Standard; and

4.2.1.1.2. performs automatic Load shedding under a common control system owned by the Responsible Entity, without human operator initiation, of 300 MW or more.

4.2.1.2. Each RAS where the RAS is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.3. Each Protection System (excluding UFLS and UVLS) that applies to Transmission where the Protection System is subject to one or more requirements in a NERC or Regional Reliability Standard.

4.2.1.4. Each Cranking Path and group of Elements meeting the initial switching requirements from a Blackstart Resource up to and including the first interconnection point of the starting station service of the next generation unit(s) to be started.

4.2.2. **Responsible Entities listed in 4.1 other than Distribution Providers**: All BES Facilities.

4.2.3. **Exemptions:** The following are exempt from Standard CIP-002-7:

4.2.3.1. Cyber Systems at Facilities regulated by the Canadian Nuclear Safety Commission.

4.2.3.2. Cyber Systems associated with communication networks and data communication links between discrete Electronic Security Perimeters (ESP).

4.2.3.3. Cyber Systems, associated with communication networks and data communication links, between the Cyber Systems providing confidentiality and integrity of an ESP that extends to one or more geographic locations.

4.2.3.4. The systems, structures, and components that are regulated by the Nuclear Regulatory Commission under a cyber security plan pursuant to 10 C.F.R. Section 73.54.

4.2.3.5. For Distribution Providers, the systems and equipment that are not included in section 4.2.1 above.

5. Effective Dates: See "Project 2016-02 Modifications to CIP Standards Implementation Plan"

B. Requirements and Measures

R1. Each Responsible Entity shall implement a process that considers each of the following assets for purposes of Parts 1.1 through 1.3: *[Violation Risk Factor: High][Time Horizon: Operations Planning]*

- **i.** Control Centers and backup Control Centers;
- **ii.** Transmission stations and substations;
- **iii.** Generation resources;
- **iv.** Systems and facilities critical to system restoration, including Blackstart Resources and Cranking Paths and initial switching requirements;
- **v.** RAS that support the reliable operation of the Bulk Electric System; and
- **vi.** For Distribution Providers, Protection Systems specified in Applicability section 4.2.1 above.

1.1. Identify each of the high impact BCS according to Attachment 1, Section 1, if any, at each asset;

1.2. Identify each of the medium impact BCS according to Attachment 1, Section 2, if any, at each asset; and

1.3. Identify each asset that contains a low impact BCS according to Attachment 1, Section 3, if any (a discrete list of low impact BCS is not required).

M1. Acceptable evidence includes, but is not limited to, dated electronic or physical lists required by Requirement R1.

R2. Each Responsible Entity shall: *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

2.1 Review the identifications in Requirement R1 and its parts (and update them if there are changes identified) at least once every 15 calendar months, even if it has no identified items in Requirement R1, and

2.2 Have its CIP Senior Manager or delegate approve the identifications required by Requirement R1 at least once every 15 calendar months, even if it has no identified items in Requirement R1.

M2. Acceptable evidence includes, but is not limited to, electronic or physical dated records to demonstrate that the Responsible Entity has reviewed and updated, where necessary, the identifications required in Requirement R1 and its parts, and has had its CIP Senior Manager or delegate approve the identifications required in Requirement R1 and its parts at least once every 15 calendar months, even if it has none identified in Requirement R1 and its parts, as required by Requirement R2.

C. Compliance

1. Compliance Monitoring Process:

1.1. Compliance Enforcement Authority

"Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the CEA may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Responsible Entity shall keep data or evidence to show compliance as identified below unless directed by its CEA to retain specific evidence for a longer period of time as part of an investigation:

- Each Responsible Entity shall retain evidence of each requirement in this standard for three calendar years.
- If a Responsible Entity is found non-compliant, it shall keep information related to the non-compliance until mitigation is complete and approved or for the time specified above, whichever is longer.
- The CEA shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program

As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

R #			Violation Severity Levels (CIP-002-7)			
			Lower VSL	Moderate VSL	High VSL	Severe VSL
R1			For Responsible Entities with more than a total of 40 BES assets in Requirement R1, five percent or fewer BES assets have not been considered according to Requirement R1; OR For Responsible Entities with a total of 40 or fewer BES assets, 2 or fewer BES assets in Requirement R1, have not been considered according to Requirement R1; OR For Responsible Entities with more than a total of 100 high and medium impact BCS, five percent or fewer of identified BCS have not been categorized or have been incorrectly categorized at a lower category;	For Responsible Entities with more than a total of 40 BES assets in Requirement R1, more than five percent but less than or equal to 10 percent of BES assets have not been considered, according to Requirement R1; OR For Responsible Entities with a total of 40 or fewer BES assets, more than two, but fewer than or equal to four BES assets in Requirement R1, have not been considered according to Requirement R1; OR For Responsible Entities with more than a total of 100 high and medium impact BCS, more than five percent but less than or equal to 10	For Responsible Entities with more than a total of 40 BES assets in Requirement R1, more than 10 percent but less than or equal to 15 percent of BES assets have not been considered, according to Requirement R1; OR For Responsible Entities with a total of 40 or fewer BES assets, more than four, but fewer than or equal to six BES assets in Requirement R1, have not been considered according to Requirement R1; OR For Responsible Entities with more than a total of 100 high or medium impact BCS, more than 10 percent but less than or equal to 15 percent of	For Responsible Entities with more than a total of 40 BES assets in Requirement R1, more than 15 percent of BES assets have not been considered, according to Requirement R1; OR For Responsible Entities with a total of 40 or fewer BES assets, more than six BES assets in Requirement R1, have not been considered according to Requirement R1; OR For Responsible Entities with more than a total of 100 high and medium impact BCS, more than 15 percent of identified BCS have not been categorized or have been incorrectly categorized at a lower category;

R #			Violation Severity Levels (CIP-002-7)			
			Lower VSL	Moderate VSL	High VSL	Severe VSL
			OR For Responsible Entities with a total of 100 or fewer high and medium impact BCS, five or fewer identified BCS have not been categorized or have been incorrectly categorized at a lower category. OR For Responsible Entities with more than a total of 100 high and medium impact BCS, five percent or fewer high or medium BCS have not been identified; OR For Responsible Entities with a total of 100 or fewer high and medium impact BCS, five or fewer high or medium BCS have not been identified.	percent of identified BCS have not been categorized or have been incorrectly categorized at a lower category; OR For Responsible Entities with a total of 100 or fewer high and medium impact and BCS, more than five but less than or equal to 10 identified BES Cyber Systems have not been categorized or have been incorrectly categorized at a lower category. OR For Responsible Entities with more than a total of 100 high and medium impact BCS, more than five percent but less than or equal to 10 percent high or medium BCS have not been identified; OR	identified BCS have not been categorized or have been incorrectly categorized at a lower category; OR For Responsible Entities with a total of 100 or fewer high or medium impact and BCS, more than 10 but less than or equal to 15 identified BCS have not been categorized or have been incorrectly categorized at a lower category. OR For Responsible Entities with more than a total of 100 high and medium impact BCS, more than 10 percent but less than or equal to 15 percent high or medium BCS have not been identified; OR For Responsible Entities with a total of 100 or	OR For Responsible Entities with a total of 100 or fewer high and medium impact BCS, more than 15 identified BCS have not been categorized or have been incorrectly categorized at a lower category. OR For Responsible Entities with more than a total of 100 high and medium impact BCS, more than 15 percent of high or medium impact BCS have not been identified; OR For Responsible Entities with a total of 100 or fewer high and medium impact BES Cyber Systems, more than 15 high or medium impact BCS have not been identified.

R #			Violation Severity Levels (CIP-002-7)

Attachment 1

Impact Rating Criteria

The criteria defined in Attachment 1 do not constitute stand-alone compliance requirements, but are criteria characterizing the level of impact and are referenced by requirements.

1. **High impact rating**
   Each BCS used by and located at any of the following:

   1.1. Each Control Center or backup Control Center used to perform the functional obligations of the Reliability Coordinator.

   1.2. Each Control Center or backup Control Center used to perform the functional obligations of the Balancing Authority: 1) for generation equal to or greater than an aggregate of 3000 MW in a single Interconnection, or 2) for one or more of the assets that meet criterion 2.3, 2.6, or 2.9.

   1.3. Each Control Center or backup Control Center used to perform the functional obligations of the Transmission Operator for one or more of the assets that meet criterion 2.2, 2.4, 2.5, 2.7, 2.8, 2.9, or 2.10.

   1.4 Each Control Center or backup Control Center used to perform the functional obligations of the Generator Operator for one or more of the assets that meet criterion 2.1, 2.3, 2.6, or 2.9.

2. **Medium impact rating**
   Each BCS, not included in Section 1 above, associated with any of the following:

   2.1. Commissioned generation, by each group of generating units at a single plant location, with an aggregate highest rated net Real Power capability of the preceding 12 calendar months equal to or exceeding 1500 MW in a single Interconnection. For each group of generating units, the only BCS that meet this criterion are each discrete shared BCS that could, within 15 minutes, adversely impact the reliable operation of any combination of units that in aggregate equal or exceed 1500 MW in a single Interconnection.

   2.2. Each BES reactive resource or group of resources at a single location (excluding generation Facilities) with an aggregate maximum Reactive Power nameplate rating of 1000 MVAR or greater (excluding those at generation Facilities). The only BCS that meet this criterion are each discrete shared BCS that could, within 15 minutes, adversely impact the reliable operation of any combination of resources that in aggregate equal or exceed 1000 MVAR.

   2.3. Each generation Facility that its Planning Coordinator or Transmission Planner designates, and informs the Generator Owner or Generator Operator, as necessary to avoid an Adverse Reliability Impact in the planning horizon of more than one year.

   2.4. Transmission Facilities operated at 500 kV or higher. For the purpose of this criterion, the collector bus for a generation plant is not considered a Transmission Facility, but is part of the generation interconnection Facility.

2.5. Transmission Facilities that are operating between 200 kV and 499 kV at a single station or substation, where the station or substation is connected at 200 kV or higher voltages to three or more other Transmission stations or substations and has an "aggregate weighted value" exceeding 3000 according to the table below. The "aggregate weighted value" for a single station or substation is determined by summing the "weight value per line" shown in the table below for each incoming and each outgoing BES Transmission Line that is connected to another Transmission station or substation. For the purpose of this criterion, the collector bus for a generation plant is not considered a Transmission Facility, but is part of the generation interconnection Facility.

Voltage Value of a Line	Weight Value per Line
less than 200 kV (not applicable)	(not applicable)
200 kV to 299 kV	700
300 kV to 499 kV	1300
500 kV and above	0

2.6. Generation at a single plant location or Transmission Facilities at a single station or substation location that are identified by its Reliability Coordinator, Planning Coordinator, or Transmission Planner as critical to the derivation of Interconnection Reliability Operating Limits (IROLs) and their associated contingencies.

2.7. Transmission Facilities identified as essential to meeting Nuclear Plant Interface Requirements.

2.8. Transmission Facilities, including generation interconnection Facilities, providing the generation interconnection required to connect generator output to the Transmission Systems that, if destroyed, degraded, misused, or otherwise rendered unavailable, would result in the loss of the generation Facilities identified by any Generator Owner as a result of its application of Attachment 1, criterion 2.1 or 2.3.

2.9. Each RAS or automated switching System that operates BES Elements, that, if destroyed, degraded, misused or otherwise rendered unavailable, would cause one or more Interconnection Reliability Operating Limits (IROLs) violations for failure to operate as designed or cause a reduction in one or more IROLs if destroyed, degraded, misused, or otherwise rendered unavailable.

2.10. Each system or group of Elements that performs automatic Load shedding under a common control system, without human operator initiation, of 300 MW or more implementing undervoltage load shedding (UVLS) or underfrequency load shedding (UFLS) under a load shedding program that is subject to one or more requirements in a NERC or regional reliability standard.

2.11. Each Control Center or backup Control Center, not already included in high impact rating above, used to perform the functional obligations of the Generator Operator for an aggregate highest rated net Real Power capability of the preceding 12 calendar months equal to or exceeding 1500 MW in a single Interconnection.

2.12. Each Control Center or backup Control Center used to perform the functional obligations of the Transmission Operator not included in high impact rating, above.

2.13. Each Control Center or backup Control Center, not already included in High impact rating above, used to perform the functional obligations of the Balancing Authority for generation equal to or greater than an aggregate of 1500 MW in a single Interconnection.

3. Low impact rating

BCS not included in Sections 1 or 2 above that are associated with any of the following assets and that meet the applicability qualifications in Section 4 - Applicability, part 4.2 – Facilities, of this standard:

3.1. Control Centers and backup Control Centers.

3.2. Transmission stations and substations.

3.3. Generation resources.

3.4. Systems and facilities critical to system restoration, including Blackstart Resources and Cranking Paths and initial switching requirements.

3.5. RAS that support the reliable operation of the Bulk Electric System.

For Distribution Providers, Protection Systems specified in Applicability section 4.2.1 above.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

This is the second draft of the proposed standard.

Completed Actions	Date
Standards Committee (SC) approved Standard Authorization Request (SAR) for posting	March 9, 2016
SAR posted for comment	March 23–April 21, 2016
SAR posted for comment	June 1–June 30, 2016
SC Accepted the SAR	July 20, 2016
60-day formal comment period with ballot	January 21–March 22, 2021
~~45~~63-day formal comment period with ballot	June 30 – ~~August 13~~September 1, 2021
45-day formal comment period with ballot	February 18 – April 4, 2022

Anticipated Actions	Date
~~45-day formal comment period with ballot~~	~~May 11 – June 24, 2021~~
~~45-day formal comment period with ballot~~	~~August 29–October 11, 2021~~
Final Ballot	~~October 19–28, 2021~~April 2022
Board adoption	~~November 4, 2021~~May 2022

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s): See Separate document containing all proposed or modified terms titled "Project 2016-02 Draft 3 Definitions"

A. Introduction

1. **Title:** Cyber Security — BES Cyber System Categorization
2. **Number:** CIP-002-7
3. **Purpose:** To identify and categorize BES Cyber Systems (BCS) and their associated BES Cyber Assets (BCA) for the application of cyber security requirements commensurate with the adverse impact that loss, compromise, or misuse of those BCS could have on the reliable operation of the Bulk Electric System (BES). Identification and categorization of BCS support appropriate protection against compromises that could lead to misoperation or instability in the BES.
4. **Applicability:**
